skills such as application, synthesis, evaluation, creation (Anderson & Krathwohl,
2001), and improve fl exibility in teaching and learning. Finally, blogs feature
hyperlinks, which help students understand the relational and contextual basis of
knowledge, knowledge construction, meaning making and experience connective
writing (Liu & Chang, 2010 ; Penrod, 2007 ; Richardson, 2009). According to
Oravec (2002) blogs encourage self-expression and collaboration, which in turn are
refl ected in enhanced critical thinking skills. A blog offers extended interactivity,
increasing students' involvement and motivation (Eteokleous & Pavlou, 2010).
Integrating Blogs in Primary Education124
Students can receive instant feedback from the instructor, peers, and other visitors,
which enhances learning effi ciency (Kaplan, Piskin, & Bol, 2010). Blog participants
perform connective writing since they need to read carefully and critically, and
develop context that is clear, organized, and convincing. There is a synthesis of
ideas, self- evaluation, and refl ection. Experiencing blog writing promotes critical,
analytical, relational, and creative thinking. It also combines collegiality and social
interaction, developing working and social relationships among teachers, educators, and professionals (Davis, 2005 ; Eid Neurolearning, 2005 ; Richardson, 2010).
Eteokleous (2011) explains the development of student-centered environments and
how students become educational content creators, having an increased role in the
teaching and learning process when blogs are used as educational tools. Instructor's
role in a blog learning environment is extremely important. Glogoff (2005) emphasizes that the instructors should be aware of the delicate balance between the synchronicity of time and place on the one hand and the need to keep discussions
focused on the topic. Additionally, Kim (2008) states that the success of the system
relies on teachers' capability in providing the appropriate resources. So, it can be
suggested that although teaching and refl ecting through blogs constitutes an effective medium for teaching, it must be applied in a proper way with the guidance of
the instructor in order to foster the best teaching practices (Eteokleous & Nisiforou,
2013a , 2013b ; Karaman, 2011).
Blog's pedagogical affordances were examined and reported by various researchers. First of all, it is supported that blogs motivate students to engage positively in
the writing process (Barrios, 2003 ; Cottle, 2009 ; Shiffl et, 2008 ; Trammel & Ferdig,
2004). Additionally, blogs enhance participation and interactive communication
opportunities (Angelaina & Jimoyiannis, 2012) promoting both individualized
(Cottle, 2009 ; Shiffl et, 2008) and group refl ection on learning experiences. The
blog's pedagogical affordances also include the support of authentic learning tasks
through peer assessment and formative evaluation of student work (Angelaina &
Jimoyiannis, 2012) as well as the promotion of critical thinking and increases learner
autonomy (Richardson, 2010). Finally, blog facilitates student collaboration within
a community of learners (Nelson & Fernheimer, 2003) and encourages and support
blended learning activities by effectively changing formal and informal learning.
Blog as Cognitive-Learning Tool
Blogs serve numerous purposes such as personal, professional, and educational.
Focusing on the educational use of blog, four extra categories can be identifi ed:
Blog as online course tool, blog as a discussion forum, blog as a research tool, and
blog as cognitive-learning tool (Eteokleous & Nisiforou, 2013a , 2013b). For the
purposes of the current paper, it is important to better explain the cognitive-learning
tool category. Eteokleous and Nisiforou (2013a , 2013b) attempted to defi ne blogs as
cognitive-learning tools and examine their role in the teaching and learning process
as well their effectiveness in achieving specifi c learning objectives.
N. Eteokleous-Grigoriou and S. Photiou125
The current paper suggests that blog integration in the teaching and learning
practice is defi ned as the use of blogs by students as a cognitive-learning tool that
enhances their learning experience and supports the achievement of specifi c learning goals. It can be integrated in all educational levels (i.e., pre-primary, primary,
and secondary, as well as higher education in numerous departments) and fi elds and
in various subjects (i.e., Mathematics, Literature, Science, etc.). This approach is
related to the learning with computers or computers as mindtools (Jonassen, 1999b),
where computers and overall technology is introduced as students' partners within
the teaching and learning process. Learning with technology and effects of technology use characterizes this trend. Learning with requires integrating computers and
overall technology as mindtools in the classrooms to support constructive learning.
Educators embed or apply technology capacity in the context of ongoing teaching
and learning in different school subjects. Based on the above, students learn how to
use various technology applications not as an end in themselves, but as tools that
help them execute their tasks and promote the balanced development of their mental
abilities. As a result they do not learn from technology, but technologies support
meaning generated by students (Bielaczyc & Collins, 1999 ; CTGV, 2003 ; Jonassen,
1999a , 1999b ; Jonassen, 2000).
Blog is integrated within the teaching and learning practice for numerous years;
however, the development of a pedagogical framework is extremely important. It
will highlight a set of key criteria and parameters for blogs to be integrated as
cognitive- learning tools within the teaching and learning process in order to achieve
real blogging. Additionally, educator's and students' role should be further examined and clarifi ed. Finally, research on the following needs to be conducted: blog's
design, format, content used and uploaded, tools and gadgets employed.
Community of Learning
Communities of learning in schools have been examined by various researchers
providing defi nitions, characteristics, the role as well as the importance of
communities of learning. According to Wenger, McDermott, and Snyder (2002)
communities of learning "…are groups of people who share a concern, a set of
problems, a passion about a topic, and who deepen their knowledge and expertise
in this area by interacting on an ongoing basis" (p. 4). Few years later, Wenger
(2004) defi ned communities of learning as "…groups of people who share a passion for something that they know how to do, and who interact regularly in order
to learn how to do it better" (p. 2). In the learning environments, the role of a community is to support and facilitate socially constructed knowledge (Job-Sluder &
Barab, 2004 ; Palloff & Pratt, 2005). Finally, Loving, Schroeder, Kang, Shimek,
and Herbert (2007) supported that "A learning community is a group of autonomous, independent individuals who are drawn together by shared values, goals,
and interests and committed to knowledge construction through intensive dialogues, interaction, and collaboration" (p. 179).
Integrating Blogs in Primary Education126
For a learning community to be developed; face-to-face interactions are not
necessary. Nevertheless, various online tools can be employed for the development
of a learning community. As Loving et al. (2007) suggest, "these virtual learning
communities can be built in two forms, synchronous and asynchronous. Blogs are
considered one of those tools that can support and promote the development of a
learning community, either a fully immersed learning community or either a blended
learning community (Oravec, 2003). Consequently, blogs have an important role to
play in building an online community of learning.
Community of Inquiry
The current study examines the development of a Community of Inquiry (CoI).

C. S. Peirce and John Dewey were the fi rst philosophers to introduce the concept of
the community of inquiry. The introductory concept described the nature of knowledge, formation and the process of scientifi c inquiry. An educational community of
inquiry is a group of individuals involved in a process of empirical or conceptual
inquiry into problematic situations. Those individuals collaboratively engage in
purposeful critical discourse and reff ection to construct personal meaning and con-
fi rm mutual understanding. The CoI requires intersubjective agreement among
those involved in the process of inquiry for legitimacy since it emphasizes that
knowledge is necessarily embedded within a social context (Seixas, 1993 ; Sharp,
2007).
The theoretical framework of the current study focuses on the Community of
Inquiry (CoI) model as has been suggested by Shea and Bidjerano (2010) where
social, cognitive, and teaching presence are related. The model is based on the work
of Garrison, Anderson, and Archer (2000) which introduced the original model of
CoI. The CoI model assumes that effective online learning requires the development
of a community that supports meaningful inquiry and learning (Shea, 2006).
Garrison et al. (2000) developed this model which assumes that deep and meaningful learning results when there are suffi cient levels of three components: teaching,
social, and cognitive presence. The model outlines the theoretical elements essential
to successful knowledge construction in collaborative online environments. The
social presence relates to the establishment of a supportive environment such that
students feel socially and emotionally connected to each other and to the instructor
in a computer-mediated environment. The elements of the social presence are demonstrated through emotional expression, open communication, and group cohesion.
The teaching presence involves the design, facilitation, and direction of cognitive
and social processes leading to personally meaningful and educationally worthwhile
learning outcomes. Elements of the teaching presence include setting curriculum
and activities, shaping constructive discourse, and focusing and resolving issues.
The cognitive presence is defi ned as the extent to which learners are able to construct and confi rm meaning through continuous suggestion and discussion in a critical community of inquiry. The elements of the cognitive presence include triggering

event (sense of puzzlement), exploration (sharing information and ideas), integration (connecting ideas), and resolution (synthesizing and applying new ideas)
(Garrison & Arbaugh, 2007 ; Swan et al., 2008).
Research Methodology
To address the above, a case study approach was employed where qualitative
(through in-classroom and blog's observations) and quantitative (through questionnaires) data was collected (Creswell, 2003). The classroom intervention took place
within the context of the Language and Linguistic and Art courses during October-
December 2011. The unit delivered was "Time Machine" and 20 fi fth graders participated at the study. For the purposes of teaching the lessons a blog was developed
using Blogger . The blog was integrated as an educational tool in the teaching and
learning process within six, 40 min lessons (fi ve Language and Linguistics lessons
and one Art lesson). A blended learning environment was developed through in-
classroom and online activities as well as homework activities. An introductory
lesson took place at the computer lab in order to familiarize students with the blog
(uses and tools) since it was the very fi rst time used by the educators and the students. Students were given notes regarding the blog use. Regarding the rest of the
lessons, both the classroom and the computer lab were used. Additionally, in some
cases students were asked to use the blog at home.
Various questions were posted on the blog throughout the fi ve Language and
Linguistics lessons. The open questions posted at the blog were related to the subject of the theme delivered ("Time Machine") and they aimed to contribute in
achieving the lesson's objectives. The educator constantly reminded students to
comment on their classmates' blog—posts, report if they agree/disagree, provide
arguments, suggestions, etc. The goal was for a discussion to be conducted, where
students' opinions, views, thinking would be revealed at the blog wall. The teaching
intervention was designed and developed by the authors in collaboration with two
teachers which then delivered the lessons.
The quantitative data collection method conducted using a questionnaire given to
students by the completion of the three lessons in the presence of the teacher. Thus,
the students had the opportunity to make any clarifying questions about the questionnaire, which was created based on the Community of Inquiry questionnaire
(Swan et al., 2008). The questionnaire consisted of two parts: (1) Demographic
Data (e.g., gender, country of origin, use and frequency of computer use, use and
frequency of Internet use) and (2) Communities of inquiry statements which consists of three main parameters: teaching, social, and cognitive presence. Each
parameter consists of several sub-parameters; as a result the questionnaire includes
a total of 34 statements. Students were asked to rank the 34 statements using a 5
point Likert scale, where 1 = Strongly Disagree, 2 = Disagree, 3 = Neutral, 4 = Agree,
and 5 = Strongly Agree. The statistical package SPSS (Version 19) was employed in
order for the quantitative data analysis to be performed. It includes descriptive

statistics, namely frequencies, percentages, averages, and standard deviations for all
variables of the questionnaire, as well as Cronbach's alpha (α) for internal
consistency.
The qualitative method of data collection was conducted by observing in-
classroom and blog activity—teacher and students' blog postings. Blog postings
were analyzed using an open coding system, attaching labels to blog postings (words
or lines of data) and then describing the data at a concrete level, before moving to a
more conceptual level (Anfara, Brown, & Mangione, 2002). Firstly, this process was
conducted within each blog questions (students' responses) and then across all blog
questions (all students' responses). The iterative coding process employed leaded to
the identifi cation of themes. It is important to clarify that a blended learning environment was employed where a combination of in-classroom and online activities
were performed. Consequently, the students evaluated the development of a CoI
based on their experience within the blended learning environment. The data collection process was conducted during October–November 2011.
Results
Demographic Characteristics
Regarding the gender of the students, 55 % was boys and 45 % was girls, while the
country of students' origin varies. Specifi cally, the majority of the students were
coming from Cyprus (25 %), followed by Georgia and Ukraine (10 %). The vast
majority of the students (85 %) use the computer, of which 25 % use it once per
week and 5 % use it daily (mean = 2.8; SD = 1.11). The majority of the students
(70 %) replied that using the Internet, of which 25 % of students answered that
rarely uses it, while 15 % use it once per week (mean = 2.5; SD = 1.19). A 5-point
Likert scale was used, where 1 = no use and 5 = daily.
Communities of Inquiry: Blended Learning Environment
The analysis of the questionnaires revealed some interesting results regarding the
development of a Community of Inquiry (CoI) through the use of blog as the main
educational tool. Specifi cally, it can be supported that a CoI was developed through
the Lesson Time Machine, where the blog was integrated as an educational tool
within a blended learning environment (combination of in-classroom and online
blog-based activities).
Generally, it can be suggested that the teacher presence has a vital impact since
the mean was 4.80 (SD = 0.242; α = 0.765). The important role of the educator is
highlighted. Specifi cally, the results suggest that the teacher was properly organized,
gave immediate and appropriate instructions, and successfully played the role of the

facilitator, so that the students felt comfortable to engage in productive discussions
and reff ections. The aforementioned mainly took place within the in- classroom
activities. On the other hand, the educator did not participate in the blog discussions
besides providing questions and clear instructions on students' responsibilities. The
educator wanted to grant students the freedom and fl exibility needed to express
themselves within the blog, without interfering or providing any guidance, help,
and/or encouragement, thus not having an active role in the blog. Nevertheless, the
educator was observing and following blog activity. The teaching presence within
in-classroom and blog activity revealed to be really infl uential and it played an
important role within the teaching and learning process. The educator facilitated
and helped students within the teaching and learning process, providing them with
clear, direct instructions. Specifi cally, direct instruction was highly apparent mainly
within in-classroom activities than blog activities, since the educator managed to
focus discussion on relevant issues, helping students to gain understanding and better realize and comprehend the subjects under investigation. In addition, within inclassroom activities the educator provided constructive feedback to the students.
Through the blended learning environment developed the topics and subjects under
investigation were clear enough, and the educator provided freedom and fl exibility
to the students, as well as increased responsibility for their own learning based on
their needs, demands, and interests.
The same picture is observed regarding the social presence, though being graded
relatively lower scores than the teaching presence. The data supports that it was
signifi cantly noticeable (M = 4.42; SD = 0.51; α = 0.709). Students felt to great extent
that they belonged to a group in which they could freely express their views, opinions, and thoughts. The interaction developed among students within in-classroom
as well as through blog's activities seemed to have strengthened the sense of collaboration. The educator managed to develop a community where the educator and
students felt closed and connected to each other, felt part of the course (developed
sense of belonging in the course—group cohesion), not only communicating for
educational purposes, but interacting socially as well (Affective Expression).
Additionally, the participants freely expressed their ideas, views, and opinions
through not only the online tools but within in-classroom, vividly participating in
the course discussion and frequently interacting with the rest of the participants
(Open Communication). Students shared and discussed with their peer views and
opinions and in some cases they felt instant connection to other peers. An initial
introduction, a welcoming note, and the online ice-breaking activities from the educator helped the students to open up and develop a sense of belonging. Channels of
communication were developed among students and the educator through the in-
classroom and blog activity showing that the open communication parameter was
highly present. Consequently, it can be supported that the social presence has been
developed through the use of blogs as educational tools.
Finally, the cognitive presence, had also a really "strong" appearance (M = 4.57;
S.D. = 0.38; α = 0.801) within the blended learning environment developed (blog
and in-classroom activity), however not as strong as the teaching presence.
Specifi cally, it emerged that the topic of the lesson stimulated in a great degree

students' interest, and online postings enabled students to understand the basic concepts of the course. The educator gave various interesting activities, motivated
students through questions; however, she did not provide adequate extra academic
and scientifi c information and resources to study. More specifi cally, the triggering
events were greatly apparent attempting to attract and motivate students. The activities developed and performed piqued students curiosity and felt motivated to explore
content related questions. It seems that the questions/activities designed and performed increased students' interest regarding the curriculum concepts under investigation and that their interest, motivation, and curiosity were enhanced. Exploration
was one of the elements of the cognitive presence that did not get high scores since
the educator did not provide adequate academic and scientifi c information and
resources to the students. Additionally, brainstorming, as a process was promoted
and implemented through in-classroom and blog discussions, which it helped students come up with answers and solutions. Finally, the total mean for the three presences was 4.59 (SD = 0.38). Revealing that the development of Community of
Inquiry was achieved in a great degree.
Blog Activity
The blog activity reveals blog role in developing a blended-learning environment
where in-classroom and blog-based activities are integrated in achieving the lesson's objectives. Overall nine posts were uploaded by the educator. Specifi cally,
seven of the posts were questions related to the subject under investigation. The
very fi rst question posted at the blog was for testing purposes (" Try to comment on
a blog post "). This question was posted throughout the introductory course conducted in the computer lab in order to give the students the opportunity to experience blogging. Their responses were used by the teacher in order to begin the
in-classroom lesson and discussions regarding "Time machine."
The second question posted at the blog was related to a video watched and discussed as an introduction to the lesson "How do you imagine a time machine? Can
you describe it? How does it look like externally and internally? What can it do?"
Students' replies focused on describing the time machine internally and externally,
and what one can do when using a time machine. During the Language and
Linguistics course the following question was posted: "Imagine that you are in the
time machine ready to travel. Where would you like to travel, into the past or in the
future and why? What would you change there?" The current question aimed to
trigger their imagination. Analyzing students' responses it is revealed that most of
them had special preference to travel into the past, and specifi cally to fi nd out where
their ancestors lived and how they behaved. Additionally, students reported that
they would like to travel to the past in order to correct their mistakes, to travel to
ancient history eras such as Ancient Greece and the Dinosaurs' Era. Finally, some
others chose to travel to the future in order to fi nd out how life would be and to make

sure that they will make their dreams come true. The students were requested to
begin addressing the questions in class and continue at home.
The next step was to discuss an article included in the Language and Linguistics
book. The educator used the students' responses in the previous blog question as an
introduction to a book article. In particular, the article was taken from the Focus
magazine, entitled "Travelling in time" and uploaded at the blog in order for the
discussion to be continued online. After studying and discussing the article in the
class, two questions were posted on the blog. The fourth and fi fth questions were as
follows: "Changing the events in the past and in the future: What would you like to
change if you went to the past or the future? What event would you like to change
and/or infl uence?" and "Persons from the past: Which person from the past would
you like to represent? What decisions would you change if you were that person?"
The students started answering the question at school and continued at home.
By the completion of the Language and Linguistics course the students were
requested to visit the blog once more in order to vote in which era they would like
to travel using the time machine. It was a multiple question voting system. The
choices were the following: Dinosaurs Era, Ice Age, Ancient Greece, their childhood, the future, the era in which their ancestors lived (parents/grandparents), and
other. The students chose to travel to the future and childhood, to the Dinosaurs Era
and their ancestors' era. Once more, the educator requested the students to use the
blog from home.
Finally, during the Art Lesson, the students were asked to imagine and draw a
time machine. Their drawings were scanned and uploaded by the educator to the
blog. A blog post accompanied the drawings delineating the following: "Fifth graders draw a time machine! Below you can fi nd your classmates drawings. Each student is requested to write a few words about his/her drawing. You can also comment
on your classmates' drawings. We are all waiting to hear your opinions." For this
post students showed minimum interest, mainly due to the lack of time.
Discussion
Blog Use
Blog was integrated as a tool at school and at home. There was no extensive use of
the blog from home for educational purposes, even though the students reported
using the Internet relatively often at home. Even if students did not highly use the
blog; its educational potential was revealed, since blog exploitation facilitated
the achievement of the lesson's learning objectives. It can be also supported that the
blog was integrated as an educational tool on a satisfactory level/degree since it
provided a platform for students to interact and discuss issues related to the subject
under investigation, activated their imagination and fi nally helped to signifi cantly
achieve the learning goals set by the educator. Overall, the blog was well organized
and designed. The effective and successful exploitation use of various blog's tools,

functions, and settings by the educator was observed and facilitated the learning
process. For example, the posts uploaded by the educator were of different content,
text, picture (student drawings) and video. The educator also employed various gadgets such as: voting (in order to perform the eighth post/exercises), calendar (for
reminding students when and where the lessons will take place as well as when the
exercises were due), blog archives.

Students
Students freely expressed their personal views, thoughts, and opinions; however,
they did not comment on their classmates' posts. Unfortunately, the blog was not
employed as a tool to promote collaboration and refl ection. This result was kind of
expected given the novice educator and student experience in blogging and the inexistence of educator's blog role and appearance. Additionally, it is supported that the
design of the activities was problematic, since they did not clearly provide instructions and guidelines to students. There was limited discussion, interaction and dialogue among the students at the blog, something that did not happen through
in-classroom activities (where the students were lively participated). Students'
responses showed that they were able to freely express their personal opinions; however, they did not comment on their classmates' responses. Thus, the blog was not
employed as a tool for promoting cooperation and refl ective learning. Specifi cally,
the teacher did not create the appropriate environment for students' interaction, dialogue and discussion through the blog. Moreover, not all students had access to computers and Internet at home. Finally, it was the very fi rst time that such as tool (the
blog) was used by both students and the teacher for educational purposes.
Educator
Given the above, it is suggested that educator's role is extremely important. Even
though educator's overall presence was really infl uential, managing to develop a
blended learning environment; it is important for a number of elements to be taken
into consideration when designing and implementing blog-based activities integrated within a blended learning environment. The students needed more guidance,
monitoring, assistance (promote interaction, debate, and dialogue) while working in
an online environment. In order to effectively and successfully integrate blogs as
educational tools within the teaching and learning process a number of factors need
to be in place. First of all, the educator should have a greater presence and involvement within blog activity. The educator needs to directly lead and guide the blog
activity. Specifi cally, the educator's participation at the blog for scaffolding, stimulation and motivation purposes considers being extremely important.
N. Eteokleous-Grigoriou and S. Photiou133
Having the same importance; specifi c and understandable instructions and guidelines regarding blog use and students' responsibilities and expectations is expected
to be given to the students. For example, the educators need to make sure that when
designing a blog and its posts (exercises), the following parameters are addressed:
frequency and consistency of use, initiative to begin discussion, initiative to continue discussion, quality of responses, minimum number of posts and responses to
classmates, deadlines, combination of blog and classroom activities; and provide
relevant information to the subject under investigation through links and extra readings. The educator's role is important and crucial. His engagement and involvement
in blog should be a continuously apparent while playing the role of the facilitator.
The educator needs to review students' posts, comment on students' responses, ask
questions, make observations, prompt and remind students to respond (Garrison &
Arbaugh, 2007). Also, it is important to motivate students, even providing grading
related motives.
One more important element is for the educator to highlight the importance of
dialogue, discussion, interaction and interactivity, coexistence, and collaboration
within a team, and fi nally the collaborative group result. The educator is responsible
in organizing lesson plans and developing activities to achieve the above learning
environments. It is also important that the educator organizes and develops well-
planned activities which use effectively blog's features, functions, and settings. For
example, blog activities are designed to be posted on the blog must have features
that promote critical thinking, refl ection, collaboration, dialogue, debate, expression
of opinions, and interaction (Zawilinski, 2009). Finally, to effectively design
blended learning environments; suffi cient time for students to use the blog should
be given, taking into account other parameters such as possession and use of computers and Internet access at home.
Conclusion
The possibility of incorporating the blog as an educational tool to a greater extent
within the primary education is highly evident given the results of the current study.
Additionally, the results of the study highlighted the employment of a blog as an
educational tool in order to design and develop blended learning environments
where Community of Inquiry is achieved. Specifi cally, the results revealed that both
cognitive and social presence as well as teaching presence contributed to knowledge
construction (Garrison & Vaughan, 2005). Nevertheless, the use of blog can be
characterized as satisfactory given the limited time it was active and its partial use
by the students. The current paper highlights the possibility of extensive blog integration as an educational tool in primary education taking into account various factors and suggests the development of a model that incorporates/explains the
requirements of effective integration blog in educational practice based on the following parameters: teacher, student, blogs, and content/activities. Through this
model, the role and interaction of the four parameters will be refl ected and explained.
Integrating Blogs in Primary Education134
Finally, it is argued that the model of the blended community of inquiry is considered more suitable for primary education. Future research should focus on adapting
the current model of community of inquiry, creating and weighting of a model to the
characteristics of primary education.

Introduction
Web 2.0 technologies can be used in education, especially for building projectbased learning activities (Duffy & Kirkley, 2004). Among these technologies, wikis
seem to offer rich collaboration possibilities (West & West, 2009). A wiki offers the
ability to edit a website by adding, modifying, and deleting pages as well as integrating hypermedia.
The open nature of the wiki technology provides opportunities for learning
(Mindel & Verma, 2006; Raman, Ryan, & Olfman, 2005; Wheeler & Wheeler,
2009), since all participants should work collaboratively in order to edit and improve
the content. Wikis as a collaboration tool can help students to write better (Mak &
Coniam, 2008) and can support collaborative knowledge creation (Raman et al.,
2005; Wagner, 2004). In addition, wikis can facilitate group learning (Carpenter &

Roberts, 2007), foster contribution to peers (West & West, 2009), and improve students' engagement (Molyneaux & Brumley, 2007).
Various skills, such as writing, IT, collaboration, and organizational skills (Lai &
Ng, 2011; Wheeler & Wheeler, 2009), can be improved with students' involvement
in wiki-based activities. Thus, students' participation in wiki projects can add value
Effectiveness of Wiki-Based Learning
in Higher Education

to learning and to their professional success (Frydenberg, 2008). It seems that in
well-designed wiki-based activities students are positive towards this technology
(Tétard, Patokorpi, & Packalén, 2009). They believe that wikis are useful for sharing
knowledge (Elgort, Smith, & Toland, 2008) and a great tool for collaboration
(Deters, Cuthrell, & Stapleton, 2010). Unsurprisingly, wikis have been used in various contexts such as developing an online textbook (Ravid, Kalman, & Rafaeli,
2008) and supporting knowledge sharing (Raman et al., 2005). Wikis can also help
teachers to manage and mark their students' work (Deters et al., 2010). However,
the wiki openness may also be a disadvantage if the context and objectives of the
activity are not well determined (Parker & Chao, 2007). As a result, there are examples in which students did not actively participate in creating or editing context
(Cole, 2009; Ebner, Kickmeier-Rust, & Holzinger, 2008).
In order to avoid these situations and to provide a rich context and simultaneously a support structure in a wiki environment, West and West (2009) proposed an
instructional design process. This process includes the following steps: establish a
purpose for the wiki project, define and classify the wiki project's learning goals,
design a rich context and problem that support the achievement of the purpose and
goals, prepare students for work in the new environment, and promote a collaborative process through which active, social learning can take place (West & West,
2009, p. 22). This approach emphasizes scaffolding. In addition, West and West
(2009) used the Bloom's Taxonomy of Learning (Bloom, 1956) to classify the main
wiki project's learning domains. From this grouping three wiki project categories
emerged: (a) knowledge construction, (b) critical thinking, and (c) contextual application. The wiki activity design was based on the framework proposed by West and
West (2009), and its learning domain belongs to the category of knowledge construction. The goal of the designed activity was to learn general information about
Web 2.0 and its applications in the frame of a first-year academic course entitled
"Introduction to ICT."
The aim of the study presented in this chapter was to investigate the effect of a
framed, rigorously designed, wiki-based activity on the learning outcome. In specific, this chapter investigates:
• Students' learning gain after the wiki-based activity
• Whether the students with lower pretest score benefited from the activity at least
to the same extent as students with higher pretest score
• Whether students' learning performance was affected by their role while carrying out the activity
• Whether students with more logged wiki edits benefited more than students with
less wiki edits
This chapter is organized as follows: Initially, the research methodology, the
profile of the participants, and the design of the activity are described. Subsequently,
the research results are presented, focusing on learning outcome as assessed by an
appropriately designed pre- and posttest questionnaire.
P. Altanopoulou et al.139
Methodology
Research Method and Materials
A single-group pretest-posttest design was adopted (Cohen, Manion, & Morrison,
2000). A questionnaire with closed questions was the data collection instrument.
The pretest questionnaire comprised both demographic (13 questions) and factual
knowledge questions (36 questions, each with four possible answers of which only
one was correct). The factual knowledge questions were primarily related to general
information about Web 2.0 and its applications, whereas the demographic questions
were related to personal information regarding ICT, Internet, and wiki usage and
adoption. The posttest comprised the same factual knowledge questions. The students were not informed that they would be asked to complete the questionnaire at
the beginning or the end of the activity.
The wikispaces service (www.wikispaces.com) was used both for the activity
announcement and as the platform provided to the students to construct their wiki.
The online questionnaire service SurveyMonkey (www.surveymonkey.com) was
used to create and distribute the questionnaires of the study. The obtained data were
organized and analyzed using Excel 2007 and SPSS v17.0. The activity presentation, students' presentation of their wikis, and completion of questionnaires took
place in the computer lab of the Department.
Procedure and Participants
All in all, 220 first-year university students participated in the study. The students
were divided freely into 44 groups comprising 5 members each. In the beginning of
the procedure an instruction on the wiki's basic functionality was given to the students. Subsequently, a compulsory assignment was presented to them in the form of
a wiki, realized by the researchers. Each team member had a specific role in the
group such as collector, organizer, editor, and verifier (West & West, 2009). The
responsibilities of each role are delineated in the following.
Eighty-one (81) of the students did not respond to either the pre- or posttest
assessment questionnaire and were excluded from the dataset. Analysis was conducted for the data collected by 139 students, 2 male and 137 female, aged 17–37
(mean=19.3, sd=3.5). The majority of the participants (127/139) were 17–22 years
old. They were attending a compulsory academic course entitled "Introduction to
ICT," offered in the first semester in the Department of Education and Early
Childhood Education at the University of Patras. Participation in the activity was
compulsory and was one of the five required mini-projects given to the students in
the context of the laboratory part of the lesson.
Effectiveness ofWiki-Based Learning in Higher Education140
Description ofthe Activity
The design of the activity was based on the framework proposed by West and West
(2009). Learning was expected to be achieved by engaging the students into four
processes: information seeking and retrieval, argumentation development and
refinement to support their thesis, cooperation among members, and their involvement with the wiki-editing process. The assignment was presented to the students
through an exemplary wiki, which was constructed by the researchers (available at
http://labtpewiki.wikispaces.com).
The exemplary wiki included the purpose and the objectives of the assignment,
detailed implementation instructions, expected learning outcome, evaluation criteria, and representative support material. In addition, the topics that students had to
cover were outlined and organized into subsections with a short description for each
one. Afterwards, the students of each group had to create their own wiki, in which
they would develop the topics of the assignment.
The topic of the designed activity was to learn general information about Web
2.0 and its applications. It was selected due to the following reasons: First, the students should be able to understand the impact of Web 2.0 on society in general and
on education in particular. In addition, the topic is suitable for covering a variety of
educational and technological aspects of Web 2.0, thus giving a fertile ground for
argumentation. Finally, it is a notable session of the course's overall outline. The
exemplary wiki included nine segment topics: (a) Web 2.0 definitions, (b) characteristics of Web 2.0, (c) YouTube and Slideshare, (d) Twitter, (e) Blogs, (f) Wikis, (g)
Skype, (h) description of an educational activity using these technologies, and (i)
potential risks of Web 2.0 use.
For this activity wikis were used to promote collaboration with peers and improve
their knowledge related to the aforementioned topics (West & West, 2009). The students had to search for information on all of these topics and seek additional material. Furthermore, it was stressed that usage of other's work should follow specific
rules since the open nature of Web 2.0 tools could lead to inappropriate use of content
from other sources, as reported in Huijser (2008) and West and West (2009). Students
were instructed on how to use and cite sources and were also informed that they
could only use freely available media or media under a creative commons license.
Each team member was assigned a specific role by the researchers. These roles
are delineated by West and West (2009). The first role was that of "collector" who
had the responsibility to obtain appropriate material relevant to each subtopic. Two
members of each group were "collectors." The second role was that of the "organizer" who was responsible to organize the collected material and to check its consistency and relatedness with the objectives of the project. The "editor" was
responsible to check grammar and syntax errors in the content and its compliance
with the provided format. The "verifier" was responsible to check the content for its
completeness, structure, and compliance with the objectives of the project. However,
all students were allowed to participate and contribute in every aspect of the
collaboration process.
P. Altanopoulou et al.141
Finally, the students had to present their work briefly during the laboratory session of the course. Each project was graded by the researchers on a 1–100 scale. The
score was multiplied by the number of the group members and was given to the
students. Subsequently, the students in each group were asked to discuss and distribute these points fairly according to each member's contribution. As far as the score
distribution is concerned, a notable differentiation was observed in only 9 out of the
44 groups. Such grade distribution differentiations possibly indicate a lack of balanced collaboration.
Results
All in all, we analyzed data from 139 first-year university students involved in a
wiki-based activity in the context of an introductory ICT course. Table 1 presents
participants' demographic-related information in our dataset.
First, a reliability analysis of the provided 36-item knowledge assessment questionnaire was conducted. Reliability refers to the extent to which an instrument,
such as a questionnaire, yields the same results under consistent conditions
(Nunnally & Bernstein, 1994). It is most commonly measured using Cronbach's
alpha, which is a measure of internal consistency. Results showed that the initial
36-item questionnaire used in the study did not have sufficient reliability
(alpha=0.69) to meet the typical minimum standard of 0.70 (Nunnally & Bernstein,
1994). Two questions increased the alpha to 0.70 if they were deleted and thus were
excluded from subsequent test score computations.
Next, students' pretest and posttest correct answers in the knowledge assessment
questionnaire were converted to a composite test score on a 0–100 scale. In addition, a normalized learning gain score was produced for each participant by using
the formula proposed in Nelson et al. (2009) and defined as
G =

Effectiveness ofWiki-Based Learning in Higher Education142
This score has the advantage of "normalizing the observed gain (the numerator)
against the amount of possible learning that could be achieved (the denominator)"
(Nelson et al., 2009, p. 1797). Table 2 presents descriptive statistics of the dependent variables measured in the study.
In all subsequent statistical analyses, we use the correlation coefficient r as an
effect size, which is calculated according to the formulas reported in Field (2009).
Did the Wiki-Based Activity Improve Students' Performance?
A dependent t-test was applied to compare students' pretest (M=43.6, SD=11.4)
and posttest (M=63.8, SD=13.6) performance, as measured by the provided knowledge assessment questionnaire. The differences between the test scores did not violate the assumption of normality (D(139)=0.98, p=0.059), and thus a parametric
test was selected. Results indicated that students achieved significantly higher
(t(138)=17.74, p<0.001, r=0.83) test scores after participating in the wikimediated learning activity. According to Cohen (1992), this is a very large effect
size, which demonstrates the learning effectiveness of a properly designed wikimediated learning activity.
Were Students with Lower Pretest Score Benefited at Least
to the Same Extent as Students with Higher Pretest Scores?
We recoded our dataset to create two between-subject groups based on students'
initial performance: (a) low initial performance (N=83), which included students
with pretest score below or equal to the median score of all students, and (b) high
initial performance (N=56), in which students with pretest score above the median
score of all students were assigned. Table 3 presents descriptive statistics of students'
pretest score, posttest score, and normalized learning gain in relation to these groups.
A two-tailed Mann–Whitney U test investigated the effect of students' initial
performance on their normalized learning gain. A nonparametric test was selected
because the assumption of normality was violated for the high initial performance
group (D(56)=0.95, p<0.05), and homogeneity of variance was also violated
(Levene's test, F(1,137)=9.39, p<0.01). Results indicated that although students
Table 2 Students' pre- and posttest scores in the knowledge assessment questionnaire and their

P. Altanopoulou et al.143
with low initial performance showed a slightly higher (3.9 %) normalized learning
gain compared to those with high initial performance, this difference was not significant (z=0.14, p=0.889). Also, an insignificant correlation (rs=−0.04, p=0.668)
between students' pretest score and normalized learning gain was found.
Additional analyses after Bonferroni correction investigated whether the wikimediated activity improved students' score for both the low and high initial performance groups. A nonparametric test was selected for the high initial performance
group because the distribution of the differences in the dependent variable (test
score) between the two related conditions deviated significantly (D(56)=0.94,
p<0.01) from a normal distribution. Results showed that students' test scores were
significantly improved in both the low and high initial performance groups:
t(82)=17.16, p<0.001, r=0.88 and z=5.56, p<0.001, r=0.53, respectively.
All in all, the above results provide evidence that the wiki-mediated learning
activity was beneficial to students with lower initial performance, at least to the
same extent as those with higher initial performance.
Did Students' Role in the Wiki-Mediated Activity Affect Their

Learning Gain?
Table 4 presents students' performance grouped by their role in the wiki-based
activity: collector (N=53), organizer (N=28), editor (N=29), and verifier (N=29).
Table 4 shows that the lowest average learning gain (30.0 %) was observed for
students with the verifier role, whereas students with the editor role had the highest
learning gain (44.4 %) on average. However, a one-way ANOVA did not unveil any

Effectiveness ofWiki-Based Learning in Higher Education144
significant learning gain differences between the four different students' roles
(F(3,135)=2.48, p=0.064).
Thus, results show that the wiki-mediated learning activity was beneficial to all
students, regardless of their specific role in the project.
Were Students with More Wiki Edits Benefited More Than
Students with Less Wiki Edits?
We recoded our dataset to create two between-subject groups based on students'
logged number of edits in the wiki: (a) low number of wiki edits (N=71), which
included students with a number of wiki edits below or equal to the median number
of wiki edits of all students, and (b) high number of wiki edits (N=68), in which
students with a number of wiki edits above the median number of wiki edits of all
students were assigned. Table 5 presents descriptive statistics of the measured
dependent variables in relation to these two groups.
The assumption of normality was violated for the high number of edits group
(D(68)=0.93, p<0.001); thus a nonparametric test was applied to investigate differences between the two groups. A two-tailed Mann–Whitney U test showed that
students with more wiki edits had a significantly higher learning gain (z=-4.32,
p<0.001, r=0.37) compared to students with less wiki edits. In addition, a significant correlation (rs=0.41, p<0.01) was found between students' number of logged
wiki edits and normalized learning gain: the more active the students were, the more
they improved their performance.
Additional analyses after Bonferroni correction investigated whether the wikimediated activity improved students' score for both the students with lower and
higher number of wiki edits. Results showed that students' test scores were significantly improved in both groups: t(70)=10.69, p<0.001, r=0.79 and t(67)=15.45,
p<0.001, r=0.88, respectively. As the effect sizes show, this improvement was of
higher magnitude for the students who were more active contributors in the wiki.
In sum, it was found that both students with low and high number of logged edits
in the wiki improved significantly their performance, but the latter had a significantly higher learning gain.

Conclusions
A study investigating the effectiveness of a wiki-mediated learning activity for ICT
education was presented. The evaluation was carried out using a one-group pretest-
posttest design. The results showed significant improvement in learning outcomes;
the average students' test score improved from 43.6/100 to 63.8/100. In addition, it
was found that the wiki-mediated learning activity was equally beneficial to students with lower and higher initial performance. These results suggest that a properly designed, framed wiki-based activity could substantially facilitate students to
learn by building content. In a similar vein, there are surveys which indicate that
wiki technology can be beneficial to students in various learning domains
(Mohammed, 2010), given that a carefully designed activity is introduced to them.
Similar findings are reported in Tselios, Altanopoulou, and Katsanos (2011) and
Tselios, Altanopoulou, and Komis (2011).
No significant learning gain differences between the four different student's roles
(i.e., collector, organizer, editor, verifier) in the wiki activity were identified. This
finding is in line with previous research (Strijbos, Martens, Jochems, & Broers,
2004; Tselios, Altanopoulou, & Katsanos, 2011; Tselios, Altanopoulou, & Komis,
2011) which indicates that roles do not affect group members' performance.
However, roles can help students who work collaboratively to build knowledge in
comparison to students with no distinct roles while collaborating (Schellens, Van
Keer, De Wever, & Valcke, 2007).
Furthermore, results showed that students who were more active contributors in
the wiki, as measured by their logged number of edits, had a significantly higher
learning gain.
However, the reported study is not without limitations. First, it should be noted
that our data is gender and age skewed; thus the findings might not be generalizable
to male students or older students involved in wiki-mediated learning activities.
Furthermore, the results obtained do not explain how the students have benefited
from their involvement in the activity. Future research goals constitute the design of
additional wiki-based activities in a variety of educational settings as well as investigation of the learners' behavioral intention to use wiki technology using technology acceptance models (Tselios, Daskalakis, & Papadopoulou, 2011). Moreover,
the relation between the observed students' activity and the learning outcome will
also be examined (Katsanos, Tselios, & Avouris, 2010).

Introduction
E-learning is a modern learning method, based on information and communication
technologies (ICT). Its main characteristics are that it overcomes time and spatial
restrictions, since learners can attend the course wherever they are, assuming they
have adequate equipment, such as a computer connected to the Internet.
Courseware is a term that combines the words "course" with "software", and was
used originally to describe additional educational material for authors and learners
apart from the e-learning platform itself. The meaning of the term and usage has
expanded and can refer to the entire course and any additional material when used
in reference to an online or "computer formatted" classroom. The main objective of
constructing courseware is to help authors and developers to carry out the construction/development process of courseware and learning contents automatically. The
secondary objective is to promote the reuse/exchange of existing learning resources
among different users and systems (Romero & Ventura, 2010).

In any courseware, each course consists of the content, the organisation and the
management of the course, the teaching/learning process, the log data, social computing tools, etc. Although the quality of a course does not depend only on its content but also on its structure, organisation, support, delivery, etc., content plays a
crucial role for the success of e-learning. In order to ensure this fact, it is necessary
to apply processes of continuous evaluation and optimization of the educational

material (Kazanidis, Theodosiou, Petasakis, & Valsamidis, 2013). Consequently, it
is necessary to provide feedback to a course author, in order to show the means to
improve its courseware (Romero, Ventura, & De Bra, 2004). The evaluation of educational material can be made either directly by taking feedback from the learners
or through automated data mining techniques applied to the courses log fi les data
(Vialardi, Bravo, & Ortigosa, 2008).
Statistical analysis methods were applied in many cases in order to obtain relevant information from e-learning data. The higher education learner-evaluation data
were analysed in Jin, Wu, Liu, and Yan (2009). The number of visits and duration
per quarter, top search terms and number of downloads of e-learning resources were
described in Grob, Bensberg, and Kaderali (2004). The number of different pages
browsed and total time spent browsing different pages was also presented in Hwang,
Tsai, Tsai, and Tseng (2008).
Data mining (DM) in education uses computational approaches to analyse educational data in order to analyse upcoming educational issues. According to Romero
and Ventura (2010) "the term DM is used in a larger sense than the original/traditional DM defi nition". Although there is a great deal of research in the fi eld of DM
in e-learning that uses typical techniques, such as classifi cation, clustering, association rule mining, sequential mining, etc., there are also a signifi cant number of studies that use techniques belonging to the broader fi eld of DM, such as regression,
correlation, etc. The application of data mining (DM) in education is a rapidly
growing interdisciplinary area which combines a variety of areas, including individual learning from educational software, computer supported collaborative learning, computer-adaptive testing (and testing more broadly), and the factors that are
associated with student failure or non-retention on courses (Baker, 2010). Although
data mining (DM) in education uses computational approaches to analyse educational data in order to study educational questions, the methods are often different
from standard data mining methods (Baker & Yacef, 2010).
The approach in this paper is twofold. On the one hand, it goes backward to
examine whether the usage of the courses by the learners is affected by the educational content exposed by the authors. One the other hand, it examines whether the
usage of the courses by the learners on a course is related to the mean performance
of the learners on this course. It proposes some new metrics and measures, taking
into account several statistics concerning the courses. These include the number of
fi les and their sizes, the number of pages that each course has on the e-learning
platform, and statistics concerning the usage of the platform for each course by the
learners, such as the number of sessions, the number of visits, the duration of each
visit. These measures and metrics aim to help course authors and/or platform administrators review course usage, and fi nd online course weaknesses. Regression analysis is also used for the identifi cation of possible dependencies.

Method
The proposed method adopts a three-level schema for an e-learning platform. It uses
six measures and three metrics for both content and usage measurement. Finally,
classifi cation, clustering, association rule mining, and regression analysis are
applied to the e-learning data. More specifi cally, the values of the measures and
metrics and the mean marks from the corresponding courses are investigated for
possible dependencies.
The Three-Level Dependencies
A view of the proposed schema of the approach is depicted in Fig. 1 .
In Fig. 1 , the Content Level (CL) includes the educational material that is exposed
to the learners by the authors. It can be assessed with the use of measures. The Usage
Level (UL) includes the usage of the educational material by the learners. Other
measures and new metrics are also used to assess the usage. The Exams Level (EL)
includes mean marks, the learners performed for each course. The mapping between
CL and UL is one to one. Although the values of the measures may change each time
(affected by authors' actions and learners' usage), the assessment usually takes place
at the end of the semester. The mapping between UL and EL is one to many, since
there are n (n> 1) opportunities for every learner to participate in the exams.
Measures and Metrics
Some measures are used in the CL and some others in the UL of the courses. With
the measures of the Table 1 , we quantify the offered educational material to the
learners by the authors in terms of input variables on a course.

Educational Content of the Course
EXAMS
LEVEL
mapping
mappings
CONTENT
LEVEL
USAGE
LEVEL
Fig. 1 The 3-level approach

This category of measures is related to the courses' online educational content of
the courses. More specifi cally, the number of pages, the number of fi les and their
corresponding sizes give an estimation of the content quantity, which is a crucial
factor of online educational content. In some e-learning systems instead of the term
"page" the term "module" is used. If the number of fi les and their size are small, this
might be due to the weakness of the author to upload enough educational content
onto the online platform. If the course has a lot of fi les with large sizes this could lead
learners to face the cognitive overload problem and not study the course effectively.
With the measures of Table 2 (Valsamidis, Kontogiannis, Kazanidis, Theodosiou,
& Karakos, 2012), we quantify the usage of the available educational material by
the learners in terms of usage variables on a course.
The second category of measures helps researchers to discover learner activity
and follow up a course. The number of sessions show how many times learners have
logged in. The number of sessions and the number of visits viewed by all users are
counted for the calculation of course activity. Each session refl ects when a user logs
in to the platform, and after some activity, logs out from the platform. If there is no
activity, there is a timeout of 30 s. The number of visits refl ects how many pages
were viewed by all users. There are some pages of the course which were viewed by
many users, but there were also some other pages not so popular. If learners of a
specifi c course visit more pages for a long time, this means that course content is
interesting and useful for the learners. This could refl ect the course quality.
Consequently, a good course in terms of quality may help learners in their study.
The number of sessions could be compared with number of visits and duration. The
two later variables show if learners fi nd the course useful and like to visit its pages.
The next step is to defi ne some metrics, in order to qualify these quantity metrics.
In Table 3 , we calculate the quality of the available educational material on a course,
in terms of usage by the learners of output variables.
VPS Visits Sessions □ / ( ) V E/

(1)
Table 1 Content measures
Measure Description of the measure
Pages (P) The total number of pages (modules) existing on the course
Files (F) The total number of fi les on the course
Size (S) The total size of the existing fi les on the course
Table 2 Usage measures
Measure Description of the measure
Sessions (E) The total number of sessions per course viewed by all users
Visits (V) The total number of visits (page hits) per course by all users
Duration (D) The duration of (total) visits per course by all users

The VPS has a range of between (0, 1]. A low number of VPS outcomes indicates
that users stay more time in a page of a course. Since the VPS metric measures the
number of visited pages divided by the number of sessions of a course, the higher
the number of sessions in the course, the lower is the fraction. On the other hand, the
author may update the educational material with more visited pages. So, the fraction
has comparable values.
VPD Visits Duration □ / ( ) V D/

(2)
The VPD expresses the number of visits per duration. A high number of VPD
means that users change pages quickly into the course. This could be an indication
that users are experiencing diffi culties discovering the desirable content or they
already have assimilated most of the course content. Both metrics refl ect users'
behaviour related to the educational material.
We also defi ne a course quality metric called smooth or distinct Course Utilisation
and user Perception metric (CUP). This metric expresses how smooth, or selective,
or even randomly visit time of users per course is distributed over the academic
semester. That is, from Eq. (3), for n online courses a constant histogram break is
used equal to 1/2 n (break = 10 and n expresses weeks (n = 1…10)). Then the CUP
metric value is calculated as follows:
CUP □ □n h x h x max min □ □ □ □ □

(3)
where h (x) the histogram density estimate:
h x k n w □ □ □ / / 1

(4)
x = cell centred at x with width w that contains k data points and n × h (x) = (2/ n) k
if CUP → 0 then we have smooth course utilisation over time, while if CUP → 1
we have only distinct weeks of course utilisation. In cases of CUP > 1 we assume
that such courses maintain either a one-time utilisation or abnormal utilisation of
very low and very high. We consider such courses as fl apping or abandoned courses.
Data Mining
Data mining techniques have been applied to e-learning systems data by many
researchers. Apart from the analytical review by Romero and Ventura (2010), there
is some more domain specifi c. Castro, Vellido, Nebot, and Mugica (2007), among
Table 3 Quality metrics
Metric Description of the metric
VPS Visits per session
VPD Visits per duration
CUP Course utilisation and user perception

others, deal with the assessment of the students' learning performance, provide
course adaptation and learning recommendations based on the students' learning
behaviour, deal with the evaluation of learning material and educational Web-based
courses, provide feedback to both teachers and students of e-learning courses, and
detect a typical student's learning behaviour. A survey by Koutri, Avouris, and
Daskalaki (2005) provides an overview of the state of the art in research of Web
usage mining, while discussing the most relevant criteria for deciding on the suitability of these techniques for building an adaptive web site. One relevant study
(Kotsiantis, Pierrakeas, & Pintelas, 2004) predicts the students' performance, as
well as to assess the relevance of the attributes involved.
Students are assessed in the fi nal exams of the courses, and they are assigned a
mark according to their performance on the course. Having measured the students'
activity in the e-learning system according to the measures and metrics, it is possible to investigate whether there is a relationship between student activity in the
platform of the e-learning system and the marks of the students in the fi nal exams.
A well prepared and implemented online course may help learners in their study and
therefore allow them to achieve a better mark. Therefore, it would be useful to check
if the previous metrics and measures are related to a learner's mark.
In the classifi cation step, the algorithm 1R (Witten & Frank, 2005) may be
applied. It uses the minimum-error attribute for prediction, discretizing numeric
attributes (Holte, 1993). The attribute Mark has to be used as class, since it describes
the education outcome. In this step the attribute/s which best describe the classifi cation will be discovered.
The clustering step contains course clustering with the use of the SimpleKMeans
algorithm (Kaufmann & Rousseeuw, 1990) for unsupervised learning. SimpleKMeans
algorithm automatically handles a mixture of categorical and numerical attributes.
Furthermore, the algorithm automatically normalises numerical attributes when
doing distance computations.
According to Baker (2010) relationship mining is a technique which discovers
relationships between variables, in a data set with a large number of variables.
There are four types of relationship mining: association rule mining, correlation
mining, sequential pattern mining, and causal data mining. In this paper we focus
on association rule mining. Association rule mining is one of the most well studied
data mining tasks. It discovers relationships among attributes in databases, producing if-then statements concerning attribute-values . An association rule X → Y
expresses a close correlation among items in a database, in which transactions in
the database where X occurs, there is a high probability of having Y as well. In an
association rule X and Y are called respectively the antecedent and consequent of
the rule. The strength of such a rule is measured by values of its support and confi -
dence. The confi dence of the rule is the percentage of transactions with antecedent
X in the database that also contain the consequent Y. The support of the rule is the
percentage of transactions in the database that contains both the antecedent X and
the consequent Y in all transactions in the database. The Weka system has several

association rule-discovering algorithms available. The Apriori algorithm will be
used for fi nding association rules over discretized e-learning platform data.
Regression Analysis
Several regression techniques have been used to predict a student's academic performance (using stepwise linear regression) (Golding & Donalson, 2006), to identify variables that could predict success in college courses (using multiple
regression), to predict university students' satisfaction (using regression and decision tree analysis), to predict high school students' probabilities of success in university (Mcdonald, 2004), to predict a student's test score (using stepwise regression)
(Feng, Heffernan, & Koedinger, 2005) and to predict the probability a student has
of giving the correct answer to a problem in an ITS (using a robust ridge regression
algorithm) (Cetintas, Si, Xin, & Hord, 2009). Yu, Jannasch-Pennell, Digangi, and
Wasson (1999) use a multivariable regression model to predict a learner's performance from log and test scores in Web-based instruction. Multiple linear regression
is used for predicting the time to be spent on a learning page (Arnold, Scheines,
Beck, & Jerome, 2005). Thomas and Galambos (2004) use regression analysis for
predicting university learners' satisfaction.
Linear regression analysis is applied on the CL. The classifi er builds linear logistic regression models. In our case, the way the mean mark is affected by the metrics
VPS, CUP, and VPD of each course is examined. The regression coeffi cients show
the marginal value of input (VPS, CUP and VPD) required measuring Mark.
Results
Study Population and Context
The recording of specifi c data from the e-learning platform is the fi rst step. The
dataset was collected from the Open eClass e-learning platform (GUNet, 2012)
which is used at the Kavala Technological Education Institute (TEI). The data are
from the Spring semester of 2011 and involve 1,534 students and 34 different
courses and are obtained from the server log fi les.
Case Study
A view of the collected data is shown in Table 4 . The values of the measures of
Tables 1 and 2 , which express measures of UL and CL, are presented. The aforementioned measures contribute to the evaluation of courses content and usage.

First Mapping Dependencies
All the DM techniques were performed using the open source Weka. The data mining methods are applied to the measures of Table 4 . The results of the classifi cation based on the OneR algorithm show that the measure Pages is better classifi ed (described) by the measure Sessions as depicted in Fig. 2 . For the three bins of the instances (low, mid and high) are described by the low bin of grades. It is easily interpretable, since only one mean mark is greater than 7.66667.

The results of the clustering based on the SimpleKMeans algorithm (Kaufmann & Rousseeuw, 1990) show that there are two clusters which correspond to high Mark (cluster 0) and low Mark (cluster 1), as depicted in Fig. 3 . For most attributes of the two clusters there is a high degree of similarity. However, the values of Sessions, Visits, Duration, VPD and Mark are not equal.
The results of the association rule mining based on the Apriori algorithm (Agrawal & Srikant, 1994) show ten rules, as depicted in Table 5 .
Table 5 shows how a large number of association rules can be discovered. There are some uninteresting rules, such as rules 8 and 9, since there is obvious dependency between Duration and Visits. Specifi cally, there is dependency between the low range of Duration (-inf-5670.666667] and the low range of Visits (-inf-4006]. There are also redundant rules, rules with a generalisation of relationships of several rules, like rule 2 with rules 1, and 7, 3 with rules 5 and 9, and 4 with rules 6 and 10. There are some similar rules, rules with the same element in antecedent and consequent, but interchanged, such as rules 1, 2, 8 and rules 5, 3, 9 respectively. But there are also rules that show relevant information for educational purposes, like those that show conforming relationships, such as rules 1, 2, 3, 5 and 7. And there are also rules that show interesting relationships, such as rules 4, 6 and 10, which can be very useful for the author in decision making about the activities of their courses. For example, in rule 10, there is a dependency between low range of Visits (-inf- 4006] and the low range of Pages (-inf-7.666667]. Similar conclusions can be drawn from the other rules.

Fig. 3 Clustering results
Courseware Evaluation Through Content, Usage and Marking Assessment158
Second Mapping Dependencies
Simple linear regression analysis was applied to the metrics and marks of Table 4 . The courses were classifi ed to three classes according to their mean marks. The fi rst class which corresponds to courses with low marks is described by the equation
Mark VPS CUP □ □ □ □ □ □ □ 1 46 0 9 2 73 . . .

(5)
The second class which corresponds to courses with mid marks is described by the equation
Mark VPS □ □ □ 1 21 0 55 . .

(6)
The third class which corresponds to courses with high marks is described by the equation
Mark VPS VPD □ □ □ □ □ □ 0 27 0 61 0 981 21 . . . .

(7)
An increase in the VPS metric leads to higher mean marks for each course. From the formulas (5), (6) and (7), the conclusion is drawn that an increase of one unit to the value of the metric VPS will increase the mean value of the Mark 0.9, 0.55 and 0.61 for the three classes respectively.

Discussion and Conclusions
This study proposes an approach for discovering dependencies based on histories from e-learning data. It tackles the problem of analysing these data at three levels. Initially it examines whether the usage of the courses by the learners is affected by the educational content exposed by the authors. It is proved by the classifi cation results and the dependency between Sessions and Pages (Modules). Then, it examines whether the usage of the courses by the learners on a course is related to the mean performance of the learners on this course. This is proved by regression results and the dependency between VPS and Mark. It proposes some measures, such as the number of fi les and their sizes, the number of pages that each course has on the e-learning platform, the number of sessions, the number of visits and the duration of each visit. New metrics are also proposed to assess course usage. Three data mining techniques, classifi cation, clustering and association rule mining, were applied to the e-learning data at the fi rst two levels. Furthermore, regression analysis was applied to the same data at the last two levels.
The originality of the study lies in the different use of existing techniques. The study builds on existing work, but also extends it in a different way, encompassing the e-learning fi eld. It has the following advantages: (1) It is independent of a specifi c e-learning platform, since it is based on the Apache log fi les and not the e-learning platform itself. Thus, it can be easily implemented for every e-learning platform. (2) It uses measures and metrics, in order to facilitate the evaluation of each course in the e-learning platform and the authors to make proper adjustments to their course educational material. (3) It uses classifi cation, clustering, association rule mining and regression analysis in order discover possible dependencies of the e-learning data.
The results reveal dependencies between content of the course and its usage by the learners. There is a dependency between the number of modules (Pages) of the platform with the number of sessions and the number of visits. The results also confi rm the assertion that there is dependency between the students' usage on an e-learning platform with their corresponding performance in the exams.
Feedback about the approach was received by the authors. The authors were informed about the indexing results along with abstract directions on how to improve their courses. Most of authors increased the quality and the quantity of their educational material. They increased the quality by reorganising the educational material in a uniform, hierarchical and structured way. They also improved the quantity by embedding additional educational material. By updating educational material, both quality and quantity were increased. A major outcome through the process of informing the authors about the results is that the ranking of the courses constitutes an important motivation for the authors to try to improve their educational material. Because of their mutual competition, they want their courses to be highly ranked.
A few authors complained that their courses organisation does not assist them to have high fi nal scores in the ranking list. They argued that, for example, the measure Pages (Modules) is heavily infl uenced by the number of web pages used to organise the educational material. Thus, courses that have all their educational material organised
Courseware Evaluation Through Content, Usage and Marking Assessment160
in a few pages have a low Pages (Modules) score. They were asked again to reorganise the material for each course in the e-learning platform according to the order taught, in order to facilitate easier use by the students.
The fact that only 34 courses in one platform were investigated is a limitation to the study. Especially for the data mining techniques which demand large datasets. However, this was ineluctable, since the case study department implements this number of online courses. But the proposed approach seems to be quite reliable if the inspection takes place over a long time period.
There are also other limitations to the proposed approach. Although ten parameters were investigated, which are not few, it could be asserted that many more could also be investigated. In addition, the infl uence of collaboration among the learners could also be investigated, since this plays a crucial role in the educational process. This omission is due to a lack of suffi cient enough related logs of the corresponding modules (wikis, chats, forums etc.) of the e-learning platform. Moreover, there are a number of students who try to read the materials only just before the exams. No one denies that a good site with good material, which is updated frequently, exists, but rarely visited. On the other hand, a bad web site may have frequent visits because student visits are related to their expected mark. So, the frequency and pattern of an individual student accessing an instructor's materials will be an indicator to show such a student's "Laziness" or "Diligence".
The results of this research are remarkable from a pedagogical point of view. On the one hand, this approach contributes to the improvement of courseware content quality, since the proposed measures and metrics, and their correlations to students' marks provide the authors a feedback about their effi ciency of their courses. Improvement of course quality provides students the opportunity of asynchronous study of courses with actualized and optimal educational material. On the other hand, since students usage results are correlated with the students' grade, an online platform may provide authors with notifi cations about their students' online actions. According to our experiment, results usage is closely related to the students' marks. An increased usage leads to better student marks and therefore to an improved educational outcome. For example, a learning platform could record student actions and after the application of specifi c algorithms classify them into predefi ned groups according to their estimated performance. Authors could study these groups of students, and try to help and motivate weak students. They could provide the advanced students with more educational content in order to achieve a more in-depth learning programme. Thus, the learning performance of all students could be signifi cantly improved.

Introduction
This chapter builds on previous work about the use of technologies for learning in
cultural institutions (Yiannoutsou, Bounia, Roussou, & Avouris, 2011) where an
analysis of selected cases revealed that technology mainly functioned as a medium
for information delivery. This use of technology treats culture as something that can
be "transferred" from the "knowledge holding" museum to the visitor. In this context museum experience is structured around the consumption metaphor: the
museum produces "information" in digital or other form, for the visitor to consume.
Studies evaluating this type of cultural experience used the term "museum fatigue"
to highlight visitor limited ability to remember, digest and utilise the information
offered (Bitgood, 2009). Another line of research, reports decrease in the audience
of museums and cultural institutions (Simon, 2010). Taking into account the above
observations we could argue that technology has been employed in various ways by
museums to support their reconnection with the public where we identify two main
trends with respect to the learning experience pursued. The fi rst focuses on refi ning
the information and the way it is delivered to the visitor. The second redefi nes the
role of the visitor and his/her relationship with the museum in the process of culture
creation. In this paper we will briefl y refer to technologies supporting the information delivery metaphor and we will further expand on how technologies can support
a learning experience based on visitor participation in the process of culture
creation.
Game Design as a context for Learning in
Cultural Institutions

Personalization and Games: Same Content
in New Clothing?
In this section we will discuss the learning implications of two examples which
we consider that involve information transfer: personalization and technologysupported games. These two examples represent the current trend in technology
development to support and enhance museum experience (see for example the
funded EC projects in FP7 and the recent call for digital culture, Cordis, 2012)
applied in order to attract more visitors to the museums. Here we will only discuss
the rationale underlying in general the learning experience that seems to be supported by these two examples.
Personalization aims at adjusting and transforming cultural experience so as to
meet the experiences, interests and knowledge at the level of the individual visitor
or the group. To this end, technology suggests the most appropriate content to the
user based (i) on visitor profi les, (ii) on the cumulative visitors' history (Bohnert,
Zukerman, Berkovsky, Baldwin, & Sonenberg, 2008 ; de Gemmis, Lops, Semeraro,
& Basile, 2008) (iii) on user-generated content (e.g. tags and comments) and on
combinations of these methods. The rationale for applying such techniques is that
cultural heritage sites have a huge amount of information to present, which must be
fi ltered and personalised in order to enable the individual user to easily access it.
Although this approach supports visits adjusted to visitor interests and previous
experience, it is underlined by the concept of visitor as consumer of information;
more fi ne grained this time. Thus, personalised interaction eager to bring visitors
closer to the museum employs tools and methodologies to accommodate the visitors' interests but at the same time reproduces the initial distance between the visitor
and the authority of the museum who owns culture and now also knows what is best
for each visitor.
The infusion of new technologies in cultural institutions and more specifi cally,
of mobile technologies have resulted in new ways of experiencing games in cultural institutions (spatial awareness) and have helped in reaching a larger audience
(not only children but also adult visitors). We focus on mobile games because they
support the cultural experience during the visit of the cultural institutions as
opposed to games appearing for example in museum web sites aiming to prepare
for the visit or enhance the experience after the visit. Many mobile games however,
created for supporting cultural experience with the aim to engage users fail to bring
at the centre of the activity the cultural content in playful ways. So there are game
and story instances (see for example Akkerman, Admiraal, & Huizenga, 2009 ;
Psaty et al., 2008) where players seem to be enjoying the cultural experience but the
question remains as to how cultural content is integrated in these games/stories and
what game characteristics invoke visitor engagement. Our observation is that quite
often visitors engage with cultural content (e.g. explore the historical centre of a
city) in the context of following the plot of a mystery story or being engaged in a
role playing game. Yet in many cases engagement with cultural content remains at
a superfi cial level as it is not smoothly integrated in the story or the game

(Yiannoutsou & Avouris, 2012). As a result, engagement with the cultural content
(e.g. responding to questions, taking pictures) becomes the "price the visitors have
to pay" in order for the interesting things and the fun to carry on (e.g. to see what
happens next in the mystery story, or who is the murderer, or to continue playing
the game). Furthermore, the output of this process is factual information (e.g. visitors end up knowing that there is a convent in the city) leaving outside other aspects
of the cultural experience (creativity, fi nding connections with own experience,
gaining ownership over the cultural experience, etc.).
To sum up, in this section we focused on the learning involved when using personalization techniques and games to support cultural experiences. We discussed
these two examples due to their wide adoption in cultural institutions during the last
years and because they are claimed to result in active visitor engagement with cultural content. Our analysis showed that the mainstream use of these approaches ends
up often in consuming or collecting factual information by the visitor where the
museum is the entity that holds the knowledge for the visitor to collect it or consume
it. This is not to imply that game and personalization technologies can only support
the information consumption metaphor. Instead, as we will show in the next section,
personalised learning and games can offer rich learning opportunities if they are
integrated in a different rationale with respect to the role of the visitor, his/her relationship with the museum and the goal/nature of learning in cultural institutions.
Participation as a Context for Rethinking Technologies
that Support Learning in Museums
Participation-based cultural experience is based on the assumption that culture is
generated dynamically through the dialectic relationship between the museum and
the visitor (Simon, 2010). Proctor (2009) used the metaphor "From Parthenon to
Agora" to illustrate the shift from the perception of cultural experience as something that the museum holds and the visitors see but don't touch, to something that
can be discussed, shared and negotiated. Apparently, the role of the visitor in this
context changes to collaborator and partner (Simon, 2010). Furthermore participatory cultural experiences imply a new relationship between the visitor and the
museum which is not restricted to one off or fi rst time visits. Instead, participation
aims also at building an enduring relationship with existing audiences and communities (museum friends, volunteers, etc.) related to the museum (Black, 2005).
Building an enduring relationship between the visitor and the museum through visitor active participation enhances the cultural experience and enriches the content
and the impact of the museum on fi rst time visitors or one off visitors too (ibid).
In the wide spectrum of participatory activities (for a detailed presentation see
Simon, 2010) we identifi ed two types of activities relevant to our analysis. The fi rst
type of activity reserves for the visitor a role similar to the documentation process
performed by the museum. The proliferation of mobile technologies and social

media has supported the creation of user generated content using various crowd-
sourcing practices. Ridge (2011) has offered a grouping of these practices:
• Stating preferences , voting on interesting objects, comments, etc.
• Tagging : unstructured text associated with objects, see for example the Steve
project http://tagger.steve.museum/ which addresses social tagging as a process
that encourages visitor engagement and provides new ways of describing and
accessing culture . Twenty-one Institutions participate in the project with 97,041
Objects. In the site appears that 8,346 users have produced 552,105 terms for the
above objects.
• Debunking, criticising : arguing against other peoples' ideas, tags, etc. (see for
example the Freeze Tag project in Brooklyn museum http://www.brooklynmuseum.
org/opencollection/freeze_tag/start.php).
• Recording personal stories : personal memories associated to museum objects or
memorabilia made available to digital collections. See for example Europeana
1914-1918 project in http://www.europeana1914-1918.eu/en .
• Linking objects or categorising : grouping of objects or associating them with
themes.
The second type of activity aims at resuming or approaching cultural experience
through engaging visitors in the creations of "meta-artefacts"—i.e. games or stories
based on compositions of elements of cultural content—which are supposed to have
a public status. The idea of involving visitors in creating computer-based public
artefacts that make use of cultural content is new. It builds on a theoretical background that acknowledges the gap in the communication between the museum and
the visitor and calls for active participation of visitors in the dialogue with the museums (Hein, 2006 ; Simon, 2010).
Three examples are known and presented here: One comes from British Museum
which included in the museum activities family workshops on game design.
Participants were invited to build their own games inspired by the collections of the
British Museum (after visit experience). The new games could be uploaded on the
Web to be played at home or shared with friends. The second example comes from
Tate Gallery where young visitors (6-12 years) create drawings through game play
(Jackson, 2011) and fi lms for pieces of art. The third example is the idea of remixing
museum content for the creation of a visitor generated narrative (Fisher & TwissGarrity, 2007). This example is grounded on the observation that visitor centric exhibition narratives should not be the objective of the cultural experience, but instead
the focus should be cultural activities promoting the construction of narratives by the
visitors. Visitor generated narratives build on the transformative connection between
the visitor and the exhibit, asserted by Hein (2006). Transformative experiences can
occur when the visitor is encountered with challenges to discover connections with
the exhibits and is provided with the tools to analyse and manipulate the exhibits in
order to transform them into something new, related to his/her experience.
Although both activity types ("crowdsourcing" and "meta-artefacts") reserve an
active role for the visitors they have a drawback: visitor generated "products"—content
or artefacts—are almost never integrated in the museum's assets because of their low

quality (Simon, 2010). This problem is related to the open ended and unstructured
participatory activities:
When it comes to participatory activities, many educators feel that they should deliberately
remove scaffolding to allow participants to fully control their creative experience. This creates an open-ended environment that can feel daunting to would-be participants. … What if
I walked up to you on the street and asked you to make a video about your ideas of justice
in the next three minutes? Does that sound like a fun and rewarding casual activity to you?
(ibid, Chap. 1, p. 13)
What Simon described above draws upon an approach which asserts that learning in museums should focus in triggering visitor creativity and subjective interpretation of cultural content leaving aside the "knowledge of the museum" which
prevails in the information consumption metaphor. Simon showed that in participatory activities this perspective has its weaknesses. In the same line comes the idea
of "objectifi ed cultural capital" (Bourdieu, 1986) which explains that cultural experience is not just an issue of access (i.e. being able to visit a museum) but it is also
an issue of background knowledge that supports the person to appreciate and understand the value of a piece of art. Museums and cultural institutions offer in the
process of culture creation not only the objects-exhibits but also the background
knowledge necessary to value the exhibits. In our view the key in this process is how
background knowledge will become the means to an end (i.e. a tool for the visitor
to generate cultural experience) and not the end itself. This means that cultural
experience is not diminished into comprehending institutional knowledge instead,
the latter needs to come into the visitor's attention as material to be negotiated, discussed, shared and used for the construction of something new. In this context we
argue that technology can play a crucial role in supporting the cultural learning
experience and we further illustrate this by focusing on the example of game design
and its potential in supporting learning in cultural institutions.
Game Design as Learning Activity in Cultural Institutions
Game play is not a new practice for museums. The introduction of digital technologies resulted in revisiting the idea of game play and storytelling in museums.
Technologies today play a key role in interaction, interpretation, learning, content
creation through crowd-sourcing, outreach, marketing, etc. (for a detailed presentation and overview see Beale, 2011). Whereas there is an extensive analysis on game
play, research in cultural heritage sites have not addressed yet the idea of game
design as an end user activity.
Interestingly, research in the fi eld of technology enhanced learning has already
highlighted the learning potential not only of game play but also of game design and
development (Kafai, 2006). Game design activities were identifi ed as having the
potential of helping learners to build a new relationship with knowledge, as learners
feel ownership over the knowledge and experience deep interaction with the learning
concepts to be integrated in the game with a functional role. As Kafai, Franke, Ching,

and Shih (1998) observed, learners negotiated with learning concepts in this context,
in order for the game to be playable.
Research in the fi eld of game design by non-technical end users—such as students—has focused on the learning activity which has been analysed from two perspectives. The fi rst one focuses on studying learning related to programming or
specifi c skills and concepts (see for example Hoyles, Noss, Adamson, & Lowe
2001) for a discussion on children's causal reasoning and rule understanding during
game construction). The second and most recent perspective acknowledges game

design as a learning goal in itself (Hayes & Games, 2008). In this trend, researchers
have coined the term "Design thinking" to encapsulate the set of learning and meta-
cognitive skills involved, such as system based thinking, self-regulation, social,
technical, technological, artistic and linguistic skills (Robertson & Howells, 2008 ;
Salen, 2007). The analysis of learning through game design shows that the learning
experience is shaped and amplifi ed by the feeling of ownership over the games created by the learners, the participation in communities that share and exchange ideas
and the motivation inherent in game play and game design (Rieber, 1996 ; Robertson
& Howells, 2008 ; Salen, 2007).
Game creation in cultural institutions as participatory learning activity should be
integrated in activities that will give the chance to visitors to interact with museum staff
and discuss, negotiate and integrate in their games different aspects of cultural content.
Game creation can be supported by technological scaffolds (such as game templates)
and personalization techniques that present the museum view in order for the audience
constructions to meet their standards and become a public artefact that can be used by
other visitors, can be shared, revisited, discussed, changed and expanded.
Game Design Platforms and Their Relationship to Learning
When it comes to technology based scaffolds for game design there is a question we
need to address: Do we need to design game-creation platforms to support learning
in museums or we can use existing solutions such as KODU, storybricks, Game Star
Mechanic, Game maker, the Games Factory and many more (for a critical review of
technologies for game design see Hayes & Games, 2008). The answer here is that
the technologies used for game design are confi gured to support not only the creation of games but also to facilitate the other objectives related and integrated in
game design (e.g. the different types of learning, or in our case the cultural experience). Thus when game design is employed for purposes other than game creation
then the design tools consist of elements and support practices related to the purpose
for which game design is employed. To make this rationale more explicit we analyse next two examples of games that support end user design of the salient features,
rules and content. The fi rst one is a prototype game that is designed to support the
learning of spatial concepts and more specifi cally, issues related to orientation, map
alignment, use of systems of reference, etc. The example we selected is designed to
facilitate learning in school but it is appropriate for our analysis here because it
N. Yiannoutsou and N. Avouris171
reveals how the characteristics and affordances of the tool can facilitate specifi c
types of learning.
The "Treasure Hunt" Template
Unlike game design platforms (like KODU) the "Treasure hunt" tool does not lead
in designing all sorts of games. Instead, it integrates the idea of game design in what
we call game templates. Game templates represent a game genre (in our example
treasure hunt) and they can produce different instances of the same genre by manipulating and specifying basic game elements (For a detailed presentation see
Yiannoutsou, Sintoris, & Avouris, 2011) like the rules and the content (treasures,
hints, etc.). It is thus apparent that game templates are more limited with respect to
the spectrum of the produced games but they allow for designing of a learning experience that is oriented towards specifi c learning objectives (as we will show next).
The other advantage of game templates is that while they allow confi guration of
certain game elements according to the learning objectives, they also provide some
ready-made non confi gurable components which are integrated in the template to
guarantee high quality of the games without requiring from the user specialised
knowledge and lots of effort (like a 3D terrain for example). In a nutshell, game
templates allow for focused learning design and produce high quality games that
can meet the quality standards of the users.
In the example we present here, the non confi gurable game elements of the treasure hunt template are the representations of the terrain. These consist of a 2D and
a 3D representation of a neighbourhood which are dynamically linked together.
This means that motion of an agent in the 3D space results in a trail on the 2D representation; a treasure and a landmark as soon as they are placed on 2D space they
also appear on 3D space (see Fig. 1 below)
Fig. 1 The terrain of the treasure hunt template
Game Design as a context for Learning in Cultural Institutions172
The dynamic link between the two representations is an important characteristic
of the template because game design takes place on the map (2D representation)
whereas game play takes place on the 3D space with the option for game designers
to make the map available or not (so as to make the game easier).
The confi gurable elements of the template are the content and the rules. The
content involves the number of the treasures and the hints that lead from one treasure to the other. The basic rule of the game remains the same, i.e. in treasure hunt
games the player has to collect a set of hints in order to be able to fi nd the treasure.
The template however provides some variations around this rule: i.e. instead of having one treasure and a set of hints, there are numbered treasures that lead from
the fi rst treasure to the second and so on. Furthermore, the designers can decide if the
game will consist of one player who moves in the neighbourhood searching for
the treasures or of one player and one thief also searching for treasures. In the latter
case the designer has to defi ne what will happen if the player encounters the thief by
selecting one of the three options available (see Fig. 2)
Another confi gurable element of the template is the defi nition of dangerous
streets (see Fig. 1). The designers can designate some streets, normally around treasures, as dangerous areas by clicking on them with the mouse. Next they need to
attribute to each area what will happen if the player and the thief step on this street.
There are three options here again, losing speed for a specifi c time period, losing all
the treasures collected or losing half of the treasures collected. The next step for the
designer is to defi ne the possibilities for the selected events to be activated by moving the cursor on a slider with values from 0 to 100 % (e.g. 60 % possibility for an
event to be activated if the player enters the street). To put it briefl y, with a set of
simple functionalities the treasure hunt template can support non technical designers to construct a rather sophisticated game.
Our concern however in this section was to show the relationship between the
characteristics (representations and functionalities) of the game template and the
learning pursued. As we mentioned earlier the treasure hunt template was designed
to promote spatial thinking and orientation skills. An analysis of data drawn from
experimentation of two groups of 14-year-old students fi rst showed that the treasure
hunt template did not put any cognitive load to students with respect to technical
issues (Yiannoutsou, Sintoris, et al., 2011). Second, student interaction with the
template (i.e. what was confi gurable and what wasn't, functionalities and representations) required that spatial concepts were used as instruments for game construction (ibid). This means that students in order to construct the game negotiated spatial
Fig. 2 Refi ning the rules of the game: defi ning the player-thief encounter
N. Yiannoutsou and N. Avouris173
concepts like the difference in the properties of the map and the 3D representation
of space—i.e. which one is more appropriate for orientation, what is visible and
what is not in each representation—the accuracy of directions, the use of absolute
frames of reference, etc. (see the next extract)
S2: Now the quiz. What should we write for the fi rst treasure?
S1: Go south
S2: Yeah, but it is not enough. All these are south (shows the streets at the bottom
of the map). She said [the Facilitator] that the directions should be precise
otherwise the game is not good. They will never fi nd it.
S1: Ok then, there is a rectangular here. It is the only south rectangular [he refers
to the shapes of the street on the map. (see Fig. 1)]
S2: That's good! Let's say "go to the southmost corner of the southmost
rectangular"
S1: They will fi nd it immediately if you are so precise.
S2: Yeah, but they will be on 3D they will not be seeing the map .
Extract 1 : Negotiation of spatial concepts (taken from Yiannoutsou, Sintoris,
et al., 2011)
The second confi gurable game to be analysed is from the fi eld of learning in cultural institutions described by Di Loretto, Divitini, Trimailovas, and Mander (2013)
The museum confi gurable game MagMar is a tool that allows students to create
question-answer games. The tool was used in, a study with 18 year old students
worked in groups to create multiple choice questions (with an indication for the right
answer) for pieces of art of a contemporary museum. The paintings were selected by
the teacher and were common for all students. Question construction was created
inside the museum and students had at their disposal a small picture of the painting
presented in MagMar, access to internet and a guide of the museum. Students were
also allowed to go to the room where the painting was located in order to fi nd material for the question construction. Correct answer to a question awarded the group
with a raise on their score. From the reported results with respect to the learning
experience we highlighted and site here two remarks:
(a) For the second item students walked around trying to fi nd content for possible
answers also in the information exposed in the exhibit (in the specifi c case, the
name of painters contemporary to the one of the focal painting). Though this is
clearly not suffi cient to draw any general conclusion, it was still interesting to
see how the game could actually motivate an exploration of the museum…
(b) When they were asked what they remembered from the museum visit, the students answered with the content of the questions they created (Di Loretto et al.,
2013 , pp. 527).
Although MagMar doesn't have the characteristics of game templates we
described earlier, it shows a rather successful implementation of the idea of visitor
participation through the construction of meta-artefacts that can be used during the
museum visit. It appears that the learning experience with MagMar proved to be
engaging, prompted for exploration and connection fi nding with other exhibits
Game Design as a context for Learning in Cultural Institutions174
(remark a) and showed that the process of question construction proved to be more
effective—from a learning perspective—than the process of question answering
(remark b). Without ignoring that there might be criticism on MagMar related to the
emphasis on factual knowledge for example, and to questions about its playful
character, it nevertheless shows the learning potential of a participatory activity like
the ones we describe here. Apart from that, the idea of question constructin which
is central to MagMar is also central to the process of culture generation as it is
expressed by J. Landy:
"Artworks are not just fancy ways of delivering messages. One of their most
interesting and useful functions is not to provide answers but to offer questions we
have to answer ourselves. Answering the questions does not involve guessing the
artist's intention. Instead, it involves injecting something of ourselves". (J. Landy
extract from the video of his course at Stanford that comes under the title: "The art
of Living" http://humanexperience.stanford.edu/artofl ivingiVideos). A similar view
comes from Simon (2010) who stresses that interesting questions with respect to
learning are not those that aim at comprehending the institutional knowledge but
those that draw on the visitor's knowledge. These two comments can offer useful
insights in refi ning the design of MagMar so as to move from factual information to
more interesting learning objectives.
It becomes apparent then that if we want to employ game design in the cultural
experience we need to create a platform that engages users with what is considered
crucial for the cultural experience. We attempted to show this with identifying in
MagMar an underlying principle which is also important in the process of culture
generation. Another suggestion is that game design tools could focus on the connections the visitor can make between the different cultural artefacts and with overarching concepts, beliefs and narratives (Falk & Dierking, 2000 ; Hein, 2006).
Integration of Participatory Activities in Museum
and Visitor Practice
The visitor doesn't have all day to engage in game design. When and how do you expect this
to happen? He/she might have a couple of hours to visit the museum and that's all
The above remark—made by one of our colleagues when we fi rst presented the
idea of game design—is added here to show the contrast between the technologies
that promote a participatory cultural experience and the average visitor practice in a
museum which involves one off or fi rst time visits. It also stresses that a new practice—like participation—related to the use of a new technology cannot occur just as
a result of the introduction of this technology (Tallon & Walker, 2008). Instead, in
order to foster this practice we need to design activities integrating this technology
by making the most out of its potential and by describing the roles of the stakeholders (i.e. museum, curators, visitors). As we mentioned at the beginning of this paper,
participatory experience assumes a long term relationship between the visitor and
the museum and requires structuring in order to result in an output which meets the
N. Yiannoutsou and N. Avouris175
quality standards of its creator and can become part of the museum assets (Hein,
2006 ; Simon, 2010). Taking all these into account we envisage learning activities
that integrate game design technologies which can have the form of onsite or online
workshops taking place regularly and focusing on specifi c parts of the museum collection each time. In this context we expect that the institutional knowledge about a
specifi c set of exhibits will be discussed, analysed and negotiated between the audience and museum curators in order to be transformed and integrated into visitor
constructed games. Social media and platforms that will allow a visitor to present
and share his/her game with his/her friends and being able to play it when they visit
the museum is an important element of the game construction process.
Concluding Remarks
In this paper we discussed the use of technology as a medium for learning in cultural
institutions. Starting with technologies to support learning as information consumption, we moved to more recent approaches that involve visitor participation in the
process of culture creation. Our analysis highlighted that participatory activities
such as game design when scaffolded by technology and integrated in museum
activities can offer rich learning experiences which reserve for the visitor the role of
collaborator and partner and entail the creation of an enduring relationship with the
museum. We further analysed the idea of cultural experience as participation
through the presentation of the idea of game templates and how their characteristics
can be related to learning.
Our analysis of two confi gurable games showed that the design of game templates
in order to support a rich and engaging learning experience should be structured
around what is considered important to learn when visiting a museum. A fi nal observation involved the design of activities integrating and at the same time demonstrating how the new technology should be used in order to pursue the envisaged
participatory learning experience. This rather new approach needs to be further investigated and supported through specifi c game-design tools and empirical studies.
Acknowledgements The treasure hunt template and research were implemented in the context of
project LeGa Innovation in Educational Practice—Learning through the Creation of Models and
Games, GSRT, R&D Actions in the Information Society, E-learning call, #26/04. Dr Kriton
Kyrimis implemented the treasure hunt template and contributed to its design.

Introduction

The use of ICT applications for the purpose of museum communication and learning tends to become a main feature of contemporary museum policy. In order to serve their educational goals, different types of museums produce ICT applications that follow the technological developments in the form and shape they take: they range from distribution material in the form of CD and DVD-ROMs to online applications or systems that can be used in terminals inside the museum. The extensive use of these applications in current museum practice has cast the spotlight on a new area of museum education research. The central issue is not anymore whether we should use technology (as it was in the past), but how we should use it, in what ways users could become involved in activities and what experiences they could gain from using technology. In this context, an extensive research project took place between 2008 and 2011 in Greece. In the fi rst stage of the project, we conducted a questionnaire-based research in order to record the use of ICT technologies for educational purposes by Greek museums (Bounia, Economou & Pitsiava, 2010). Based on the results of the fi rst phase, in 2010-2011 a systematic qualitative study was carried out on the educational applications that were at the time offered by Greek museums, in order to explore the possibilities inherent in each type of media used, in conjunction with the venues these media are associated with, their target groups, objectives and educational philosophy. In addition we aimed to explore

Digital Applications in Museums: An Analysis
from a Museum Education Perspective

whether and to what extent theoretical perspectives on museum learning, as these have been developed in the relevant literature during the last couple of decades, have been taken into consideration for the creation of such applications.

Theoretical Framework

The last 20 years or so have seen an evolution in understanding what kind of learning happens, or should happen, in museums (Perry, 2012). While in the past theories of learning focused on a "transference model", i.e. one that placed emphasis on information passing from the (museum) educator to the visitor/audience, current museum education theory has embraced different, inclusive and participatory models of learning. Instead of accepting their role as simply passing along information to visitors, museum professionals are involved in attempts to enable visitors to make meaning and actively create knowledge for themselves based on their identities and previous experiences.

The role of constructivism has been crucial in this discussion. According to Hein (1998 , 34), "learning requires active participation of the learner in both the way that the mind is employed and in the product of the activity, the knowledge that is required". Learners, in other words, are not just passive recipients of knowledge but active meaning makers, since "knowledge does not exist independently of the learner … It is constructed by the learner" (Hein, 1999 , 75). Furthermore, Hein and Alexander (1998) go further to argue that museums are, and should be, constructivist environments, where visitors can construct their own meanings by actively engaging with exhibits, programs, objects and phenomena (Perry, 2012 , 13).

According to the interactive model of museum experience, personal context is very important for museum learning, as "learning is a very personal experience, self motivated, emotionally satisfying and very personally rewarding and always constructed from a base of prior knowledge" (Falk & Dierking, 2000 , 33). In addition, sociocultural context is equally or sometimes even more important. Museum visitors' research has highlighted the importance of social agenda for museum visiting (Perry, 2012 , 11). The social context of a museum visit infl uences the perspectives and the experiences of every visitor (Falk & Dierking, 1992 , 3). In the words of Falk and Dierking (2000 , 37) "learning is both an individual and a group experience".

Museum educators have extensively used both these theoretical models in order to argue for a people-oriented (as opposed to object-centred) model of museum learning. Paris and Mercer (2002), summarising museum education research, suggested three models for the relationship between visitors and museum objects. The fi rst is the model of passive reception, i.e. the one where a linear, one-way communication is expected. In this traditional approach, museums are expected to provide information, in a creative and effective way, which is easily understood by the visitors. Despite its shortcomings, this model is still active in many institutions around the world. The second model refers to active construction, and is based on the theories of constructivism, as developed before. The third model is called "transactions" and

refers to a highly personalised understanding of learning, where the encounter of the visitor/group of visitors with the exhibits serves to reinforce or develop personal identity and beliefs in a rather idiosyncratic manner.

What all these theories have in common is the understanding that museums are spaces where a special kind of interaction takes place: visitors bearing their personal and/or social agendas encounter museum objects and use this encounter to create meaning, i.e. to learn. Learning within the museum environment is thus understood as a broad process, incorporating many different notions and strategies, ranging from passive reception to active construction and transaction (Perry, 2012 , 15).

Within the context of museums, J. Dewey's notion of "experience" and its value in education is also highly relevant. Dewey emphasises active practice, but also the fact that experience in order to be educative has to be organised. In other words, experiences should not be just "hands-on" but also "minds on" in order to be effective (Hein, 1998 , 2). Museum education has been historically related to Dewey's "learning by doing" philosophy (König 2002 , 34-35), since museums are places where experience is built through the encounter with material objects, but also by the very fact that museum visit is an activity in space and it involves human beings as material entities. It provides multiple opportunities for visitors to experience the world, and consequently it can encourage creative individual thinking and acting—the basis of a democratic society (see also König 2002 , 34-35; Sauter, 1994 , 171-187).

This experiential approach also relates to the possibilities offered by museums to integrate in the learning process senses other than the sight. Activities during which visitors design, draw, construct and change their environment and themselves are integral parts of museum education programmes (Rottmann, 1998), because "active learning occurs when people … interact with information and experiences at hand" (Tishman, 2009 , 2).

An important part of this interaction is the presence of museum exhibits. Museum education has always been concerned with the creation of suitable conditions for visitors' encounters with objects. Learning in museums is different than learning in schools or other similar environments, since it takes place "not in the shadow of objects" (Kerschensteiner 1925, quoted in König 2012 , 24) as in the case of schools, where books and words hold the primary position, but through objects. Museum exhibits have a tangible quality and usually aesthetic value. They are "real things", and they can allow for a large number of different narratives to be developed around and through them. Roberts (1997) has highlighted the idea of "narrative" as an educational tool along with the ability of museums in particular to become places par excellence for the construction of narrative.

In order to work with museum objects, museum education places special emphasis on how we "ask" objects (Durbin, Morris, & Wilkinson, 1990 ; Hennigar Shuh, 1999 ; Hooper-Greenhill, 1994). Museum objects are characterised by a set of values (or qualities) that make them suitable for communication and learning. They are tangible, and they have survived from the past to the present, thus being a unique gateway to that past. They challenge the senses, inspire observation and discussion and provoke creativity. They can support educational processes for the understanding of reality and the past through the senses. They are open to different interpretations,

providing opportunities for multiple narratives to be constructed around them and for open-ended learning experiences, meaning making and transaction. Finally, museum objects may serve aesthetic purposes. According to Weschenfelder and Zacharias (1992), the starting point of all museum education design and planning is (and should be) the pedagogical use of the values/qualities that museum objects have.

In the case of ICT applications for museums, the role of museum objects comes at the centre of attention, this time for a different reason. How are possibilities offered by authentic, "real" museum objects altered when they take digital form (see also Doonan & Boyd, 2008)? In this case, issues regarding the quality of digital representation, the advantages of digital copies for enhancing visitors' experience and the enlargement of experiences through new forms of digital mediation are brought to the forefront (also Bayne, Ross & Williamson, 2009 , Frost, 2010). Nowadays the borders between real, virtual and illusion, symbolic and abstract and tangible reality and its simulation are more and more fl uid (Zacharias, 1995 , 72), resulting in a growing loss of the experience of reality through the senses. This fact points out the importance of providing opportunities for the connection of the digital with the real world, for expanding the digital experience into the real world.

On the other hand, information and communication technologies provide increased educational opportunities for interaction, active involvement and personalisation. They provide, or can do so, museum visitors with opportunities to select content and create their own individual routes in their approach to knowledge, as well as opportunities to contribute content and exchange ideas and information with others, thus enhancing the social dimension of their experience. In addition, interactivity and the stimulation of users on an intellectual, emotional and social level are facilitated via the introduction of ICT technologies into museum education (Roussou, 2010 ; Witcomb, 2006).

The theoretical framework presented above poses a series of issues regarding museum education and the use of ICT applications in museums. The main concern has been whether digital learning environments can support experience and meaning making by the museum visitors, taking into account the values/qualities of museum objects, the knowledge and experiences that users bring with them, the social dimension of the museum experience and the emphasis of museums on creative and experimental learning.

As a result, a series of research questions were developed, which informed the process and the data analysis. We therefore investigated the extent to which ICT applications created and employed by Greek cultural institutions:

- Take into account the previous knowledge and identity of the user and promote meaning-making processes according to the constructivist approach to museum learning
- Take into account the decisive role played by the social dimension of the educational process in the formation of the visitor's experience
- Promote processes that encourage a constructive encounter between visitors and museum exhibits
- Use the educational values/qualities of museum objects

- Promote creative activity on the part of the users
- Offer possibilities of expanding the digital experience into the real world
- Explore the possibilities of interactivity to encourage a more active interpretation of museum material

Research Methodology

For the purposes of this research we collected a total of 25 applications that Greek museums of varying type, size and scope (Table 1) provided to the researchers and explicitly identifi ed as "educational". These were either in the form of a portable medium (CD-ROM/DVD-ROM) or web based; it was important that the institutions themselves considered these applications as "educational" and defi ned them as such, because this allows us to identify indirectly how institutions feel about education in general. We decided not to include in the research media or applications aiming mainly to museum communication, such as museum websites and social media, since their aims and objectives are not primarily educational (Bounia et al., 2010).

In order to analyse the applications we used qualitative content analysis (Krippendorff, 2004). The tool for this analysis was a form (Table 2) developed by the researchers based on the theoretical approaches and research questions presented above. The aim of the analysis was:

- To investigate the extent to which these applications utilise the aforementioned theories
- To study the opportunities for learning that each of the applications offers to their users

The aim of the study was neither to test the usability of each application nor to evaluate their use by the intended audience. This has been a research performed in order to evaluate the use of museological perspectives in the design of applications

aimed to complement museum learning.
After recording the identifi cation parameters of each application (namely institution, title, application form, funding, target group, languages) (see Table 1) the analysis form consisted of the following fi elds (Table 2):
• Presupposed knowledge/experience of the user
• Signifi cance of collections/objects (authenticity, materiality, aesthetic value, narrative)
• User involvement:
- Creativity-experimental learning
- Experience expansion in the real world
- Social context
Each of these parameters corresponds to a museum learning concern discussed previously.

Results

General Characteristics: Target Groups

A wide range of bodies of varying size, legal status and fi nancial strength are actively involved in the production of educational multimedia applications in Greece. The number is growing as well as the interest of museums to acquire a presence in the digital sphere. These bodies seek opportunities to produce such applications either through funding by European programmes or through other kinds of funding, often by private foundations. Of course, there are also a number of self- funded initiatives, which refl ect the strong interest and even anxiety of some bodies to acquire a digital "educational voice". While the older applications take the conventional form of a CD/DVD-ROM, the latest ones are Internet based as the importance of easy user access is being increasingly recognised, while at the same time the technological developments providing such possibilities are constantly expanding. In most cases (23 out of 25) the applications are meant to be used outside the museum; in just two cases they are used on museum premises. In other words, the applications are meant to "accompany" visitors home after their museum visit, so as to consolidate the content of the visit and to reinforce and possibly extend the museum experience. In the case of applications accessible on the Internet, once again these are used at the user's personal space without an actual visit to the relevant museum being necessary. At the same time, it is also possible to see how these applications can motivate users to actually visit the museums that provide them, and so, in this respect, they can claim to have the role of introduction to the respective institutions.

As far as the user groups are concerned, three (3) applications are aimed at the "general public", while seven (7) are targeted specifi cally at school groups and the educational community. In three cases the school groups are further defi ned according to their educational level (primary or secondary) such as in the web application of the Historical Museum of Crete. "Children" in general also feature as a target group; more specifi cally, in these cases it is mainly the lower age limit of the users that is defi ned (usually ages 7-10). It is evident, therefore, that the applications treat the public, even the children/teenage public, as a unifi ed whole in contrast to museum education activities, which are usually aimed at highly specifi c age groups.

Table 2 Analysis form

1. General information Institution, title, application form, founding, target group, languages
2. Contents of applications Presupposed knowledge/experience of the user Signifi cance of collections/objects (authenticity, materiality, aesthetic value, narrative)
3. User involvement Creativity-experimental learning Experience expansion in real world Social context

An exception to this can be found at the Natural History Museum at Axioupolis, where the applications form part of the museum education activities and provide different activities for three different age groups: infants and the fi rst to second grades of primary school, the third to fourth grades of primary school and the fi fth to sixth grades of primary school (Economou, Nikonanou, Kasvikis, Economou, & Samaroudi, 2011). It is also worth mentioning that there are no applications in our sample which are intended for special needs groups, despite the fact that digital technologies can provide for different special needs (e.g. enlargements for visually impaired users).

Almost half of the applications (14 out of 25) are offered just in the Greek language. In the case of digital discs (CD-ROMs) there is usually a choice of other languages than Greek, such as in the application for the Costakis Collection, which is also offered in English and Russian, and also in the educational game produced by the Museum of the Macedonian Struggle, which is also offered in English and German, and the application of the Historical Archive of the Aegean—Ergani offered in English and French. Greek and English are offered in eight (8) applications (CD-ROMs and web applications), and the rest is only in Greek (see Table 1). This choice of languages is also relevant to the target audience of the educational provisions of the museums: most of the institutions want to use their applications to cater for tourists as well or for the audience of countries which have a special interest in their collections (as for instance in the case of the Costakis Collection which consists of paintings by Russian artists).

Contents of Applications: The Role of the Object

As far as the contents of the applications are concerned, the analysis examined to what extent the applications presuppose knowledge on the subject by the user. The applications were not found to presuppose any special knowledge on the part of the user, at least no greater level of knowledge than that provided by the applications themselves. In other words, these applications are self-contained packages in which both the provision of knowledge and the suggested activities function as a complete educational unit. They do not refer to the museum environment, and they do not correspond to activities or knowledge that users have had from previous visits or other experiences.

The second parameter that was examined in this section concerns the place that museum objects occupy in each application. Most of the applications (22 out of 25) contain museum exhibits at the centre of their content; in some cases (e.g. "The Parthenon Frieze"), the exhibits are the central feature of the content, while in some others (e.g. "Bring out the Oil for Us") museum exhibits play a minor role (even though they are still there). Applications of the fi rst type can also prepare users for a visit to the museum housing the relevant object, where they will be able to recognise the object in their real encounter with it on the museum premises. In most of the cases where a digital museum object occupies a central place in the application,

museum education processes are used in approaching it, such as observation, examination and interpretation (e.g. the Benaki Museum's "Play with a Painting on Your Screen"). More generally, it seems that the role museum objects occupy in the applications depends on their uniqueness or general appreciation, as, for instance, is the case with the Frieze from the Athenian Acropolis. In the case objects are considered more "common" or interesting for qualities other than aesthetics and uniqueness, as for instance in the case of the olive pressing machinery, their role in the applications is not that central and the focus goes more to their use or construction technique rather than the objects themselves.

When it comes to the values/qualities of objects, it is clear that those of authenticity, materiality and aesthetics can be used only to a limited extent in a digital environment since they are inseparably bound up with approaching the material substance of real museum objects (Bounia & Nikonanou, 2008). Similarly, despite the fact that in traditional museum educational programmes museum objects are at the centre of the educational process, in the digital applications they are not used in the same way, especially in the narrative.

In order to examine perceptions of materiality and aesthetics, we examined the quality of the digitisation in conjunction with the possibilities for making a visual examination of the object as well as the provision of three-dimensional images (Frost, 2010). The latter has not been used extensively in most of the cases—probably because of the cost of production—except for one case: the application produced by the State Museum of Contemporary Art; in this application technology is used to provide detailed views of art objects.

In order to focus on aesthetics in particular, we also examined the representation of digital spaces. The approach followed in this process is largely based on the conventional aesthetics of children's books, comics or animations or on aesthetic choices oriented towards the aesthetics of the museum objects in each collection (e.g. Costakis Collection). Exception to this is the application of the Numismatic Museum that offers a "screen" with an active "fairytale-like" image and numerous stimuli and prompts encouraging the user to explore and connect to organisations and events "outside the screen". It seems that museums present their objects in similar manners whether in the real or the digital environment: art museums tend to place more emphasis on the aesthetics, uniqueness and materiality of their objects, whereas museums of technology or natural history tend to place more emphasis on the processes and the circumstances connected to their collections and not necessarily on the objects as unique material testimonies.

As for another important value/quality of museum objects, i.e. the possibility to encourage multiple narratives, we realised during the process of analysis that this is very little exploited in the digital applications, although it is not subject to the same limitations of digital space as the three previously mentioned qualities/values. In terms of their narrative content, most of the museum objects presented in the applications have "closed" narratives, based on elements of a factual nature, while users are not encouraged to develop their own individual interpretations of them. Of particular interest in this respect is the application by the Numismatic Museum, which, using the museum exhibits as a starting point, provides users with the opportunity

to access further information via web links and make more imaginative connections (such as with not-for-profi t environmental groups when discussing coins bearing marine animal symbols).

User Involvement

Learning is not just about content; it is also about processes which concern what the user does and in what kind of context the interaction between learner and content happens (see also Dimaraki, 2008). As a result, it was important to examine whether and how users of the applications were encouraged to interact with museum material, whether and how creativity was promoted and fi nally whether, and how, the social context of the museum visit was exploited to encourage learning within the museum. Most applications present the user with a variety of activities, which provide different opportunities for interaction.

Most applications draw a distinction between "serious" and "play-based" learning, either providing extensive texts and information as more or less a prerequisite of "play" or offering activities that serve as a "gateway" to knowledge. In the fi rst category belong applications, which require the user to read the information and then to test his/her newly acquired knowledge by fi lling in crosswords and word search puzzles. Examples of such an approach are those of the "Games" section of the Alani Archaeological Museum's application or the multiple-choice questions provided in the application of the Historical Museum of Crete.

In the second category belong activities that serve as a "gateway" to knowledge; in these cases, the user receives information concerning the object that he/she is asked to "discover" as a result of the activity and not as a prerequisite for it. This is the case of the puzzles and memory games created by the Museum of Byzantine Culture or the Museum of Cycladic Art. In some other cases of the same category, such as the application of the Benaki Museum entitled "Hidden Treasure" or the games of the Numismatic Museum, the user gets access to information about museum objects, their provenance and so on after choosing them in the context of the activity.

The question regarding these cases is whether, and to what extent, users are motivated to explore the new knowledge provided to them after they have fi nished with the activity, since this new knowledge is not necessary in order to complete the activity.

Very few applications examined in this research place an emphasis on personal interpretations and the construction of individual meaning along the line of constructivist learning, as this has been discussed above. An exception to this is the creative activities suggested to users in some cases, usually related to art collections and art museums. For instance, the State Museum of Contemporary Art encourages users to employ symbols and elements from the museum artworks in order to create their own works of art and the Iakovidis Digital Museum encourages users to import their own texts. However, this allows for limited personal interpretation and does not take advantage of many other possibilities available through museum objects (Rakhochkine, 2003 ; Weschenfelder & Zacharias, 1992 , 174-88).

Interestingly no attempt is made to link digital to non-digital activities, either creative ones or experimental ones, despite the fact that such an attempt would help towards a more comprehensive use of the materiality of the objects and the involvement of the senses. In the few cases where users can print out their own digital creations, these serve more as a souvenir of their use of the application and less as a stimulus for creative off-screen activities (e.g. "The Fortifi ed City of Mystras"). In other words, there is no attempt to extend the scope of the educational activity beyond the confi nes of the screen in order to support educational processes that exploit the involvement of the senses.

Finally, as far as the social context of the experience is concerned, we came to realise that all of the applications examined are targeted at the individual user; that is, they do not involve multiple users or collaboration between users, even when they are targeted to school groups. It is evident, therefore, that the social dimension of the users' experience does not lie at the heart of the applications' educational design, despite its importance in the overall experience of museum visitors.

Conclusions

The aim of the research presented in this chapter was to explore whether and to what extent ICT applications created and used by cultural institutions in Greece incorporate the principles of museum education and take advantage of the possibilities offered by new technologies to maximise their effectiveness and appeal. We performed a qualitative content analysis, which highlighted some very interesting and thought-provoking issues.

Greek institutions invest increasingly more in the production of digital applications, thus aiming to enrich their educational provisions and encourage more visitors to take advantage of the museum collections and the knowledge they provide. These applications tend to be web based, so as to be as widely accessible as possible. This is also evident by the fact that the applications aim to address the needs of a wide variety of users and they do not target specifi c groups or needs.

Unlike real museum experiences though, where encounter with the museum object is at the centre of the educational process, museum digital applications do not take full advantage of the possibilities offered by them. Multiple interpretations, individual meaning making, encouragement of alternative or additional ideas produced by the user/visitor, social interaction, interactivity, creativity and engagement are not encouraged or supported to the extent that they could be. The applications seem to reinforce the model of passive reception, where the museum provides cultural content and the user is expected to accept and internalise the knowledge

provided. It is therefore necessary to reconsider the creation of museum educational
applications and to design them taking into account museum education theory and
the special qualities/values museums and their collections hold. It is important for
museum educational applications to encourage a more active involvement of users
with museum objects and to provide opportunities for more creative, engaging and
N. Nikonanou and A. Bounia193
enabling activities. At the same time, greater emphasis should be placed on strengthening the social dimension of the overall experience by utilising the possibilities
that information and communication technologies offer for user involvement and
collaboration and for the exchange of ideas and content.
This research aims to contribute to the discussion regarding digital media use in
museum education. We argue that it is time to reconsider the efforts made so far and
to promote an interdisciplinary approach that will offer a more personal, rewarding
and multi-layered learning experience for all.
Acknowledgements The authors would like to express their thanks to Nikos Avouris for always
being available for collaboration, to Andrew Hendry for his help with the English text as well as to
the anonymous reviewers of the second Symposium on Digital Applications for Museum Learning,
where this chapter was fi rstly presented. Of course, all mistakes and shortcomings remain our own.

Introduction: Technology Uptake
The belief that technology in its various instantiations will transform educational
practice is very prevalent and dates back for at least a century. The assumption
behind the introduction of technology into educational systems was that it will
eventually make them more meaningful, interesting, and relevant for students,
thereby drastically improving the quality of learning. However, if there is one consistent fi nding from the past three decades of research on ICT use in education, it is
that technology has failed to transform teaching and learning practices.
There are two interrelated problems with technology use. First , research indicates that the extent of technology use in classrooms is rather low: teachers do not
appear to use technology in their practices to any considerable extent (Hinostroza,
Labbé, Brun, & Matamala, 2011 ; Norris, Sullivan, Poirot, & Soloway, 2003 ; Ward
& Parr, 2010 ; Webb & Cox, 2004 ; Wikan & Molster, 2011). Second , even when
teachers do embrace technology, it gets integrated in ways which sustain rather than
transform existing practices (Condie, Munro, Seagraves, & Kenesson, 2007 ; Cuban,
2001 ; Cuban, Kirkpatrick, & Peck, 2001 ; Donnelly, McGarr, & O'Reilly, 2011 ;
Eteokleous, 2008 ; Hayes, 2007 ; Hermans, Tondeur, van Braak, & Valcke, 2008 ; Li,
2007 ; Norton, McRobbie, & Cooper, 2000 ; OFSTED, 2004 ; Player-Koro, 2013 ;
Prestridge, 2012). On an international level, the SITES 2006 study indicated that
ICT adoption does not necessarily mean that traditional practices are abolished
Technology Integration in the Most Favorable
Conditions: Findings from a Professional
Development Training Program

(Law, 2008). Similar evidence is reported on a national level, e.g., the UK (Selwyn,
2008 ; Smith, Rudd, & Coghlan, 2008 ; Yang, 2012) Ireland (McGarr, 2009) and
Greece (Vosniadou & Kollias, 2001). The low rate of classroom technology use and
the way technology is used to support existing practices are the primary reasons why
the vision of transforming education through technology has yet to be realized.
Why has it proven so diffi cult for teachers to use technologies in their practices?
Researchers have sought to determine the reasons behind this technology resistance.
More than a decade ago, Becker (2000a) identifi ed four enabling conditions for
technology adoption: technology access, training, curriculum compatibility, and
constructivist beliefs. Ertmer (1999 , 2005) attempted to further systematize technology resistance into obstacles that can be distinguished into fi rst-order and second-
order barriers. Typically, fi rst-order barriers are extrinsic to teachers while
second-order barriers are teacher related.
First-order barriers are beyond the direct control of the teacher and have to do with
what is provided by the local and state authorities in terms of technology infrastructure and support structures such as equipment, training, and support. First, technology access is one of the main conditions upon which technology integration
depends. Several studies report that one of the strongest predictors of technology
use is technology access (Becker, 2000a ; Eteokleous, 2008 ; Granger, Morbey,
Lotherington, Owston, & Wideman, 2002 ; Norris et al., 2003). Second, a certain
level of technological competence is required if teachers are to use technology.
A possible lack of technical skills might potentially undermine technology integration. Several studies report that the greater the personal ICT competence the more
likely the teachers were to use ICT in their classrooms (Eteokleous, 2008 ; Prestridge,
2012). Moreover, classroom integration of technology has been predicted by computer experience (Mueller, Wood, Willoughby, Ross, & Specht, 2008 ; Wood,
Mueller, Willoughby, Specht, & Deyoung, 2005). Third, technical support can also
be a hindrance to technology adoption. Several studies report that access to technical support can be a facilitator of technology use (Hayes, 2007 ; Penuel, Fishman,
Yamaguchi, & Gallagher, 2007). Finally, the issue of leadership is often stressed as
teachers need not only technical but also administrative support. Some studies
report that principals and school administrators can play a facilitatory role in terms
of technology adoption (Hayes, 2007 ; Law, 2008).
Technology adoption is clearly contingent on eliminating these fi rst-order barriers .
Addressing fi rst-order barriers required lavish funding so as to ensure the availability
of resources and training, both technical and pedagogical. Additionally, educational
authorities have restructured curricula so as to accommodate technology use and
foster technology integration. Progress on all fronts related to fi rst- or der barriers has
been steadily made over the years (Ertmer, 2005). The underlying assumption that
guided much of the thinking was that providing resources and support would somehow naturally lead to greater technology adoption (Ertmer, 1999). It turned out,
however, that resources and support were a necessary but not a suffi cient condition
for technology integration: second-order barriers played a critical role.
Second-order barriers involve teacher beliefs about teaching and learning (Ertmer,
1999). Teacher beliefs about teaching and learning might shape whether and how
I. Karasavvidis and V. Kollias199
teachers eventually integrate technology in their classrooms. Therefore, teacher
beliefs have been the focus of much attention in the literature (Hermans et al., 2008 ;
van Braak, Tondeur, & Valcke, 2004 ; see also Baggott la Velle, McFarlane, John, &
Brawn, 2004 ; Ward & Parr, 2010). While addressing fi rst-order barriers was relatively straightforward, addressing second-order barriers proved considerably more
challenging (Ertmer, 2005). Generally speaking, second-order barriers have been
addressed mainly via professional development training (PDT) programs and activities of many forms.
Professional Development Training on ICT Pedagogy
Ertmer (2005) argued that teachers are likely to think about technology in the same
way they think about other educational innovations. Consequently, examining how
teachers approach innovations and what makes PDT programs effective might help
understand teachers' response to PDT on ICT integration in the classroom.
According to the literature on PDT, three properties have been singled out as being
critical for its success: form, length, and content. As far as form is concerned, many
forms of PDT have been found to be effective: workshops (Ertmer, Ottenbreit-
Leftwich, & York, 2007 ; Shriner, Schlee, Hamil, & Libler, 2009), seminars and
conferences (Ertmer et al., 2007), independent learning (Gray, Thomas, & Lewis,
2010), school-based professional development by staff (Gray et al., 2010), and personal coaching (Miller & Glover, 2007). When it comes to length PDT should be
both continuing (Miller & Glover, 2007) and sustained (Garet, Porter, Desimone,
Birman, & Yoon, 2001). Finally, with regard to content , research suggests that PDT
is more likely to be effective if it has a pedagogical rather than a technical orientation (Law, 2008 ; Law & Chow, 2008b). It is also likely to have an impact if the
primary focus is on the academic subject (Garet et al., 2001).
While some essential features of successful PDT have been identifi ed, there are
still areas of critical importance which are largely unexplored. More specifi cally, in
addition to form, length, and content, it has been argued that teachers themselves
are one of the most critical determinants of PDT success because their previous
experiences might infl uence the outcomes of any in-service training regardless of its
form, length, and content . The argument is that we need to consider what teachers
themselves bring to PDT sessions in terms of former experiences and practices
(Penuel et al., 2007). For example, Coburn (2004) has convincingly demonstrated
that teachers' responses to innovation appear to be mediated by their preexisting
world views and practices. Additionally, teachers' local contexts should also be
carefully considered when determining the effectiveness of a PDT program, as the
demands posed by the contexts of practice make teachers set specifi c priorities
(Penuel et al., 2007). PDT is bound to be interpreted in terms of the existing policies,
schedules, budgets, curricula, hardware, software, technical, and administrative support of teachers' local contexts. For instance, Zhao and Frank (2003) found that the
more strongly teachers believed that computers were compatible with their teaching
styles, the more often teachers reported using computers in their practices.
Technology Integration in the Most Favorable Conditions…200
Many teacher background variables have been systematically explored as predictors of ICT classroom use (e.g., Hermans et al., 2008 ; Law & Chow, 2008b ; Tondeur,
Hermans, van Braak, & Valcke, 2008 ; van Braak et al., 2004 ; Ward & Parr, 2010).
However, teacher background variables have not been systematically investigated as
predictors of PDT success even though their signifi cance has been recognized in the
aforementioned literature (Coburn, 2004 ; Penuel et al., 2007). In particular, when it
comes to PDT that is related to ICT integration in the classroom, researchers have
rarely focused on how teachers with specifi c backgrounds respond to PDT .
But in what ways can teachers belonging to specifi c groups be important for understanding the effectiveness of PDT for technology integration? As we argue in this
work, this is because examining teachers with specifi c—and more particularly
favorable—background properties is one way of determining the possible upper
range of technology integration that we can reasonably expect from PDT programs.
Technology integration can vary greatly along the sustain-transform continuum. At
one extreme, teachers might make no or limited use of technology. In this case, the

impact of technology will range from negligible to small. At the other extreme,
teachers might use technology a great deal. In this case, depending on the ways
technology gets used, its impact might be far-reaching, ultimately leading to the
transformation of teaching and learning practices. As the preceding literature review
shows, the majority of teachers do not use technology in their practices and those
who actually do tend to domesticate it rather than use it to change their practices.
Examining how the most committed, skilled, qualifi ed, or experienced teachers
respond to PDT in ICT use is a possible test of success for current in-service PDT
programs since it can be a measure of their maximal effectiveness along the sustain-
transform continuum of technology use. In other words, if PDT stands any chance
of achieving our highest aspirations relevant to transforming current educational
practices, then teachers with such qualities are the best possible candidates for
proving the case for PDTs.
To the best of our knowledge, there are no studies on how teacher background
properties such as skills, expertise, or qualifi cations might infl uence the effectiveness of a PDT . Consequently, we draw mainly on studies indicating certain teacher
background properties as being either highly conducive to technology adoption or
closely related to it. It seems reasonable to assume that the more properties facilitating technology integration teachers have before attending a PDT program, the less
ground these teachers would have to cover in terms of learning while attending the
PDT . Our assumption is that teachers with such properties will show the best and
most favorable response to PDT as they would have to make less progress compared
to other teachers.
ICT Use as a Function of Teacher Background
Only a handful of studies have closely examined specifi c teacher groups with respect
to technology adoption and use . One group of studies focused on exemplary technology-
using teachers to extract those background properties that make them distinct .
I. Karasavvidis and V. Kollias201
Exemplary technology-using teachers use technology in their practices in innovative,
non conventional ways. In such studies the typical focus is on determining what makes
these teachers exemplary technology users, documenting their practices, investigating
their beliefs and pedagogical philosophies, and determining factors that either facilitate
or hinder their efforts to use technology (Angers & MacInmes, 2005 ; Becker, 2000b ;
Becker & Riel, 2000 ; Ertmer et al., 2007 ; Hadley & Sheingold, 1990 , 1993 ; Leftwich,
2007 ; Riel & Becker, 2008). This body of research shows that exemplary technologyusing teachers are different from other technology-using teachers and other teachers in
general in a number of ways. More specifi cally, exemplary technology-using teachers
actively seek more professional development activities than ordinary teachers, take
release time to follow such activities, are more willing to take risks and experiment
with technology, and overall have a high level of commitment to improving their students' learning through technology (Angers & MacInmes, 2005 ; Becker & Riel, 2000 ;
Hadley & Sheingold, 1990 ; Leftwich, 2007 ; Riel & Becker, 2008). While the contribution of such studies to our understanding of technology integration is critically important, this line of research has not focused on the processes through which these teachers
became exemplary. As a consequence, the personal learning trajectories of exemplary
technology- using teachers are unknown, especially in relation to PDT on ICT pedagogy . However the aforementioned characteristics of exemplary technology-using
teachers can work as rough guidelines in an attempt to locate groups of teachers with
background properties that maximize the potential of in-service PDT.
One group of teachers with special background properties which might be important for technology integration are teachers with constructivist beliefs. Several studies have indicated that exemplary technology-using teachers are also highly likely
to employ a constructivist, student-centered approach to teaching (Becker & Riel,
2000 ; Dexter, Anderson, & Becker, 1999 ; Hermans et al., 2008 ; Matzen & Edmunds,
2007 ; van Braak et al., 2004). Overall, a systematic relationship between constructivist approaches to learning and technology use has been reported in the literature:
constructivist beliefs are correlated with a higher rate of technology adoption. While
the relationship between constructivist teaching philosophies and technology use
has been well established in the literature, how exactly teachers who are very familiar with constructivist teaching and learning in a given subject area or grade level
respond to in-service PDT on pedagogical uses of ICT has not been explored.
Another group of teachers with specifi c background characteristics that might be
important for technology integration are teachers of high academic qualifi cations.
Compared to ordinary teachers, teachers who hold postgraduate degrees have by
defi nition a higher degree of specialization. Riel and Becker (2008) found that a
particular area in which professionally engaged teachers are differentiated from
other teachers is that they have invested more in their own education and master's
degrees were considered to be an indication of such an investment. As Riel and
Becker (2008) report, professionally engaged teachers were more likely to (a) have
a constructivist teaching philosophy and (b) use ICT more frequently and differently than other teachers (e.g., more tool applications, wider variety of applications). Although specialization might infl uence how teachers respond to PDT, how
teachers with a high degree of specialization, such as master's or Ph.D. degrees,
respond to PDT has not been investigated.
Technology Integration in the Most Favorable Conditions…202
Focus of the Study
Overall, there is a knowledge gap in terms of how specifi c teacher groups respond
to in-service PDT on ICT pedagogy . The present multiple case study aimed to
examine how one such group of teachers responded to a PDT program on ICT pedagogy. More specifi cally, our target was a group of three primary school teachers
who participated in an in-service PDT program offered by a University Training
Center (hereafter UTC) in Greece. These teachers were selected among the other
participants in the PDT program because they deviated maximally from the average
teacher in several ways. First, they had a high degree of expertise in the fi eld of science education as they all held relevant Ph.D. degrees. Second, they had a record of
academic publications in refereed journals, having authored or coauthored scholarly
papers in the area of science education. Third, they were all very experienced, as
their teaching experience ranged from 10 to 20 years of service. Fourth, none of
them were ICT novices as they all had previously used ICT in their teaching practices. Finally, two of them had participated in national funded research projects
which aimed to support science teaching with ICT while the third earned her Ph.D.
in a Teacher Education Department in Greece with a reputation for targeting ICT in
the teaching of science. For these reasons, the three teachers had backgrounds
which clearly set them apart from the general teacher population .
Given that these teachers participated in an in-service PDT program, their backgrounds were highly relevant for two main reasons. On the one hand, their specialization in science education ensured that they were, by defi nitio n , among the most
theoretically sophisticated teachers in terms of constructivist teaching philosophies
and pedagogies . Based on the literature reviewed above, they were the most likely
to respond favorably to technology integration given that constructivist beliefs are
related to classroom technology use (Becker & Riel, 2000 ; Dexter et al., 1999 ;
Hermans et al., 2008 ; Matzen & Edmunds, 2007 ; van Braak et al., 2004). On the
other hand, the fact that the three teachers held not only master's but also Ph.D.
degrees indicates a very high level of specialization . Thus, based on the fi ndings of
Riel and Becker (2008), this specialization would greatly facilitate in-service PDT
training on ICT pedagogy. Therefore, we assumed that from the whole teacher population these three participants were the most likely to respond favorably to PDT
not just on a superfi cial but also on a substantial level . In fact, we would go as far
as to argue that teachers of such backgrounds represent the ideal audience for seeding technology innovation concepts.
Given that the three teachers who participated in the PDT held constructivist
teaching philosophies and had high academic qualifi cations, this multiple case study
examined how they integrated technology in their practices along the sustain-
transform continuum.
Given the design challenge of creating instructional scenarios, implementing them
in their classrooms, refl ecting on them in the context of the PDT, and then revising
their initial instructional scenarios the following research questions were addressed:
1. How did the teachers integrate technology in their designs?
2. Where is technology integration situated on the sustain-transform continuum?
I. Karasavvidis and V. Kollias203
3. What were teachers' refl ections on their designs?
4. How did the teachers revise their initial designs?
The fi rst question aims to provide an account of technology integration in the
context of their practicum so as to map out how the different technologies were
prescribed to be used. The second question explored whether technology integration
supported established practices or transformed them into new directions. The fi nal
two questions mapped out the teachers' responses by way of refl ection or redesigning to the design challenge, its implementation, and the feedback they received in
the UTC.
Method
Participants and Setting
Following the general European Union (EU) policy guidelines, the Greek authorities have adopted a two-level PDT program for primary and secondary teachers. In
2000 the Greek Ministry of Education (MoE) initiated a large EU-funded PDT program of teacher in ICT (see Demetriadis et al., 2003 ; Jimoyiannis & Komis, 2007 ,
for a comprehensive account of this program). The program had an explicit technological literacy orientation and aimed to develop teachers' ICT skills and competences. It had a total duration of 50 h and was conducted at special school-training
centers (STC). Thousands of teachers participated in this ICT training that continued through most of the decade.
In 2007 the MoE established EU-funded UTCs in academic institutions around
the country (Jimoyiannis, 2010 , provides a detailed account of this program). The
objective of these UTCs was to provide high-quality in-service PDT in the area of
pedagogical technology integration across the curriculum. The PDT curriculum
involved pedagogical issues regarding technology integration in all academic subjects and grade levels. Each PDT program lasted for 350 h and spanned a period of
6 months. All primary and secondary teachers who had successfully completed the
former training program were eligible for participation and could apply for a position. After completing the UTC in-service training programs, the participants could
take a centralized exam and, if successful, become offi cial ICT mentors in their
respective academic subjects. Following the cascade model which was adopted for
this PDT program, these teacher mentors would then provide pedagogical ICT
training for their fellow teachers in local STCs (see Fig. 1).
Starting in late 2007, three main in-service training programs were offered at the
UTC of the University of Thessaly, the authors' host institution. The present work
draws on data collected from the third in-service training program (2011-2012).
This program followed the general guidelines for successful PDT in terms of form
(lectures, seminars and workshops, independent learning, and personal coaching
through mentors), length (it was extensive covering 350 h and spanned a period of
6 months), and curriculum (clear pedagogical rather than technical orientation).
Technology Integration in the Most Favorable Conditions…204
A total of eight primary teachers signed up for the third in-service training program.
In this work we focus on three of these eight teachers because they naturally formed
a group of teachers with very special backgrounds.
PDT Curriculum
The in-service PDT program offered at the UTC in the University of Thessaly comprised a general part and a subject-and-grade-level specifi c part. The former had a
broad, introductory goal and addressed issues related to educational policy in the EU
and Greece, history of educational technology, learning theories, and how they relate
to educational software, taxonomies of educational software, technical and administration issues related to the school ICT laboratories, and adult education. This general part lasted for 160 h and provided the foundation upon which the second,
subject-specifi c part could build. The second part which lasted for 190 h focused on
how to specifi cally integrate technology in the teaching of various academic subjects
and grade levels. Both subject-specifi c and general-purpose software tools were
introduced. Particular emphasis was given to technology integration according to the
research literature for each academic subject. To this end, a number of experts specializing in the teaching of academic subjects were contracted as teachers. Following
the MoE mandates to ensure the highest possible quality of training, only university
staff or Ph.D. holders of various specializations were eligible to teach at the UTCs.
In addition to the theory (i.e., general and subject- specifi c part), the training program
also included a short 30-h practicum section. As part of the requirements of the
practicum section, the participants had to implement two of their instructional scenarios (a) in their own classrooms and (b) in collaborating STCs. Four teacher ICT
mentors who had already successfully completed previous versions of the University
of Thessaly UTC in-service PDT program were also contracted to mentor the
planning and refl ection components of the practicum section.
Fig. 1 A cascade model of PDT
I. Karasavvidis and V. Kollias205
Design, Procedures, and Data Collection
Following the rationale of qualitative methodology (Lincoln & Guba, 2000), the
present study was conducted as a multiple case study (Yin, 2009). The study was
designed as a case study in an attempt to understand how teachers of constructivist
philosophies and high academic qualifi cations responded to an in-service PDT program on ICT pedagogy. In this multiple case study design, each teacher was treated
as a separate case in order to determine common underlying patterns through
replication.
The overall procedure followed is depicted in Fig. 2 . The teachers attended the
350-h in-service PDT program which involved both theory and practical applications of ICT across the curriculum. The theory section was concluded with the
design of ICT-based instructional scenarios. These instructional scenarios were put
to practice in the practicum section . Each teacher selected two of the instructional
scenarios designed in the course of the training and implemented them in their
classrooms. The practicum section was followed by a feedback session where the
teachers shared their experiences with the group and received feedback and
suggestions from their fellow teachers, the teacher ICT mentors, and the authors. In
the refl ection session which followed, the teachers were asked to revise their instructional scenarios in light of their experiences and the feedback received.
Due to the nature and focus of the study, many different types of data were collected in the course of the PDT. For the purposes of the work reported in this chapter, we draw on the following data sources:
(a) Instructional scenarios. As artifacts, instructional scenarios were of primary
interest as they embodied a teaching plan. The participating teachers developed
several instructional scenarios, following a detailed template that was provided
as part of the requirements of the training program. The teachers had the freedom to create any instructional scenario, in any subject, using any of the ICT
tools available, in any way they saw fi t. Following the theory and practice
guidelines of the PDT, the main requirement was that the integration of technology in their designs would have to have high added value.
(b) Group discussions. Whole-group discussions were also of primary interest as it
is during these that the teachers provided explicit accounts of their instructional
scenarios, thereby disclosing the rationale behind their designs. Group discussions were held during the feedback session and took place at the UTC with the
authors and the ICT-mentor teachers. These group discussions were tape-
recorded, and large portions were transcribed verbatim for further analysis.
Fig. 2 Overview of the procedure
Technology Integration in the Most Favorable Conditions…206
(c) Revised instructional scenarios . Revised instructional scenarios were meant to
embody teachers' refl ections following the implementation of instructional scenarios in their classrooms and the feedback session that followed. By refl ecting
on the elements the teachers perceived as problematic, revised instructional scenarios helped pinpoint the "corrective" measures needed. The revised instructional scenarios were also formally required for evaluation purposes.
(d) Participant observations and fi eld notes . In the course of the practicum and
refl ection sections, the authors took various notes of informal communications
with the participants (e.g., personal e-mails, informal discussions), questions
posed in the practicum section, and problems which surfaced in planning and
teaching. All such observations and notes were then combined with the rest of
the data to facilitate the analysis.
Data Analysis
Instructional scenarios and revised instructional scenarios were the data sources
through which we addressed the fi rst two research questions. They were analyzed
following established qualitative data analysis procedures. For each teacher case,
this involved data reduction, data display, conclusion drawing, and verifi cations
(Miles & Huberman, 1994). Each instructional scenario comprised several activities, and for the purposes of this work we used the instructional activity as our main
unit of analysis. Following a qualitative content analysis approach, we initially used
rough descriptive categories to classify technology use in each instructional activity,
arriving at general profi les of ICT use per instructional scenario. Subsequent passes
led to successive generalizations and mutual agreement between the researchers on
the main categories of technology use in the teacher designs. The categories used
are described next. These categories were used as indicators of constructivist theoretical underpinnings for the teachers and as a means of assessing which constructivist principles found their way to the instructional scenarios.
1. T echnology tools . This category included the various types of software tools
used such as stand-alone software or network applications (e.g., web browser).
This category assessed the presence of a constructivists' preference for a multitude of information sources so as to address students with different proclivities
and intensify the social embeddedness of the information provided. Although a
stand-alone software may indeed be specially designed in addressing particular

disciplinary needs, the current availability of easily accessible learning resources
through the Web makes them natural candidates for lessons addressed to digital
natives.
2. Information modality . This category addressed the types of content that the technology made available and included text, images, video, and audio. This category assessed the importance of providing information of different modalities so
as to supply multiple different representations of information.
I. Karasavvidis and V. Kollias207
3. Information context . This category described the nature of the information
sources used, distinguishing between educational and authentic sources. It
assessed the extent to which authentic information resources and real-time data
possibly of local and personal interest were employed in the instructional scenarios. Although including information in the context of school necessitates distancing from the offi cial sources by learned communities, the bulk of information
available on the web by varying sources of expertise makes it practically feasible
to assess authentic information sources.
4. Students' role in technology use . This category referred to who used technology
(student vs. teacher), whether technology was used as a tool to process information (yes/no), the locus of choice of technology tools and sources (student vs.
teacher), the locus of choice relative to how technology tools were used (critical
decisions regarding technology use were made by the students vs. the teacher),
and the mode of technology use (individual vs. group use). This category
assessed various indicators of constructivist concerns for promoting student
agency in the learning process. From a constructivist learning viewpoint, (a)
students rather than teachers are expected to be the main users of technology, (b)
students are expected to use technology as a tool to process information rather
than simply consume information, and (c) students are supported in making the
choices regarding technology use.
5. Technology function . This category examined the specifi c role technology played
in terms of learning for every instructional activity. Technology was used for
providing information, providing representations (without manipulation by the
students), and providing opportunity for limited simulation (manipulation
demands were minimal). This category assessed the constructivist tendency to
harness the potential created by the access to rich information sources and to
strong tools for data exploration (e.g., to assess rich information sources, to synthesize information from various—often divergent—sources, to use real-time
data to draw conclusions) and to use the visualization affordances of the technology (e.g., to conceptually facilitate the transition from abstract to the concrete, to
use multiple representations perhaps in parallel to student manipulation). Finally,
since all instructional scenarios were related to science education, it also assessed
the presence of technology uses that are in sync with current constructivist learning environments in science education which capitalize (a) explorations of a
physical phenomenon in ways impossible in real life, (b) experimentation
(hypothesis formation and testing), and (c) developing science process skills.
Each instructional scenario activity was assessed with respect to the categories
mentioned above. All six instructional scenarios we analyzed were related to science education, four belonged to earth science, one to physics, and one to environmental studies. The analysis of the transcriptions of the group discussions and the
participant observations and fi eld notes focused on themes pertinent to the third
research question, i.e., how the teachers refl ected on the design challenge and its
implementation. On the one hand we examined if teachers thought that their designs
refl ected signifi cant departures from their current practices. On the other hand, we
Technology Integration in the Most Favorable Conditions…208
looked at whether they experienced the design of instructional scenarios as a challenging activity. These data were triangulated with the teachers' assessment comments about the implementation of their instructional scenarios that were included
in their instructional scenario reports.
Results
Technology Integration
The fi rst question focuses on how the teachers integrated technology in their
designs. The instructional scenarios were the main data sources used to answer in
this part of the analysis. In order to identify patterns, each instructional scenario for
every teacher was treated as a separate case. Despite differentiations, the analysis of
the instructional scenarios revealed similar patterns of technology integration. Due
to space limitations, one instructional scenario per teacher was randomly selected
and is presented here.
Tables 1 , 2 , and 3 present the results of the analysis of one lesson that each teacher
planned and carried out in the practicum section with respect to the categories of
technology tools, information modality, information context, and technology func-

tion. Each lesson was actualized within two periods, which is approximately 90 min.
Each table row represents the different instructional activities in each lesson.
As can be seen in Tables 1 , 2 , and 3 , technology use involved (a) digital learning
resources and (b) interactive software applications. More specifi cally, taking into
consideration all of the designs, technology use was characterized by the use of both
general-purpose tools (such as a web browser) and the use of special-purpose educational software. The browser was primarily used for accessing information on the
World Wide Web and, to a lesser extent, for running web-based simulations and
animations. Although Web 2.0 sources (blog, wiki) were used in two cases by
teacher A, they were employed as information sources and the students were not
involved with the more constructive functionalities of these tools. The other type of
technology use involved stand-alone educational software. It should be noted however that the stand-alone software that was used was the result of research work
aiming towards addressing student misconceptions in the relevant natural science
domains. Overall, the browser reigned as the main software tool as it was dominant
in designs of two out of the three teachers.
In terms of modality, Tables 1 , 2 , and 3 show the presence of not only the textual
mode but also visual modes. Visual modes included realistic videos, simulations,
realistic videos that were annotated, realistic images, and charts. This variety is in
accordance to the professed constructivism of the teachers. On the other hand auditory modes have attracted less attention.
In terms of authenticity, only some of the information sources used were authentic ones. The majority of the sources were educational, i.e., were tailor-made for
educational purposes. Moreover even the authentic sources that were used were
authoritative in nature, thus coming as close as possible to univocal educational
sources. However the sources were appropriately selected so as to suit the targeted
students' age range.
Finally, with respect to the category of students' role in technology use, the
results do not show much variation. In all of the designs, technology was exclusively used by the students who collaborated in small groups to complete the assignments. However, technology tools and sources were explicitly selected by the
teachers. Moreover, the ways both the technology tools and the information sources
were to be used by the students were highly prescribed by the teachers through
worksheets. The worksheet was the main tool through which the teachers tried to
balance some freedom of choice for the students with a detailed specifi cation of the
technology use. Finally, technology tools were mainly used as a gateway to information, not as tools to process data and information or otherwise transform it.

Technology Integration in the Most Favorable Conditions…210
On the whole, the designs of the instructional scenarios were infl uenced by constructivist principles. The students were the main users of various information
sources and simulations in ways that facilitated the expression of their alternative
conceptions and a reality check of these conceptions. Nonetheless, two constraining
factors characterize most of the categories:
(a) Limitations of openness: Capitalizing on Web 2.0 functionalities, accessing
confl icting information sources, and accessing people outside the walls of
classroom are all nonexistent in the teacher designs.
(b) Limitations of students' agency: How and for what purpose technology is used
are prescribed by the teacher, and any source of challenge (like confl ictual
information) is avoided.
Technology Integration Along the Sustain-Transform
Continuum
The second research question focused on the technology leverage for implementing
science education instructional scenarios that were clearly going past current practices in Greece. The initial instructional scenarios and the revised ones were the
main data sources for this analysis. Teachers' refl ections were also used as a secondary data source but are reported in detail in part c of this section. The main functions
of technology can be seen in the rightmost column of Tables 1 , 2 , and 3 . More specifi cally, when situating the function that technology performs in the context of the
instructional scenarios we arrived at two main categories that express the leverage
of technology: accessibility and visualization . The fi rst refers to making accessible
content which would be inaccessible without technology. The second refers to the
visualization of physical phenomena and models in the context of providing 2D/3D
static or dynamic representations as well as other forms of representation.
The fi rst main function that technology played in the designs involved making
inaccessible information easily tangible. For example teacher B used a meteorological site run by a state agency to make accessible to students real-time data on the
current weather in different sites in Greece and Europe. Undoubtedly, using technology to access information which would be inaccessible through other means utilizes
the potential of technology to add currency, relevance, authenticity, multimodality,
and interest to one's teaching. Overall, the teachers used the information resources
to enrich the curriculum content which had to be delivered . On the other hand technology was not used to support engagement with students' own concerns and questions. Moreover, once the information was accessed no further demands of creative
craftsmanship either in processing the information or in interpreting the information
were put on the students. The absence of confl ictual or diffi cult-to- interpret information was further minimizing opportunities for this craftsmanship to be needed.
The second main technology function involved visualization. Instructional scenarios, worksheets, presentations of the instructional scenarios, and refl ections on
the instructional scenarios all centered on some form of presentation to the students.
I. Karasavvidis and V. Kollias211
As the analysis of the instructional scenarios suggests, although technology was
used by the students themselves, technology was largely used for demonstration
purposes in order to "show" something as clearly as possible, so that (a) student
misconceptions are eradicated through cognitive confl ict and (b) students are provided with crucial external representations that facilitate the understanding of the
intended concept or process. For example, in the course of an instructional activity
teacher C asked the students to stop a simulation showing coordinated representations of the Earth and its position relative to the Sun at specifi c time intervals. After
each simulation freeze, the students had to answer specifi c questions which were
given in the worksheet. Undoubtedly, supporting visualization is one of the main
strengths of technology , and it is understandable why the teachers made such an
extensive use of technology-enabled visualizations. On the whole, the teachers did
take into consideration students' alternative conceptions and constructed sequences
of predefi ned experiences alternating raw production of students' ideas with the
"corrective" experience of superb visualization afforded by technology .
When considering the whole corpus of the instructional scenarios the following
common patterns emerged. First, simulations appeared in the teachers' designs, but
their use was extremely limited. For example, in the case of the coordinated representations time was the only variable that could change. Moreover the directions in
the student worksheets specifi ed the specifi c values of the time variable where the
students were instructed to freeze the simulation. Consequently, while on the surface the students appear to be actively controlling the simulation, from a learning
point of view nothing much would have been different had the teachers used a video
projector for a whole-class display of the simulation and had they posed similar
questions to the whole class.
Second, technology use by students for constructing hypotheses or transforming
and representing knowledge or managing the tasks was extremely sparse. There is
only one exception to this pattern, teacher C, who on one occasion used GoogleEarth
to create limited opportunities of manipulation and provided students with a genuine
inquiry question. However the conditions were unfavorable (time allowed, place of the
activity in the overall design) and rendered such an inquiry practically impossible.
Third, technology-enabled visualizations seemed to compete with physical
artifact- enabled visualizations as if the two were struggling to occupy the same slot
in the script of the didactical sequence. There are several manifestations of this. On
the one hand, simulations were used sequentially and not in parallel with more traditional "experiments." For instance, teacher A introduced a simulation quite some
time after a relevant experiment. On the other hand, teachers underplayed the visualizing and representational affordances of hands-on artifacts (such as the globe, construction, and manipulation of 3D artifacts). The teachers did not use the opportunity
to combine digital simulations with the use of hands-on artifacts; instead, they
showed an extreme faith on the effi ciency of digital visualization as a learning tool.
Finally, technology was often used (especially by teachers B and C) to stage a guided
presentation of the features of the visualized physical model and to compare these
features with selected and heavily transformed pseudo-authentic digital materials.
In this fi nal case digital reality took the place of physical reality both in terms of the
experimental means and of the observations.
Technology Integration in the Most Favorable Conditions…212
Teachers' Refl ection on the Design Challenge
and its Implementation
The third research question centered on teachers' refl ections on the whole PDT
experience and specifi cally looked at the teachers' perceptions of the design challenge and its implementation.
Technology integration as a challenge
Overall, the teachers did not experience the designs in the practicum section of the
PDT as a real challenge. This is not surprising given their high level of expertise. As
teacher A noted in the discussion of the refl ection session:
I have been using ICT in my teaching before this [PDT] program. I was certainly using ICT
in Science Education which is a subject I know really well. So, it's not that I learned something new that I've just started using in my teaching…That doesn't mean I did not profi t
somehow from attending the PDT. It [ICT] was more useful for other [academic] subjects.
But here [science education], since I taught in a domain that I know well, I feel that I would
have still delivered even if I had not attended the PDT (Teacher-A)
Here the teacher clearly delineates what she thought of the PDT, stressing that
she did not fi nd it informative enough in her domain of expertise. Overall, the teachers who participated in this study were very confi dent with their theoretical underpinnings in science education and often cited relevant sources in their refl ections.
For example, in the following excerpt, teacher A explains the theoretical guidelines
that guided their designs:
From the point of view of current approaches to Instruction in the Natural science, learning
is not just acquiring information but a continuous process of resolving of inner cognitive
confl icts. Those confl icts are created and resolved through active participation, communication and interaction between the student and the learning and social environment in the
classroom (Teacher-A)
This statement clearly refl ects the constructivist convictions of the teacher,
refl ecting both the nature of science learning and an instructional approach to science teaching.
In another occasion teacher C articulated his own stance about when the use of
ICT may be productive, largely corroborating our conclusions (section on
"Technology Integration Along the Sustain-Transform Continuum" above) about
the added value that teachers attributed to technology

… my conclusion regarding the use of ICT or what we call “digital resources” etc. is that
you aim to use ICT whenever you have no particular or no other ways of representation,
alternative ways of representation, presentation of a new concept or phenomenon and the
second way [of ICT use] is to use ICT in conjunction with the experiment etc. what we call
multiple representations, that is as an complementary medium, as a supplementary tool to
promote better understanding (Teacher-8)
Teachers' openness to change
Given that the main functions of technology involved information access and
visualization, in the group discussion session the authors suggested other ways of
I. Karasavvidis and V. Kollias213
technology integration, linking back to the theory and practices of the PDT program.
It was pointed out to the teachers that technology might have been well integrated
in their designs, but this integration was limited with respect to the potential of
technology to support new forms of teaching and learning. Teachers' responses to
our proposals were completely unexpected. Not only did they defend their designs
but also claimed that both their designs and the ways technology was integrated in
these designs were nothing short of exceptional. From our point of view, it was puzzling that the teachers did not seem to be open to suggestions and refused to even
consider other proposals for contemplating new ways of technology integration
which would have resulted in a more substantial level of technology use, a level that
would have entailed a change in the teaching practices. In an effort to ground the
discussion in a concrete way and since visualization was a pivotal point in all of
their designs, each participant was asked to explicitly describe the function of visualization in terms of learning for his/her design. While the UTC training program
provided a broad conceptual framework for understanding technology use across
the curriculum, the teachers approached visualization ad hoc in their designs; that
is, they neither examined visualization in terms of a learning theory or a specifi c
conceptualization of learning nor did they consider the special mediating role visualization was to play in their students' learning . It was as if visualizations themselves would somehow provide most of the support needed by the students leaving
teachers with the task of selecting and pacing the appropriate technological tools to
supply the visualizations in a “just-in-time” fashion. Therefore, there appeared to
be dissociation between the concepts presented in the training curriculum and the
concepts the teachers invoked to explain why exactly they chose to use technology in
the ways they did . Essentially, they conceived technology as a gateway to information, fi tting a slot in the science education teaching script that they had mastered as
opposed to addressing the technology's learning functions and the role of technology
in mediating the learning of science content.
Teachers' Revised Instructional Scenarios
In addition to designing instructional scenarios, the PDT also involved implementing these scenarios in real-world settings and the teachers tried them out in their
classes in the practicum section of the program. Due to the PDT design, the teachers
were asked to refl ect on their experiences and to describe in detail how they would
change their designs based on their experiences with (a) the actual technology use
in their classes and (b) the feedback they received in the refl ection session. More
specifi cally, they were asked to revise their instructional scenarios as they see fi t so
as to achieve the maximum level of technology added value for the same learning
objectives. The resulting accounts of technology use would be idealized, free from
any sorts of constraints (time, curricular, infrastructure, student background knowledge, etc.). The analysis of these “idealized” instructional scenarios indicated that
the teachers stood by their original designs. The only changes made were minor
Technology Integration in the Most Favorable Conditions…214
ones and were unrelated to technology use or function per se . Consequently, information access and visualization remained the main technology functions in the
revised instructional scenarios.
Discussion
The last century has been characterized by recurrent visions of transforming education through various technologies. The high hopes that technology integration into
teaching practices would lead to their transformation have not been validated
(Condie et al., 2007 ; Cuban, 2001 ; Cuban et al., 2001 ; Donnelly et al., 2011 ;
Eteokleous, 2008 ; Hayes, 2007 ; Hermans et al., 2008 ; Li, 2007 ; Norton et al., 2000 ;
OFSTED, 2004 ; Player-Koro, 2013 ; Prestridge, 2012). Teachers either resist using
technology or use technology to sustain rather than transform their practices
(Donnelly et al., 2011 ; Law & Chow, 2008a ; Player-Koro, 2013). This failure to
transform education through technology has been attributed to fi rst- and second-
order barriers (Ertmer, 1999 , 2005). As research shows, fi rst-order barriers are a
necessary but not a suffi cient condition for technology integration. Therefore
second- order barriers need to be addressed, and one of the main tools to address
them has been teacher training, both preservice and in-service. While there is a
substantial body of research on what makes professional development effective, the
importance of factors related to teachers' backgrounds has not been thoroughly
explored yet (Coburn, 2004 ; Penuel et al., 2007). The present work contributes to
this knowledge gap by examining how a group of teachers who had constructivist
teaching philosophies and high academic qualifi cations responded to an extensive
in-service PDT program on ICT pedagogy. The special characteristics of the teacher
participants provide a measure of the limits of PDTs as a means to promote technology integration in educational practices in transformative ways.
Due to both the teachers' characteristics and the design of the PDT they participated in, there were no fi rst-order barriers hampering technology integration. With
regard to second-order barriers, these teachers were science education experts and
science education is a fi eld where constructivism is championed more than any
other educational fi eld (Duit & Treagust, 1998). It should also be noted that in
Greece most Ph.D. dissertations in science education adopt some version of the
constructivist paradigm. As the literature shows, teachers who have constructivist
beliefs are more likely than other teachers to use technology and also tend to use it
in more student-centered ways (Becker & Riel, 2000 ; Dexter et al., 1999 ; Hermans
et al., 2008 ; Watzen & Edmunds, 2007 ; van Braak et al., 2004). On the other hand,
one of the potential barriers to technology integration is the time and effort required
by teachers to adopt an innovation (Hayes, 2007 ; Penuel et al., 2007 ; Sandholtz &
Reilly, 2004 ; Tyack & Tobin, 1994). Teachers are often reluctant to embrace an
innovation because there is a lot of work involved in adopting it. In our case, however, the teachers were already accomplished, i.e., had a sound theoretical foundation which in principle should require minimal work and effort on their part
I. Karasavvidis and V. Kollias215
regarding technology integration. Overall, because the teachers did not have much
theoretical ground to cover, we expected that their responses to PDT would be very
positive in two principal ways. First, in terms of technology integration, we expected
that technology would be instrumental in the success of a lesson. Second, we
expected that technology would not be a mere add-on to current teaching practices
but it would leverage them leading to transformations .
The former was fully corroborated by our fi ndings as the teachers integrated
technology in their lessons in a fi tting way, closely following the general principles
of constructivist learning . Firstly, the students themselves were the main users of
technology. That did not mean the use of technology for drill and practice purposes
as is common for novice teachers to do. A wide assortment of digital learning
resources was used in the instructional scenarios, giving them currency and relevance. These means were effective in promoting student engagement and facilitated
the students' recall of relevant prior knowledge. Secondly, collaborative work and
learning were promoted as the students worked in small groups to complete the
assignments. Students were indeed prompted to discuss the information and visualizations provided by technology, and certainly some questions could be solved
through the joint effort of the students. Thirdly, technology was instrumental for the
actualization of these designs and served the teachers' goal of achieving conceptual
change in the science topics targeted in each lesson. The teachers themselves
reported positive results through assessments they had embedded in the instructional scenarios and realized during the implementation of their designs. Based on
teachers' backgrounds and expertise, such high levels of technology integration
were hardly surprising and, as corroborated by their own comments, were to a certain degree mastered before following the current PDT program.
The latter, however, was not supported by our fi ndings. The analysis of the
instructional scenarios and in particular the specifi c technology functions the
teachers used indicate that technology was assimilated into their current practices.
To illustrate the nature of this assimilation, we will consider in some detail the
dominant instructional paradigm of current science education practices in Greece.
More specifi cally, this paradigm is an adaptation of the model of the “inquiry-
scaffolding teaching method” (Schmidkunz & Lindemann, 1992 , as reported in
Apostolakis et al., 2006). The science education teacher books for grades 5 and 6
elaborate on this didactical model and provide the general guidelines for its use.
According to the rationale covered in the teacher books, each lesson follows a specifi c sequence because
students' participation in inquiry is not unguided, but follows specifi c stages and is guided
through specifi c actions, so as to be practically realizable. At every point the teacher can
follow how students learn (Apostolakis et al., 2006 , p. 32).
This sequence includes a fi rst stage where the teacher transforms the subject he/
she has to teach into an initial question or problem. Relevant prior knowledge is
brought forth, and students are supported in proposing their ideas (“hypotheses”)
about the solution to the problem. Student misconceptions surface at this stage.
Then the students perform one or more experiments that the teacher has selected for
Technology Integration in the Most Favorable Conditions…216
them. As the teacher book suggests, during this phase the teacher should not be too
intrusive, allowing students to “really engage in inquiry.” However, the time constraints of the implementation indicate that the authors of the teacher guide consider
the experiments so well chosen that the students are either expected to arrive themselves at the intended conclusions or that they will be easily convinced by the arguments provided by the teacher. In the next stage, the teacher book proposes to hold
a discussion through which the class arrives at the intended interpretation of the
experiment and gradually towards answering the initial problem. There is no providence for the cases where students might propose new ideas that could be tested
through alterations to the experiments or through new experiments. While the
experiments do address students' misconceptions, they do not leave much space for
student initiative and creativity in the unfolding of the inquiry. During the closing
part of the lesson the teacher guide recommends that students compare their fi nal
answers with the ones they gave initially. In the fi nal stage proposed by the teacher
book, students should work on teacher-assigned exercises that are expected to lead
to a deeper understanding of the science material covered.
As outlined in the teacher guide above, the dominant science education paradigm
in Greece is strongly concerned about the pacing of the instruction, trying to balance
its constructivist theoretical underpinnings and the appropriation of conceptual change
literature with constraints that are inherent in the Greek educational system. Therefore
it does not take into account students' own needs and the scaffolding demands placed
on the teachers should they choose to support these needs. Out of the four main ICT
affordances that Webb (2005) outlined in her review of science learning with ICT-rich
environments, this dominant paradigm is compatible only with the following two:
(a) promoting cognitive development and (b) relating science to students' own experiences and data in the broader real world. The other two affordances namely
increasing students' self-management and enabling them to track their progress so that
teachers' time is freed to focus on supporting and enabling students learning; and facilitating data collection and presentation of data that helps students to understand and interpret
the data, and additionally frees students' time so that they have more time to focus on
developing conceptual understanding (Webb, 2005)
are not compatible with the concern about teacher control expressed in the above
model. This view is in line with other literature proposals for using ICT in science
education. For example, Chang (2013) argued that addressing student needs is probably a main factor in successful scaffolding of science learning through simulations.
On the other hand, Osborne and Hennessy (2003) noted the critical role ICT can
play for introducing students to scientifi c inquiry, for developing hypothesis formation and testing, for advancing science process skills, and for solving open-ended
problems through various technological tools.
The examination of instructional scenarios against this backdrop leads to the
conclusion that the teachers incorporated technology in their existing practices .
There are two main indications of this. First, the way that information was used in
the instructional scenarios expressed a strong concern for effi ciency in time management: all the information aimed to direct students towards the intended “correct”
interpretation . Even in the cases where authentic sources were used, they were as
I. Karasavvidis and V. Kollias217
“school like” as possible: they were used in ways that would not demand judgment
and evaluation, only the selection of bits and pieces of relevant information (for an
alternative way of using information sources see Bell, 2000). Real-time, detailed,
complex, and authentic data sources were utilized in ways that looked more like a
guided tour. Finally, Web 2.0 resources were only used to access authoritative information indicating an entrenched practice that avoids introducing real- life confl ict in
the classroom. Second, technology was exclusively used in order to provide authoritative information . There is a striking similarity here between this technology role
and the role “experiments” play in the “inquiry-scaffolding teaching method” (as
adapted in the teacher guide).
Overall, the ways teachers integrated technology in their instructional scenarios
do not show any signifi cant departure from established science education practices
in Greece . Considering teachers' backgrounds this was not expected as the
conditions for transformation were very favorable. Zhao, Pugh, Sheldon, and Byers
(2002) reported that one of the factors that might affect classroom technology innovations is the distance from existing practice. In our case this distance was relatively
short given the teachers' starting point. Consequently, the teachers did not have
much ground to cover in order to integrate technology in a transformative manner,
i.e., along the lines proposed by Osborne and Hennessy (2003).
Interestingly enough, not only was technology merely assimilated into existing
practices, but the teachers also refused to question their teaching practices and were
not open to suggestions along this direction, that is, despite the persistent efforts
from the authors to explicitly point out the limitations in the ways they had integrated
technology in their teaching in the practicum section. In retrospect, there are several
possible explanations for this type of resistance. First , as the participants in our study
were already accomplished teachers and researchers, they probably did not come to
the PDT thinking that they would need to radically transform their teaching practices , much less of course in science education which was their domain of expertise.
In all likelihood, they considered that such radical transformations of their teaching
conceptions and practices had already taken place in the course of their professional
histories. Second , resistance might be due to the fact that the teachers felt that the
level of ICT integration they had already achieved was part of the roadmap that other
teachers (that they soon would be mentoring) would have to pass through in order to
achieve more highbrow goals. In this sense, they were probably excusing themselves
from putting cognitive resources in the direction of further pedagogical experimentation. Third , it could well be that we have experienced a ceiling effect as the teachers
were already accomplished and there was no room for progress . Unlike other PDT
studies (e.g., Dwyer, Ringstaff, & Sandholtz, 1990 ; Levin & Wadmany, 2005 ;
Prestridge, 2012) in which the entry level of teachers who participated was that of an
“average,” “traditional” teacher, in our study the three teacher participants could not
be considered “average” or “traditional” by any measure. Finally , it could be that the
constructivist practices teachers had adopted might have been producing better
results in validated tests than the practices of the average Greek teacher who still
strives to meet the guidelines of current teacher guides. This means that they did not
have many reasons to feel “pedagogical discontentment” (Southerland, Sowell,
Technology Integration in the Most Favorable Conditions…218
Blanchard, & Granger, 2011) with the teaching model they were following. It is
likely that neither their former practices nor the PDT program succeeded in generating the “pedagogical discontent” needed for energizing the teachers' search for ICT
integration of higher quality.
In terms of the sustain-transform technology integration continuum, we argue
that the responses of the teachers to the in-service PDT marks the upper limit of the
possible range of technology integration , at least in the context of Greece. Our fi ndings suggest that the teachers in our study who were very advanced theory-wise and
already using fully compatible teaching practices could not go past a certain degree
of technology use, that of sustaining existing practices . Although there were no fi rst-
or second-order barriers, the highest level of integration reached was to use technology as a gateway to information and supplying visual representations . When
considering this against the dominant science educational paradigm in Greek education we see that neither of these uses suggests a transformation of teaching practices. Interestingly enough, the teachers did not signifi cantly modify their initial
designs, even after (a) trying them out in their classroom and (b) receiving feedback
from the authors which highlighted several limitations and missed opportunities for
adopting new technology-based practices. This suggests that their vision of technology integration did not go past the ways they were integrating technology in their

practices before attending the PDT. As our fi ndings indicate, a more substantial
level of technology integration, namely one that would go past information accessibility and visualization and move towards new teaching practices, is probably not
very likely even in the most favorable conditions, i.e., with teachers who have constructivist teaching philosophies and very high qualifi cations.
Implications
The fi ndings of the present study have important implications for in-service PDT on
ICT pedagogy. If accomplished teachers can only go so far after attending an extensive in-service PDT program such as the one described in this study, then one can
only wonder how far average teachers might go in terms of technology integration
so as to achieve the much desired transformation. Not only did the participants not
move past a given level of integration, but they also refused to consider other types
of technology use. If this is the upper limit obtainable by teachers who hold constructivist philosophies and are highly qualifi ed, how realistic is it to expect any
further transformation of teaching practices through technology? That is, if technology integration does not lead to teaching practice transformation in the most favorable conditions, as the ones described in this study, then perhaps the time has come
to rethink PDT programs in ICT integration .
PDT has come to the spotlight because of the importance of second-order barriers for technology integration. As second-order barriers are considered to be intrinsic to teachers, the focus that much of PDT literature puts on teachers is
understandable. In the end, the teacher is broadly acknowledged as the most critical
I. Karasavvidis and V. Kollias219
mediating factor for classroom technology use (Ertmer, 2005). The present study
clearly indicates potential limitations of current PDT programs if our objective is
the transformation of educational practices through ICT. We argue that to address
these limitations we will need to reconceptualize the way we approach in-service
PDT programs on ICT pedagogy. As we see it, there are three issues pertinent to this
reconceptualization.
First, w e need to redefi ne what technology integration really means . We need to
be very explicit about the range of integration as well as its nature. For example, if the
objective is simply to integrate technology so as to enrich the curriculum, then the
ways the teachers in our study integrated technology in their lessons are exemplary.
From this point of view, current implementations of PDT programs can be very effective. However, if the objective is to integrate technology so as to change current
teaching practices in specifi c directions (such as to foster student-centered learning,
meaningful learning, problem-based learning), then the ways our participants integrated technology in their teaching practices are quite limited. It is imperative to
defi ne clearly what this direction actually is. In this sense, technology integration
would have to be explicitly described not only in terms of teaching practices but also
in terms of student learning and the crucial mediating role technology can play in
order to achieve this learning. Recently, other researchers have also called for a
reconceptualization of what it means to teach with technology and stressed the
importance of sketching out such a vision (e.g., Ertmer & Ottenbreit- Leftwich, 2010).
Second, we need to address other possible background variables that could infl uence the effectiveness of PDTs . For example, the presence of pedagogical discontent
(Southerland et al., 2011) that was mentioned above is such a variable that might
make a difference. Such variables need not be strictly personal. They may be constructs that are strongly determined by the context of teachers' practices. For example
even teachers with constructivist beliefs may not have the opportunity in terms of
time or available assessment instruments to test the limits of their current designs and
thus to experience pedagogical discontent. Or they may not feel psychologically safe
to try innovations because they do not have the administrative support to try out very
innovative designs in order to conceptualize and desire new goals for their students.
Finally, while a focus on the individual teacher is indispensable, we need to
broaden this focus to take into consideration not just the teachers themselves but
also the contexts in which they function . Ultimately, the "grammar of schooling"
(Tyack & Tobin, 1994) is very important as it is these contexts that shape teacher
beliefs and attitudes. Take for example the ACOT report conclusion, in which
Dwyer et al. (1990) argue:
Although the direction of change in ACOT classrooms is promising, the pace of change is
slow, for even when innovative teachers alter their practices and beliefs, the cultural norms
continue to support lecture-based instruction, subject-centered curriculum, and measurement-
driven accountability. (p. 2).
This clearly delineates the power current norms have in shaping teacher thinking
and consequently to teacher responses to ICT integration—even for innovative
teachers. The importance of the context of an innovation has been stressed (Penuel
et al., 2007 ; Starkey, 2010). Therefore, regardless of technology familiarity and
Technology Integration in the Most Favorable Conditions...220
constructivist beliefs about learning, the material conditions of actual practice (i.e.,
curriculum, legislation, high stakes testing, working conditions, resources) exert
signifi cant pressures on how teachers eventually come to view innovations in general and technology in particular. As it has been demonstrated, all these infl uences
might eventually shape an object of activity for teachers that is markedly different
to the one envisaged by educators, reformers, researchers, parents, politicians, and
other stakeholders (Karasavvidis, 2009). For the most part, PDT research has failed
to employ theoretical frameworks that take into consideration not only the teacher—
as the alleviation of second-order barriers clearly demands—but also other contextual factors that have the power to shape teacher thoughts and practices. Future
studies need to draw on theoretical frameworks that help conceptualize PDT programs in systemic terms so that the individual teacher no longer remains the focal
point of attention and the sole unit of analysis.
Conclusion
The current research addressed a gap in the current literature with respect to the way
teacher background properties such as expertise and qualifi cations might infl uence
the effectiveness of PDT programs. The fi rst main study fi nding is that even after
attending an extensive in-service PDT program, three teachers with constructivist
teaching philosophies and high academic qualifi cations integrated technology in
ways that sustained rather than transformed their existing practices. The second
study fi nding is that the teacher participants found it very challenging to consider
other types of technology integration that would be more on the transform end of the
sustain-transform continuum. As teachers who hold constructivist beliefs and have
high levels of qualifi cation are expected to exhibit the most favorable response to
PDT programs, this work raises serious concerns with respect to how far contemporary PDT programs can go in the direction of transforming teaching practices
through technology. Despite its main limitation, namely the small number of teachers who participated, we think that the present study contributes to delineating the
upper limit of technology integration that could be realistically expected from mainstream PDT programs. Further research in this direction should take the "grammar
of schooling" into consideration and carefully examine the shaping infl uences of
context on teacher beliefs and, consequently, on their responses to PDT.

Introduction
Among various programs of technological equipment in schools, one-to-one programs (1:1) are those that neutralize the access factors. Massive computer endowments are considered by administrators, educators, families, and politics as a part of any major change in a school. However, the relative failure of One Laptop Per Child (OLPC) program (Warschauer & Ames, 2010) shows that personal computers have no pedagogical or didactical added value without other basic plans such as teacher training, reasonable number of students per teacher, resources, and electricity. In a conservative competitive system, like in Western countries, computer uses in classrooms are not raising learning outcomes more than ordinary technology. For the Maine (USA) project, Silvernail (2005) argues that students' results are not affected by computers because the ability to search and fi nd knowledge is not part of the institutional assessment which is based on learning by heart.
However, the way teachers rule the classroom is affected by technology. Windschitl and Sahl (2002) claim that some teachers tend to create a more constructivist pedagogy which is close to the evidence reported by Bebell and Kay (2010). If the teaching modifi cation mechanism is not clearly identifi ed, we suggest that ICT implementations may be a way of affi rming a pedagogy overhaul. For example, Karsenti and Collin (2011) report that in Canada, at the Eastern Township School Board, technologies were part of an institutional renewal strategy in a similar way to

the Grimes and Warschauer (2008) studies on a one-to-one laptop program in California. An example of this phenomenon is the emblematic adjudicate youth program realized with Seymour Papert (Cavallo, Papert, & Stager, 2004) or the Apple Classrooms of Tomorrow project (Dwyer, Ringstaff, Haymore, & Sandholtz, 1994).
In this perspective, achievement of ICT, as reported by Zucker and Light (2009), can be seen not only by direct effects of ICT on cognitive activities but also through a general pedagogical and didactical improvement, where computers constitute the visible part of the iceberg. Beyond schools saturated with technology, teachers' testimonies in regular lower secondary schools are central for understanding what are the key features of a sustainable and an effi cient use. In the Norwegian context, Wikan and Molster (2011) report that almost two-thirds of their sample were using ICT once a month, similar to France (Khaneboubi, 2007). In Sweden, on the basis of a focus group methodology, Erixon (2010) claims that insuffi cient access to computers is one of the most important reasons for not using ICT during classroom. The most frequent uses of ICT by teachers in secondary schools are for sustaining motivation and search, as pointed by Wikan and Molster (2011). Drent and Meelissen (2008) in the Netherlands claim that early adopters are the "anchor point for stimulating the innovative use of ICT in education." In particular, those teachers are well socialized and technically skilled in regard to their pedagogical needs.
Jimoyiannis and Komis (2007), in a quantitative study with Greek teachers, report that personal factors such as subject matter, teaching experience, or gender are associated with their perceptions about ICT in education. In England, Hennessy, Ruthven, and Brindley (2005) report that commitment in ICT activities is tempered by the infl uence of external constraints.
In France, after active national policies supporting the training of teachers for integrating technologies into their school practices, an approach of new artifacts has been developed, conceiving them as tools (Baron & Bruillard, 1996). Since the 1980s, this approach still dominates. Technology endowment programs in the French schools continue to be accumulated without necessarily being accompanied by national plans for teacher education. Furthermore, mandatory uses of ICT in the curricula are very sparse and decisions about curricula tend to reserve computing into specialized courses. The French one-to-one programs (Jaillet, 2004 ; Khaneboubi, 2010 ; Rinaudo, Turban, Delalande, & Dhana, 2008) show a weak state support in regard to the local authorities' implication.
In this chapter, we report a study conducted in 2012 following a fi rst work made in 2010, in four lower secondary schools where teachers and students have a relatively better access to technology and digital resources than in other French schools. Three of them were involved in a national state program on digital textbooks; they had been endowed in 2010 by a local state authority called "académie." Consequently, they were also involved in a series of programs that aim at identifying the conditions and limitations of ICT implementation. The disciplines mostly concerned were mathematics, social studies, literature, and technology and, occasionally, foreign languages and biology. We seek to understand dynamic and evolutions by taking "pictures" at two different times and, according to the actors, trying to retrace what happened.

The purpose of our survey, partially funded by the local state authority, was to get a better understanding of the evolution of ICT uses in the everyday teachers' professional running pattern in order to identify propitious and obstacle factors. To what extent computers are a signifi cant tool in the classrooms to achieve a teaching task? Do teachers have an equal access to equipment? What is the infl uence of organizational factors on teachers' utilizations of technologies?
Data Collection Methods
The investigation method has been guided by the framework made by Fulton, Glenn, and Valdez (2003 , 2004), who draw a list of necessary elements propitious for teaching with ICT. This framework has been adapted to the French context; seven factors were defi ned as follows:
- The role of the leadership in the school management: Is there a team for piloting ICT projects in the school? What is the importance of ICT in the general school project?
- The roles assumed by teacher(s) responsible for ICT in the school: In each secondary school one or several teachers are discharged for a part of their teaching duty to help and conduct pedagogical use of ICT among his or her colleagues. Very often, this function is allocated to early adopter as described by Drent and Meelissen (2008).
- The manner in which the support and maintenance are performed: In the French context, the national state is responsible for teaching contents and human resources, while authorities on buildings, equipment, and maintenance are devolved to local administrations such as territorial councils and city councils.
- Financing from local communities, state local authority, ministry ....
- State policy on ICT as well as local policies.
- Different support settings for teachers of different disciplines in their use of ICT: Training, guidance, meeting ....
- School position in the environment and links with parents and with local associations.
In the next section, we describe a preliminary study that has nurtured and served the construction of the study conducted in 2012. They are both based on Kathleen Fulton's framework.
The 2010 Pre-study
In 2010, we sought to get a better understanding according to the methodological elements explained in the previous section by performing 30 interviews with innovative teachers and management teams (Bruillard et al., 2011), following an

ethnographic perspective as documented by Woods (1996). For each middle school, we have conducted interviews with:
- The management team
- Teachers responsible for ICT
- Teachers-librarians
- Teachers who use digital textbooks or any kind of ICT
The interviews focused on the school characteristics, teaching experience of the teachers responsible for ICT and how they managed these responsibilities, organization of the endowment program in digital textbooks, and changes in teachers' practices related to these new means as well as those occurring due to other technologies available. We did not meet all the teachers, and only ICT users. Interviews showed disparities in the access to the computer room, and the Internet weaknesses were not perceived in the same way by all teachers. Furthermore, it was often suggested that all teachers were not equal in front of technical and educational assistance.
Literature teachers in particular (often women) seemed unaware of the existence of some equipment. Teachers responsible for ICT said that they did not have time to perform maintenance on all computers. For this reason, there was a high probability that computers used by teachers less close to the management team or in conflict with it did not get the same comfort of use as other teachers. Therefore, it seemed fruitful to test the hypothesis that all teachers do not have the same possibilities in front of infrastructure and equipment deficiencies and that technical assistance is not distributed equiprobably: patterns according to gender, age, or subject taught were potentially observable.
The 2012 Study
Since the 2010 study focused on innovative teachers in a qualitative way, in 2012 we sought to reach a greater number of teachers with a questionnaire in order to get a clearer outline of the dynamics at work in the schools and the possible new (declared) practices in the classroom and for preparation. Therefore, in 2012, interviews were conducted in three middle schools with eight teachers and managers and a questionnaire was filled by 89 teachers in four schools (Beauné, Khaneboubi, Tort, & Bruillard, 2013). This amount of exploitable questionnaires represents approximately 45 % of the teacher target population. Among the five schools participating in the first survey, one school was left out because of the difficulties encountered during the initial investigation.
Schools A, B, C, and E are located in suburban areas near Paris. School D is part of a rural area. Establishments A, B, and C are located in high-poverty area. However, these schools have a relatively large equipment and are known for their significant use of ICT in teaching and learning activities. Each one hosts approximately 500 students and 50 teachers and has more than 100 computers distributed in computer labs, libraries, technology classrooms, etc. There are at least one

computer lab and two sets of laptop per school. All the classrooms of the sixth and seventh grades are equipped with a computer and a projector in most cases. In three schools, all rooms are equipped with a computer. However, Internet and network access are not reliable in most places. The stability of the teaching staff such as managers' departures, teachers responsible for ICTs' departures, or major changes in the teams of teachers is not accomplished. In two institutions, an important and frequent turnover has been reported.
In short, in 2012 a quantitative and a qualitative study was made to complete a 2010 work. The first round of interviews made in 2010 was the foundation of our quantitative survey of 2012. Interviews were conducted with administrators and teachers responsible for ICT in three schools (A, D, and C); observations and informal interviews were conducted in the staff room for two schools (A and E). The interviews focused on the changes that occurred between 2010 and 2012. A particular issue was to establish a balance after 2 years of using digital textbooks. We seek to document the changes in the practices that have been observed between the two periods of data collection. When it was possible, interviews were conducted with managers and teachers responsible for ICT as in 2010. We have managed to conduct interviews with the same people or with those who occupy the same function in our school sample.
In those schools which get significantly more equipment than average schools, new equipment is not so frequent. No major changes in the equipment have been reported. Between 2010 and 2012, the main technology that entered the French school was interactive tablet. Less than 20 were endowed in one college of our sample. The weakness of the Internet access has not evolved. Analysis of speeches from managers and teachers responsible for ICT permits a comparison of evolution, a description of the inertia in the teachers' team involvement, and the dynamics at work in the schools.
Teachers' Questionnaire
The questionnaire fulfilled in 2012 is a part of a longer term project. We have sought

to build a database during several years in order to make comparative studies and
report experiences of teachers while there are technological developments. We also
aim at sharing our raw database. For now it is possible to present how the various
factors that can be found in the literature are combined in our context.
Based on the interview analysis of the 2010 study, a fi rst draft of the questionnaire
was tested in one middle school and one high school in another region. An anonymous four-page questionnaire (shown below in Appendix) was stabilized, with
about 60 questions grouped into six themes linked to ICT practices:
· Personal and professional information (status, discipline, experience background …)
· Mode of the course preparation (frequency uses of software, Internet, digital
textbook, etc.)
· Classroom activities (frequency uses of equipment in and out of the classroom,
student activities with ICT …)
ICT Use in Secondary Education: Schooling Necessities and Needs for Human Resources230
· Student assessment activities (where, how, what …)
· Classroom preparation activities (communication with administrators, colleagues,
parents …)
· Usage at home (personal equipment, social network uses…)
A total of 89 questionnaires were collected. We stayed in the teacher room in
four schools (A, C, D, and E) for 2 days on average, and we proposed to every
teacher we met to fi ll the questionnaire. In the French context, the participation of
volunteers is unavoidable to sample our target population, and other sampling
method is not possible in lower secondary schools. The sample is not as important
as we expected, but the collection rate is similar to other studies using the same
method (Khaneboubi, 2007 , 2010). We collected between 19 and 25 questionnaires
in each school among teachers who agreed to answer. Three half-days were required
for school A, two full days in school C, and one half-day in school E. In school D,
questionnaires were given to the teacher responsible for ICT who assured the distribution and the collection of questionnaires. In the four schools considered, a total of
89 questionnaires were collected which represents approximately 45 % of our target
population.
How to estimate the characteristics of individuals who have not responded to the
questionnaire? First, the sampling of volunteers excluded teachers who were not
favorable to ICT. Frequently, surveys on technologies tend to "attract" users or
teachers favorable to ICT and to "scare" the teachers less comfortable with technology. Then, for three schools, only teachers who attended the staff room were likely
to respond to the questionnaire. Teachers who have a disciplinary room where they
spend break times are excluded. The disappearance of smoking rooms has also
excluded smokers from the sample.
Survey analysis has been made by performing univariate summaries and chi square
test. Main ideas expressed during the interviews were crossed with questionnaire
data. A regression logistics has been computed to describe three variable interactions.
Open questions have been recoded in categories. On this basis, occurrences of the
category have been graphically represented in barplot with a package implemented in
the software named R (R Development Core Team, 2011). Translation has been made
for Figs. 3 and 4 by searching for the best analogy between French and English.
Sampling Presentation
The questionnaire required 20 min to be completed. This is a relatively long time
that demands concentration and, like all surveys of this type, a form of intrusion into
the professional privacy of respondents. Non-responses are more frequent toward
the end of the questionnaire than at the beginning. They are also more frequent for
open questions and tables. Finally, the format of the open questions includes impassable ambiguities. For example, if teachers distinguish Word and Excel , they do not
distinguish Writer from Calc and only declare " Open Offi ce " or " Libre Offi ce ."
M. Khaneboubi and A. Beauné231
Those 89 usable questionnaires were fi lled by 57 % of women and 43 % of men.
Three-quarters of the sample had a class of sixth grade and 80 % of ninth grade.
As shown in Fig. 1 , teachers aged over 40 years are signifi cantly fewer than the
age group 25-40 years. More than half of the sample is made up of teachers between
25 and 40 years. Most of the staffs of school C are less than 40 years old, while
school D shows greater dispersion. Distribution in age groups is consistent with the
population of teachers in the direct environment because those schools are located
in an area which welcomes fresh tenured teachers.
As shown in Fig. 2 , we found in the sample 17 % of people who teach mathematics,
13.5 % literature, 11 % social studies, and 18 % foreign languages. Proportions of the
disciplines represented in the sample are consistent with the students' schedule discipline. There are more women who teach literature and foreign languages than mathematics and gym. As for age groups, the gender distribution is consistent with the trends
of the population from which the sample is coming from.
Respondents appear to be quite familiar with the Web: 46 % have a personal
account on Facebook, and 63 % report frequently using technologies; only seven
of them have a personal web page, four have a blog, and three have a Twitter
account. Only 15 % consider themselves advanced, while 79 % feel that they
have a beginner or an intermediate level. Men outnumber women to report an
advanced level.

Results
ICT in the Classrooms
As shown in Fig. 3 , teachers' main activities in classrooms are search for information , exercises , dynamic geometry , and screening activities . Seventy-eight percent
of the sample report that they ask their students to do information search. Among
them, 57 % state that they require students to do it at home, 44 % at the school
library, and 37 % in the computer lab.
However, these activities have only a relative importance for students with only
34 % who declare assessing activities with ICT, including 16 % for literature and
3 % for geometry. Usage in lesson by students is modest: only 46 % report having
made one or several students use the computer. Those elements reveal that the
importance of ICT in the classroom is humble in regard to teaching progressions.
This does not mean that technologies are not part of the teaching system.
Seventy-two percent of teachers claim to use computers in their classroom almost
every day, but the observations made in the staff room tend to show that it is probably mainly for administrative purposes. Only 34 % use the computer lab once a
month or a little more and 11 % once a week. As shown in Fig. 4 , in the classroom
the Internet is the most widely cited and then comes offi ce suites and dynamic
geometry application.

Classroom Preparation with ICT
On the other hand, usage for classroom preparation appears large and stable.
In preparing the course, technologies are particularly sought. Professional
web sources are preferred when researching information for setting the course.
ICT Use in Secondary Education: Schooling Necessities and Needs for Human Resources234
However, software packages are more important than disciplinary software, except
for dynamic geometry application.
Eighty-three percent of the sample report seeking information frequently to
prepare their classes. Most viewed websites were fi rst institutional websites, then
teachers' personal websites, and, third, professional association websites. YouTube ,
Wikipedia , and Google are much less cited. There is a signifi cant link between the
use of digital textbooks to prepare lessons and equipment reliability and availability.
In sum, when the material's availability is medium or low reliable, teachers are
signifi cantly less likely to report using the digital textbooks to prepare their classes.
The preferred instrument for the preparation of courses is the word processor:
87 % reported using it more than once a week and 62 % almost every day. Thus, 43 %
reported using an image-processing software more than once a month. Disciplinary
software mostly used in the preparation of lessons are free dynamic geometry
software: Geogebra , Geospace , Geoplan , Cabrigeometre , and Sesamath .
1
In general,
there is a predominance of proprietary software. For example, MSWord is the most
cited word processor with 24 occurrences whereas Libre Offi ce and Open Offi ce
come with 14 occurrences. Overall, free and open-source software are present but in
a secondary place.
Technologies appear mostly used professionally by teachers to communicate
with each other: 76 % claim that they use ICT to write to their colleagues and 58 %
with management and administrators. Seventy-four percent use the online homework notebooks. We fi nd the same proportions for the application counting the
missing students as 74 % reported. In addition, 95 % reported using the online
application for entering assessment results.
Infrastructure Issues
It is essential to enlighten some contrasts between the discourses of the administrative teams and those of the teachers, noted in the staff rooms. Administrators tend to
report that things are going well or that practices with ICT are more frequent,
whereas in the teachers' breakroom, a lot of claims are expressed: about delays in
digital textbooks' delivery, classrooms that are not equipped with interactive whiteboards, network dysfunctions, problems related to software for managing the school
life, equipment maintenance, etc. In two schools, the replacement of teachers
responsible for ICT had important implications: several remarks evoke responsibilities that are going beyond the scope of the teachers responsible for ICT in terms of
time, remuneration, and sometimes also skills.
1
Sesamath (www.sesamath.net) is an association aiming to spread under a free and open-source
license documents and educational software for mathematics.
M. Khaneboubi and A. Beaunié235
We noted that changes had occurred in the management teams between
the endowment and the 2012 study. A new head teacher had taken a position opposite to that of his predecessor and did not provide specifi c information about the
continuity of the endowment program. Similarly, two teachers newly responsible
for ICT said that everything was going well overall, thanks to a continuous handover.
In contact with the ancient responsibles, they also evoked a solid foundation but
they declared that it is diffi cult to make as well as them. They also said that they
refuse certain tasks or that they are not qualifi ed for it, such as setting up computers
to access and deploy new textbooks.
The lack of technical support given by institutions appears as a source of discontent among teachers responsible for ICT. Some data from the questionnaire show
this phenomenon. First, teachers responsible for ICT are sought for technical support almost exclusively: as 34 % stated, and only between 7 and 12 % indicated
requesting them for a pedagogical dimension which is their main assignment. This
result is probably linked to the departures of experimented teacher responsible for
ICT in two schools. Secondly, to the question "Do you give help to someone using
ICT in education?" 24 % responded "yes," including 21 % who stated that it is
for their colleagues. Thirty-four percent of respondents indicated asking their colleagues for help and educational aspects on the technical aspects.
During interviews, infrastructure access has been highlighted as a determinant
factor on practices. In these quite well-endowed schools with technological equipment, organizational and practical diffi culties in the management of computer fl eet
appear. These problems hinder the development of ICT usage: few signifi cant evolutions in terms of classroom practices are declared despite the tenacity of teams
and the almost intact motivation to seize the means in helping their students
succeed.
Access to Equipment
Nine out of ten teachers reported having a computer in their room, a projector,
and a computer room in the school. Fifty-two percent indicated that the material
is highly available and 39 % medium or low. Forty-fi ve percent indicated that the
equipment is very reliable, while 38 % described it as slightly or moderately
reliable: it is mainly Internet connections that are not robust and computers
obsolete.
Evidence shows that the equipment is not perceived as available in the same way
for all teachers: gender and seniority appear as discriminating factors in the perception of this availability. By performing a chi-square test in Table 1 , we found that
female teachers are signifi cantly more likely to report that the material is medium to
low available whereas men teachers are signifi cantly more likely to respond that the
material is available (chi-squared = 4.2286, p -value = 0.03975).
ICT Use in Secondary Education: Schooling Necessities and Needs for Human Resources236
By performing a logistic regression as described by Dalgaard (2004) we can
claim that in our sample, with an equal seniority, men have 3.2 greater chance to
declare equipment "very available" than women.
Seniority in the profession is also an issue to access equipment: teachers recently
tenured are less likely to agree that the material is available. In three schools, interviews show a difference of treatment between old and new teachers; older teachers
often have their own classrooms and signifi cantly more equipment than new teachers. The difference among the old and the new teachers can be a source of tension
within the teams.
Discussion
The purpose of our survey was to get a better understanding of the dynamics of ICT

uses in the everyday teachers' professional running pattern in order to identify propitious and obstacle factors. We considered, in this research, an initial situation and
the evolution of this situation of four schools that were involved in a national endowment program on digital textbook. These schools are better endowed with technology and digital resources than the other French schools. Interviews were conducted
in three middle schools with eight teachers and managers, and a questionnaire was
fi lled by 89 teachers in four schools.
According to our results, we can underline that in those relatively favorable
contexts for technology uses, ICT is not a major concern for teachers. Above all,
leading pupils to the exam success is the main goal, and technologies are not perceived as a reliable medium to do so. The departures of teachers locally responsible
for ICT impacted the coordination and the development of ICT's uses in teachers'
practices, even if this could appear as a local and punctual need. Teachers who
responded to our questionnaire used technology as a vehicle for their cultural practices in consistence with their age groups (Donnat, 2009) and professional affi liation (Bourdieu, 1984).
For investigators, in order to engage in these schools, create trust, and approach
a global vision, it is necessary to implement a long qualitative research based on
ethnographic methods and to combine it with a questionnaire survey. Two years
after the fi rst endowment in these schools, the managers' interest was not the same
as in the fi rst investigation and, thus, access to the schools was made more diffi cult
for collecting data. The complexity of the phenomenon we have sought to characterize only allows modest interpretations. It would be necessary to test further our
Table 1 Equipment
availability based on gender
Medium or low availability High availability
Women 24 21
Men 11 25
M. Khaneboubi and A. Beauné237
results in other contexts and to investigate the fi eld with a much more qualitative
method. This study attempts to outline elements that are prominent in our methodological context, but it deserves a more ambitious continuity.
For teaching purposes, offi ce software are cited more frequently than disciplinary software. The main activity with the technologies is information search, but it is
mainly requested to be done outside the classroom. This result concurs with Wikan
and Molster (2011), who report that the use of ICT is mainly for sustaining motivation and for resources. Uses of a computer with a projector in the classroom remain
as one of the most important elements in the practice. We can't identify an important use of technology for assesment. The use of technologies by teachers in the
classroom seems to be determined by the infrastructure's quality and the equipment
reliability. Gender and seniority are discriminating factors in the availability perception of technologies. This element is convergent with what Jimoyiannis and Komis
(2007) have reported on gender.
On the other hand, usage for classroom preparation is important. Training and
educational support are essentially made by peers, and institutional support is
almost exclusively sought for technical reasons. As Erixon (2009) shows, insuffi -
cient access to computers is one of the most important reasons for teachers not using
ICT in their teaching. We can presume that teachers did not have an equal access to
computers. In our context, it is highly possible that technology is one of the "apanage" of individuals with a good legitimacy and a signifi cant weight in their establishments. Thus, a male teacher with seniority in his school will probably have a
better access to the equipment than a new young female teacher. To confi rm this
trend, it would be necessary to examine the possible interaction between the taught
discipline and the availability of equipment which is not permitted at this time with
our number (89) of respondents.
Leader postures on ICT and animation are a key feature pointed by Drent and
Meelissen (2008). As in a one-to-one project, teachers' use of ICT is revealing a
major issue of the general professional context. In all professional fi elds, seniority
is an indicator of legitimacy (Bourdieu, 1999). Moreover, disciplines do not have
the same prestige or importance. Other factors such as gender, diploma, and institutional status are a source of disparity. Depending on the school history and traditions, the ambience may be created in several ways. In other words, institutions can
promote achievement against archaism such as gender equity vigilance and
generational diversity program. From those impulses, a general organization of the
day-to- day work is collectively made and supported by the chief administrator. This
could be an extension of this work to characterize these elements in a long temporality and to link those evolutions with changes in the use of ICT.

Introduction
The Internet provides quick and easy access to a large variety of information
resources and tools and therefore has the potential to support instructional
approaches that are consistent with current learning theories and educational reform
efforts, such as inquiry-oriented learning (Schofi eld, 2006). A typical characteristic
of these approaches is that learning activities evolve around open-ended questions
and ill-structured problems that are relevant to the real world. Activities also involve
student interaction and collaboration and require the use of, as well as promote the
development of, high-level cognitive and self-regulatory learning strategies.
Research has shown, however, that web-based learning, and online inquiry in particular, is very demanding and challenging both for the students and for the teachers.
Typically, students do not have suffi cient prior knowledge and fully developed cognitive skills to grapple with new subject matter while carrying out online inquiry
tasks (Kupier, Volman, & Terwel, 2005 ; Quintana, Zhang, & Krajcik, 2005 ; Zhang
& Quintana, 2012). Also, teachers need to be able to design learning activities that
engage students in meaningful learning, to select and provide appropriate resources,
and to possess a large repertoire of pedagogical techniques so as to effectively support their students (Wallace, 2004).
What do teachers need to know in order to design and implement web-based
instruction that utilizes the wealth of information resources available on the web in
ways that enhance student learning? The present study addresses this question
through an analysis of the lesson plans submitted by preservice teachers after attending an introductory course on the educational applications of ICTs. The study aims
Teacher Preparation for Educational
Technology

Independent Researcher , PO BOX 20103 , Kalamaria , 55101 Thessaloniki , Greece
e-mail: ivekiri@otenet.gr246
at examining preservice teachers' understandings of Internet use in the classroom,
so as to identify needs that should be addressed in teacher preparation for ICT
educational integration.
Literature Review
The Internet provides teachers with access to a wealth of information and a variety
of representation tools which they can use to improve teaching and learning. When
using it as an information source learners can fi nd content represented in multiple
visual formats, including photos, diagrams, graphs, videos, and animations, having
thus more opportunities to connect ideas and to construct rich mental models of the
concepts and phenomena they study (Moreno & Mayer, 2007 ; Osborne & Hennessy,
2003). In addition, the Internet can enable learning experiences that otherwise
would not be feasible inside the classroom. Interactive representations of content
such as interactive models and simulations enable students to test hypotheses,
observe patterns and relationships in data, and draw their own conclusions (Osborne
& Hennessy, 2003). Students can explore questions of personal interest and importance by accessing authentic sources (e.g., data archives of governmental organizations, museum collections, news archives of TV and radio stations) and real-time
data (e.g., satellite maps, reports on recent earthquakes) (Schofi eld, 2006).
The above make the Internet an ideal information resource for inquiry-oriented
approaches to learning (Schofi eld, 2006). Inquiry learning is hard to defi ne because
there are many conceptualizations and approaches to inquiry instruction, even
within the literature of the same fi eld such as science education. However, all of
these approaches share three critical elements: they evolve around authentic, complex questions, require student active engagement, and include at least some part of
the investigation cycle (question generation, study design, data collection, drawing
conclusions, and communicating fi ndings) (Anderson, 2002 ; Minner, Levy, &
Century, 2010). The Internet can support student inquiry in multiple ways. Students
can utilize the wealth of internet resources to ask open-ended questions about real-
world issues that are more interesting and meaningful to them. They can collect
real-time and authentic data as well as design and carry out virtual experiments to
test theories and predictions. They can engage actively in knowledge construction
because they have to interpret, organize, compare, and integrate all this information
to draw their own conclusions from their investigations.
While the Internet is an incredibly valuable resource that can support teaching and
learning in diverse ways, its use yields many challenges for both teachers and students. Information on the Internet is unstructured and unfi ltered. Inexperienced users
can get lost or distracted while navigating their way through hypertext and may come
across content that is not credible, relevant, or age and task appropriate. Users need
to know how to perform productive searches, to identify and select the right sources,
to evaluate and make sense of content that is presented in multimedia formats, and to
coordinate different information sources. Research shows that fi nding relevant and
I. Vekiri247
credible information online is a time-consuming and diffi cult task for young students,
who have several misconceptions about the nature of the Internet, do not understand
fully how search engines work, and lack suffi cient prior knowledge to come up with
good keywords and to select relevant websites from the list of their search results
(Julien & Barker, 2009 ; Kupier et al., 2005 ; Wallace, Kupperman, Krajcik, &
Soloway, 2000). As a result, in online inquiry-oriented activities students tend to
spend much of their time searching for information than engaging deeply with content (Wallace et al., 2000 ; Walraven, Brand-Gruwel, & Boshuizen, 2009 ; Zhang &
Quintana, 2012). Also, not only elementary students but also adolescents and many
adults are not able to discriminate between reliable and unreliable information, and
they often use insuffi cient and superfi cial criteria to judge the trustworthiness of
information, such as the appearance of a website, the amount of content, and the presence of pictures (Kupier et al., 2005 ; Walraven et al., 2009 ; Wiley et al., 2009).
In addition to the challenges regarding information search and evaluation, students face several diffi culties in their efforts to process the information they fi nd,
especially when they have to coordinate facts and data from multiple sources (Rouet,
2006). Due to the hypertext structure of web documents, comprehending Internet
text is a cognitively demanding activity that requires prior knowledge on website
structures and a range of self-regulation strategies, because readers in a sense compose their own texts through the choices they make on what to read and which links
to follow (Coiro & Dobler, 2007). Another challenge is the multimodal nature of
most online texts. Students often lack "visual literacy" skills to interpret and extract
important information from graphs, diagrams, and other complex visual displays as
well as to synthesize information from verbal and pictorial presentations of content
(Hannus & Hyönä, 1999 ; McTigue, 2009). Finally, integrating information from
multiple sources requires readers to evaluate the trustworthiness and the nature of
each source (e.g., fi rst-hand data vs. a report), corroborate information across
sources, and combine information from all sources to create a coherent whole
(Rouet, 2006). Young students tend to follow the easy way to get answers to open-
ended questions. They hope to fi nd a website that provides "the right answer" and

do not spontaneously engage in evaluation, selection, and synthesis of information
from multiple sources to draw their own conclusion (Wallace et al., 2000 ; Walraven
et al., 2009). In general, students are good at well-structured tasks, requiring the
retrieval of specifi c pieces of information from given websites, but not as successful
at ill-structured tasks that involve navigation, collection, and synthesis of information across multiple sites (OECD, 2011).
Web-based instruction is very demanding for the teachers because most websites
are not designed for teaching and learning purposes. Leaving aside the textbook,
which provides some structure for instruction, and working with the Internet require
extensive planning on teachers' part. Teachers need to search and select online
resources that meet the needs of their students, to transform them into instructional
materials, to design learning activities that are aligned with the curriculum, and to
build curricular coherence so that students "experience a reasonable progression of
ideas" from one activity or website to another (Wallace, 2004). Giving students
open-ended research assignments may require less preparation but places excessive
Teacher Preparation for Educational Technology248
demands on teachers during lesson enactment in the classroom. They need to
monitor the work of their students, whose research activities typically develop into
completely different directions as each group or individual comes across different
content, and to provide them with extensive scaffolding due to the diffi culties they
face with the search, evaluation, and critical synthesis of the information they fi nd
(Wallace, 2004 ; Zhang & Quintana, 2012).
Although school access to the Internet has become widespread in many countries, research shows that the Internet is underused in the classroom or it is used in
ways that do not utilize its full potential to enrich student learning (Schofi eld, 2006).
This is in line with research on ICT educational integration in general, showing that,
not only in Greece but also in other developed countries with higher ICT educational adoption rates, many teachers have not embraced ICTs, while most of those
who have integrated technology into their teaching have not employed it in ways
that support critical and active learning (Jimoyiannis & Komis, 2007 ; Osborne &
Hennessy, 2003 ; Webb & Cox, 2004). According to relevant empirical studies and
literature reviews, the problem is not so much teachers' lack of ICT skills but mostly
their lack of knowledge about how to teach with ICTs (Jimoyiannis & Komis, 2007 ;
Osborne & Hennessy, 2003 ; Webb & Cox, 2004).
Scholars have drawn on Schulman's idea of pedagogical content knowledge
(PCK) and proposed the notion of PCK of educational technology (Margerum-Leys
& Marx, 2002) or technological pedagogical content knowledge (TPCK) (Angeli &
Valanides, 2009 ; Mishra & Koehler, 2006) to describe the knowledge sources that
teachers need in order to successfully integrate technology into their teaching.
According to the various conceptualizations of TPCK (for a review see Voogt,
Fisser, Pareja Roblin, Tondeur, & van Braak, 2012), teaching with ICTs requires not
only technological knowledge, content knowledge, and pedagogical knowledge, but
also new, complex forms of knowledge that develop from the integration of knowledge about technology, pedagogy, and content. These other forms involve knowledge of the role of particular technologies in teaching and learning (technological
pedagogical knowledge), effective pedagogies for teaching specifi c content (PCK),
affordances of certain technologies for representing specifi c content (technological
content knowledge), and how to teach specifi c content with technology in a specifi c
context (TPCK). TPCK is a unique body of situated knowledge that develops when
teachers have to transform content, pedagogical, and technological knowledge so as
to solve problems regarding the use of technology as a teaching and learning tool in
various contexts (Angeli & Valanides, 2009 ; Benson & Ward, 2013 ; Mouza &
Karchmer-Klein, 2013).
Studies on the instructional use of the Internet as an information resource show
that both in-service and preservice teachers feel ill prepared to teach with the
Internet and express the need for web-related pedagogy, particularly for selecting
appropriate resources and tools, for designing activities in which these resources are
used creatively by the students to promote deep learning, and for techniques to scaffold the students (Childs, Twidle, Sorensen, & Godwin, 2007 ; Lee & Tsai, 2010 ;
Wallace, 2004) However, there is little research about what it takes for teachers to
I. Vekiri249
teach effectively with the Internet and what they need to be taught to inform teacher
education practice. The present study looked at preservice elementary school teachers' fi rst attempts to design a web-based lesson, in which the Internet was used as an
information resource, in order to identify challenges, misunderstandings, and learning needs that should be addressed in teacher preparation for educational technology integration. Lesson plan analysis addressed the following questions:
1. What learning activities did preservice teachers include in their lesson plans?
2. In case when they selected and provided specifi c Internet resources to their students, what were the characteristics of these resources?
3. What guidance and support did they consider providing to the students, through
both the materials they designed (e.g., student worksheets) and the specifi c techniques they were planning to employ in the classroom during instruction?
Method
Participants and Context
Participants were 30 preservice teachers who were enrolled in a 4-year undergraduate teacher education program in Greece during the spring term of 2009. At the time
of the study all students were attending an introductory course in educational technology that was offered in the third year of the program. The purpose of the course
was to familiarize students with educational software programs that were approved
by the Ministry of Education and were available in public schools for the teaching
of elementary school subjects. More specifi cally, students were expected to develop
knowledge and skills for evaluating and selecting educational software as well as
for designing learning activities that involved the use of educational software.
All course sections were led by the author. Instruction took place in a computer
lab and involved lectures, group work, and discussions. Students explored a variety
of software programs that differed in their pedagogical design, ranging from multimedia encyclopedias, tutorials, and behaviorist drill and practice programs to constructivist software designed to support open problem solving and inquiry-oriented
learning in various subject areas. Typically students collaborated in small groups to
examine an educational scenario involving the use of a particular software program
and were guided with worksheets to complete specifi c learning activities by undertaking the role of elementary school students. These scenarios and worksheets were
either part of the software packages or were developed by the author. Educational
scenarios employed a variety of student-centered, constructivist approaches to
learning, such as problem solving of open geometry problems, a science teaching
sequence designed to promote conceptual change through hypotheses testing and
experimentation with a simulation, and inquiry-oriented learning in history and
geography where students had to investigate open-ended questions by organizing,
Teacher Preparation for Educational Technology250
interpreting, and synthesizing information presented in verbal and various visual
formats. The worksheets that were used in the context of these scenarios modeled a
wide range of student scaffolding techniques that have been discussed in the literature (Puntambekar, Stylianou, & Goldstein, 2007 ; Quintana et al., 2005 ; van de Pol,
Volman, & Beishuizen, 2010), such as simple illustrated instructions on how to use
particular software features; prompts that recommended specifi c steps or requested
students to provide hypotheses, predictions, observations, and conclusions; as well
as prompts and tables for organizing information and drawing conclusions. Lectures
and discussions focused on the pedagogical design of each software program, its
affordances and the instructional approaches it could support, the potential diffi culties that elementary students might encounter while learning with it, and the scaffolding they would need to successfully meet the learning goals of the lesson. Also,
through discussions focusing on the analysis of each educational scenario, students
were encouraged to make connections between curriculum learning goals, pedagogy, and characteristics of the software.
One of the 3-h course sessions, which was structured in a similar manner, focused
on web learning. After an introductory lecture that addressed the challenges of web
learning for elementary students as well as the areas in which they need pedagogical
support, preservice teachers examined two educational scenarios (one designed by
the author and one found online) that introduced them to a variety of online information resources and some of the ways these resources could be utilized in instruction. In these scenarios students explored specifi c research questions using
pre-selected web resources, guided with worksheets. However, the scenarios differed in their pedagogical approach. The fi rst modeled an inquiry-oriented approach,
as it requested students to draw their own conclusions by organizing and comparing
information from multiple sources, including authentic data, while the other scenario requested students to answer a series of factual questions using a variety of
sites that provided predominantly encyclopedic knowledge. Preservice teachers
then compared the two scenarios focusing on the types of learning they promoted,
the affordances of the information resources, potential challenges for elementary
school students, and the types of support that was provided through the student
worksheets.
One of the course requirements, to be fulfi lled at the end of the course, was the
design of a 2-h lesson involving the use of ICTs. Students were provided with fi ve
options (i.e., using a specifi c software program to teach a specifi c curriculum topic),
one of which involved teaching an earth science topic using information resources
from the Internet. The topic, which was included in the sixth-grade geography curriculum, was entitled "Natural disasters and their impact in human lives" and
addressed the causes and the impact of earthquakes and volcanoes as well as the
phenomena of erosion, weathering, and deposition. Preservice teachers were provided with detailed instructions on what to consider in designing their lesson plans
(see section "Data" below) and were expected to use pedagogical approaches and
techniques that were modeled through the scenarios that they had explored in class
during the semester. Of the 116 undergraduate students who completed this requirement 30 designed a lesson that involved teaching earth science with the Internet.
I. Vekiri251
Data
The data of the present study consist of the lesson plans submitted by the 30 preservice teachers who chose to design a hypothetical lesson in which sixth-grade students were going to use learning and informational materials on the web. Following
the instructions that were provided, in these lesson plans preservice teachers had to
present the learning goals of the lesson; discuss the knowledge and skills as well as
the misunderstandings and diffi culties that sixth-grade students might have relative
to the content and the use of online materials based on the literature (i.e., relevant
articles and lecture slides that were included in course materials); explain in detail
how they would carry out the lesson and which teaching methods and techniques
they would use to support their students so as to attain the goals of the lesson;
describe how they would assess their students; and, fi nally, provide all the materials
they would use (e.g., worksheets, slides, tests, pre-selected websites) and explain
the rationale for their selection or design.
Analysis of instructional practice artifacts, such as lesson plans and learning materials designed by prospective or in-service teachers, has been used successfully in teacher
education research for the study of teacher thought processes and practices (e.g.,
Mouza & Karchmer-Klein, 2013 ; Silver, Mesa, Morris, Star, & Benken, 2009), either
as an alternative to or in combination with classroom observations and survey methods.
Although artifact analysis is a less direct method of teaching effectiveness research
compared to observations of actual teaching, relevant studies show that it enables
researchers to accurately characterize classroom practice and to draw valid inferences
about teacher knowledge and beliefs (Borko, Stecher, & Kuffner, 2007 ; Matsumura,
Garnier, Pascal, & Valdés, 2002). In the present study preservice teachers' lesson plans
were analyzed so as to identify knowledge gaps and possible misunderstandings
regarding the use of the Internet as an information resource in teaching and learning.
Data Analysis
Guided by the research questions of the study, data analysis attended to three issues:
the activities that preservice teachers had designed, the characteristics of the web
materials they had selected, and the guidance and support they had considered providing to their students.
The unit of analysis was the activity. Activities, which involved tasks assigned to
the students and instructional sequences carried out by the teacher, were identifi ed
based on preservice teachers' lesson plan descriptions and student worksheets.
Specifi cally, transition from one activity to the other was recognized through
changes in at least one of the following: the learning goal, the content, and the
teaching-learning approach. Activities that did not involve or were not directly relevant to the use of Internet resources (e.g., teacher-led question answering in the
beginning of the lesson to elicit student knowledge and experiences relevant to the
topic) were not included in the analysis.
Teacher Preparation for Educational Technology252
Activities . Instructional activities were classifi ed based on (a) whether they were
teacher directed or student centered and (b) the complexity of the online research
task that was assigned to the students (e.g., well-defi ned query to answer a factual
question vs. ill-structured research).
Websites . Websites that had been selected by preservice teachers, to be used in
teacher-led instruction or student-centered activities, were analyzed in terms of their
level of multimodality and interactivity . Multimodality refers to the range of modes
(verbal and nonverbal) that were used to present information (Moreno & Mayer,
2007). Each selected webpage was examined for the types of nonverbal representations (e.g., diagram, map, photo, animation) that were present besides printed words
or narration. Then a multimodality score was calculated to characterize the range of
pictorial representations that were utilized in the entire lesson plan. Specifi cally,
each lesson received 1 point for each type of visual representation that was utilized.
Two levels were used to code interactivity based on the classifi cation system
proposed by Moreno and Mayer (2007). A website provided low interactivity if it
allowed the user to perform simple navigation and search actions, such as click on
a link or button to move, select an option, or enter a simple query. High interactivity
was enabled when users could manipulate a simulation, control the pace and order
of a presentation, and receive feedback to their input.
Support . The coding scheme for analyzing teacher support, as refl ected in preservice
teachers' activity descriptions and student worksheets, was developed through multiple readings of the materials. I looked for scaffolding techniques that have been
recommended in the literature (e.g., Kupier et al., 2005 ; Li & Lim, 2008 ; Quintana
et al., 2005 ; Segers & Verhoeven, 2009 ; Wallace, 2004 ; Zhang & Quintana, 2012),
which were modeled or explained to preservice teachers during the course, as effective or needed to guide students with three aspects of web learning: searching for
information, evaluating information, and processing of information. Examples of
relevant techniques involve explaining how particular search engines work, modeling or recommending specifi c steps and actions, providing keyword lists, navigation
instructions and criteria for evaluating the trustworthiness of information on websites, and asking questions or providing prompts that help students retrieve, compare, organize, and interpret information. The fi nal coding scheme for the techniques
that were identifi ed during this iterative process is presented in Table 1 .
When the development of the fi nal coding scheme for activity type and teacher support was completed, one-third of the lesson plans were coded by an independent examiner. Inter-rater agreement was 94 % for activity type and 89.5 % for teacher support.
Results
Analysis of the teaching and learning activities that preservice teachers designed
shows that they utilized the Internet in four ways: (a) they used visual web resources
to enrich teacher-directed instruction , that is, teacher presentations and class
I. Vekiri253
discussions; (b) they included search activities requiring students to perform an
open- search web query; (c) they designed information retrieval activities in which
students would explore the content of one particular website to obtain factual information; and (d) they designed open-ended research activities requiring students to
search for, retrieve, and synthesize information about a particular topic from multiple web sources. Web-search activities involved searching for images and/or videos
relevant to lesson topics. Information retrieval activities included viewing images,
animations, and videos or reading a webpage with the purpose of obtaining factual
information, running a simulation (e.g., build a volcano and watch it explode), and
locating geographical information using Google Earth. Although the last two activities involved learning through interaction with a system, they were categorized as
information retrieval activities because students were asked to either make a simple
observation or answer a factual question (i.e., use Google Earth to fi nd the location
of particular volcanos). Often in information retrieval activities students were
guided with questions, to be provided orally by the teacher or through worksheets,
that aimed at helping them focus on and retrieve specifi c pieces of information.
Finally, in open-ended research activities students were asked to gather and present
information about a topic (e.g., the volcano of the Greek island Santorini, the most
disastrous earthquakes, or the most important volcanos on earth). These activities
were open ended in some sense because they required gathering information from

Teacher Preparation for Educational Technology254
multiple sources (although it was likely that someone might locate a single webpage
containing enough information to cover the topic). However, none of these activities
involved the investigation of a complex, authentic question, requiring students to
come up with their own answers by interpreting, comparing, and integrating information, which is an essential element of inquiry-oriented learning.
None of the participants designed a "traditional" lesson where ICTs would be
used exclusively by the teacher to explain content or stimulate discussions. Most
preservice teachers (n = 17) used a combination of teacher-directed instruction and
activities to be carried out by the students, while the remaining 13 based their lesson
solely on information search, retrieval, and/or research activities. Overall, 15 participants included information retrieval activities, 15 designed open research activities, and 8 used web-search activities. Typically, students did not combine
information retrieval with open research activities. It seems that they either adopted
a "structured" approach, involving information retrieval activities, which in some
cases were combined with teacher-directed instruction and/or search activities, or
an "open" approach involving open research activities that were often combined
with teacher-directed instruction and/or search activities.
Twenty-seven preservice teachers selected webpages or materials found online,
such as photos and videos, to be used either in teacher-directed instruction or in
student activities. These websites or materials were analyzed for their level of multimodality, and a score was calculated for each lesson. Participants used fi ve types
of representations: photos, maps, diagrams, animations, and videos. The mean multimodality score for their group was relatively low (M = 2.55), indicating that on
average preservice teachers had utilized a small range of visual resources in their
lesson plans. A closer inspection of the data showed that while half of the participants (n = 14) had selected at least three types of representations, many participants
(n = 10) had used only photos. Typically, teacher presentations and discussions were
enriched with static visual displays, which were primarily photos and to a lesser
extent maps and explanatory diagrams, although some participants also included
videos and animations. In addition, preservice teachers tended to select sites that
enabled little interactivity. Only fi ve participants selected interactive representations
of content (e.g., simulations, Google Earth) to be utilized in the context of information retrieval activities.
An incidental fi nding from the analysis of the websites was that about half of the
participants had selected at least one resource that was inappropriate relevant to the
activity for which it was used. Specifi cally, some preservice teachers (n = 7) had
included content from unreliable sources such as commercial sites and personal
blogs, treating them uncritically as authoritative sources, although some of them provided scientifi cally inaccurate information. In addition, about half of the participants
used texts from sites that were designed for adults to provide students with background encyclopedic information on lesson topics. However, these texts could not be
easily accessible to elementary students due to text length and excessive use of scientifi c terms and sophisticated explanations. Also, some of the selected resources provided affordances not clearly tight to lesson learning goals, such as a simulation
that enabled students to create different types of volcanos by manipulating gas and
I. Vekiri255
viscosity levels. Finally, many preservice teachers selected images and videos that did
not communicate information clearly and effectively due to poor quality (e.g., low
resolution) or the provision of many unnecessary and irrelevant details.
An examination of the techniques that preservice teachers had considered using
so as to support their students, either orally or in the form of prompts and questions
in student worksheets, showed several interesting patterns. First of all, as Table 1
shows, most participants included a small range of techniques which focused mostly
on the search process and to a lesser extent on information processing. Regarding
the latter, the majority of the participants who planned to provide support on information processing used questions to help students retrieve specifi c pieces of information. Also, only one preservice teacher thought to provide students with support
on how to evaluate the trustworthiness of web content.
Another interesting pattern is that students were more likely to provide support
for the information retrieval activities than for the research activities. Typically, in
information retrieval activities preservice teachers guided students to locate specifi c
pages, by providing them with keywords or specifi c URLs, and gave navigation
instructions for websites that offered many options. This guidance was expected
because elementary students were going to use pre-selected sites. On the other hand,
participants who designed open research activities provided minimal or no guidance
on how students should search for, evaluate, and choose appropriate sites for their
projects. In addition, in information retrieval activities most preservice teachers provided students with questions to help them focus on important information when
exploring the content of websites. On the other hand, the vast majority of participants who included open research activities in their lesson plans did not consider
providing support to help their students retrieve, comprehend, organize, compare,
and integrate information that was relevant to their topics. Finally, students who
included web-search activities were likely to provide some support for the search
process, but only two of them thought to give students some instructions on what to
do with the results of their query.
Discussion
The data of this study represent preservice teachers' fi rst attempts to design a lesson
that involved teaching using Internet information resources. This particular group of
undergraduate students had one more year of study in their teacher preparation program, involving more coursework on teaching methods in the subject areas as well
as fi eld experience in local public schools and, therefore, more opportunities to
further develop their knowledge and skills about teaching and learning. So, it is
likely that their instructional materials would have been more sophisticated if they
had been asked to design a similar lesson near the end of their fourth year in the
program. Also, in the present study preservice teachers designed hypothetical lessons which were not going to be implemented in a real classroom with real students
and real technologies. This suggests that their ideas were not fully developed
Teacher Preparation for Educational Technology256
because preservice teachers did not have to think through all the details of an actual
lesson enactment, and their lesson plans were based on a hypothetical, abstract
classroom context.
Despite the above limitations, the patterns that emerged from the analysis of the
data provide useful insights into the possible misunderstandings and knowledge
gaps that preservice teachers may have about teaching with the Internet and about
online inquiry. Therefore, the conclusions of the present study can guide the design
of future teacher education and professional development courses and seminars
focusing on teaching with ICTs and, more specifi cally, on teaching with the use of
Internet information resources.
It is encouraging that all participants included in their lesson plans instructional
activities that involved the use of ICTs by their students, as opposed to the use of
technology exclusively as a demonstration tool in teacher-directed instruction. Two
distinct patterns emerged in their approaches. About half of preservice teachers
used a "structured" approach that involved information retrieval activities or some
combination of information retrieval activities, teacher-directed instruction, and
search activities, while the other half used an "open" approach, involving open
research activities or some combination of open research activities, teacher-directed
instruction, and search activities. Participants adopting a structured approach
appeared to be aware of the difficulties that their students might have with the information search process, with website evaluation and navigation, and with the extraction and comprehension of relevant content. So they provided guidance by directing
students to pre-selected sites and by helping them locate and focus on important
information through navigation instructions and factual questions. However, this
approach was over-structured because it limited independent learning and focused
on the acquisition of fragmented factual knowledge. Students were not encouraged
to engage actively with content by exploring hypotheses, organizing and comparing
information, and making new connections among ideas. On the other hand, preservice teachers who adopted an open approach seemed to have unrealistic expectations about elementary students' abilities to learn via open online research with
minimal guidance (Kirschner, Sweller, & Clark, 2006 ; Quintana et al., 2005). These
participants provided some support for the search process but no guidance on how
students were going to evaluate, select, and utilize the resources they would fi nd
online in order to achieve the learning goals of the lesson. Also, none of the preservice teachers designed an activity addressing an authentic inquiry question.
Elementary students were given some general topics or questions that required the
collection of factual information (e.g., "The volcano of Santorini," "What were
some of the most disastrous volcanic eruptions?"), as opposed to questions requiring them to draw conclusions through the corroboration and integration of information from multiple sources. It would be quite hard even for experienced teachers to
design an inquiry project that could be realized within two periods. However, it was
expected that preservice teachers would have included in the design of their lesson
plans more opportunities for deep and meaningful learning, utilizing some of the
pedagogical techniques that were modeled throughout their educational technology
course. It was also interesting that a large number of preservice teachers designed
I. Vekiri257
open research activities, although this approach was not modeled during the educational technology course. On the contrary, both through the lecture and the discussion of the educational scenarios that focused on web learning, it was stressed that
open research learning is an ineffective approach when implemented without extensive teacher scaffolding due to the many challenges that young students face with
the search, selection, evaluation, and processing of information.
The analysis of the types of support that preservice teachers had considered for
elementary students showed that most of the techniques they described concerned
the information search process. This indicates that preservice teachers were generally aware of some of the difficulties that elementary students might have with
online search and could also come up with specific techniques to make this process
more manageable. However, preservice teachers demonstrated a limited repertoire
of techniques to scaffold elementary students with web learning beyond the level of
factual information extraction. Very few participants considered assisting students
with the evaluation, selection, organization, critical analysis, and integration of
information or with the preparation of their project presentations. And none of the
participants considered it necessary to provide specific suggestions to help students
comprehend and think critically about the visual resources.
Overall, preservice teachers made extensive use of videos and static visual displays (i.e., photos, diagrams, and maps), but about half of them did not utilize the
full range of content representations that were available online. Specifi cally, ten
preservice teachers used only photos and only fi ve participants selected interactive
representations of content, which have the potential to engage students more actively
in learning. However, even these fi ve participants did not take full advantage of the
representations' affordances because their proposed use by the students was limited
to making simple observations and to retrieving factual information as opposed to
asking questions, testing predictions, or observing patterns. Also, those who chose
the "build-a-volcano" simulation were possibly attracted by the interactivity it provided, but they used it in a way that was not clearly relevant to their lesson goals. In
addition, according to the analysis of preservice teachers' website selections, many
of the participants did not know how to select appropriate sites for young students
in terms of the quality, trustworthiness, and age appropriateness of their content.
The fi ndings of the present study point out several issues that should be addressed
in teacher preparation programs regarding web-based instruction. In line with the
TPCK framework (Angeli & Valanides, 2009 ; Benson & Ward, 2013 ; Mouza &
Karchmer-Klein, 2013), they highlight that, in order to use the Internet productively
and creatively as an information resource, teachers need to develop complex forms
of knowledge that require the integration of knowledge about technology, pedagogy, and content.
First of all, as previous studies have shown (e.g., Childs et al., 2007 ; Wallace,
2004) it is clear that preservice teachers are in great need for instruction on how to
select appropriate web content. Selecting Internet resources involves several complex criteria that require the consideration of the technological characteristics of the
resources, their affordances for learning and their credibility, the subject matter, the
learning goals and the teaching approach, as well as students' prior knowledge and
Teacher Preparation for Educational Technology258
digital skills. Based on the fi ndings of this study, preservice teachers need to learn
how to evaluate websites for:
(a) Their general quality as learning resources using established, research-based
text-design and multimedia-design principles (Hartley, 2004 ; Mayer, 2005).
(b) The nature and credibility of their source.
(c) Their appropriateness for students of particular age relative to their prior knowledge and navigation abilities.
(d) Their relevance relative to lesson content and learning goals.
(e) Their affordances regarding the types of learning they can support.
In addition, preservice teachers need to develop technological pedagogical
knowledge about inquiry-oriented approaches to web-based instruction as well as
about students' potential difficulties with web-based learning, which concern not
only the process of information search and evaluation but also the comprehension of
multimodal documents and the critical analysis and synthesis of information from
multiple texts and data sources. Teachers need to also develop TPCK about techniques for scaffolding students to engage successfully and productively both with
the processes and with the content of online inquiry.
All the above are complex forms of knowledge which develop progressively and
require extensive teacher involvement in critical reasoning and problem solving
regarding authentic instructional situations (Angeli & Valanides, 2009 ; MargerumLeys & Marx, 2002 ; Mouza & Karchmer-Klein, 2013). In order to help preservice
teachers integrate knowledge of content, pedagogy, and technology, teacher preparation programs should provide student teachers with opportunities to analyze, plan,
enact, and refl ect on web-based instruction in the content areas. This in turn may
require that, at some level in the teacher preparation program, educational technology courses are integrated with fi eld practicum and teaching method courses, so that
preservice teachers are supported to transform and integrate theoretical knowledge
obtained through separate courses into practical forms of technological pedagogical
and technological pedagogical content knowledge.
In agreement with what research has shown about experienced in-service teachers
(Osborne & Hennessy, 2003 ; Schofi eld, 2006 ; Wallace, 2004), the participants of
this study could not find an alternative or a balance between two extreme approaches
to Internet use in the classroom: the open research and the over- structured approach,
both of which, for different reasons, do not enable learners to engage actively with
content. In the open research approach students are likely to encounter many inappropriate sites and to spend most of their time and effort searching for relevant
information, which severely reduces the cognitive resources they can allocate to the
comprehension, evaluation, and synthesis of the information (Segers & Verhoeven,
2009 ; Zhang & Quintana, 2012). Without enough guidance and scaffolding, students typically gain only superfi cial understandings of their research topics. Poor
learning outcomes may also be observed with the over- structured approach. The
latter offers security and direction, but, by focusing on factual learning and by constraining students' independence, it limits their opportunities to develop deep content understandings and critical skills. The fact that these two extreme approaches
I. Vekiri259
have been observed not only in the preservice teachers of this study but also among
experienced in-service teachers is related to the nature of the Internet itself and

reflects teachers' confusion regarding how to both capitalize on its potential to support independent, student-centered learning and set boundaries so as to ensure that students learn something while using it (Schofield, 2006 ; Wallace, 2004). Although several scholars (e.g., Li & Lim, 2008 ; Segers & Verhoeven, 2009 ; Zhang & Quintana, 2012) have been exploring the effectiveness of particular approaches (e.g., web quests), scaffolding techniques, and technological tools that aim at maximizing the benefits of web-based instruction and online inquiry for students, there is clearly a need for more research in this area to provide productive suggestions for teachers regarding alternatives to these two typical extremes.

Introducing Conversational Agents
In the field of artificial intelligence, the terms "agent" or "intelligent system" refer to any entity that perceives its environment through sensors and acts upon it using effectors (Franklin & Graesser, 1997). However, through the prism of e-learning, a "pedagogical agent" refers to a computer-generated character typically employed to fulfil a series of pedagogical aims in an educational system (Gulz, Haake, Silvervarg, Sjödén, & Veletsianos, 2011).
In our work, we focus on "conversational agents," a subgroup of pedagogical agents that engage in a conversation with the learners using natural language. The type of communication occurring between a conversational agent and a learner can be text based, oral, or even nonverbal, including body language movements and facial expressions (Kerly, Ellis, & Bull, 2009).
Moreover, the graphical representation of conversational agents may also vary, ranging from a two-dimensional cartoonish appearance to a three-dimensional photo-realistic character (Veletsianos, 2010). Conversational agents that have a visual representation are frequently mentioned as "embodied" conversational agents (Cassell, Sullivan, Prevost, & Churchill, 2000). Research has repeatedly identified the agent visual appearance as an important design element, which affects learners' stereotypes or expectations of the agent intelligence (e.g., Haake & Gulz, 2008 ; Veletsianos, 2010). Indeed, the agent embodiment had a major impact on the evolution of conversational agents from the impersonal characters found in the intelligent tutoring systems (ITSs) of the past to the tangible personalized pedagogical agents of today (Gulz et al., 2011).
Conversational Agents for Learning:
How the Agent Role Affects Student Communication

Another important factor regarding the agent design is the role of the agent in the learning environment. Conversational agents have been developed to serve multiple pedagogical roles including—but not limited to—coaches, tutors, motivators, or learning partners (Haake & Gulz, 2009). Many studies have been conducted to explore the various roles and uses of conversational agents in individual learning settings, where the agent has engaged in one-to-one interactions with the learner (Kerly et al., 2009). Agents acting as peer learners have been shown to lower students' anxiety and promote students' empathy (Chase, Chin, Oppezzo, & Schwartz, 2009). Additionally, it was reported that such agents tend to be less intrusive than agents acting as instructors (Baylor & Richards, 2010).
More recently, taking into account the pedagogical benefits of computer-supported collaborative learning (CSCL) (Dillenbourg, 1999), researchers have expressed their interest in assessing the use of conversational agents in providing dynamic collaborative learning support (e.g., Chaudhuri, Kumar, Howley, & Rosé, 2009 ; Walker, Rummel, & Koedinger, 2011). A study revealed that conversational agents can efficiently utilize both social and task-oriented intervention strategies to support students' collaboration (Kumar, Ai, Beuth, & Rosé, 2010). Furthermore, other studies explored the positive impact of conversational agents on collaborative learning settings by emphasizing on discourse scaffolding (Stahl, Rosé, O'Hara, & Powell, 2010), reflective prompting (Walker et al., 2011), or reasoning elicitation (Kumar, Rosé, Wang, Joshi, & Robinson, 2007).
Encouraging as such findings may be, several key questions have emerged. For instance, what types of collaborative problems are best suited for such conversational agent systems? (Harrer, McLaren, Walker, Bollen, & Sewall, 2006) Should the supportive prompts provided by the agent be solicited or unsolicited? (Chaudhuri et al., 2009) How can the different roles of the agent (e.g., tutor, peer, motivator) affect peer dialogue? What is the impact of the agent presence ("persona effect") on the behavior of students working together? (Veletsianos & Russell, 2014)
Following this potentially promising research direction, we have argued that conversational agents for collaborative learning can be designed by focusing on the role of the teacher as well as the peers' interactions occurring while students work together (Tegos, Demetriadis, & Tsiatsos, 2012). Based on this rationale, we have developed a prototype conversational agent system, named MentorChat (Tegos, Demetriadis, & Tsiatsos, 2014). In the following sections, we present an overview of the MentorChat system and an evaluation study exploring how the students' perceptions of the agent and their conversational behavior may be affected by the different roles (peer or tutor) of a conversational agent.
MentorChat System Overview
MentorChat is a cloud-based multimodal dialogue system that utilizes an embodied conversational agent to scaffold learners' discussions (Tegos et al., 2014). We have developed MentorChat as a domain-independent dialogue system that (a) promotes
S. Tegos et al.267
constructive peer interactions using facilitative agent interventions (prompts) and (b) enables the teacher to configure the support provided by the conversational agent.
MentorChat can support discussions in English or Greek and was implemented using modern web technologies, such as HTML5, CSS3, and AJAX. The system infrastructure is based on a client-server model, which allocates workloads between the server and the clients. Its architecture comprises three main modules: the student, the teacher, and the conversational agent module (Fig. 1).
The conversational agent of MentorChat is based upon the following three models:
• The peer interaction model, which records and stores the students' interactions in a computational format
• The domain model, which utilizes the teacher's domain knowledge representation in conjunction with the pattern-matching algorithms to determine whether an agent intervention would be appropriate
• The intervention model, which examines a series of various micro-parameters (e.g., the time passed since the last agent intervention) to determine if an intervention will eventually be displayed
A teacher can use MentorChat to design, deploy, and monitor an online dialogue- based learning activity. These can be accomplished using the MentorChat administration panels, which are available in the teacher's interface. More specifically, the teacher may set up the discussion topics/phases of the collaborative
Fig. 1 MentorChat system architecture
Conversational Agents for Learning...268
activity (activity structure panel), manage the participating users and groups (user management panel), monitor groups' discussions (monitoring panel), or configure the agent domain model for the activity by inserting a set of rules or creating a concept map (domain modeling panel).
Students entering MentorChat are asked to collaborate with their partner(s) on a given task (Fig. 2, A) using text-based synchronous communication. During the students' dialogue, an animated humanlike conversational agent (Fig. 2, B) analyzes their discussion providing supportive interventions that trigger fruitful peer interactions on key domain concepts. Each agent intervention is dynamically displayed in a pop-up frame, next to the peers' chat frame (Fig. 2, C), allowing learners to complete their ongoing conversational interaction before answering the agent question.
Method
MentorChat was used in an experimental activity, which was conducted in the context of a computer science course offered by the Second Chance School of Thessaloniki in Greece. The aim of the study was to explore the impact of two different agent roles (peer vs. tutor) on students' perceptions and behavior. The total participants of the study were 24 Second Chance School students (13 males and 11 females), who were not able to attend mainstream secondary education for various socioeconomic reasons. Students were adults whose age ranged from 19 to 67 years (N = 24, M = 37.4, SD = 13.36). Although their nationality also varied (e.g., Albanians, Bulgarians, Greeks), all of them spoke Greek in class.
Fig. 2 A (translated) screenshot of the MentorChat student interface
S. Tegos et al.269

Procedure
In the course lectures, the students were introduced to the concepts of the Internet
and the web-based applications. The classroom sessions involved many discussions
around synchronous and asynchronous communication tools, micro-blogging, blogging, and social networking. The MentorChat environment was also presented to
the students as an example of an online collaborative learning environment.
After a 3-week period, an experimental activity was carried out in the computer
lab of the Second Chance School for 2 teaching hours (90 min). The participating
students were asked to use MentorChat to discuss the web applications they had
learned and used in class. They were also informed that during their conversation a
virtual peer or tutor would raise some questions, which they should discuss within
their group in order to provide a joint answer.
The agent was confi gured by the two classroom teachers to raise issues regarding
social networking, search engines, and modern communication tools. In particular,
the teachers used the MentorChat domain authoring panel to form the agent domain
model by entering a set of rules. Each rule consisted of a domain concept (a key
word or phrase—e.g., "Mozilla Firefox") along with a particular intervention. The
interventions were refl ective questions that asked students to elaborate on the subject and provide a thoughtful joint response (e.g., "If you want to create a webpage
featuring articles in a chronological order, should you use a blog or a wiki? Why?").
During the students' discourse, the conversational agent displayed the teacher-
defi ned intervention whenever the associated domain concept (keyword or phrase)
was identifi ed. Subsequently, the students were encouraged to discuss with each
other and provide a joint response, typing their answer into the agent answer box
(Fig. 2 , C). In addition to this intervention method, which was active throughout the
students' discussion, a fi nal intervention was also made by the agent at the end of the
activity. More specifi cally, before exiting the activity, the agent reminded students
all the teacher-defi ned domain concepts that had not mentioned during their discussion, providing them with the option to continue their conversations on the suggested topics (e.g., "It seems that you have not discussed wikis. Do you want to
continue your discussion or fi nish the activity?"). If students' discussion included all
the teacher-defi ned domain concepts, the agent did not display any intervention.
Compared Conditions
The teachers assigned the students into small groups consisting of two or three
members (six dyads and four triads). Each student was given a score, which indicated students' expertise in computer science (based on the course grades and in-
class performance), and the fi nal groups emerged in such a way as to be slightly
heterogeneous. According to Rovai (2007), the above method constitutes an effective strategy for creating an educational context that facilitates peers' online discussions and promotes equal participation.

Furthermore, a combined score was also calculated for each group based on the
average of the individual students' scores. Taking this score into account, instructors
stratifi ed the student groups by their domain knowledge and assigned them to two
conditions so that both conditions were balanced in terms of the overall scores of the
groups.
Our two-condition experimental design involved (a) six groups (four dyads and
two triads) interacting with a conversational agent that enacted the role of a peer
(P condition) displaying the interventions in an informal manner (Fig. 3 , A) and
(b) fi ve groups (two dyads and three triads) interacting with an agent that enacted
the role of a tutor (T condition) employing a more formal appearance and
communication style (Fig. 3 , B). Each of the teacher-defi ned agent interventions
was tailored according to the different agent communication styles in the two
conditions (Fig. 3).
Data Collection and Analysis
Post-task Questionnaires
After the activity, students were asked to fi ll in a post-task questionnaire, which
aimed to explore students' opinions about the MentorChat interface and the agent
interventions. The questionnaire included three multiple-choice questions, two
open-ended questions, and ten Likert-scaled questions. Measures of central tendency were computed for all questionnaire items. Additionally, a series of Pearson
product-moment correlation coeffi cients was calculated to examine the relationships among the questionnaire variables.
Fig. 3 The agents acting as peer (A) and tutor (B) in the P and T conditions, respectively

Interviews
Interviews were conducted in order to record details of how the students worked or
perceived the learning activity. The interviews were semi-structured and lasted for
about 10 min each. They focused on students' opinions about (a) the collaborative
dialogue-based activity as a whole, (b) the usability of the MentorChat tool, and (c)
the pedagogical effi cacy of the conversational agent interventions. Students were
interviewed individually. All interviews were transcribed verbatim and analyzed in
search of common themes using the open-coding process of the constant comparative method (Corbin & Strauss, 1990).
Discourse Data Observations
Following the completion of the activity, the authors examined the text fi les of all
group discussions. In particular, the authors acted as independent raters assessing
the degree of formality/informality of users' responses to the agent. A scoring
rubric, deriving from Moskal's study (2000), was used to measure the formality of
students' utterances on a simple 2-point scale (0 for formal and 1 for informal). The
inter-rater reliability for the scoring process was found to be high (Kappa = 0.82;
ICC = 0.83). Following this asynchronous process, raters participated in a roundtable discussion elaborating on each group dialogue to draw joint inferences.
It should be noted that the individual student constituted the unit of analysis for
the post-task questionnaires and the interviews, whereas the discourse data observations involved both individual- and group-level analyses.
Results
Post-task Questionnaire Analysis
The post-task questionnaire results revealed that most students were familiar with
instant messaging applications (F = 70.83 %), while only some of them used them on
a daily basis (F = 41.2 %). They also rated their typing speed as slightly below average (N = 24, M = 2.38, SD = 1.27) on a 5-point scale ranging from 1 (slow) to 5 (fast).
Table 1 presents the descriptive statistics computed for the Likert-scale questions
that measured the user acceptance of the MentorChat tool. Likewise, Table 2 presents a selection of the results relating to the agent behavior.
Furthermore, a Spearman's product-moment correlation analysis revealed two
signifi cant correlations among the questionnaire variables. First, there was a negative correlation between the "learners' age" and the "system ease of use" (r = −0.51,
p = 0.01). Second, the "learners' typing skill" was found to be positively correlated

with the "comprehensiveness of the interface options" (r = 0.48, p = 0.02). These
correlations were anticipated since younger students are typically more familiar and
experienced with the interface and functionality of instant messaging applications.
Given that the normality and the homogeneity of variance criteria were satisfi ed,
we proceeded to apply parametric statistics to our individual-level questionnaire
data. More specifi cally, a series of independent samples T-tests was performed comparing the scores of the questionnaire variables in the P and T conditions. The analysis did not reveal any signifi cant difference in the scores for the two conditions.
Nevertheless, although nonsignifi cant (t [22] = 4.76, p = 0.07), worth mentioning is
the difference in how students in the two conditions perceived the content of the
agent interventions. In respect to the agent interventions appearing during students'
discussions, the students who interacted with the peer-agent (P condition) considered its interventions as more comprehensible (M = 4.00, SD = 0.35) than the students who interacted with the tutor-agent (T condition) (M = 4.92, SD = 0.05).
Interview Analysis
The qualitative data that derived from the analysis of the interview transcripts indicated fi ve common themes, as presented in Table 3 .
Table 1 The questionnaire results concerning the MentorChat tool

1.31 0.48
I understood the subject better through answering the agent
questions.
4.25 1.07

Discourse Data Observations
The examination of the groups' discussions revealed a series of patterns regarding
the students' interaction and conversational behavior. First of all, we observed that
when participants entered their group discussions, they posted a number of messages (N = 10 groups, M = 7.10, SD = 4.15) that played a purely social function and
were not related to the task. Although a lot of students (10 out of 24) initiated their
discussion typing in "Greeklish" (i.e., writing in Greek but using Latin characters),
all of them altered their typing to Greek when at the beginning of the activity they
saw the agent prompt urging them to use Greek characters.
Furthermore, the agent interventions displayed, especially at an early stage of the
activity, seemed to have caused some confusion in half of the groups (5 out of 10).
More specifi cally, a relatively high number of task coordination contributions was
identifi ed in students' utterances after the fi rst agent intervention occurred. Taking a
closer look at the students' dialogues we found that, despite the agent explicit
instructions (Fig. 2 , C), some peers (8 out of 24) could not understand at fi rst if they
should individually answer to the agent or provide a joint response. In fact, in some
occasions, some of these students rushed to provide a response without reaching an
agreement with their partner.
It should also be noted that even though all students communicated with each
other in a friendly manner, we observed a considerable difference in the way the
learners interacted with the agent in the P and T conditions. Specifi cally, the descriptive statistical analysis of the rubric scores indicated that the student groups (N = 5) in
the P condition responded to the agent questions in a far more informal way (M = 0.84,
SD = 0.21) as compared to the student groups (N = 5) in the T condition (M = 0.18,
SD = 0.16). In particular, the students in condition P responded to the agent as they
would respond to a question of their human partner(s) (e.g., "Hi Elena! I can help you
with the webpage …") while the students in condition T engaged in a more formal
communication with the agent (e.g., "From my point of view, the webpage should be
developed …"), as a student would answer the question of a human tutor in class.
Table 3 Common themes identifi ed
No. Theme
1 Agent voice usefulness (e.g., "the agent voice drew my attention to the agent intervention")
2 Spelling auto-correction suggested (e.g., "it would be nice to have a spelling auto- correction
feature activated while composing new messages")
3 Directed agent interventions suggested (e.g., "each agent intervention should address only
one group member and explicitly state who is being addressed")
4 Interdisciplinary use of agent suggested (e.g., "besides computer science, agent
interventions could also be helpful in other learning contexts such as language
learning")
5 Agent for educational purposes only (e.g., "the use of an agent, which monitors peers'
discussions, would not be appropriate when chatting with friends out of educational
settings")

Moreover, an examination of the agent interventions made revealed that most of
the groups (seven out of ten) did not discuss all the teacher-proposed topics and,
hence, triggered an agent intervention at the end of the activity. Although these
agent interventions reminded these groups of the domain topics not discussed, only
some of them (four out of seven) decided to resume their discussion on the topics
proposed. Nevertheless, we consider that this happened mainly due to the limited
duration of the learning activity.
Discussion and Conclusions
The main goal of the study is to investigate whether the different roles (peer or tutor)
of the conversational agent may affect students' perceptions of the agent and their
utterances. The study results indicate that the different appearance and communication styles of the agent affected the formal/informal style of the students' responses
to it (discourse data observations) but did not conclude in any signifi cant difference
in students' opinions about the agent (post-task questionnaires).
More specifi cally, all students had a favorable opinion regarding the user interface and the usability of MentorChat (Table 1). Moreover, students believed that the
agent interventions were simple and comprehensible and made the discussion more
interesting. They also stated that the agent interventions helped them recall and
identify valuable points of the topics being discussed (Table 2 , rows 3 and 4) or
understand the domain subject better through answering the agent questions
(Table 2 , row 6).
Furthermore, all the students seemed to appreciate the agent interventions and
the analysis did not reveal any signifi cant difference between P and T conditions.
The students in both conditions perceived the agent as a valuable discussion facilitator whether acting as a tutor or a peer (Table 2). Students' perceptions were not
adversely affected by the different appearance or communication styles of the agent.
However, although no statistically signifi cant differences were reported in the
post-task questionnaires, there is some evidence to suggest that students in the P
condition considered the agent interventions as more comprehensible than the students in the T condition. Based on our fi ndings, we argue that the friendlier interventions of the peer agent had a more positive impact on students, making them feel
as if they were engaged in human-to-human conversation, and eventually more willing to focus on prompt information.
This result seems to support the "personalization principle" of multimedia learning theory as described by Clark and Mayer (2011). This principle suggests that
instructional designers should use a conversational rather than formal communication
style so that learners interact with the interface in a way that resembles human-to-
human conversations. Indeed, although the students interviewed reported being aware
that the virtual character was not in an actual conversation with them, they seemed
more likely to act as if the agent was their conversation partner in the P condition.
Moreover, the discourse data revealed that students in the P condition responded
to the agent questions in a more friendly/informal way as compared to students in

the T condition. This result shows that the appearance of the agent or the conversational style of the agent interventions may infl uence students' conversational behavior. Hence, the different role of the agent in a collaborative learning activity can
impact on specifi c social characteristics of students' utterances.
This fi nding appears to be consistent with the outcomes of other studies exploring
how the different roles and appearances of contextually relevant conversational
agents can affect learners' impressions, stereotypes, or engagement (Veletsianos,
2010). For instance, Rosenberg-Kima et al.'s study (2010) indicates that the strategic

use of pedagogical agents of various races and genders can provide learners with
social models that are similar to them, thus increasing their interest towards the agent.
Furthermore, Gulz et al. (2011) highlight that a key challenge for the agent
design is to manage students' expectations about the social profi le of the conversational agent. Students have expectations of both what the agent may be able to say
to them and how it will address them. Thus, a good match between the students'
expectations of the agent's social profi le can alter how the students perceive the
agent's general personal features (e.g., a humorous or a serious character, a fi gure of
authority, or a peer) as well as enhance the pedagogical objective of making the
conversation engaging and motivating.
In spite of the various study limitations, such as the small number of participants
and the limited duration of the activity, we consider that this study provides preliminary evidence and valuable insights into the potential effect of the conversational
agent roles (peer or tutor) and their subsequent appearance and communication styles
in collaborative learning settings. We consider that teacher-confi gurable conversational agents have a pedagogically benefi cial role to play in the e-learning systems of
the future. We expect this study to contribute towards exploring various agent roles
or interventions that can improve collaboration in everyday instructional situations.
Acknowledgments The authors would like to thank Kleoniki Agrafi otou and Normperta
Magkitouka for their continued support in this project. We are also grateful to the students and
teachers of the participating school for their valuable comments and suggestions.

Introduction
Biofeedback is a means for gaining control of our body processes to increase
relaxation, relieve pain, and develop healthier, more comfortable life patterns (Wall,
2004). Biofeedback gives us information about ourselves by means of external
instruments. Biofeedback training familiarizes the person with the activity in his/her
various body systems, and therefore he/she may learn to control this activity to
relieve stress and improve health.
Educational activities in complex learning contexts produce negative or positive
emotions. Stress is such an emotion that might have an impact on the educational
activity and learning outcome. Therefore, student's stress-level self-awareness and
self-regulation can be a major issue in the educational process. Furthermore, student's stress-level awareness by the tutor could help the tutor to adapt the educational approach in order to promote the student's positive emotions.
The recent interest in the link between emotions and learning is based on the
assumption that deep learning is not entirely limited to cognition, discourse, action,
and the environment, because emotions or affective states are inextricably bound to
the learning process (D'Mello, Craig, & Graesser, 2009 ; Lepper & Henderlong, 2000 ;
Linnenbrink & Pintrich, 2002 ; Meyer & Turner, 2006 ; Stein & Hernandez, 2007).
A very important feature of learning environments is the support provided to students and to the instructor. The emotion recognition in many cases can be considered
as students' motivation in order to regulate their emotional state or trying to relax
their teammates in cases of high anxiety during collaborative learning activities.
This chapter aims to (a) identify whether anxiety awareness can motivate
the students to regulate their emotions; (b) explore if a well-known biofeedback

technique (i.e., diaphragmatic breathing) supports the students supported to regulate
their stress lever; (c) evaluate students' acceptance of biofeedback device and sensors during a learning activity; and (d) examine the usefulness of student's anxiety
awareness for the teacher.
The chapter is structured as follows: The next section is devoted to student academic emotions and adaptive learners' support. Then, the biofeedback device for
anxiety awareness is described. Section "Pilot Study" presents a pilot study that has
taken place in order to evaluate the usefulness of the biofeedback device for the
educational activities. The last section presents the concluding remarks and our
vision for the next steps.
Student Emotions and Adaptive Learners' Support
Emotions are very important functions that affect students' academic motivation,
behavior, performance, health, and development of their personality. Research from
1950s (Zeidner, 1998) investigated students' anxiety and produced suffi cient knowledge in order to support the educational practice. The impact of emotions during
problem solving as well as during the participation in educational activities seems
to be very important. More specifi cally, emotions can affect positively or negatively
the learning process (Allen & Carifi o, 1995). Efforts to study diffi cult subjects at
deeper levels of comprehension involve a complex coordination of cognitive processes and affective states (D'Mello, 2012). In the academic context, the treatment
focused on the problem seems to be the most appropriate adjustment. The emotion-
oriented treatment may also be an adaptive solution. The following factors seem to
be important to students' motivation and can be controlled by the teachers in order
to stimulate positive emotions for the educational process:
• Teaching quality and motivation : Factors, such as lack of structure, lack of clarity, and excessive demands, are known to enhance the students' anxiety during
the test (Pekrun, 2006 ; Zeidner, 1998 , 2007). Also if the learning environment
meets the students' needs, then students' engagement is encouraged (Hatfi eld,
Cacioppo, & Rapson, 1994 ; Pekrun, 2006 ; Zeidner, 1998 , 2007).
• Collaboration : Collaborative activities and structures in the classroom (Johnson
& Johnson, 1974) in many cases promote positive academic emotions (Pekrun,
2006 ; Zeidner, 1998 , 2007).
• Management of students' mistakes : Managing mistakes as learning opportunities
rather than as a personal failure, and linking benefi ts to achievements, might help
students develop adaptive emotions (Pekrun, 2006 ; Zeidner, 1998 , 2007).
• Challenging and deep inquiry : The authors of the model of dynamic affective
conclude that the main pedagogical strategy that yields in deep learning is the
challenging which can inspire deep inquiry instead of comfortable learning environments (D'Mello & Graesser, 2012).
Our proposed approach to challenging and deep inquiry would systematically
scaffold the student out of the confused state which can cause frustration and high

anxiety. This approach would presumably work better for less experienced learners
with lower domain knowledge and lower ability to self-regulate their learning activities and their emotional states. Moreover, our approach might be systematically used
as adaptive support to the learning activity. This approach is a biofeedback- based
approach that aims to keep the student on the qui vive and active but not stressed.
More specifi cally, this method aims to (a) wake the student if he/she is very relaxed
or bored trying to avoid deactivation and (b) support the student to relax applying a
biofeedback technique called diaphragmatic breathing if the student is stressed.
The synthesis and analysis of emotions is an interdisciplinary scientifi c fi eld
consisting from the combination of computer science, psychology, and cognitive
science (Allen & Carifi o, 1995). In order to apply this proposed approach we have
implemented a biofeedback device for anxiety awareness. Next section presents this
device.
Description of Biofeedback Device for Anxiety Awareness
The biofeedback device for anxiety awareness is based on two physiological techniques in order to collect bio-signals from students who are engaged in a learning
activity. The techniques used are the following:
• Galvanic skin response (GSR): This is a test of the sweat function, which measures the change in conductivity of the skin during the fl ow of low-voltage current
after a stimulus. The recording of the conductivity (or the inverse of conductivity,
i.e., resistance) is based on the application of external constant voltage to the skin
(Lykken & Venables, 1971).
• Photoplethysmography (PPG): PPG is a simple and low-cost optical technique
that can be used to detect blood volume changes (BVP) in the microvascular tissue (Challoner, 1979).
The biofeedback device (Fig. 1a) collects, identifi es, and utilizes bio-signals
resulted by physiological reactions to stressful situations, such as epidermal ephidrosis (GSR, Fig. 1b) and heart rate (HR, Fig. 1c). The device is connected to a
computer and collaborates with dedicated software in order to convert bio-signals
into a stress level (relaxed, waking, or anxious) on the screen as well as to advise the
user to regulate stress through relaxation techniques.
The software (Fig. 2) has the following functionality for each person:
• Displays the student code (Fig. 2a).
• Displays the emotional state progress bar and color (green for relaxed, orange for
waking, or red for anxious) as depicted in Fig. 2b .
• Recommend the user to apply a biofeedback technique in order to relax in case
of high anxiety level (Fig. 2c).
The tutor can monitor the students' stress level in real time as depicted in Fig. 3 .
The next section presents a pilot study that has taken place in order to evaluate
the usefulness of the biofeedback device for the educational activities.

Pilot Study
As referred before this chapter aims to (a) identify whether anxiety awareness can
motivate the students to regulate their emotions; (b) explore if a well-known biofeedback technique (i.e., diaphragmatic breathing) supports the students in order to
regulate their stress level; (c) evaluate the students' acceptance of biofeedback
device and sensors during a learning activity; and (d) examine the usefulness of
student's anxiety awareness for the teacher.
A pilot study has taken place in the postgraduate course "Educational Virtual
Environments" of the Postgraduate Studies Program of the Informatics Department
at the Aristotle University of Thessaloniki, Greece. Four educational activities were
taken place. Two of them were synchronous in the same place, and the other two
were synchronous from distance.
The activities were applied on 13 students, 4 males and 9 females, and each of
them concerns oral examination. In each session each group has been examined by
presenting its project and answering to tutor's questions. Every member of a group
has presented his/her contribution. The schedule of activities and the deliverables of
each activity were clearly stated at the beginning of the semester.
Method
The students were divided into four groups, one consisting of four people and the
others of three. Each group had identical assignments. The collaborative technique
used in educational test activities was fi shbowl (Leonard, Dufresne, Gerace, &
Mestre, 1999).
For the evaluation of the activities the students answered to 23 questions. The
questions were divided into two groups. The fi rst group included questions about
the evaluation of anxiety recognition support to the educational activity and
biofeedback- relaxing technique. The second group followed the Unifi ed Theory of
Acceptance and Use of Technology framework (UTAUT) (Venkatesh, Morris,
Davis, & Davis, 2003).
In addition an unstructured interview was taken by each student separately and

by the professor who was teaching the course in which the activities occurred. The
professor (tutor) was watching the students' anxiety measurements from the monitor application.
Materials
In all activities the students were connected to the biofeedback device for measuring
their stress level (Fig. 1). The tutor was aware about every student stress level using
the stress level-monitoring application depicted in Fig. 3 .
Anxiety Awareness in Education: A Prototype Biofeedback Device282
The fi rst oral examination activity and stress-level measurement took place at the
classroom. It could be considered as the familiarization activity, since extra care was
taken to practical matters on using the implemented device. For example most of the
students had trouble to get connected properly to the GSR and HR sensors.
The second and third oral examination activities have taken place from distance,
and they were supported by an open-source videoconferencing tool called the Big
Blue Button (http://www.BigBlueButton.org/). The students presented the basic
technical characteristics and architecture of the systems they were implementing.
Finally the fourth activity that was the fi nal examination took place at the same
time within the classroom. Each group presented the implemented system and its
evaluation.
Instruments
Two questionnaires have been fi lled by the students. For the needs of the fi rst questionnaire the participants were separated to control and test group with identical
questions.
In both kinds of questionnaires the fi rst question was a nominal scaled about
student's gender and the others were interval-scaled questions following the fi ve-
level Likert scale (Likert, 1932) (from 1 = strongly disagree to 5 = strongly agree).
Evaluation Procedure
An important issue of this work was to identify whether anxiety awareness can
motivate the students to regulate their emotions and to explore if a well-known biofeedback technique (i.e., diaphragmatic breathing) supports the students to regulate
their stress level. In order to evaluate this issue a two-step evaluation process has
been followed. In the fi rst step of this process the students fi lled a psychometric
questionnaire (Spielberger, Gorush, & Lushene, 1970) in order to collect data about
their emotional mentality. In the second step and according to the results of this
questionnaire the students have been separated into two groups (control and test)
consisting of equivalent number of stressful and relaxant members. The control
group was consisting of two males and fi ve females, and the test group was consisting of two males and four females. The difference between these groups was that the
students belonging in the control group were not aware about their stress level and
they didn't receive any biofeedback messages.
Evaluation Results, Discussion, and Conclusions
Investigating if students' stress-level awareness can augment to educational and
leaning activities, the majority of the students (61.2 %) answered that they "strongly
agree" that this information would be useful in examination activities. Also, most of
H. Apostolidis et al.283
the students (53.8 %) agreed that stress-level awareness would be useful to workshops. However, most of the students do not think that students' stress-level awareness can augment distance-learning teleconferences and individual studying.
Furthermore, independent sample t -test was applied to identify whether anxiety
awareness can motivate the students to regulate their emotions with confi dential
interval of 95 % and assuming equal variances. The signifi cance for equal variances
was 0.290 > 0.05 satisfying the homogeneity assumption. The mean of the test group
was signifi cantly greater than the mean of the control group, and the effect size was
greater than 1. This could be interpreted that the test group having the representation
of the measurements was more motivated than the control group.
Concerning the support of the diaphragmatic breathing technique to the students
to regulate their stress-level question, most of the students answered (38.5 % of
them agree and 30.8 % strongly agree) that they believe it helped them to be more
relaxed. However, there was no signifi cant statistical difference between control and
test group.
Concerning users' acceptance of biofeedback device and sensors during a learning activity, the UTAUT model (Fig. 4) has been applied to all students with common questions.
In order to examine the reliability of the question groups, Cronbach's alpha
reliability test has been applied. For the performance expectancy group of six questions the reliability was 0.73, for the expectancy effort (three questions) was 0.712,
and for the behavioral intension (four questions) was 0.745. So the three question
groups approved reliable. Concerning the diffi culty of connecting to the sensors of
the developed device most of the participants (46.2 %) answered that they strongly
agree that it is diffi cult and 30.8 % of the participants found little inconvenience.
Also about the diffi culty of using this device in parallel with the main activity, a
strong majority (69.2 %) found it a little inconvenient. So the majority of the participants had a little diffi culty with the device without any serious problem. Then
Spearman's correlation signifi cant at the 0.05 level was applied to performance
expectancy, effort expectancy, facilitating conditions, gender, experience, voluntariness of use, and behavioral intension. Signifi cant correlation approved between (a)
performance expectancy and facilitating conditions (0.610*), (b) performance
expectancy and behavior intension (0.573*), and (c) experience and behavior intension (0.586*). Also signifi cant correlation approved between expectancy effort and
voluntariness of use (0.630*).

Anxiety Awareness in Education: A Prototype Biofeedback Device284
According to the teacher the screen of the monitor application, where he could
have a representation of his students' emotional state, was very useful especially at
the distance activities and supported him in regulating his behavior when he was
noticing that there were stressful conditions. The professor who was responsible for
the evaluation activities was interviewed. He mentioned two signifi cant benefi ts
from using the biofeedback device in an educational activity: (a) Awareness of the
class emotional state for both distance and onsite activities : In distance-education
activities class anxiety awareness appears to be quite helpful for the teacher. It is a
factor that reduces academic distance between the teacher and the students. In addition, the prototype device enables the teacher to better understand students' anxiety
level. Furthermore, he/she had a more comprehensive awareness about his/her class
during the examinations. (b) Teacher's self-regulation during oral examinations : As
the professor reported, the awareness about students' anxiety helped him to support
the students to relax during the oral examinations. This resulted to establish a better
academic context during the examination.
After completing the questionnaires the students were interviewed separately.
All students suggested that the anxiety measurement may be useful to learning
activities such as examinations and workshops.
In summary, all the participants were willing to reuse these sensors in other academic activities. All students admitted that stress-level awareness can motivate the
students to regulate themselves. From the teacher's point of view students' stress-
level awareness support him to realize his students' emotions and to adapt his
approach, rhythm, and pace of oral examination. Our future plans involve (a) repeating learning activities with bio-signal measurements on a larger scale with more
students, (b) examining more bio-signal measurement techniques in addition to
GSR and HR, and (c) applying these measurements in collaborative distance-
learning activities.

Digital Storytelling: Defi nition and Benefi ts
As narration is the symbolic presentation of a sequence of events (Scholes, 1981),
storytelling might be defi ned as a form of narrative (Lathem, 2005 ; More, 2008).
Narrative is defi ned as a sequence of events which refer to a unifying subject represented in a perspicuous order in time (Carroll, 2001 ; Worth, 2005). The terms "narrative" or "story" are used interchangeably in the literature (Velleman, 2003 ; Worth,
2005). It is well known that children begin to write their stories through images that
often entail a symbolic function. They use pictures to create a sequence with a plot,
which tells a story (Gershon & Page, 2001). Children's stories may be short and serve
different aims such as telling a personal tale, recounting a historical event, or making
a presentation aimed to give information or instructions on a particular topic of interest (Robin, 2006). This process, refl ecting an old concept, has been defi ned as storytelling and has been used extensively in different levels of education (Lathem, 2005 ;
Robin, 2006 ; Valkanova & Watts, 2007 ; Yuksel, Robin, & McNeil, 2011). It refers to

a linear narration of a story with a starting point, a middle point (climax), and an
ending point (Gershon & Page, 2001). Storytelling may include text as well as other
forms of media such as images, sounds, animation, and videos (Lathem, 2005).
Following the expanding use of digital media, it has been developed into a different
form of creation and presentation. Digital storytelling (DS) is based on digital images,
videos, text, and sounds to form a genre in order to present a story to readers, viewers,
and listeners via a computer system (Li, 2007 ; More, 2008 ; Robin, 2006). In educational terms, new instructional methods, based on the use of technology, have been
developed for facilitating learning. As Levin (2003) argues, known concepts are
adjusted in a new pedagogical setting and enhanced with the use of technology.
There is a range of DS software such as PhotoStory3 , Animoto , ComicLife
StoryBird , Digital Vaults , VoiceThread , and Glogster , Kerpoof that offer the tools to
create a story with images and text through a computer system. Users can freely
place images in a sequence in order to create their own story, since there is no correct or wrong order. Digital storytelling offers several benefi ts to the educational
process in variable domains and for different learning groups (Heo, 2009 ; Kulla-
Abbott & Polman, 2008 ; Li, 2007 ; Meadows, 2003 ; More, 2008 ; Robin, 2006 ;
Yuksel et al., 2011). In particular, Kulla-Abbott and Polman (2008) suggested that a
digital storytelling program can assist students in improving their writing skills
because learners need to create and organize a sequence of images in correspondence to their ideas for making a story. They also concluded that DS can make students more engaged and creative, by helping them to discover different ways to
express their own ideas. Other researchers, such as Valkanova and Watts (2007),
asked children to make sound "voice over" in a narrative form for their own videos.
They reported that this procedure enabled children to express themselves verbally
and visually in an artistic, productive, and inspiring way. The same conclusion was
reached by Burgess (2006), whose research offered evidence for the positive effect
of DS for creative thinking. Sadik (2008) explored teaching and learning through
the application of digital storytelling with Microsoft Photo Story 3 and found that it
increased their comprehension and learning. Meadows (2003) observed that when
students used multimedia software to visualize their thoughts, they were more active
and engaged with the subject matter. Li (2007) evaluated the integration of multimedia technologies into higher education and concluded that through DS students

improved their learning. Furthermore, DS has been used as an educational tool for
learners with special needs. O'Neill and Dalton (2002) used successfully digital
story books for teaching literacy to students with learning diffi culties.
Overall, researchers agree that DS is an effective approach that engages learners
and supports teachers to effectively integrate technology into learning. Its application with special learning groups has been examined in a few research projects
(Daigle & Sulentic Dowell, 2010 ; Daigle and Free, 2007 ; Gal et al., 2005 ; Tartaro,
2005). Researchers have also examined the implementation of DS to students with
ASD regarding activity schedules via computer applications (Stromer & Kimball,
2004 ; Stromer, Kimball, Kinney, & Taylor, 2006). Activity schedules are defi ned as
a set of pictures or words that cues someone to engage in a sequence of activities
(McClannahan & Krantz, 1997 ; Stromer & Kimball, 2004). They can be considered
as a form of storytelling, as they are often used to display a sequence of steps for the
K. Chatzara et al.289
completion of an activity and this could also form a story constructed with a
sequence of images and text. Moreover, the potential benefi ts of activity schedules
presented with computer support have been well documented (Stromer et al., 2006).
The Education of Students with Autism
Autism spectrum disorders (ASD) have been identifi ed as pervasive developmental
disorders with neurobiological background, causing impairments and delays in
social communication and imagination (Barry & Burlew, 2004 ; Welton et al., 2004).
Consequently, children with ASD prefer to get engaged in solitary repetitive activities, avoiding social interaction. Moreover, they have a cognitive bias to local processing, that is, they pay special attention to details which prevents them from
grasping the purpose or the steps of an activity (Carnahan, Musti-Rao, & Bailey,
2009 ; Odom, Collet-Klingenberg, Rogers, & Hatton, 2010 ; Rajendran & Mitchell,
2007). Also, persons with ASD present major diffi culties in executive functioning
(Carlson, Mandell, & Williams, 2004 ; Pellicano, 2007), which involves organizing
and following sequences of steps. Therefore, educating people with ASD can be
challenging and it is necessary to adopt appropriate educational methods matching
closely the needs of these individuals. A range of educational interventions utilizing
visual methods have been successfully applied to children with ASD for overcoming the aforementioned diffi culties. Structured teaching has been found to be an
effective educational method for increasing on-task behavior and independence of
children and adults with ASD (Ganz, 2007 ; Hume & Reynolds, 2010 ; Mesibov,
Shea, & Schopler, 2005). The main component of Structured Teaching is the application of visual structure in the physical environment, in daily schedules and tasks,
so that individuals with ASD can follow predictable routines and visual instructions
for executing tasks and participating in activities.
On the other hand persons with ASD seem to have a strong motivation to use
computers for both learning and leisure (Heo, 2009 ; Moore et al., 2000 ; O'Neill &
Dalton, 2002 ; Valkanova & Watts, 2007). The use of computers offers the opportunity to the learner with ASD to interact in a controlled environment, which is predictable and with minimal social stimuli. Besides, it has been found to be effective
for students with ASD by increasing their attention span and their performance in a
range of academic tasks as well as by developing a repertoire of social skills and
behaviors (Bernard-Opitz et al., 1994 ; Moore et al., 2000 ; Tanaka et al., 2010 ;
Williams, Wright, Callaghan, & Coughlan, 2002). There is considerable evidence
showing that the main characteristics of people with ASD related with their learning
are the following: (a) they have a different way of communication, (b) they prefer a
predictable environment, (c) they fi nd it diffi cult to understand emotional cues, (d)
in general, they prefer images to text or oral information, (e) they concentrate better
in structured environments, with clear expectations and visual instructions, (f) they
learn by repetition of learning tasks, (g) they need frequent breaks in their schedule,
and (h) they take pleasure using computers for learning and leisure (Bernard-Opitz
et al., 1994 ; Hume & Reynolds, 2010 ; Moore, McGrath, & Thorpe, 2000).
Digital Storytelling and ASD290
Therefore the use of computers may entail several benefi ts associated with the
special characteristics of persons with ASD (Golan & Baron-Cohen, 2006 ; Mineo,
Ziegler, Gill, & Salkin, 2008 ; Moore et al., 2007; O'Neill & Dalton, 2002 ; Williams
et al., 2002). In particular, computers:
• Are predictable and thus they are controllable devices. They do not display
emotional behavior which can often be confusing for persons with ASD.
• Enable nonverbal or verbal expression.
• Present a less threatening environment compared to an adult or a peer.
• Can be used repetitively.
• Provide positive reinforcement.
• Are easy to use.
• Can be tailored to the individual needs of each learner.
• Are based on special hardware solutions designed to help persons with special
needs.
• Are versatile, since they use software which can be adaptive and adaptable to
users' needs and special interests.
Digital Storytelling and Students with ASD
In the fi eld of ASD, DS has been used to achieve student involvement as it relies
heavily on visual information; a suitable way of presenting stimuli to this special
group of learner (Daigle & Sulentic Dowell, 2010 ; Flippin et al., 2010 ; Stromer et al.,
2006 ; Stromer & Kimball, 2004). It also provides a framework integrating images
and text to form a story that narrates useful information. In addition, this method
could be viewed as an alternative means of instruction in an inclusive classroom.
Social Stories describe social situations aimed to share social information (Gray,
1998 ; Gray & Garand, 1993). Sansosti, Powell-Smith, and Kincaid (2004) presented Social Stories through DS to children with ASD and reported positive effects
of the intervention recommending further research on the use of DS for effective
learning. In addition, Heo's recent research (2010) indicated that DS increases children's involvement in the learning of subject matter. His research was conducted
over a period of 6 weeks with 17 fi fth graders and his analysis showed evidence that
DS can offer a motivating and effective learning experience. It is commonly agreed
that the creation of a story through digital media engages children's interest and
increases their creativity and involvement in a subject matter being taught (Meadows,
2003 ; Robin, 2006 ; Valkanova & Watts, 2007 ; Yuksel et al., 2011). However, their
use, in special learning groups, has not been thoroughly examined (Daigle &
Sulentic Dowell, 2010 ; Gal et al., 2005 ; Tartaro, 2005).
In Daigle and Sulentic-Dowell's initial study (2008) on the use of DS as an intervention to improve the academic performance and social interactions of a sixth
grade student with high-functioning autism, positive fi ndings were reported. Similar
fi ndings were documented by Gal and his colleagues (2005) and Tartaro (2007) who
K. Chatzara et al.291
combined DS with virtual peers for children with ASD. Also, Lindsey-Glenn and
Gentry (2008) reported promising results following the use of DS to improve
vocabulary skills of students with ASD.
It is notable that the software tools that have been used in the aforementioned
studies have not been designed specifi cally to cater for the special needs of this group
of learners. Subsequently the software does not accommodate the components of
structured teaching suitable for persons with ASD. Educators use the existing software by modifying its scope and operation in order to teach social skills to children.
Special education teachers need to organize the learning material and the way information is presented in order to maximize the achievement of their instructional goals.
The Di.S.S.A. Environment
The present chapter presents a software system of DS targeting children with special needs. The software created is called Di.S.S.A., which stands for Digital
Structured Storytelling for Autism. The software is designed and developed purely
for this research work and is programmed in action script 3 in Adobe Flash authoring environment. It is an online application. This is the fi rst time such software,
based on combining visual supports with elements of structured teaching, is developed to cater specifi cally for persons with ASD. To our knowledge, similar software
development has not been published.
The system is aimed to help people with ASD learn social skills through storytelling with the use of images, as sole text is, often, not the preferred way of presenting information. It evaluates user's performance and presents information about
user's progress. Its design is imposed by the need for a structured way of presentation, which has been proposed as appropriate for this group of learners (Mesibov
et al., 2005). Persons with ASD need to be aware of the meaning of an activity and
clear guidelines on how it will be done, how long it will be, and when it will be
fi nished. If this information is missing, they get confused and cannot perform tasks
independently. The development of Di.S.S.A. accommodates the above components
and users always know where they are in the application, what the purpose of their
actions is, and what the desired outcome is.
The design of the system (Di.S.S.A.) is based on the A.D.D.I.E. (Analysis,
Design, Development, Implementation, Evaluation) model. A.D.D.I.E is a framework that lists generic process for instructional design software (Dick & Carey,
1996 ; Leshin, Pollock, & Reigeluth, 1992). The content is adapted to the individual's capabilities by providing different levels of access (users have different capabilities depending on the severity of ASD), then the content is presented accordingly
to the adaptation module, the user creates the story, the system evaluates user's
performance, and a story with different actors but with the same concept is presented so that the users can interpret in a conceptual way the given task (children
with ASD have diffi culties generalizing what they learn in one setting to another
setting) (Stromer et al., 2006).
Digital Storytelling and ASD292
Stages of the Application
The system is adaptive to cater for different levels of ASD and evaluates user's tasks
in order to provide feedback for user's performance. The architecture is based on
experiential learning (Kolb, 1984) and follows the basic steps of experiential
learning; namely, experience—refl ective observation—conceptualization, and active
experimentation.
When the application launches for the fi rst time, a questionnaire is presented that
is fi lled by an adult, such as the parent or the special education teacher. The questions of this instrument refer to the student's skills and preferences, the level of ASD,
the use of text, movements, sound, or text messages, the number of pictures used
and the visibility of the evaluation model. The relevant story is picked up from the
stories pool (Figs. 1 and 2). The story is adapted to suit user's special characteristics
and preferences. The system decides how information is presented to users (adaptive
approach) with respect to the adaptivity dimensions of user and content. This is not
an intelligent system as the system follows a series of production rules (if …then).
The user logs into the system by inserting his/her name. The system "remembers" him/her next time he or she logs in and automatically starts from the last point
he or she left the application. This function is accommodated, considering that students with ASD might give up trying while using the application. As repetition helps
them comprehend the task, the system "remembers" them so that they can continue
their trials from the point they stopped last time. Users (teachers, parents, or students
with ASD) choose a social skill to learn.
Fig. 1 The design of Di.S.S.A.
K. Chatzara et al.293
The user is presented with four levels of graduated diffi culty for constructing a
story (Fig. 3). That is, he or she can choose the length of the story by selecting either
three, four, six, or eight images as breaking an activity into distinct steps has been
proved to be an effective method for achieving task mastery and independence in
special education (Swanson & Hoskyn, 1998). In the case of the system being used
by the student without supervision he or she can choose the desired level independently. In all other cases, a professional or a parent will select the appropriate level
of diffi culty for the student with ASD, considering the student's ability level and the
severity of autism.
Next, a sequence of images making a story is presented (Fig. 4a). Following this
presentation, the images are placed randomly in the screen (Fig. 4b) and users are
asked to rearrange the pictures in the correct order to create the story. An example
of a story (i.e., "opening up a present") is presented in Fig. 4 . For a realistic representation, the images used are photographs. A step-by-step procedure is followed.
At this point, Di.S.S.A. has been designed following structured teaching which
Fig. 2 Screenshot from Di.S.S.A. showing how the user can pick up a story
Fig. 3 Screenshot of the Di.S.S.A. showing the selection of level of diffi culty for users
Digital Storytelling and ASD294
places a strong emphasis on the execution of a sequence visually presented (Mesibov
et al., 2005 ; Stromer et al., 2006). Therefore, the user can move to the next step only
if he or she is correct in selecting the fi rst picture of the sequence.
Feedback/Evaluation
The system provides sound messages to refl ect user's actions such as messages that
inform the user for the correct or false completion of tasks. The messages "lead"
users to the right direction in order to make the correct decision. The system tells the
users orally and through text messages what they have to do and what the outcome
will be at all stages of performance. Text messages are presented too, in order to
build a relationship between images and words. For the evaluation of use, their performance is recorded, stored, and compared with past trials for the same story by the
same user. Depending on the outcome of the evaluation, the system executes a
refl ective function by selecting the same story theme, but with different images.
This is necessary given the need for skill generalization. Therefore, a new story is
presented to make sure the learner has acquired the social skill being practiced independently of the particular sequence of images.
A "present" is given every time the user places an image in the correct place.
Persons with ASD are very fond of animals (O'Haire, McKenzie, Beck, & Slaughter,
2013). So the system is designed to include an animated animal that places itself in
a different area in the screen other than the user's working space, to prevent any
distractions (Fig. 5). The user is given a different present for every story to avoid
boredom. In the end of the session the user can save a collection of all animated
animals in the system.
Following task completion, a result log is presented that contains the number of
errors of the user and the duration of engagement in each task. This is a useful tool
for comparing data to check for improvements between different trials of the same
user (Fig. 6).

K. Chatzara et al.295
Fig. 5 A "present" is given every time user puts an image
Fig. 6 Sample evaluation log with data about task performance
Pilot Application of Di.S.S.A.
A pilot application of Di.S.S.A. was carried out with four pupils (7-11 years) with
a formal diagnosis of mild autism. Two aspects of the application were evaluated:
user's satisfaction and user's task accomplishment. The evaluation was conducted
in collaboration with the parents of the children and took place in their homes.
Digital Storytelling and ASD296
The researcher met with the parents to demonstrate the application and explain to
them how to operate it. Each child used the system on their own with instructions
and supervision by their parents, who had chosen the level of diffi culty that was
suitable for their own child. Each child learned three social skills by using DiSSA
and three social skills with DS software for typically developing children. The software used is Photo Story by Microsoft that doesn't use steps when operated and its
interface design is "busy" as it is addressing typically developing children. It is used
to create a story but it does not accommodate features as correct sequence of images
and subsequently a module of informing the user for the correct completion of
tasks. The stories were aimed to teach them: (a) to cross a road, (b) to open a present, and (c) to wash their teeth.
Interviews with the parents were carried out by the fi rst author of this chapter. In
general, the fi ndings were positive for both aspects of the application and all children with ASD reported that they enjoyed using the application. Their parents
emphasized that their child had learned the sequence—stressing that story was easier than using printed images or other educational tools. They mentioned that their
children showed a strong motivation to operate the application and seemed highly
concentrated on the tasks. Also, they repeated patiently the whole procedure as
often as it was required. In contrast, when they were asked to repeat the task with
the DS software not specifi c for ASD, their parents had to spend more time to convince them to practice the repetition. Parents reported that their children appeared to
view Di.S.S.A. much more like a game than as a learning tool. They particularly
liked the animated "presents" and this function (to collect as many animals) motivated their engagement with the application.
One of the parents described user's experience as an enjoyable activity: "My son
didn't want to leave the application. He liked using it."
The same parent added: "My son wanted to use it even after he did all three stories. He asked for more stories. I think he thought it is a game, maybe because he
was getting the animated animal as presents when he was fi nishing a task and he

wanted to get more presents."
Another parent reported that his son learned the sequence of images very easily
comparing tasks with printed images that he had tried before. Also, he reported that
his son considered the application as a game and not as a lesson. He said: "I think
that my son wanted to get as many more animals as possible, I am not sure but I
think that this is one of the reason he liked using DiSSA."
Another comment was the following: "My son got confused with the other software and I needed to stand by him all the time he was operating it. I needed to tell
him every time he was placing an image if he used the right one. When I left him
alone for a while he got upset."
In summary, the main fi ndings of the pilot application were the following: (a)
children with ASD liked more using Di.S.S.A. than the DS software nonspecifi c for
ASD, (b) the structured style of presentation helped them maintain their attention on
the task, (c) they could operate Di.S.S.A. almost independently, and (d) they learned
the tasks given faster using Di.S.S.A comparing to the DS software nonspecifi c for
ASD. The above are important fi ndings for children with ASD as they address
K. Chatzara et al.297
crucial elements in their learning process as these children have different learning
characteristics than their typical peers. The special needs that complicate their
learning are diffi culties with verbal expression, diffi culties with remembering verbal instructions, their short attention span, the lack of organizational skills, the dif-
fi culties to generalize the skills taught and to make transitions from one task to the
other. Since Di.SS.A. utilizes greatly visual processing and presents information in
a structured way through computer systems it carries the potential to be an appropriate method for teaching social skills to this special group of learners.
Following the positive outcomes of the pilot application, an intervention with
more participants has been scheduled to take place, including persons with differing
levels of autism severity.
Conclusions
Despite the changes of the format of narrative storytelling over the years, its purpose
remains the same. Digital storytelling serves the same principles as the inclusion of
new media using computer technology. The number of available DS systems is
indicative of their importance for teaching academic and leisure skills. Their use, for
learners in the autistic spectrum, has been introduced in the last decade and systems
appropriate for this special group of learners need to be designed and evaluated.
Di.S.S.A is our fi rst attempt to design DS software specifi cally for users with
ASD. It utilizes components of Structured Teaching, such as minimal use of written
messages and extensive use of images, for the instruction of social skills to persons
with ASD which have been recommended as appropriate for students with
ASD. Another useful feature for professionals and parents is the continuous
evaluation which allows them to record user's competence in the learning task.
It is anticipated that the use of DS is a promising method for making learning
more appealing, raising students' productivity and positive affect during individual
or collaborative activities. Future work includes testing the application to a large
number of people with AS, in different settings, targeting not only social skills but
other skills too such as safety and hygiene skills and other learning subjects such as
mathematics and history.

Pretesting Mathematical Concepts with the Mobile Phone:
Implications for Curriculum Design
Abstract
One of the neglected elements when teaching at a distance is establishing what learners
already know at the beginning of the course or module. Unlike the face-to-face environment, in distance learning there is no opportunity for administering diagnostic activities
just before the onset of instruction. This means that both the weak and more advanced
students receive the same level of support since there is no mechanism for differentiating
their learning needs. This paper describes the characteristics of a diagnostic test aimed at
determining student understanding of the basic calculus concepts of the derivative and the
integral, using the mobile phone as the method of delivery. As a proof-of-concept exercise,
10 questions designed to test concept attributes and procedural knowledge involving the
two basic calculus concepts were given to a sample of 30 students at the beginning of the
course. The implications for curriculum design were then analysed in terms of the didactical functionalities and the communication strategy that could be developed with reference
to the mobile phone.
Keywords: Prediagnostic testing; mobile phone; distance learning; undergraduate calculus teaching; Realistic Mathematics Education; didactic functionalities
Introduction
Imagine the following scenario:
You are a student wanting to take a distance calculus
course, but you aren't sure that you are really up to it. It has
been a while since you did your high school mathematics.
You quickly access the UNISA Web site via your phone for
the pretest they offer and take it. The results indicate the
areas you need to revise before joining the course. You
contact a social network friend who has been in a similar
situation. He or she immediately texts back a message
attaching an online calculus manual that you need to go
through. Once home, you continue your preparations for
the next pretest on your computer.
The scenario is based on the observation that mobile learning is an emerging and rapidly
expanding field that provides new opportunities for learning improvement. Strictly speaking, mobile learning is a very broad term that is used in different contexts and that involves
a number of mobile devices such as mobile phones, personal digital assistants (PDAs), various forms of handheld devices, and even notebooks. For the purposes of this article, I am
using the term mobile learning to refer to handheld pocketsize technologies that can be put
in your pocket at the point of learning. In the South African distance education environment, where the majority of students simply cannot afford access to web-based learning,
the use of a mobile learning strategy seems to be a viable and rational alternative for providing instructional support.
Previously, the adoption of mobile learning was constrained by slow networks, limited services, and hesitancy on the part of organisations to invest in devices whose shelf life was too
short. Mobile phone penetration and adoption were not really matched by a parallel uptake
of mobile learning, despite predictions of a possible mobile learning revolution (Wagner,
2005). Reasons posited for the delay in adoption included limited and non-standardised
broadband distribution capacity (Wagner, 2005), device attributes such as screen size, battery life, and security (all of which hinder learning), limited resources, and a lack of organisational acceptance (Brown, Metcalf, & Christian, 2008).
The limitation of mobile content development and distribution is slowly changing as demonstrations of the potential and actual roles of mobile technologies increase. Consumers
(including distance students) who are apt mobile users have established a demand for mobile technology use. According to Traxler (2007), mobile devices are creating a new "mobile
conception of society in which we are beginning to look at new ways of creating and accessing knowledge, performance, art forms, and even new economic activities" (p. 4). However,
not enough research has been conducted to identify the actual functionalities that should be
targeted when designing instruction using the mobile device in teaching.
Within the context of distance teaching, a neglected element is the establishment of learners' prior knowledge at the beginning of the course or module with a view to offering the
learner appropriate support. This type of diagnostic testing, prior to the onset of a learning
unit or module, is slightly different from the pre-enrolment tests offered via paper (postal
system), by telephone, or through prerequisite courses. While pre-enrolment testing establishes learner readiness for participating in a course, the precourse diagnostic testing is
conducted to determine the amount and level of support a learner will require to advance
successfully within the course. Unlike the face-to-face environment, in which a teacher has
the time to briefly find out where the learners are before the course begins, in distance

learning there are few opportunities for administering diagnostic activities once students
have enrolled for each course or module. This means that both weak and more advanced
students receive the same level of support since there is no quick mechanism for responding
to individual learning needs (as would be the case in a traditional classroom). The problem
is exacerbated by the large number of students enrolled in any distance learning module.
This paper describes the characteristics of a precourse diagnostic test aimed at determining initial student understanding of the basic calculus concepts of the derivative and the
integral, using the mobile phone as the method of delivery. The aim of the project was to try
to find out what the didactic functionalities of a simple mobile phone were and how these
could be exploited to inform supporting learning mathematics at a distance. The questions
posed were as follows:
• Can we use the mobile phone to facilitate the administration of diagnostic activities
quickly?
• If we are going to use the mobile phone, what are its didactic functionalities?
• How can these functionalities be exploited in order to inform teaching and learning as
well as curriculum design in distance education?
The Role of the Mobile Phone in Providing Learning Support
There have been a number of examples of successful mobile learning interventions. For
instance, Wei and Chen's (2006) e-book interface design allowed students to enter queries
on the text which were transferred to a discussion forum accessible through the mobile
phone. Hartnell-Young and Vetere (2008) personalised learning by letting students capture everyday aspects of their lives in order to reconstruct their lived narratives within a
classroom environment. Kinsella (2009) built a mobile application which allowed students
to anonymously post questions to the teacher, who was then able to give summarised feedback to all participating students in real time. The reports from South Africa have been
predominantly around the SMS "short message system" usage. These include Viljoen and
Carlcook's (2005) exploration of the experiences of adult learners' use of SMS as a support
tool while enrolled in the University of Pretoria's distance education unit and Van Rooyen's
(2010) investigation of student responses to the integration of SMS as support tool systems
in an accounting module at UNISA.
The current smart phones have multimedia conduits which, if exploited, are potentially
useful for teaching and learning in many subjects. Students can collect evidence and data
via audio and video recordings and by taking photographs. Students can send short text
messages between mobile telephone devices or even send messages that include multimedia objects (e.g., video images and audio recordings). All these features can make a difference to the way in which students build new knowledge (Daher, 2010).
Mobile Phone Use in Supporting Mathematics Learning
Mobile phone usage in mathematics learning is slowly increasing. For example, in their
Pretesting Mathematical Concepts with the Mobile Phone: Implications for Mobile Design
Kizito
Vol 13 | No 1 Research Articles January 2012 41
research, Yerushalmy and Ben-Zaken (2004) established that the mobile phone was a tool
capable of opening up fascinating opportunities for learning because of its mobility, availability, and flexibility. Professor Yerushalmy and her team at the University of Haifa developed Java-based mathematical applications that can be installed on most mobile phones.
The devices operate as minicomputers and are used for constructing graphs, solving equations, and sketching functions. Their Math4Mobile phone applications for learning algebra,
geometry, and calculus can be accessed from the Web at www.math4mobile.com. This team
has developed activities for elementary, middle, and high school students. Dynamic lessons
where students explore mathematical concepts can be accessed from mobile phones. This
means that students who have no access to classroom computers are not excluded from
these learning opportunities.
On the basis of their research study, Roschelle, Patton, and Tatar (2007) claim that using
mobile devices transforms the mathematics classroom into a student, assessment, knowledge, and community-centred entity. Genossar, Botzer, and Yerushalmy (2008) analysed
the learning processes and experiences that occurred within a mobile phone learning environment. They found that, apart from making the dynamic mathematical applications
more accessible, the mobile phone-enabled students to engage in real, authentic tasks. For
instance, students could record simple dynamic events with their cell phones' video cameras and later convert the video clips into mathematical models using the mathematics applications. The mobile phone learning environment also allowed the students to work collaboratively by sharing graphs and formulae and solving
problems collectively. This helped
establish a community of mathematics learners. In a recent study (2010), Daher confirmed
the formation of collaborative communities of budding young mathematicians. Preservice
teachers collected data that supported the finding that middle school student knowledge
building could be fostered through learning mathematics in a mobile phone environment.
Students jointly engaged in and solved authentic mathematical problems with the help of
mobile phones.
In South Africa, the Meraka Institute (a research institute) has been at the forefront of
the innovative use of mobile/cell phone technology to support the teaching and learning
of mathematics. The Institute has been able to develop a mobile tutoring system, Doctor
Maths, which runs on the MXit platform. MXit is a very popular instant-messaging service
that is accessible via cell phones and that has over three million school-age subscribers.
Volunteers from the Department of Engineering at the University of Pretoria offer real-time
mathematical support to the high school students using the MXit chat facility on students'
cell phones at reduced rates. From an initial enrolment of just 20 students, to date the
service has grown to support over 1,000 students (Van Rooyen, 2010). However, even with
this evidence, it is still difficult to clearly isolate the actual functionalities that should be
targeted when designing instruction using the mobile phone in teaching.
Diagnostic Testing in Distance Education
The aim of the precourse diagnostic testing carried out in this project was to determine,
as quickly as possible, students' prior knowledge of the subject at the beginning of an in-
Pretesting Mathematical Concepts with the Mobile Phone: Implications for Mobile Design
Kizito
Vol 13 | No 1 Research Articles January 2012 42
troductory distance calculus course. The type of pre-testing administered in this project is
slightly different from the multiple-choice computerised diagnostic testing administered
to determine students' mathematical skill competencies with a view to suggesting remedial strategies (Appleby, Samuels, & Treasure-Jones, 1997). Prior research done at the undergraduate level consistently reveals that students start calculus courses with a limited
view and understanding of the functional concept (Tall, 1996; Ferrini-Mundy & Lauten,
1993). In addition to this, students often exhibit cognitive difficulties when interpreting the
functional concept using algebraic and graphical representations (Schnepp & Nemirvosky,
2001). The aim of this project was to ascertain if the students who enrolled for the calculus
course at UNISA had an understanding of the two basic calculus concepts, the derivative
and the integral, and to subsequently build on that knowledge to inform future instructional design decisions.
The use of precourse diagnostic testing in order to support student learning is not a new
idea. Over the years, the recognition that students' initial beliefs and ideas about particular
phenomena form the basis of their future learning was used to design and develop diagnostic instruments to test and support student learning (Halloun & Hestenes, 1985). Currently, there are many examples of computer-assisted tutoring and testing systems (Chiou,
Hwang, & Tseng, 2009; Springer & Pear, 2008). The advent of web technology has also
provided us with a platform on which web-based diagnostic systems can be accessed by
face-to-face and distance students alike (Bälter, 2009).
For this study, it was important to identify, as a proof-of-concept exercise, how the mobile
phone could be used to enhance the learner's experience in a way that current distance
learning provision was failing to do. The main aim of the study was to establish what the
didactic functionalities of a mobile phone were and how they could be exploited to inform
prediagnostic testing design at a distance.
Theoretical Framework of the Study
The learning transaction between teacher and student in a distance learning environment
cannot occur without some form of technological mediation. The theoretical framework
used in this study therefore includes ideas borrowed from two parent frameworks, an instructional design (or teaching and learning framework) together with a framework for
analysing the role played by technology. The next sections are elaborations of these two
frameworks; note that these two frameworks were combined for the final analysis of the
project outcomes.
The Instructional Design Framework
The prediagnostic testing in this project is part of a larger project that examines the developmental efforts required to adapt the instructional design perspective of Realistic Mathematics Education (RME) to the teaching and learning of calculus via distance education.
RME was first introduced at the Freudenthal Institute in the Netherlands in the 1970s in
response to a call for reform in mathematics education. RME is based on Freudenthal's
Pretesting Mathematical Concepts with the Mobile Phone: Implications for Mobile Design
Kizito
Vol 13 | No 1 Research Articles January 2012 43
(1973; 1991) belief that mathematics education should take its point of departure in mathematics as a human activity, rather than mathematics as some sort of ready-made system.

The fundamental idea is that by designing instruction in which both everyday situations
and mathematical activities are mathematised, students can be helped to reinvent mathematics and (as a result) attain a better understanding of the subject.
The approach capitalises on mathematising (regarding or treating a subject or problem in
mathematical terms) as a central learning activity together with guided reinvention and
emergent modelling as central processes within the learning experience (Gravemeijer,
1994; Bakker, 2004; Zulkardi, 1999).
• Guided reinvention involves reconstructing "a natural way of developing a mathematical concept from a given problem situation" (Bakker, Dorman, & Drijvers, 2003).
• Emergent models are models that initially represent problem situations, but later on
develop into models of abstract mathematical objects and relations (Bakker, Dorman,
& Drijvers, 2003).
From a design perspective, the teacher needs to have some idea about where his/her students are in terms of the projected learning in order to design appropriate learning activities based on ideas that are less sophisticated than the mathematical concepts being developed. This is why the diagnostic test needed to be
administered quickly. In this case, the
diagnostic test was directed to getting a sense of students' initial knowledge of the concepts
of derivative and integral at the beginning of the course.
Framework for Analysing the Role Played by the Technology
Since the transaction between teacher and student in a distance learning environment cannot occur without some form of technological mediation, a type of construct was required
to analyse the role played by the technology. Cerulli, Pedemonte, and Robotti's (2005) perspective of didactical functionalities fit well with this requirement. Cerulli et al. (2005) regard didactical functionalities as those properties (or characteristics) of a given information
and communication technology (ICT) and its modalities of employment which may favour
or enhance teaching and learning processes in reaction to a specific education goal.
Another construct borrowed from Cerulli et al.'s (2005) approach was the education experiment cycle (EEC) model. This was used to identify the critical phases within the project.
The EEC model has three main phases: (a) the planning phase involving the setting up and
sequencing of activities; (b) the putting into practice phase, in which the planned activity is
implemented; and (c) the diagnostic phase, which involves evaluating the actors (teachers
and students) involved. A tool's modality of employment can be analysed in any (or only
one) of the three phases, depending on the educational goal.
In order to illustrate the universality of their theory, Cerulli et al. (2005) demonstrated how
the perspective of didactic functionalities could be combined with different teaching and
learning theoretical frameworks in order to delineate the didactical purposes of the tech-Pretesting Mathematical Concepts with the Mobile Phone: Implications for Mobile Design
Kizito
Vol 13 | No 1 Research Articles January 2012 44
nological tools employed in the course of teaching and learning. Examples of the teaching
and learning frameworks examined were Brousseau's theory of didactic situations, Nardi's
version of activity theory (concentrating on computer-mediated learning), and the theory
of instruments of semiotic mediation.
• Brousseau's (1997) theory of didactic situations organises the teaching process into
three parts: (a) the non-didactical, which is not specifically organised to allow for
learning; (b) the didactical, in which the teachers explicitly organise tasks to teach students forms of knowledge in a specific manner; and (c) the adidactical. The adidactical
refers to the process of channelling students into solving problems that are designed to
provoke students into finding their own solutions. As a result, students acquire the desired forms of knowledge and reasoning for understanding given concepts. At the heart
of Brousseau's theory is the milieu, which describes the middle ground of the teaching and learning cognitive space in which the teacher, the learner, and all the facets
of the teaching/learning environment interact. The basis for this theory is a Piagetian
view of learning, where the learner goes through the universal processes of assimilation
and adaptation in well-defined stages of learning development until he or she reaches
the complete adidactical situation of taking full responsibility for his or her learning.
Analysis of tool use in this case focuses on interactions and retroactions or feedback.
The modality of employment involves situations where the learners interact with a tool
and receive feedback. This can be achieved in either the planning or implementation
phases. The didactical functionalities are defined in terms of the user's retroactions.
• Activity theory is a research framework entrenched in a set of viewpoints derived from
the work of the Russian psychologists Vygotsky, Leont'ev, and others in the 1920s
(Nardi, 1996; Engeström, 1999). Activity theorists seek to understand and scientifically explore individual consciousness (cognitive acts) rooted in everyday practice and
embedded in social mediums composed of people and artefacts (Nardi, 1996). Artefacts
here may be either tools or symbol systems (e.g., languages). In this project, the point
of reference is Nardi's version of activity theory as applied to human computer interaction (HCI) research. Consequently, the examination of tool use in this context shifts to
the structuring of activities. The modalities of employment are geared toward creating
activities designed to encourage the engagement of all participants. In this case, the
didactical functionalities are defined in terms of how the tools are used to structure the
activities.
• The last example Cerulli et al. (2005) refer to is one using the theory of instruments of
semiotic mediation. This approach is derived from a Vygotskian social cultural theoretical view of learning, in which the development of meaning is based on a phenomenological experience of the learner with other members of the society, with the help
of an artefact or tool. According to Mariotti (2002), the artefact serves as a semiotic
mediator because it is used by the teacher to help the learner construct meaning. For
the learner, meanings emerge as he or she participates in an activity involving the artefact. Here, the modalities of employing the tool require setting up activities involving
the tool as well as orchestrating discussions using signs developed by the tool to assist Pretesting Mathematical Concepts with the Mobile Phone: Implications for Mobile Design
Kizito
Vol 13 | No 1 Research Articles January 2012 45
meaning making.
The Combined Framework
For this project, Cerulli et al.'s (2005) perspective of didactic functionalities and the RME
approach to instructional design were combined to create a framework for designing and
evaluating the precourse assessment activities. The RME framework was used to guide the
design of the preassessment activities. The resulting theoretical framework, consisting of
a combination of RME and the perspective of didactic functionalities, is shown in Figure
1. In terms of the perspective of didactic functionalities, the tool being considered in this
research was the mobile phone within the mobile learning platform. The goal was to establish the tool's didactic functionality. The didactic functionalities of the mobile phone were
analysed in only one modality of employment, that of diagnostic testing.
Figure 1. RME and the perspective of didactic functionalities in prediagnostic testing design using the mobile phone as a didactic support tool (diagram developed by the author).
Method
A prediagnostic test aimed at determining initial student understanding of basic calculus
concepts (the derivative and integral) was delivered using both print and the mobile phone.
Thirty volunteer students took a 10-item prediagnostic test that was delivered using both
print and the mobile phone. The students were UNISA students who had completed their
first semester in a first-year calculus course. The researcher for the study was the curriculum designer, who also played an instructor role in this pilot study.
The questions were designed to gauge the students' understanding of functions, their interpretation of graphs, and their understanding of the terms the derivative and the integral
(see Appendix). Questions 1 and 2 were designed to test students' understanding of the
function and its graphical representation. Questions 3 to 7 tested students' understanding
of the derivative, including personal definitions, graphical interpretation of the concept,
and use of simple formulae. Questions 8 to 9 tested students' personal definitions of the
integral and included one typical integral evaluation problem. Question 10 was designed to
check the students' understanding and graphical interpretation of both the derivative and Pretesting Mathematical Concepts with the Mobile Phone: Implications for Mobile Design

The Hot Lava software integrated an authoring system with a mobile delivery and tracking
system. The integrated system of components provided a fast and efficient way of designing, creating, editing, deploying, and tracking content that could be delivered to different
mobile phone models. One advantage of Hot Lava was that the content could be delivered
on a variety of mobile phones. The other main advantage was its ability to track and see
which students were logged in and when they registered. On individual screens, the instructor could see the order in which students attempted the questions and the number of
attempts at each question before a final answer was submitted. I could also see how much
time students spent on the test.
Results
Only nine students (30%) of the group preferred to take the test on the mobile phone. Those
who declined to take the test on the phone felt that they were more comfortable working
with mathematics on paper. However, all of the students who took the test on the mobile
indicated that they enjoyed it. There were no notable differences in terms of overall student
performance on tasks. There were a few differences in terms of the number of questions
completed (due to input issues), the turnaround time for receiving the answers, and the
availability or nonavailability of a system for tracking student responses. Table 1 is a comparative summary of some of the findings.
Table 1
Comparison of Students who took the Print and Mobile Versions of the Test
Print version Mobile version
Number of participants involved
21 9
Number of completed tests 17 9
Time taken to complete test Not available 7 minutes and 45 seconds
Time spent on each question Not available 46.5 sec
Questions not completed None Q5 and Q8 (which required written
inputs)
Discernible difference in performance on questions
None None
Tracking information from the Hot Lava tracking system revealed that the average time
spent on the mobile test was 7 minutes and 45 seconds.
Responses
The test sought initial student interpretations of the function, the difference quotient, and
the concepts of derivative and integral. The following questions were used to guide the inquiry in terms of the four constructs.Pretesting Mathematical Concepts with the Mobile Phone: Implications for Mobile Design
Kizito
Vol 13 | No 1 Research Articles January 2012 48
• Could students recognise that a function represented a relationship between the variation of one quantity (input) with the variation of another quantity (output)?
• Were students aware that the difference quotient
$\frac{f(b) - f(a)}{b - a}$
represented a ratio between a change in output and a change in the input quantities?
• Did students associate the derivative with a rate of change of a quantity at a specific
instant?
• Could students link the integral to an accumulated area under a curve?
Responses from the Printed Version of the Test
From the printed version of the test, only 17% of all participating students provided an acceptable interpretation of the concept of function.
The responses related to the difference quotient revealed that the majority of students had
not yet developed a satisfactory interpretation of the difference quotient
$\frac{f(b) - f(a)}{b - a}$.
For
example, one student referred to the quotient as the "gradient of the tangent to curve," even
though the line drawn connecting the two points, (a, $f(a)$) and (b, f (b)), was not a tangent
line. Another student defined the quotient as "the region between the graph y (f (x)) and the
line." No respondent mentioned anything about the average rate of change of a function,
which was what the quotient represented. A number of students said that the value of the
quotient increased or the gradient became steeper as b moved close to a. The respondent
who defined the quotient in terms of area said that "the area covered by the curve and the
line as b moved closer to a." One student correctly stated that "as b moves nearer to a, the
gradient of the chord approaches the gradient of the curve at point (a, $f(a)$))."
The general descriptions of the derivative given by the students depicted the derivative as
an entity resulting from mathematical manipulations. Below are three examples of derivative definitions:
A derivative is a task that gets an expression out of a
function and makes that found expression be a function
on its own;
A derivative is a function or constant obtained from
differentiating a previous function one or more times;
. . . a derivative is a mathematical equation or constant
obtained after def.
All the students using the print version were able to interpret the integral sign $\int_a^b f(x)\,dx$
correctly. Responses included descriptions such as ". . . this is integration of the function (x)
with respect to x between limits a and b" and "the term that means the total area between Pretesting Mathematical Concepts with the Mobile Phone: Implications for Mobile Design
Kizito
Vol 13 | No 1 Research Articles January 2012 49
the f (x) and the x-axis within the limits b (which is the upper limit) and a (which is the
lower limit) on the x-axis." There was also a computational or procedural definition: "to
integrate means to raise the power of the function f (x) by 1 and divide the top function by
what you get after raising the function." The majority of students carried out the graphical
evaluations of integrals correctly.
Responses from the Mobile Version of the Test
Responses from students using the mobile version were similar to those who used the print
version. Students still confused the difference quotient and the derivative. One respondent
defined the difference quotient as "the gradient of the curve found from first principles, an
approximate value of its gradient." Students gave the correct interpretation of the integral
and acceptable responses to Q9 and Q10, which involved graphical interpretations. The
multiple question items on the mobile phone were all completed, but some of the items that
required filling in were not completed. In contrast, all students completed all 10 items when
using the print-based format.
Conclusion and Future Directions

Even though the sample size was quite small, one can deduce that the important didactic
feature of the tool (the mobile phone) was mainly the speed and ease of tracking and analysing student responses. From this preliminary study, it was clear that the utility of the
mobile phone for pre-enrolment diagnostic testing in distance learning could be enhanced
if the phone was used in conjunction with a mobile phone platform such as Hot Lava. As
far as the adoption of an RME perspective in the design of instruction is concerned, the
phone would be useful in quickly determining a student's starting point before embarking on any form of learning. Simple diagnostics tests could also be interjected at different
teaching points during the course of learning to check student progress. In terms of student
precourse testing, it seemed that the most prominent didactic functionality of the mobile
phone was the speed and ease of tracking and analysing student responses.
One of the limitations of the mobile device was the students' difficulty in handling questions
that required manipulating symbols and equations. The mobile phone interfaces of the
smart phones used were unable to handle this effectively. Another drawback to using the
Hot Lava platform was that this platform is too expensive to maintain in a developing world
context. For example, the cost for the initial testing was US$1,000 for the 30 students, and
this fee did not include the additional charges required for each student registering on the
Outstart-Hot Lava Web site.
Taking into account the limitations of this study (e.g., small sample size), one can draw the
following conclusions:
• The mobile phone (embedded within a mobile phone platform such as Hot Lava mobile) can be used for precourse testing in a distance teaching and learning environment.
• The modality of employment for the tool in this project was as a diagnostic tool. The Pretesting Mathematical Concepts with the Mobile Phone: Implications for Mobile Design
Kizito
Vol 13 | No 1 Research Articles January 2012 50
tool's didactic functionality was positively influenced by the speed and ease of tracking and analysing student responses but negatively affected by issues of availability
(related to cost) and ease of use (linked to the difficulty of manipulating symbols and
equations).
• For effective delivery and acceptance by users, one would need to find a way of using
mobile devices where issues of affordability and ease of usage are adequately addressed.
Tim O'Reilly (2008) projects similar futuristic design ideas when he imagines future mobiles that have sensor-rich interfaces (having features such as a microphone, a camera, a
touch screen, an accelerometer). These devices are also able to link to an array of cloud
services that support data recognition and retrieval in order to contain assets such as voice
recognition and location sensors (GPS or cell triangulation). The technology is certainly
advancing very quickly, and it is therefore possible that in the near future devices and affordable systems allowing easy manipulation of symbols and more opportunities for quality
student-teacher interactions will be within reach of the majority of students. For now, it
becomes more efficient to make instruction design decisions based on the required human
functions and make adjustments as the technology progresses.
While it is essential to understand the strengths and weaknesses of a particular technology
such as the mobile phone and use this information to deploy good pedagogical practices
to achieve specific learning goals, we should—as do Jay Cross, Tony O'Driscoll, and Elif
Trondsen (2007)—ask the question: "What can this technology do that will enhance the
learner's experience that my current learning provision does not?" For example, precourse
assessment provision could be leveraged by organising it around a functional set of student
needs, such as flexibility of symbol manipulation and affordability. One would then be able
to examine the affordances the mobile device allows and map it onto students' ease of use
and course instructors' priorities to develop relevant precourse assessment content.
In general, students preferred the paper-based tests, although they welcomed the increased
opportunities for communicating with their tutor. Interviews would have to be integrated
into future studies to explore in-depth perceptions of student experiences of mobile phone
use. The results from this proof-of-concept project can inform the design of projects involving precourse assessment with a larger number of students. More focused research is still
required to determine how best to turn the capabilities of the mobile phone into a leading
component of the testing environment in distance education.Pretesting Mathematical Concepts with the Mobile Phone: Implications for Mobile Design

From problem solving
to modelling
the emergence of models and modelling perspectives
NICHOLAS MOUSOULIDES, BHARATH SRIRAMAN
AND CONSTANTINOS CHRISTOU
More than 25 years ago, a research project in the U.S investigated the question: "What
is needed by students, beyond having a mathematical idea, that enables students to
use the mathematical idea in everyday problem solving situations? (Lesh, Landau &
Hamilton, 1983). The answer to this question has begun to emerge after 25 years of
systemic work in the domain of modeling. In this paper, we chronicle the emergence
of models and modeling perspectives (MMP) from the genre of problem solving
research via a synthesis of the major strands in the extant literature.
An increasing number of mathematics education researchers have begun
focusing their research efforts on mathematical modeling at the school
level. This is evident in numerous research publications from groups of
researchers in Australia (English, Galbraith and colleagues), Belgium
(Verschaffel and colleagues), Denmark (Niss, Blomhøj and colleagues),
Germany (Blum, Kaiser and colleagues), Netherlands (de Lange and colleagues) and the U.S (Lesh, Schoenfeld and colleagues). Among the questions that have been raised, is how well prepared are learners today to
solve the problems that they will encounter beyond school, in order to
fulfil their goals in work, as citizens and in further learning? (Christou,
et al., 2005; OECD, 2004; Doerr & English, 2003; Schoenfeld, 1992).
How can students work with problems that are less obviously linked to
school mathematics and require students to deal with unfamiliar situations by thinking flexibly and creatively (Lesh & Doerr, 2003a, 2003b)?
It is necessary to distinguish problem-solving activity as described by
Nicholas Mousoulides, University of Cyprus
Bharath Sriraman, The University of Montana

24 Nordic Studies in Mathematics Education, 12 (1), 23-47.
Schoenfeld (1992) and other researchers (for example, see English, 2003)
from the activity of solving traditional word problems. Traditional word
problems usually present simplified forms of decontextualized world
based situations. The purpose of such word problems is only the exercise for specific type of mathematical learning, such as addition or subtraction (Wyndhamm & Saljö, 1997). The use of word problem solving
in school mathematics hardly matches this idea of mathematical modeling and mathematization, which is the structuring of reality by mathematical means (Freudenthal, 1991). Student work with that type of
solving problems is absent of heuristics and mathematical strategies and
the result is a prevalence of mechanical and mindless solutions (Greer,
1997). A second, probably worse, consequence of student work in solving
traditional word problems is the absence of high level cognitive and metacognitive processes involved. This absence is forwarding students to look
for key words and employ direct translation strategies to solve a problem
(Schoenfeld, 1992). Burkhardt & Pollak (2006) take the modeling perspective of applied mathematicians in contrasting the pure versus applied
nature of mathematics relevant for today's world.
While the 'pure' and 'applied' viewpoints have many things in
common, including delight in the elegance of mathematics, they
differ in others that are important for the design of school curricula
- notably the central importance of teaching modeling. (p. 178)
This call is consistent with recent initiatives to emphasize the applied
nature of mathematics used in emergent professions. Steen (2001) argued
that in spite of the rich and antiquated roots of mathematics, mathematicians among others should acknowledge the contributions of researchers
in external disciplines like biology, engineering, finance, information sciences, economics, education, medicine etc who successfully adapt mathematics to create models and tool kits with far reaching and profound
applications in today's world. These interdisciplinary and emergent applications have resulted in the field of mathematics thriving at the dawn of
the 21
st
century (Lesh & Sriraman, 2005a, 2005b).
Another important perspective to mathematical modeling is that it
should also foster critical mathematics education (Skovsmose, 1994,
2000). Although the National Council of Teachers of Mathematics
(NCTM, 2000) calls for purposeful activities along with skillful questioning to promote the understanding of relationships among mathematical ideas, this recommendation can be pushed further and modeling
activities can be used as a way to cultivate critical thinking and critical

literacy (D'Ambrosio, 1998; Gutstein, 2006; Michelsen, 2006, Skovsmose, 2000; Sriraman & Lesh, 2006). In other words, modeling problems Nordic Studies in Mathematics Education, 12 (1), 23-47.
From problem solving to modeling
25
situated in the real world can also be used to foster critical mathematical
literacy. Critical mathematical literacy
1
holds that the aim of mathematics learning and teaching is not simply to impart procedural skills and
functional literacy but create situations in which students are able to identify, interpret, evaluate and critique the mathematics embedded in social
and political systems and claims. The literature also reports success of the
critical approach using data from newspapers, maps, advertisements, and
ecological data etc as a means of getting students to think about the basis
for decision-making and the inequitable societal distribution of resources
(Gutstein, 2006; Sriraman & Lesh, 2006).
Lesh & Sriraman (2005a) contend that in mathematics and science:
A Modeling is primarily about purposeful description, explanation, or
conceptualization (quantification, dimensionalization, coordinatization, or in general mathematization) – even though computation
and deduction processes also are involved.
B Models for designing or making sense of complex systems are, in
themselves, important "pieces of knowledge" that should be emphasized in teaching and learning – especially for students preparing
for success in future-oriented fields that are heavy users of mathematics, science, and technology. Therefore it is important to initiate and study modeling, particularly those of complex systems that
occur in real life situations from the very early grades.
This perspective traces its lineage to the modern descendents of Piaget
and Vygotsky, but also to American Pragmatists like John Dewey, George
Herbert Mead and Charles Sanders Pierce. The philosophy of this perspective (Lesh & Sriraman, 2005a, 2005b) is based on the premise that:
- Conceptual systems are human construct, and that they also are
fundamentally social in nature.
- The meanings of these constructs tend to be distributed across a
variety of representational media (ranging from spoken language,
written language, to diagrams and graphs, to concrete models, to
experience-based metaphors.
- Knowledge is organised around experience at least as much as
around abstractions – and that the ways of thinking which are
needed to make sense of realistically complex decision making
situations nearly always must integrate ideas from more than a
single discipline, or textbook topic area, or grand theory.N. MOUSOULIDES, B. SRIRAMAN AND C. CHRISTOU
26 Nordic Studies in Mathematics Education, 12 (1), 23-47.
- The "worlds of experience" that humans need to understand and
explain are not static. They are, in large part, products of human
creativity. So, they are continually changing – and so are the
knowledge needs of the humans who created them.
The models and modeling perspective adapts Zoltan Deines' instructional principles to design model eliciting activities. An example will help
better illustrate the notion of a model-eliciting activity. Suppose students
are asked to "rate" the quality of all the potential players on a volleyball
team and then select the team based on a consensus on the ratings. This
task requires students to gather/procure "objective" data related to players
speed, endurance, past performance, special abilities and reach "subjective" consensus on the criteria most valued for the selection of the team.
This is a model eliciting activity because it invokes the six instructional
principles of Lesh et al. (2003) namely, (1) the reality principle (i.e., does
the situation warrant sense making and extension of prior knowledge/
experiences?), (2) the model construction principle (i.e., does the situation create the need to develop (or refine, modify, or extend) a mathematically significant construct?, (3) the self-evaluation principle, (does
the situation require self-assessment?), (4) the construct documentation
principle (i.e., does the situation require students to reveal their thinking about the situation? (5) the construct generalization principle (i.e., is
the elicited model generalizable to other similar situations?) and finally
(6) the simplicity principle (is the problem solving situation simple?).
The construct of 'model-eliciting' circumscribes a problem solving situation, its mathematical structure, the mathematical models generated
as well as the problem solving processes that are invoked by the given
situation. Authentic examples of model eliciting activities based on the
design principles of Dienes are found in Lesh & Doerr (2003a). A recent
adaptation of the volleyball problem for the Danish context is the handball problem designed by Iversen and Larson (2006). The model eliciting
perspective is based on the premise that modeling research should take
into account findings from the realm of psychological concept development to develop activities which motivate and naturally allow students
to develop the mathematics needed to make sense of such situations.
More generally, models and modeling perspectives emphasize promising
aspects associated with both sociocultural theories and theories of situated cognition. Neither of these latter perspectives necessarily forces
researchers to re-examine their own basic assumptions about the changing nature of elementary mathematics – nor the changing nature of "real
life" problem solving situations in which some type of 'mathematical
thinking" is useful. In fact, just as in traditional research on problem
solving, both of these perspectives tend to begin with the assumption that Nordic Studies in Mathematics Education, 12 (1), 23-47.
From problem solving to modeling
27
the researcher already possesses clear and accurate conceptions about the
nature of elementary mathematics – and about what it means to "understand" relevant concepts and processes (Lesh, personal communication,
November 23, 2005).
A modeling perspective to problem solving leads to the design of an
instructional sequence of activities that begins by engaging students with
non-routine problem situations that elicit the development of signifi-
cant mathematical constructs and then extending, exploring and refining those constructs in other problem situations, leading to a generalizable system (or model) that can be used in a range of contexts (Lesh &
Doerr, 2003a, 2003b; English & Doerr, 2006). For instance, in problem
solving activities, referred to as model eliciting activities (Lesh & Sriraman, 2005a, 2005b), the products that students produce go beyond short
answers; they include sharable, manipulatable, modifiable, and reusable conceptual tools (e.g. models) for constructing, explaining, predicting and controlling mathematically significant systems (Lesh & Doerr,
2003a, 2003b).
Students' descriptions, explanations, and justifications form an integral component of the models the students produce. In contrast to many
of the problem situations students meet in school, modeling activities
are inherently social experiences, where students work in small teams to
develop a product that is explicitly sharable. Numerous questions, issues,
conflicts, resolutions, and revisions arise as students develop, assess, and
prepare to communicate their products (English & Doerr, 2006; Lesh &
Sriraman, 2005a,2005b).
In an attempt to review the related literature and provide a coherent
state of affairs, the literature review in the present paper is organized into
three major discussion strands. The first major strand situates mathematical modeling as being a problem solving activity and issues related to the
teaching, learning and assessment of modeling are discussed. The second
major strand presents some basic principles for designing modeling activities and finally, the third strand discusses the benefits for students and
teachers in working with thought revealing modeling activities.
Mathematical modeling as a problem solving activity
Inadequacy of traditional teaching approaches
A number of researchers raise the question of the appropriateness of
current teaching approaches in teaching mathematics and in mathematical problem solving in particular (Doerr & English, 2003; Sriraman &
Lesh, 2006). The inadequacy of traditional approaches is even worse in N. MOUSOULIDES, B. SRIRAMAN AND C. CHRISTOU
28 Nordic Studies in Mathematics Education, 12 (1), 23-47.
the case of students' work with problems that are less obviously linked to
school mathematics and require students to deal with unfamiliar situations by thinking flexibly and creatively (Lesh & Doerr, 2003a, 2003b). A
necessary distinction should be made between 'problem-solving' activity,
as proposed by Polya (1973) and Schoenfeld (1991) and relates to Dewey's
reflective thinking and the activity of "solving problems" and the traditional
use of word problems in a school environment. Polya (1962) stressed that
"in solving a word problem by setting up equations, the student translates
a real situation into mathematical terms; he has an opportunity to experience that mathematical concepts may be related to realities, but such relations must be carefully worked out" (p. 59). National Research Council
documented that mathematical problem solving rather deals with data
and observations from science. Mathematical modeling is far more than
just calculation or deduction; it involves observations of patterns, testing
of conjectures, and estimation of results (Schoenfeld, 1992). Word problems appear in most textbooks usually represent recontextualized forms
of decontextualized descriptions of everyday life situations. In most of
the cases, such problems are just exercises for specific types of mathematical learning, such as addition or subtraction (Wyndhamm & Saljö,
1997). Hiebert et al., (1996) pointed out that solving such word problems cannot prepare students for everyday life, since students are not
able to transfer the specific domain-related knowledge (mathematics)
and also more general problem- and solution-related skills. Their recommendation was to base instructional design on problem solving in outof-school situations, rather than on problem-solving models of limited
applicability (Hiebert et al., 1996).
A significant number of recent research studies pointed out that the
practice of word problem solving in school mathematics hardly matches
this idea of mathematical modeling and mathematization (Reuuser &
Stebler, 1997; Kaiser, Blomhøj & Sriraman, 2006; Kaiser & Sriraman,
2006; Mousoulides et al., 2006). As a result, students readily 'solve'
unsolvable, even absurd, problems if presented in ordinary classroom
contexts. Students do not have opportunities to do mathematics; students
look for key words, employ direct translation strategies when solving
stereotyped word problems and their ability in solving these problems
is influenced by contextual information (Greer, 1997, Verschaffel, De
Corte & Lasure, 1994; Yoshida, Verschaffel & De Corte, 1997).
The role of context in mathematical modeling
Although modelling problems are contextualized by nature, and authentic problems always manifest themselves in a context, it is nevertheless Nordic Studies in Mathematics Education, 12 (1), 23-47.
From problem solving to modeling
29
important to explicitly address the role and the nature of contexts used.
The role of context is very important in mathematical modeling, since
modeling requires a context in which to "frame" the problem and "develop"
the mathematics. This meaning of contextual teaching and learning is
close to the notion of situated learning (de Lange, 1992). Researchers
have documented a number of different functions a "realistic context" can
play in problem solving. De Lange (1987) listed the following functions:
enabling concept formation, facilitating model formation, providing a
wider range of utility and more interesting practice problems. Similarly,
DaPueto and Parenti (1999) reported the following factors for using a
realistic context in mathematical problem solving:
A Facilitating collaboration, interaction and contribution of students
who have different styles of exploration/understanding/use of concepts, different levels of formalized knowledge, etc,
B helping more balanced development of reflective learning and experiential learning, and
C facilitating the design and restructuring of the schemata through
which knowledge is organized (p. 7).
A number of researchers commented on the importance of contextual
based problem solving. Bohl (1998) identified the lack of relevance as a
critical factor in engaging students in problem solving. Bohl (1998) documented that the use of contextual settings has the potential to assist
students in actively be engaged in problem solving. Pace (2000) further
pointed out that students need to experience real-world situations in the
chosen context before they can create models for solving world based
problems related to the same context. Contextual based teaching encourages the development of an active learning environment which in turn
generates better mathematical understandings by the students (Pace,
2000). In line with previous findings, Gravemeijer and Doorman (1999)
stressed that research on the design of Realistic Mathematics Education
(RME) based activities has shown that the use of personalized contexts
improved word problem solving by increasing the meaningfulness of
contexts and enhancing student motivation. Gravemeijer and Doorman
(1999) also claimed that "well-chosen context problems offer opportunities for the students to develop informal, highly context-specific
solution strategies" (p. 117).
Research has also indicated a number of possible limitations related
to the use of contexts in problem solving. The choice of context may
be a turn-off to particular students or be so familiar as to inhibit some N. MOUSOULIDES, B. SRIRAMAN AND C. CHRISTOU
30 Nordic Studies in Mathematics Education, 12 (1), 23-47.
approaches judged as unreasonable (Choi & Hannafin, 1997). McNair
(2000) pointed out that if the situation and experience used are not familiar to the students, then instruction may degenerate into the presentation
of abstract ideas related to the context. Finally, Resnick (1988) addressed
that there is a need for finding ways to create in the classroom situations
of sufficient complexity and engagement that they become mathematically engaging contexts in their own right.
Affective factors and mathematical modeling
The importance of the affective domain and students' communication in
classroom work is stressed in a number of research studies (Lesh & Doerr,
2003a, 2003b; Gravemeijer, 1997; Verschaffel, De Corte & Borghart,
1997). Yoshida, Verschaffel & De Corte (1997) reported that mathematical problem solving is now also focussed to student attitudes and beliefs
and their capacity to apply their mathematical knowledge in non-routine
problems. Verschaffel and his colleagues (1997) documented that student
efficacy beliefs could act as a predictor of student achievement in solving
authentic problems. The importance of considering student conceptions
is also pointed out by Confrey & Doerr (1994), who argued that the use
of learner-centered modeling tools and approaches can create positive
beliefs in the mathematics classroom. The use of realistic mathematical
modeling problems can enhance student sense-making, while bringing
real-world situations into school mathematics is a necessary condition
to foster a positive attitude towards mathematics. In line with previous
findings, Bonotto and Basso (2001) interestingly reported that bringing
real-world situations into school mathematics is a necessary condition to
foster a positive attitude towards mathematics for many students.
While the use of modeling as a problem solving activity can positively
change student beliefs towards mathematics, a significant hazard in teaching mathematical modeling is teachers' pre-conceived beliefs, and the
projection of those beliefs onto their students. Verschaffel and his colleagues (1997) reported a strong and resistant tendency among teachers
to exclude real-world knowledge when teaching arithmetic word problems. Teachers' pedagogical beliefs stressed that non routine problems
are less important and the goal of teaching word problem solving is to
find the correct numerical answer. Verschaffel and his colleagues (1997)
concluded that these teacher attitudes and beliefs about the significance
of real world knowledge in problem solving have a negative impact of their
teaching practices and consequently on their students' learning processes
and outcomes. Nordic Studies in Mathematics Education, 12 (1), 23-47.
From problem solving to modeling
31
A quite interesting aspect of the relation between teachers' beliefs and
implementation of authentic problems in the classroom is raised in the
work of Doerr and English (2006). They documented that selecting and
teaching appropriate activities whose features can promote powerful
student learning can be a key component in teachers' negotiation of both
mathematical knowledge and pedagogical content knowledge. The new
roles in the practice of problem solving that teachers adopt and the negotiation of their knowledge can be the first steps in changing teachers'
attitudes and beliefs towards mathematical modeling in a positive way
(Doerr & English, 2006).

Assessment in mathematical modeling
Niss (1987) pointed that assessment of modeling could be problematic,
since modeling is difficult to assess, let alone test, by traditional evaluation
tools. Niss (1993) further clarified that assessment takes time and cannot
be standardised. It does not imply that assessment cannot be exercised
on a sound foundation of reflection and reasoning and articulate criteria
and be subject to clear communication (Niss, 1993).
A number of different types of assessment being used to evaluate
students' modeling abilities and understanding of models are found in a
review of the literature. Crouch and Haines (2004) used a multiple choice
format, in developing several test questions related to modeling. Kitchen
(1993) proposed questions requiring students to set up a model, interpret
a solution, or criticize a model based on the data, while Bell et al. (1992)
and Hjalmarson (2005) suggested the use of an analytic scoring scale, by
assigning point values to various dimensions of the modeling work.
Model eliciting activities: design and research
Modeling processes in problem solving
The modeling approach to problem solving suggests that there is not a
single powerful procedure between givens and goals and a set of 'strategies' for overcoming any difficulties in this procedure. Indeed, the modeling approach indicates a number of trial procedures between givens and
goals in order to succeed a solution. This includes a number of iterative
cycles, in which students move back and forth from givens to goals, go
back and again moving towards goals to test their hypotheses, refine their
results and to improve their solutions (Lesh & Doerr, 2003a, 2003b). N. MOUSOULIDES, B. SRIRAMAN AND C. CHRISTOU
32 Nordic Studies in Mathematics Education, 12 (1), 23-47.
A number of relevant works (Lesh et al., 2003; Blum & Niss, 1991) have
documented the different processes involved in mathematical modeling
as problem solving activity. In particular, students engage in the following processes: (a) Understand and simplify the problem. This included
understanding text, diagrams, formulas or tabular information and
drawing inferences from them; demonstrating understanding of relevant
concepts and using information from students' background knowledge
to understand the information given. (b) Manipulate the problem and
develop a mathematical model. These processes included identifying the
variables and their relationships in the problem; making decisions about
variable relevancy; constructing hypotheses; and retrieving, organising,
considering and critically evaluating contextual information; use strategies and heuristics to mathematically elaborate on the developed model.
(c) Interpreting the problem solution. This included making decisions,
analysing a system or designing a system to meet certain goals, and diagnosing a malfunction and proposing a solution. (d) Verify, validate and
reflect the problem solution: This included constructing and applying
different modes of representations to the solution of the problem; generalizing and communicating solutions; evaluating solutions from different
perspectives in an attempt to restructure the solutions and making them
more socially or technically acceptable; critically checking and reflecting on solutions and generally question the model (Blum & Kaiser, 1997;
Lesh & Doerr, 2003a, 2003b).
Student and teacher models
A model is an internal conceptual system plus the external representations of that system used to interpret other complex systems (Lesh &
Doerr, 2003a, 2003b; Lesh, Doerr, Carmona & Hjalmarson, 2003). Typically, this definition of model has only been used in reference to student
or teacher thinking and learning (e.g., Doerr & Lesh, 2003). To provide
a parallel construct at the researcher level, a design experiment carried
out from a models and modeling perspective (a modeling design experiment) should be consistent with this definition. The design tested by the
experiment encompasses two parts (similar to a model). Namely, the
design includes theoretical assumptions (i.e., researcher-level conceptual systems about mathematical knowledge, models, teacher development, etc.) and external artifacts
2
(Lesh & Doerr, 2003a, 2003b; Lesh
& Sriraman, 2005a, 2005b). Models consist of an internal conceptual
system and external artifacts or representations (Lesh & Doerr, 2003a,
2003b; Lesh et al., 2003). In addition, models incorporate a number of Nordic Studies in Mathematics Education, 12 (1), 23-47.
From problem solving to modeling
33
external representations (e.g., a graph, a table). In constructing models,
students identify, select and collect relevant data, express limitations and
conditions of a model, interpret the solution in context, communicate
effectively and describe situations using a variety of representation
forms.
Characteristics of modeling activities
The different tools being designed and created to facilitate students' and
teachers' externalization of their thinking and understandings of problem
situations aim to elicit their thinking and thus researchers are referring to
these tools as model eliciting activities (Lesh et al., 2003; Lesh & Sriraman, 2005a, 2005b). As stated earlier, in model eliciting activities students need to: (a) develop a model(s) that describes a real-life situation,
(b) use their models to describe, revise, and refine their ideas; and (c)
use a number of representational media to explain (and document) their
conceptual systems. Model-eliciting activities can be designed to lead to
significant forms of learning because they involve mathematizing - by
quantifying, dimensioning, coordinating, categorizing, algebraizing, and
systematizing relevant objects, relationships, actions, patterns, and regularities. An example of a model eliciting activity for students is intended
to reveal the way students are thinking about a real life situation that can
be modelled through mathematics. The solution calls for a mathematical model to be used by an identified client who needs to implement the
model adequately. As a result, students must clearly describe their thinking processes and justify not a single solution, but rather all (or most of)
the optimal and appropriate solutions (English, 2003). Students' engagement with such mathematical tasks results in developing math concepts
through the need to develop powerful math ideas in order to solve a
problem. Thus, they are given a purpose (and End-in-View) (English
& Lesh, 2003) to develop a mathematical model that best describes,
explains, predicts, or manipulates the type of real-life situation that is
presented to them. In this way, model-eliciting activities allow students
to document their own thinking and learning development. The aim of a
modeling activity engages problem specification and validation, engage in
critical usage of modeling, participation and communication skills; foster
creative and problem solving attitudes, activities, competencies; provide
the opportunity for students to practice applying mathematics that they
would need as individuals in society; to contribute to a balanced picture
of mathematics; to assist in acquiring and understanding mathematical
concepts (Battye & Challis, 1997). N. MOUSOULIDES, B. SRIRAMAN AND C. CHRISTOU
34 Nordic Studies in Mathematics Education, 12 (1), 23-47.
Types of the modeling activities product
Model Eliciting Activities include three types of products; tools, constructions and problems.
1 Product as a tool: Tools fulfil a functional or operational role and they
include:
A Models. Models are used for ranking items, people and places;
determining loan payments and may form the base of complex
systems such as company's financial operations (ranging from productive systems to administrative systems and societal systems
such as income tax and insurance models.
B Descriptions and explanations. Descriptions and Explanations illustrate and verify the results of an experiment or investigation or may
describe why something that appears superficially correct is mathematically incorrect.
C Designs and plans. Used in all walks of life, designs and plans must
meet detailed and complex criteria and must incorporate appropriate mathematical and representational systems.
D Assessment instruments. They are used in a wide range of contexts
such as assessing learner's progress, and selecting staff. They normally undergo rigorous development that incorporates cycles of
testing, refining and applying. (Lesh & Doerr, 2003a, 2003b)
2 Product as a construction. A construction normally requires students
to use given criteria to develop a mathematical item. They do not define
the nature of the product rather they set parameters for the design of the
product. A construction can be in the form of:
A Spatial constructions.
B Complex artefacts. Inventions are a good example of complex artefacts. The criteria for their design frequently focus on deficits in
existing artefacts or on perceived societal needs.
C Cases. Cases make use of persuasive discourse to adopt a stance
on an issue, to recommend one course of action over another, or to
highlight an issue in need of attention. Cases are especially effective
when they draw upon mathematical data to support their claims.
D Assessments. They are the products of applying an assessment tool.
Such products can serve a number of purposes and usually suggest
or imply courses of action. (Lesh & Doerr, 2003a, 2003b)Nordic Studies in Mathematics Education, 12 (1), 23-47.
From problem solving to modeling
35
3 Problem as a product. The ability to pose problems is becoming increasingly important in academic and vocational contexts. During modeling cycles involved in model eliciting activities students are engaged
in problem posing, that is, they are repeatedly revising or refining their
conception of the given problem. During the model eliciting activities,
students find ways to judge strengths and weaknesses of alternative ways
of thinking and whether a given response is appropriate and good enough
(Lesh & Doerr, 2003a, 2003b; English & Lesh, 2003).
Principles for modeling activities
One defining characteristic of a design experiment is that the researchers
create, test, and modify a design within the context of use (Design-Based
Research Collective, 2003). For example, the researchers may be testing
a new curriculum or teaching method in a classroom (e.g., Erickson &
Lehrer, 1998; Verschaffel, De Corte & Borghart, 1997). This characteristic is consistent with model-eliciting activities that ask students to
develop mathematical models to explain real-life situations. The development of a design or model is also often cyclic (Lesh & Lehrer, 2003). In
a typical series of cycles, the student expresses thinking in some artifact
or product, tests the artifact, and then revises the artifact. For example,
a student creating a consumer guide for buying a car developed a spreadsheet for scoring characteristics of cars, asked other members of their
group or class to test the appropriateness of their scoring guides (to test
the product), and then revised the product based on testing results to
improve their solution (improve the product) (Hjalmarson, 2005). The
students' revisions are guided by a purpose (end-in-view) that describes
the functions the final product should be able to perform (English & Lesh,
2003). Similarly, for modeling design experiments, researchers should
have some end-in-view for the product under development. The end-inview should guide researcher decision-making about revisions that are
made to the product from research cycle to research cycle.
An important caveat is that for design experiments using a models
and modeling perspective, the assumptions and understandings of the
teachers (and researchers) may change throughout the study. It is imperative to document those changes as they are made (Lesh & Sriraman,
2005b). Often, researchers are interested in the students' development
of responses or in how student models change within a session or between
modeling sessions. So, rather than studying fixed constructs or examining snapshots of constructs in isolation, researchers may be studying changes in constructs over time and across problems and individuals. Capturing change and the effects of change can be a goal of design N. MOUSOULIDES, B. SRIRAMAN AND C. CHRISTOU
36 Nordic Studies in Mathematics Education, 12 (1), 23-47.
experiments with a models and modeling perspective. So, both components of the design (theoretical assumptions and artifacts) will change
just as for students' models both the internal conceptual system and the
external representations change. This characteristic is another example
of how the researcher-level design experiment should be consistent with
the student-level.
For model-eliciting activities, a crucial component is the local context
that situates the task. The context guides the students' development of
solutions, aids in their decision-making about whether a way of thinking is 'bad' or 'good', and helps them place the end-in-view in a context
that is real to the students (English & Lesh, 2003). The context situates the usefulness of the design and aids development since the final
product should be useful in that context (Design-Based Research Collective, 2003). However, this does not suggest that the products are not
generalizable to other situations (or contexts). As with model-eliciting
activities where students develop a product for a particular client that
is generalizable to other (similarly structured) situations, designs should
also be generalizable to other educational situations. This proviso means
that the researcher needs to outline precisely the conditions under which
the design was used and possible modifications that may need to be made
for the design to be appropriate for different situations (Design-Based
Research Collective, 2003).
Collaboration is also a component of design experiments following the
modeling perspective that parallels assumptions about student learning.
Collaborators may include researchers, teachers and students proceeding along multiple levels of development similar to multi-tiered teaching experiments (Kelly & Lesh, 2000; Lesh & Kelly, 2000; Schorr &
Lesh, 2003). Researchers need teachers to help design, test and implement products. Products should be developed with teachers' questions
about their own practice in mind (e.g. personal meaningfulness), and
researchers can provide resources to aid teacher development (DesignBased Research Collective, 2003). There may also be multiple teachers or
researchers involved in the development of any product. This characteristic can aid the triangulation of interpretations about results and the generalizability of results if products have been tested in multiple contexts.
Collaboration also aids the documentation of results by requiring that
strategies or tools need to be communicated to other people for comment
(e.g., individual teachers develop a ways of thinking sheet or concept map
to share with the group) (e.g., Koellner Clark & Lesh, 2003).Nordic Studies in Mathematics Education, 12 (1), 23-47.
From problem solving to modeling
37
Appropriateness, usefulness and benefits of modeling activities
It is imperative that mathematics educators take students beyond the
traditional classroom experiences, where problem solving rarely extends
their thinking or mathematical abilities or where modeling competencies
are developed. There is a strong need to implement worthwhile modeling experiences in the elementary and middle school years if teachers
are to make mathematical modeling a successful way of problem solving
for students.
Modeling activities have been found appropriate to enhance students'
and teachers' capacities to engage in problem solving, thereby laying the
foundation for exploring complex systems (Lesh et al., 2003). These
activities are highly innovative learning experiences (English, 2003). A
number of related features have emerged, indicating a number of benefits
of modeling activities, both for students and teachers. Modeling activities
provide a pathway in understanding how students approach a mathematical task and how their ideas develop; these activities appear to provide
a strong basis for teachers to interact with students in ways that would
promote their learning (Doerr, 2006). In the following part of the literature review we summarize the benefits for students and teachers while
working with thought revealing modeling activities, including benefits in
student mathematical literacy and conceptual understanding, in student
social development, in student metacognition, and in teacher pedagogical
approaches and teaching practices.
Mathematical literacy and student conceptual understanding
Related research in mathematical modeling indicated that student work
with modeling activities assisted students to build on their existing understandings and to be successfully engaged in thought-provoking, multifaceted complex problems (Lesh & Doerr, 2003a, 2003b; English, 2003).
Modeling activities set within authentic contexts, allow for student multiple interpretations and approaches, promoting intrinsic motivation and
self regulation. A number of related research studies showed that the use
of modeling activities encouraged students to develop important mathematical ideas and processes that students normally would not meet in
the traditional school curriculum (English & Watters, 2004; Zawojewski,
Lesh & English, 2003). The mathematical ideas are embedded within

meaningful real-world contexts and are elicited by the students as they
work the problem. Furthermore, students can access these mathematical
ideas at varying levels of sophistication. Student work in modeling activities facilitates student development of generalizable conceptual systems.
Students move beyond just thinking about their models to thinking withN. MOUSOULIDES, B. SRIRAMAN AND C. CHRISTOU
38 Nordic Studies in Mathematics Education, 12 (1), 23-47.
them for solving an important world based problem. English (2003)
reported that there was considerable evidence that students' mathematical ideas had improved after they worked in a sequence of modeling activities. Mathematical language improved but also considerable fluency with
the use of tables and data were acknowledged (English, 2003). However,
there was an acceptance that students needed to know basic operations
to be effective in these activities. Gravemeijer and his colleagues (2000)
related their work in connection with Freudenthal's (1971) comprehension of mathematics as an activity that involves solving problems,
looking for problems, and organizing subject matter resulting from prior
mathematizations or from reality.
Lesh and Doerr (2000) have pointed out that modeling activities
can promote students' conceptual understanding. They clarified that in
modeling activities students are not simply working with ready made
models. Since models are interacting systems based in more complex
conceptual systems, Lesh and Doerr (2003a) claimed that models must
be constructed in a meaningful way. This construction leads to conceptual understanding and mathematization (Lesh & Doerr, 2003a, 2003b;
Sriraman & Lesh, 2006).
Harel and Lesh (2003) further stressed the importance of modeling
activities by highlighting that student work on modeling activities can
enhance student conceptual systems. They documented that conceptual
systems are developed first as situated models that apply to particular
problem solving situations. Then, these models are gradually extended
to larger classes of problems as they become more sharable, more transportable, and more reusable. The aforementioned features of modeling
activities helped students be successful beyond problem situations for
which models were created (Harel & Lesh, 2003).
Lesh and his colleagues (2003) and English (2003) investigated the
role of modeling activities with regard to student algebraic reasoning.
Lesh et al., (2003) reported that modeling activities provide opportunities for students to explore quantitative relationships, analyze change,
and identify, describe, and compare varying rates of change, as recommended in the Grades 3-5 algebra strand of the Principles and Standards
for School Mathematics (NCTM, 2000). In addition, English (2003)
pointed that elementary probability ideas emerging when young students
linked the conditions and constrains of problems (e.g., drug pain relief
activity). The above research studies have also highlighted the contributions of these modeling activities to young students' development of
mathematical description, explanation, justification, and argumentation.
Modeling activities are inherently social activities, and as so, students
engage in numerous questions, conjectures, arguments, conflicts, and Nordic Studies in Mathematics Education, 12 (1), 23-47.
From problem solving to modeling
39
resolutions as they work towards their final products. Furthermore, when
they present their reports to the class they need to respond to questions
and critical feedback from their peers (English & Watters, 2004; Zawojewski, Lesh & English, 2003; Lesh & Doerr, 2003a, 2003b; Sriraman
& Lesh, 2006).
An important parameter in students' work in modeling activities is
students' use of their informal knowledge. Researchers have observed
the interplay between students' use of informal, personal knowledge and
their knowledge of the key information in the problem (Zawojewski,
Lesh & English, 2003; Mousoulides et al., 2006). In a number of modeling activities, students' informal knowledge helped them relate to and
identify the important problem information (e.g., understanding and
interpreting the conditions for the solution of a problem). Doerr (2006)
and Doerr & English (2003) also documented that students embellished
their written reports with their informal knowledge and most importantly, many students recognized when their informal knowledge was
not leading them anywhere and thus students reverted their attention to
the specific task information (Doerr, 2006; Zawojewski, Lesh & English,
2003; Lesh & Doerr, 2003a, 2003b).
Concluding points
As the literature review has pointed out, it is vital that the mathematics education research community continually revisit the fundamental
question: What does it mean for a younger student to understand models
and modeling? Another important point we stress is that the models and
modeling perspectives in North America and other parts of the world
(like Cyprus and Australia) have evolved out of the limitations of problem
solving research and the need to take into account the claim (which we
hear from many) that the nature of problem solving (and 'mathematical
thinking') has changed dramatically in the past 20 years (see Lester &
Kehle, 2003; Lesh, Hamilton & Kaput, in press).We also think there is
a real need for research about: (i) the nature of new 'real life' situations
where some type of mathematical thinking in needed for success, (ii)
what it means to understand relevant knowledge and abilities, (iii) how
these ideas and abilities develop, and (iv)how development can be documented and assessed. There is also a need to focus on a call for research
which takes into consideration what we already know about concept
development in children. Sriraman & Lesh (2006) argue that today, when
some kind of mathematical thinking is needed to solve real problems,
the products that need to be produced often involve much more than
short answers to pre-mathematized questions. For example, they often N. MOUSOULIDES, B. SRIRAMAN AND C. CHRISTOU
40 Nordic Studies in Mathematics Education, 12 (1), 23-47.
involve developing conceptual tools (or other types of complex artifacts)
which are designed for some specific decision maker and for some specific decision-making purpose – but which seldom are worthwhile to
develop unless they go beyond being powerful for a specific purpose to
being sharable with others and re-useable beyond the immediate situations in which they were first needed. Consequently, solution processes
often involve sequences of iterative development → testing → revising
cycles in which a variety of different ways of thinking about givens, goals,
and possible solution steps are iteratively expressed, tested, and revised
(e.g., integrated, differentiated, or reorganized) or rejected. That is, the
development cycles often involve a great deal more than simply progressing from pre-mathematized givens to goals when the path is not obvious.
Instead, the heart of the problem often consists of conceptualizing givens
and goals in productive ways.

Notes
1 It is important to distinguish between mathematical literacy for critical citizenship (D'Ambrosio) and the formatting power of mathematical models
in society (Skovsmose). This indicates a need for critical competencies
towards modeling and the use of models.
2 By this we mean representations of the researcher-level conceptual system
in the form of interventions, curriculum, etc
Nicholas Mousoulides
Nicholas Mousoulides is a Ph.D. candidate, researcher and educational
personnel of mathematics education at the University of Cyprus. His
research focuses on the implementation of ICT in mathematics education and the effect of integrating modeling in the learning and teaching
of mathematics. He participated as a researcher in seven European and
national research projects. His main research interests are modelling and
applications, curriculum development in computer based environments,
and student cognitive and mathematical development.
Bharath Sriraman
Bharath Sriraman is associate professor of mathematics at the University
of Montana, with a wide range of eclectic research interests including
mathematical modelling. He received his PhD from the department of
mathematics at Northern Illinois University, USA. Bharath is the editorin-chief of the Montana Mathematics Enthusiast, <http://www.montanamath.org/TMME/>, associate editor of ZDM - the International Journal
on Mathematics Education (formerly known as Zentralblatt für Didaktik
der Mathematik), consulting editor of Interchange: A Quarterly Review
of Education, and reviews editor of Mathematical Thinking & Learning as well as ZDM. He holds very active research ties with researchers working in his domains of interest in Australia, Canada, Cyprus,
Denmark, Germany, Iceland, India, Turkey and USA.Nordic Studies in Mathematics Education, 12 (1), 23-47.

Arit UYOUKO PREFACE
This volume contains the Doctoral Student Consortia Proceedings of the 20th
International Conference on Computers in Education (ICCE 2012). For this year, the
Doctoral Student Consortia (DSC) brings together PhD students working in the broad
research areas of computers in education in the following seven sub-themes: (1) Artificial
Intelligence in Education/Intelligent Tutoring Systems and Adaptive Learning
(AIED/ITS/AL); (2) Computer-supported Collaborative Learning and Learning Sciences
(CSCL/LS); (3) Advanced Learning Technologies, Open Contents, and Standards
(ALT/OC/S); (4) Classroom, Ubiquitous, and Mobile Technologies Enhanced Learning
(CUMTEL); (5) Digital Game and Digital Toy Enhanced Learning and Society (GTELBS); (6)
Technology Enhanced Language Learning (TELL); and (7) Technology, Pedagogy and

Education (TPE).
The DSC aims to provide an opportunity for a selected number of PhD students to present, discuss and receive feedback on their dissertation work-in-progress from a panel of established researchers with expertise in the same research areas. The DSC is meant to help students to shape their research methodologies, and to develop analysis methodologies at the early stages of their PhD research using the guidance and feedback that they get from the invited mentors. Mentors can also provide insights into fruitful areas for future research. The DSC also hopes to nurture a supportive learning community and promote interactions among the young researchers who come from a number of different institutions and across different countries in the Asia-Pacific region and beyond. It also provides opportunities for theme-based forums to discuss evolving methodological and theoretical issues of central importance to the community. The DSC and the related social events are financially supported by the Asia-Pacific Society for Computers in Education (APSCE).
A group of senior PhD students (Kevin Kai-Wing CHAN, Chia-Jung CHANG, Jaime GALVEZ, Anita HUANG, Wai Ying KWOK, Rose Ru-Whui LEE, Tuck Leong LEE, Mengmeng LI, Larry Lei Chun LIN, Boon See TAN, Arit UYOUKO) who were highly recommended by the APSCE Special Interest Group Chairs (SIG) Chairs/Co-Chairs were invited to be the organizers of this prestigious event. This group of senior PhD students is guided by the DSC Chairs (Weiqin CHEN, Chen-Chung LIU, and Hiroaki OGATA). The DSC chairs helped oversee the whole process of organizing the DSC and provided guidance along the way. With a strong sense of responsibility and enthusiasm, this highly dynamic group has been successful in organizing the DSC for ICCE 2012. It is clear that by entrusting this group of senior PhD students with the responsibility of organizing this important event and editing the DSC Proceedings, they were able to form a vibrant and supportive research community within a short period of time; which is one of the main goals of the APSCE. This year we received a total of 10 submissions, and 9 of these papers were selected and have been included in the Proceedings. Each selected paper went through a rigorous blind review by independent peer reviewers to ensure the work was of high quality. We hope that the papers in the proceedings on various research topics will stimulate additional research ideas and discussions among the young researchers.
We would like to thank all the invited mentors in making this year's DSC a highly successful event. Finally, we would like to take this opportunity to record our sincerest appreciation to the local organizers in Singapore for their valuable support and arrangement in organizing the DSC.
On behalf of DSC Co-Chairs

Abstract: Technology has made it convenient for students today to learn outside of the classroom. However, learning in this kind of setting introduces challenges such as proper time management, maintaining motivation and avoiding distractions. This research investigates how student learning progresses in this unsupervised learning environment and proposes an automated support mechanism that promotes self-regulation to help students learn. The proposed system is not bound to any domain and its methodology supports learning in naturalistic settings. Results gathered from students' use of a system prototype confirmed the problems students encounter when learning in this environment and their need for support. It also showed that helping students self-regulate made them aware of their learning behavior and helped them identify ways to improve their learning efficiency.
Keywords: learning, unsupervised learning environment, feedback, self-regulation
Introduction
Student learning is not bound to formal learning settings in classrooms. Students continue to learn on their own in the library, in their homes or with their peers. Technology has made it even easier for them to learn because it gives them easy access to information anytime and anywhere. However, informal learning settings introduce challenges such as the need to self-motivate, manage time and resist distractions to learn effectively.
In formal learning settings, students are discouraged from engaging in non-learning activities such as chatting with friends or playing games. Students are also required to use certain skills and solve problems within given time frames. However, informal learning settings give students more control over their time and goals. Students can engage in non-learning activities freely which may benefit them by helping them de-stress and disengage from feelings of frustration and helping them move into more positive emotional states which allow them to regain motivation and resume learning [5]. The duration, frequency and type of non-learning activity will have different effects on students thus there also has to be a certain configuration for non-learning activities to be helpful. Students know themselves best so they are also the best persons to identify what is most effective for them. Our goal is to improve students' learning efficiency as they learn in informal learning settings by helping them self-regulate.
1. Literature Review
Self-regulation is a systematic process for promoting the attainment of goals and is composed of the cyclic phases of forethought, performance and self-reflection [6]. Forethought involves the formulation of goals for the learning session which serve as guides 2 on what activity to do. Performance involves doing activities that will accomplish the previously defined goals and monitoring progress to identify if there is a need to adjust goals or strategies. Self-reflection involves the assessment of the learning session, attribution of the causes of unfavorable behavior during the learning session and the identification of possible strategies to increase learning efficiency in succeeding learning sessions.
Self-regulation facilitates good learning behavior and its benefits have not only spawned research in traditional classroom settings, but also in more modern settings such as in computer-based learning environments. Systems like MetaTutor [1] and Process Coordinator [4] allow students to keep track of the self-regulation strategies they use and also suggest strategies that can help them accomplish their goals as they learn in computer-based formal learning settings. However, these systems expect students to engage only in learning related activities during the session. Research has shown that students use and actually prefer learning activities outside of the classroom apart from classroom-based activities [2]. Students' preference for learning in this domain and the challenges they encounter highlight the need to support them.
2. Proposed Research and Preliminary Research Questions
This research investigates the interplay between students' learning and non-learning activities while learning in an informal learning setting and the support that can be given to help students self-regulate and increase learning efficiency. We limit our work to informal learning settings that involve the use of a computer because work done on or in front of a computer can be logged automatically and because computer systems can provide automated support to help students self-regulate.
We use the term unsupervised learning environment to refer to informal learning settings wherein students learn by using a computer without supervision from a teacher. In this environment they need to identify their own goals, manage their learning, avoid distractions and self-motivate to learn efficiently. We aim to accomplish the research's goals by answering the following general and specific questions:
How do we help students self-regulate in an unsupervised learning environment to improve learning efficiently?
1. How can we help students define and prioritize their learning goals?
2. How can we help students become more aware of their activities while learning and encourage them to change their behavior that is not helpful to learning?
3. How can we help students self-reflect and identify ways to improve their learning?
4. Does helping students self-regulate when they learn in an unsupervised learning environment improve their learning efficiency?
3. Architectural Framework
The framework we are using for this research consists of three cyclic phases with elements based on the three aforementioned self-regulation phases and is illustrated in Figure 1. In the interaction phase, students are asked to identify and input their goals at the beginning of a learning session. After which, students start the learning session wherein information about their actions such as applications used, timestamps and screenshots of the desktop and webcam are recorded and stored in an interaction database. The system provides timely feedback to help students keep track of their activities and progress and to help them identify if there is a need to adjust them. In the annotation phase, students review their learning session with the help of the desktop and webcam screenshots recorded. Students 3 then annotate their activities on the computer (e.g., browsed a web page, read a textbook), identify if it is related to their learning goals or not and indicate when they felt distracted from their learning goals. Students are also asked to comment on the system's feedback during the learning session and rate their learning efficiency for the session. In the modeling phase, a machine learner will be used to create a predictive model from the annotated data to identify which conditions cause students to become distracted. Another machine learner will be used to incrementally adjust a feedback model to fit the students' feedback preferences. Feedback adjustments result in changes in feedback type, frequency and conditions. The updated distraction and feedback models are used by the system in the next learning session to decide when and what type of feedback should be given to the student. Over time, the adjustments will result in better models of the students' behavior and feedback preference thus, improving the feedback mechanism.
Figure 1. Architectural Framework of the Proposed System
4. Preliminary Results
An initial prototype of the system with both the interaction and annotation phases was created and tested on four students doing academic research [3]. The subjects were mostly graduate students working on different domains (i.e., computer science and physics) but were all required to do research and present results to their respective supervisors once a week. Academic research was considered an unsupervised learning environment because students did their work on a computer, managed their own learning and didn't receive direct guidance from their supervisor. Each student used the system for approximately two hours in one learning session per day over the period of five days resulting in 10 hours of data per student. After each learning session, students spent about an hour to annotate their data, which is around half of the learning session's duration. Surveys and informal interviews were also conducted to further verify and understand the students' learning behavior.
A transition likelihood metric was used on the annotated data to identify the likelihoods

of transitioning between states, wherein each state consisted of a student's emotion and intention (i.e., learning or non-learning). The results showed that students transitioned between feelings of engagement and confusion which were indicative of cognitive disequilibrium, a state commonly experienced by students when learning. Students were also constantly shifting to non-learning activities which may have served as distractions. However, students shifted back to learning which indicated that non-learning activities may also have served as rewards and de-stressors that helped motivate students to resume learning at a later time. Both effects of non-learning activities were also reported by students in the survey results collected. During the interview, we found out that students used varying measures for learning efficiency which included the number of completed learning goals, the amount of time spent in learning activities and the difference between what they learned from the session and their self-expectations. Furthermore, students said that they were able to identify what caused them to learn inefficiently and also what they could do to improve their learning behavior.
The next step in our research is to use our preliminary results to design and automate feedback provision based on the students' annotations, learning efficiency ratings and proposed solutions for improving their learning behavior. This feedback also needs to be verified if it translates to actual learning improvements through pretests and posttests.
5. Conclusion
This research investigated learning in an unsupervised learning environment and proposed a self-regulation based automated support mechanism to help students learn. The designed methodology allows students to learn in a naturalistic environment and helps them become more aware of how often, how long and which non-learning activities were helpful or harmful to their learning. The methodology also allows students to self-reflect and identify how they can improve their learning efficiency. The kind of support given by the system is not domain dependent so it is able to provide support for learning as long as it is done on or in front of a computer. Self-regulation is an important skill for life-long learning which the system promotes through honing students' self-regulation skills outside formal learning settings without the need of human supervision.

Exploring Discourses: Third Culture Kids'
digital lives
Jeanette HANNAFORD
PhD Candidate, Griffith University, Australia
jeanette.hannaford@griffithuni.edu.au
Abstract: An important question for research is the ways in which children from globally mobile families negotiate the different Discourses they encounter through mass-media digital technologies, the home, and the classroom. The study reported on here took the form of a multiple case study, which was undertaken at a European International School over the course of a school year. This paper focuses on students' digital game play documented within the different contexts of classroom and out-of-classroom environments. It reports on the social dynamics and the productive outcomes made possible in spaces such as these, and the ways these children negotiated, appropriated or embraced the Discourses that they found as part of their ongoing work in establishing social identity.
Keywords: Identity, digital play, third culture kids, literacy education
Introduction
Issues of identity are of intense significance for the globally mobile child, and so too is digital play, as a forum for both pleasure and community. To inform contemporary pedagogy and curriculum in school, more information is needed about the ways in which issues of identity present themselves in on and offline contexts, and the ways in which children in turn negotiate them. To explore children's integration of digital games into their lives, for my Master's research study I held a series of after school computer clubs in the International School in which I was teaching. Through these clubs, I investigated the children's imaginative engagement with internet games [1] [2]. This research prompted more questions, particularly concerning identity and digital play, and the challenges these distinctive young people face in negotiating the worlds of the internet, home and school. For the last two years I have explored this topic as a full-time PhD student.
1. Related work with key references
My research draws on a wide selection of literatures, briefly summarised here in the following three topics:
1.1 Identity
Questions of identity and subjectivity are central to this research. So too is language use in both print and multimodal contexts for establishing these constructions of identity. Sociolinguists such as James Gee point to strong connections between language use, specifically how terms and concepts are framed and the everyday language used to speak about them, and the processes by which people perceive themselves and are positioned 6 within society. Gee calls on the notion of Discourse to explain key distinctions and operations here [3]. In his writings about identity, Gee uses a capital letter to distinguish between the familiar use of the word 'discourse' to mean a dialogue, and 'Discourse', by which he refers to a socially-formed grouping embedded with cultural practices. Gee theorises that we all have experience of a unique primary Discourse, our formative social communication learning from our parents, which is shaped by cultural influences such as national and religious Discourses, as well as a comprehensive range of secondary Discourses, our necessary ways of communicating differently in different situations, such as may be encountered within digital environments and school communities.
1.2 Third culture kids
The site of the research is an International School that prioritizes the children of intergovernmental organizations' employees. The majority of these children are expatriates, many of whom live a peripatetic life and thus live as outsiders from their home country, and to a large extent from the country where they currently reside. Consequently, these children have quite different formative experiences than children who have matured primarily within one culture. Such children have been labelled as "global nomads" [4] or "third culture kids" [5], and as Sears notes, these children can be seen as "exemplars" of an increasingly mobile world [6 p.79]. The growth of new digital technologies has presented a new range of options for the ways these children live their lives. Such changes consequently have important implications for the educational institutions that serve these children.
1.3 'New' Classroom Literacies
In 1996, the New London Group collaborated to produce a manifesto that seeks to broaden the scope of literacy pedagogy to accommodate both technological changes, and changes in the social landscape. Literacies occur within a broad social context, and within a wider range of spaces and Discourses than is dealt with by traditional classroom settings. Educational research therefore needs to move beyond classroom doors and into students' wider communities [7]. The research undertaken here adopts such a sociocultural approach, and is grounded in the idea that communicative production can best be understood within the social and cultural practices from whence it is formed.
2. Research Questions
The central research question in this study is 'how do third culture kids negotiate the Discourses of home, school and new media'. In researching this question, it is also necessary to identify some of the key Discourses these culturally diverse children encountered in the different intersecting spaces and places of digital culture, the classroom, and the home, and to explore the ways in which these children position themselves in relation to these Discourses. To refine the focus, this topic is being broken down into a number of specific directions.
One direction concerns the social dynamics established by the participants when playing or working in a group, both in school, and in out-of-school contexts. This includes group dynamics within virtual spaces. This focus works towards understanding the central research question as each student's differing Discourse backgrounds can be glimpsed within social interactions such as these. Questions being explored in this direction are: 7
When the children play internet games in a room together, or work in collaborative learning situations utilizing digital technologies, what are the characteristics of the group dynamic that develops? And then:
How do the individual children negotiate their relationships within these different places and/or within virtual group settings?
A second direction is concentrated on the need to know more about how game play, and other uses of digital technologies, factor in the performance of, and development of, these children's language and literacy skills. Students produce and share meaningful texts via internet games and social networking sites used at home, and games and other digital platforms used in the classroom. Exploring this production works towards understanding the broad topic as the research is grounded in a sociocultural position that language is central to identity; that identity is one and the same as its expression or performance through literate practices. Specific questions being explored in this direction are:
What are the characteristics of the texts which children produce utilizing mass-media digital technologies in the home?
How do they differ from texts produced in classroom situations when digital technologies are utilized?
What evidence do these literate productions provide of the students' negotiation of the Discourses that surround them?
3. The contribution of the proposed research
Young people in the 8-13 year age group are at a stage of vital importance in how they see themselves, and in the development of their points of view and values, yet this age group remains under-investigated in most areas of educational research. This study specifically contributes to the literature due to the unique nature of its third culture kid participants, and aims to bring investigations of identity and the third culture kid into a digital-age focus. This broad research topic directly addresses Jackie Marsh's declaration of the "urgent need to map children's engagement with cultural texts in a global context" [8 p.12].
4. Research methodology
The research is guided by case study procedures. Over the course of the past school year, twenty International School students aged from 8 to 13 years kept a journal recording their at-home digital play. These journals were then used as an aide-memoire at weekly meetings where the students discussed their use of digital games and other media. The students were also observed in the classroom, focusing on the children's experiences with digitally enhanced learning. An opportunity to attend an after-school computer club during which students played on their own choice of internet games was also offered. Interviews were held at the beginning and the end of the school year with the students. Their teachers and parents were also interviewed.
The research employs qualitative research methods to ensure the authentic, "messy complexity of human experience" can be seen and contemplated [9 p.3]. The design encompasses two different kinds of triangulation to impart validity, a methodological triangulation and a data triangulation [10]. First, three methods have been employed to collect information from the child participants; taped interviews and discussions, observation notes, and journals. Secondly, three different data 'categories' have been engaged as interviewees: children, parents, and teachers. 8
Appadurai [11] maps contemporary global fluidity within a set of five different categories of flow: ethnoscapes, mediascapes, technoscapes, financescapes, and ideoscapes. These "scapes" provide an illuminating framework for exploring the contemporary childhood of the globally mobile child. The data, which is now in the initial stages of analysis, is being initially codified according to these categories. This involves selecting representative sections of dialogue and image as the data is transcribed and collated. These selections highlight typical and atypical responses, as well as characteristic responses for different age and/or gender subgroups.
5. Preliminary results
The data is in the early stages of analysis and it is not yet possible to draw conclusions. Two papers utilizing early findings have been written and are currently under consideration for publication. One centres on the experiences of one family who had recently moved into the school community, and considers the complex and conflicting pressures, expectations and possibilities they encountered at home, at school, and in their online play, at this moment of cultural transition. The other reflects on the differing attitudes observed between the school community and the children's families, with respect to the role of digital play in children's lives, and suggests that schools need to understand parental positions around technology and digital culture, and reflect on these as they plan their digital futures.

Abstract: There have been tremendous ways of developing creativity, yet instead of traditionally formal instruction, games are the best media to spur creativity, as creativity can easily and spontaneously be evoked through games. On the other hand, metacognition is a good way to promote creative thinking, as metacognition which contains the abilities such as self-planning, self-monitoring, and self-evaluation can foster creative-relevant cognitive processes. Games are exactly the ideal platform that provides a playful context for metacognitive awareness prompting creative processes. Based on the advantages of games and that design is a creativity-relevant cognitive and constructive process, this research adopts the means of digital game-based learning (DGBL) to propose a metacognitive approach to inspiring creativity through a creativity game of players as game story designers.
Keywords: creativity assessment, game story design, game story creativity, creativity
Introduction
Creativity has been widely acknowledged as one of appreciated 3Cs today-creativity, curiosity, and courtesy. Many studies revealed that creativity is associated with and also facilitates divergent thinking, critical thinking, flexibility, and so forth, which are the vital elements to promote learning. However, is creativity inborn or acquired? Creativity, like other potentials, demands inspiration and practice to receive its whole-scale development. There have been tremendous ways of developing creativity, yet instead of traditionally formal instruction, games are the best media to spur creativity, as creativity can easily and spontaneously be evoked through games.
1. Purpose and Significance of the Proposed Research
Based on the advantages of games and that design is a creativity-relevant cognitive and constructive process, this research adopts the means of digital game-based learning (DGBL) to propose a metacognitive approach to inspiring creativity through a creativity game of players as game story designers. The purpose of this research contains three aspects. First of all, this research attempts to explore what kind of creativity assessment is appropriate for game story design. Second, this research investigates the effects of inspiring creativity through a game of players as game story designers. Third, this research tries to understand in which game story constructs were the students good at and short of creativity? 10
The significance of this research is that this research proposes an entertaining and metacognitive approach to inspiring creativity in replace of traditionally formal instruction of creativity. Besides, the devised creativity game can prompt players' creativity-awareness for distinctive game story constructs and creativity dimensions. This research provides valuable information for game design course instructors as well as game story design evaluators.
2. Literature Review
This research is based on the integrated rationales of game, creativity, and metacognition. Some selected literatures are briefly discussed as follows.
2.1 Game and Creativity
The literature has widely discussed the relationship between games and creativity. Some major advantages of games are described as follows. First of all, game play is a wonderful source of relaxation and stimulation for the brain and body-a sure and fun way to develop the ability of creativity [3]. Second, game play can arouse curiosity which leads to discovery and creativity [3]. Third, creativity can be activated by intrinsic motivation through games [5]. Fourth, games can stimulate divergent thinking which promotes creative learning [2].
Noticeably, game play as engagement fosters the cognitive and affective dimensions of the creative process, as well as the development of domain-relevant skills and creativity-relevant skills [5]. There are five creativity-relevant cognitive processes: problem framing, divergent thinking, mental transformations, practice with alternative solutions, and evaluative ability. Through game play, these creativity-relevant cognitive processes can be facilitated in learning. Evidently, games not only a brilliant means to mediate learning but also a fantastic catalyst to boost up creativity. Thus, games are the best approach to an enjoyable learning environment prompting creativity which in return inspires creative learning.
2.2 Game and Metacognition
The literature has extensively discussed over metacognition in the past decades. Metacognition refers to the ability or awareness of understand and monitor one's own thoughts [4]; simply put, thinking about one's thinking. Many studies have reported that metacognitive awareness can be fostered with proper instructional strategies. Likewise, the conditions that have been proven to foster metacognitive awareness through instructional strategies are similar to the conditions established in games [6]. Differently, games provides a context in which players can enjoy a playful activity. Using games to prompt metacognitive awareness can encourage motivation, promote engagement, and increase pleasure-an ideal means much better than formal instruction.
2.3 Metacognition and Creativity
Creativity involves f innovation, imagination, uniqueness, etc. Many studies have explored how to promote creativity through a variety of means and strategies. It has been demonstrated that metacognition is a good way to promote creative thinking, as metacognition which contains the abilities such as self-planning, self-monitoring, and self-evaluation can foster creative-relevant cognitive processes [1, 5]. 11
3. Implementation of Game Story Players as Designers Approach
Grounded on the rationale of the triangular relationships of creativity, metacognition, and games, game story constructs and six types of creativity are presented in a metaphorical way in the devised creativity game, requiring players as game designers for inside-game- story players. Through designing, it stimulates players' metacognitive awareness that simultaneously prompts creativity awareness.
4. Method
4.1 Research Design
This research consists of three phases. In the first phrase, a creativity assessment rubric for game story design is developed and tested its validity and reliability. In the second phrase, a standard creativity test is selected and used to pretest and posttest a control group that is treated with a learning system containing selected instructional materials on creativity. For the experiment group, a questionnaire is used to pretest the participants' knowledge of creativity for game story design, and then the creativity game proposed by this research is conducted on the participants. In the third phase, the game story design projected done by the experiment group at the end of the semester will be assessed with the devised assessment rubric by three raters. Two groups will be compared in terms of different instructional treatments.
4.2 Preliminary Research Questions
Three research questions are formulated as follow: First, in which game story constructs are the students good at and short of creativity? Second, whether the proposed game treatment better promotes creativity? Third, how do the students view such a metacognitive approach to creativity inspiration?
5. Preliminary Research Work Achieved and Future Work
This proposed research has come to the phase of pilot study. An analytic rubric of game story creativity has been devised and the paper of rubric design has been accepted in the 2012 International Conference of Computers in Education. Based on the analytic rubric, initial ratings have been conducted and the validity and reliability of the analytic rubric are being examined. Besides, the game structure diagram of the creativity game as well as a questionnaire has been initially drawn. Future work will focus on the development of the creativity game and the evaluation of its effectiveness.

Exploration of Signature Pedagogy Using ICT
for English Grammar Learning in Elementary
School Education
Wai Ying KWOK
Department of Mathematics and Information Technology,
The Hong Kong Institute of Education,
Hong Kong
waiyingk@ied.edu.hk
Abstract: This research aims to explore a signature pedagogy that addresses the trends toward the pedagogical goals and the technological integration for English grammar learning in the twenty-first century. Based on a twofold literature review, a potential signature pedagogy with three variations in the use of two selected types of information and communication technology (ICT) resources has been designed for supporting English as Second Language (ESL) learners at the elementary school level to learn English grammatical knowledge. An empirical study which combines qualitative and quantitative methods is planned to evaluate the effectiveness of the designed signature pedagogy in a real classroom environment. Three classes of Grade 4 ESL learners will be invited to learn the target topic with the selected ICT resources during a one-month trial teaching, under three settings: inclining to form-focused approach; balancing form-focused approach and communicative approach; or inclining to communicative approach. The empirical study will conduct attainment tests, classroom observations, questionnaire surveys and semi-structured interviews to investigate the impact of the designed signature pedagogy on the achievements, processes and perceptions of students in the learning of elementary English grammar. This research will finally advise a signature pedagogy that fully exploits the use of the two selected types of ICT resources for supporting ESL learners to learn elementary English grammar.
Keywords: Elementary school education, English, grammar, ICT, signature pedagogy
1. Research Motivation
In many Asian cities such as Hong Kong where English language is not the native language of the majority of the population, this language is one of the major subjects that receive much attention in elementary school curriculum. There is a decade-long emphasis on the pedagogical integration of ICT into the delivery of elementary English language curriculum [1, 2]. In Hong Kong, in this curriculum, grammatical topics such as tense and agreement are considered to be the very important but most difficult component due to the inherent differences in the language systems between Chinese and English languages.
A signature pedagogy refers to a collection of discipline-specific teaching methods that focus on preparing learners to think like the experts in the target discipline for a skilful demonstration of discipline-specific knowledge for learning and daily pursuits [3]. Through the routinized approach to classroom teaching, a signature pedagogy could promote learners to habitually bridge abstract knowledge and regular practice for the deep learning of core knowledge in the target discipline. The implementation of signature pedagogy is regarded as important in the learning of rule-based topics. It is therefore good to implement 14 significant pedagogy in the teaching of English grammar, which is a topic comprised of language rules. This research is motivated to address the emergent need in the field of ESL education for more investigations into signature pedagogies which meaningfully use ICT resources for supporting English grammar learning in ESL classrooms.
2. Research Context
This research aims to explore a signature pedagogy that maximizes the potential of ICT resources for supporting ESL learners at the elementary school level to learn English grammar. This research is comprised of two stages for progressively designing, evaluating and then establishing a signature pedagogy that fully exploits the use of ICT resources for learning elementary English grammar.
2.1 The First Stage: Designing a Potential Signature Pedagogy Using ICT for English Grammar Learning
The first stage of this research focuses on a twofold literature review for designing a potential signature pedagogy that coordinates the pedagogical goals and the technological integration for English grammar learning in the twenty-first century. Based on an in-depth review of research literature on the pedagogical approaches for teaching elementary English grammar in the recent decade, ESL teachers over the world are found to mainly adopt two pedagogical approaches in English grammar lessons. The first approach is the form-focused approach, which focuses on inculcating learners with knowledge about variation forms and usage patterns of diverse types of linguistic units to generalize prescriptive grammar rules. The second approach is the communicative approach, which focuses on engaging learners in authentic learning tasks in the collaborative learning setting for applying grammatical knowledge in classroom interactions.
Based on an in-depth review of research literature on the use of ICT for learning and teaching English grammar system in the recent decade, ESL teachers over the world are found to mainly adopt two types of ICT resources in English grammar lessons. The first type is online learning websites specific for grammar learning. This type of ICT resources typically provides a set of static grammar notes, multimedia illustrative animations and dynamic multimedia simulations for rules explanation. The second type is online communication tools general for daily interaction. This type of ICT resources typically offers a range of written or oral communication software for interpersonal interaction in the synchronous or asynchronous mode.
The findings of the twofold literature review, concurred with the advocacy by established academics (such as [4]), suggest that a potential signature pedagogy for English grammar learning should make a strategic combination for leveraging the effect of the form-focused approach and the communicative approach. On the one hand, there should be inquiry learning activities under the form-focused approach, in which learners browse the selected online learning websites with topic-specific notes and worksheets to realize and

conceptualize usage conditions of grammatical rules. On the other hand, there should be collaborative learning under the communicative approach, in which learners use the selected online communication tools to share and discuss target knowledge, and then to integrate and apply knowledge about grammatical rules. It should be noted that there is flexibility for varying the proportion of these two types of learning activities during English grammar lessons according to the learning needs of students. 15

2.2 The Second Stage: Evaluating the Designed Signature Pedagogy for English Grammar Learning

The second stage of this research will be an empirical study which focuses on evaluating the designed signature pedagogy in a real classroom environment. Three research questions are made for the empirical study:

(i) What are the achievements of elementary ESL learners toward English grammar learning under the designed signature pedagogy?

(ii) What are the processes of elementary ESL learners toward English grammar learning under the designed signature pedagogy?

(iii) What are the perceptions of elementary ESL learners toward English grammar learning under the designed signature pedagogy?

An elementary school that has rich experience in ICT in education will be purposefully sampled in Hong Kong as the partner school for the empirical study. A trial teaching in the form of one-month supplementary course, which amounts around 20 one-and-a-half-hour lessons, will be arranged in the partner school. Three classes of Grade 4 students, each consisting of around 30 students with similar learning ability, will be randomly selected and then assigned to one of the following three settings varying in the proportion of learning activities during lessons:

Setting 1: The proportion of inquiry learning activities under the form-focused approach is higher than that of collaborative learning under the communicative approach.

Setting 2: The proportion of inquiry learning activities under the form-focused approach is the same as that of collaborative learning under the communicative approach.

Setting 3: The proportion of collaborative learning under the communicative approach is higher than that of inquiry learning activities under the form-focused approach.

The proportion of inquiry learning activities under the two approaches will be further delimited by taking the empirical findings of research on digital classrooms (such as [1] and [4]) and the current practice in ESL classrooms in Hong Kong into consideration. During the trial teaching period, students in each of the three settings will be grouped into pairs to learn English grammar, with the use of the two selected types of ICT resources and tailor-made learning worksheets. In each lesson, students will first be taught the target knowledge by the teacher and then, they will explore this topic with the assigned learning materials in pairs. The author will take charge of the classroom instruction for the one-month trial teaching.

Four methods will be adopted in the evaluation work to investigate the effect of the designed signature pedagogy. First, students in all the three settings will sit for identical pre-test and post-test [5] before and after the trial teaching, respectively. The test papers will include a series of questions that assesses knowledge of the students about key grammatical knowledge of English language, such as tense and agreement. Second, an interaction analysis [6] will be conducted to investigate the effect of the designed signature pedagogy on the learning process of students in each of the three settings. Two student groups will be randomly selected in each setting. The six selected student groups will be observed and videotaped in all lessons throughout the teaching period for collecting data on the learner-learner and learner-technology-learner interactions in the learning activities. A systematic analysis of the interactions for constructing target knowledge will follow to trace the learning process among students under the designed signature pedagogy. 16

Third, a questionnaire survey [5] will be conducted at the end of the trial teaching. All students will be asked to complete a self-administered questionnaire to indicate their perceptions of the implementation of the designed signature pedagogy for English grammar lessons. Fourth, one-fifth of the students in each of the three settings will be randomly selected for the semi-structured, individual interviews [5] to further investigate their perceptions of the implementation of the designed signature pedagogy. The selected students will be asked to describe the changes in their process, motivation and achievement in the learning of English grammar through the lessons that implement the designed signature pedagogy.

The empirical study is going to be conducted in a real classroom environment. The evaluation results obtained at this stage will contribute to the establishment of a signature pedagogy that uses ICT resources for maximizing the learning effectiveness among ESL learners in English grammar learning in elementary school education.

3. Research Contribution

In the Asian cities where English language is not the native language of the majority of the population, local ESL teachers in elementary school education, in general, lack sufficient evidence-based recommendations which support them to plan and implement effective and efficient methods for the pedagogical use of ICT in English grammar lessons. In addition, there is a lack of comprehensive research on technology-mediated signature pedagogy for the field of ESL education [4, 7].

This research contributes to the pedagogical advancement in the use of ICT in ESL education. It will not only help to enhance the learning of grammatical knowledge among ESL learners, but also help to cover the lack of comprehensive research in the field. The outcome of this research will be a potential signature pedagogy to maximize the effectiveness of ICT resources on the learning of elementary English grammar among ESL learners. This can provide ESL teachers with insights into the innovative design of technology-mediated pedagogies for the teaching of the target topic.

Impact of Students' Perceptions of ICT-Supported Learning Environment on Approaches to Learning for Principles of Accounting in Secondary Schools

Boon See TAN
Faculty of Educational Studies, Universiti Putra Malaysia, Malaysia
bstan_29@yahoo.com

Abstract: This research aims to study the impact of students' perceptions of ICT-supported Learning Environment and their personal characteristics on approaches to learning in the context of Malaysian accounting education at secondary school level. Students are facing the learning problem where they lack the opportunity to experience deep approaches to learning due to the teacher-centred teaching approach and immaturity of the curriculum and assessment design. In view of these problems, the Ministry of Education (MOE) has revised the curriculum and assessment from content-based to skilled-based with the aim to enable students to practise deep approach to learning with ICT. However, to what extent the new environment is able to stimulate deep approach to learning is the main issue underpinning by the present study which will be investigated through a correlational research design employing the Structural Equation Modeling (SEM) analysis method. Contributions and preliminary results of this study are discussed.

Keywords: Perceptions of ICT-supported learning environment, deep approach to learning, surface approach to learning, students' characteristics, Principles of Accounting

Introduction

A business or organisation communicates its results and position to its stakeholders through the use of financial statements. Given that financial statements are among the deliverables of an accounting task, accountancy is widely referred to as the "language of business". Basically, accounting is seen to involve the process of identifying, measuring, and communicating economic information to permit informed judgments and decisions by users of the information [1]. Fundamental to the identifying and measuring processes, is the application of the double-entry book-keeping system to record financial transactions which conducted under the procedures named as accounting cycle. It involves a set of steps in preparing the financial statements for a given period. All these steps are inter-linked and it requires students to employ deep approach to learning in order to master the whole set of accounts throughout the accounting cycle rather than fragmentally studying on each of the accounting procedures. The deep approach to learning represents a personal commitment to learning through seeking meaning of the contents, trying to relate parts to each other, associating new information with existing prior knowledge or to personal meaningful context. It is contrasted with surface approach to learning which is characterised by motivation to acquire only sufficient knowledge to complete the task or pass the subject through rote learning [2, 3, and 4]. 18

In 2010, the Malaysian Ministry of Education (MOE) has committed an effort to transform the curriculum and assessment of the fundamental accounting subject in secondary schools, the Principles of Accounting, from content-based to skilled-based with the aims to enable students to practise deep approach to learning with ICT [5]. The effort undertaken is to overcome the learning problems which will be discussed in the next section. However, to what extent the effort is able to impact positive changes in students' learning is the main issue underpinning the present study.

1. Research Motivation

Unlike other disciplines, accounting is a technically-oriented subject and hence, the teaching of accounting was found to be dominated by the objective of training students to know facts and solve problems from a procedural perspective [6]. Thus, it was observed by few researchers that students always perceive that learning accounting is simply about learning a set of rules and evidences suggest that they tend to adopt a surface learning approach compared to other subjects [7, 8].

Similarly, in the Malaysian context, students' learning for the subject of Principles of Accounting has yet to achieve deep approach as it was found that most of the accounting teachers tended to use the teacher-centred teaching methods such as lecture, drill and practice and demonstration of problem solving by teachers [9]. Such methods could lead to surface learning where the lower-level procedural skills are acquired without processing information for meaning. This problem could be attributed to the former curriculum and assessment of Principles of Accounting (before year 2010) which were arranged in such a way that the process of accounting cycle was fragmented by its steps. Students learnt each part of the process through the method of drill and practice where they were exposed to exercises or problems which were related to that portion of process only. In other words, there were different sets of exercises or problems for each of the steps of accounting cycle e.g. exercises for journal-entry were unrelated to exercises in trial balance. The division of the book-keeping procedures negates the students' skills and knowledge to relate every aspect of accounting into a coherent whole [10]. Under this learning content structure, students were more oriented towards surface approach to learning as they treated parts of the subject as separate entities and failed to master the full set of accounts. Moreover, students lacked exposure and were not encouraged to engage in deep learning approach through technology [11]. It further proves that students are lacking ICT skills to handle a full set of accounts where these skills have long been heralded as a crucial element in both professional accountancy and accounting education [12].

The launch of the revised curriculum and assessment signifies the commitment of MOE to improve learning quality which enables students to have a coherent understanding of accounting through enhancing their competencies in preparing a full set of accounts with the assistance of ICT. The overarching question now is how effective is the ICT-supported learning environment as perceived by students in influencing their deep approaches to learning? What are the other factors which influence students' approaches to learning? Is the perceived ICT-supported learning environment a mediator factor between individual personal characteristics and approaches to learning? All these stand as the general motivation for the present research.

2. Research Questions

The research questions for the present study are suggested as below: 19

I. Do the students' perceptions of ICT-supported learning environment (in terms of Personal Growth, Assessment, and Relationship) influence their approaches to learning?

II. Do the students' characteristics (in terms of Prior Accounting Knowledge, Academic Ability, Preconceptions of Accounting, and ICT Proficiency) influence their approaches to learning?

III. Is the students' perceived ICT-supported learning environment a mediator between their characteristics and approaches to learning?

3. Contribution

This study adds to the body of accounting education and student learning literature by investigating students' approaches to learning in the ICT-Supported Learning Environment through examining their perceptions of the environment and personal characteristics. It was commented that the direct investigations of students' perceptions are scant, particularly in relation to technological innovation in the learning environments [13]. Thus, this study makes a prima facie contribution for accounting educators to obtain the captured reflective voice of students. Furthermore, the findings of the present study could provide important information for educators on which aspect of the learning-teaching context can be altered for the sake of improvements in teaching and learning, curriculum, and assessment that encourages deep learning approach.

4. Methodology

This research employs a correlational research design. It aims to establish the empirical relationships of students' perceptions of ICT-Supported Learning Environment, their personal characteristics, and aproaches to learning through using of Structural Equation Modeling (SEM) analysis method. A closed-ended questionnaire will be distributed to secondary school students who have completed their school-based assessments of Principles of Accounting. The questionnaire will be adapted from the instruments of Learning Process Questionnaire (LPQ; reliabilities for the subscales: .58-.75)[14] for measuring approaches to learning; Technology-Rich Outcomes-Focused Learning Environment Inventory (TROFLE; reliabilities for the subscales: .77-.95)[15] and Course Experience Questionnaire (CEQ; reliabilities for the subscales: .67-.88)[16] for assessing Perceptions of ICT-Supported Learning Environment; and Expectations of Learning

Accounting Inventory (ELAcc; reliabilities for the subscales: .67-.92)[17] and ICT Skills Audit Scale [18] for appraising the individual student's characteristics.

5. Preliminary Results

To ensure the successful implementation of the revised curriculum by 2010, a "try-out" project was conducted in 150 technical and national secondary schools nationwide in Malaysia in 2007. Studies on students' receptiveness on the ICT-supported learning environment have been conducted in the "try-out" project which involved 1,322 respondents. The results revealed an overall positive tendency of all the dimensions of receptiveness (with mean values above 3.5 of a 5-point Likert scale) by students with the under-achievers demonstrating significantly higher receptiveness in terms of the dimensions of Skills Acquisition (*M* = 3.818, SD = 0.522), Teaching Competency (*M* = 20 3.755, SD = 0.707), and ICT Liking and Utility (*M* = 3.819, SD = 0.587) than the high-achievers (*M* = 3.714, SD = 0.768), t = 2.913, p = 0.002 (one-tailed); (*M* = 3.606, SD = 0.832), t = 3.464, p = 0.0005 (one-tailed); and (*M* = 3.618, SD = 0.776), t = 5.316, p = 0.0000 (one-tailed) [19].

Scaffolding Teachers' Construction of a Learning Trajectory for Mathematics Supported by ICT

Miguel PEREZ
School of Computer Science, Physics and Mathematics, Linnaeus University, Sweden
miguel.perez@lnu.se

Abstract: In this paper, we present preliminary results related to a developmental project where we explore how technology can be used to improve teachers' teaching practices and their students' learning of mathematics. We have adopted a teacher-centered, collaborative approach that challenges the participating researcher to develop strategies for finding different forms of scaffolding to support the teachers' participation in this project. So far, we have used the software GeoGebra to provide competence development for the teachers in terms of mathematical representations. This software will also have a central role when investigating how the teachers perceive and make use of different affordances provided by technologies when addressing a specific learning goal related to the teaching of algebra at a lower secondary school.

Keywords: Affordances, co-design, GeoGebra, Hypothetical Learning Trajectory (HLT)

Introduction

We are currently involved in a developmental project with two mathematics teachers at a lower secondary school in Sweden where we explore how to make use of ICT to improve the teachers' mathematical teaching practices and their students' learning of mathematics. Drawing inspiration from the methodology of co-design [8] our objective is to develop technology-enhanced mathematical learning activities. Co-design provides a user-centered, collaborative approach to design research, suitable when requiring expertise from different areas, in our case mathematics, pedagogy and technology.

Involving different stakeholders and especially teachers in the design process is a key factor for an innovative learning activity to find its way to teachers' everyday practice [10]. The teachers' role in the co-design process should be regarded as dynamic and their influence should be increased in latter design iterations [10] with particular focus on refining the interplay among various forms of scaffolding required when implementing the activity in order to provide favorable conditions for its integration in the regular curriculum [11]. This methodological approach puts increasing demands on the teachers as the design process progresses and challenges the researchers to identify and provide appropriate theoretical and methodological underpinnings to support the teachers in the continued design process.

1. The Hypothetical Learning Trajectory ZZ

Within the iterative process of design research different phases of preliminary design, teaching experiment and retrospective analysis can be identified [2]. The preliminary design includes the development of a Hypothetical Learning Trajectory (HLT) which can be described as "the consideration of the learning goal, the learning activities, and the thinking and learning in which students might engage" [9, p. 133]. Although the notion of HTL has a constructivist origin [9] it has been used from other perspectives. Gravemeijer, Bowers, and Stephan have for example used the instructional theory Realistic Mathematics Education (RME) to guide the formulation of a HLT to develop classrooms activities that reflect the view of mathematics as a human activity and learning as a process within a social context [4]. For our objectives, this property makes the notion of HLT a highly adaptable and flexible tool suitable when discussing different aspects of teaching and learning within the co-design group.

The effects of integrating technologies in educational settings, are not necessary transparent. Even if technologies can be used to address some problems related to teaching, there is a possibility that they introduce new unexpected problems [5] [6]. Lindwall and Ivarsson claim that a common problem is that students tend to "exclusively focus on the operational aspects of the task without actually approaching the subject matter content" [6, p. 376]. This suggests that even if the intention of a learning activity is to afford students to work towards a predetermined learning goal, students might still focus on other aspects and other affordances. Another challenge for the designer of a HLT is that, each tool, although seemingly similar in many aspects, can have divergent effects on how students interact in an activity [6]. The result could be unexpected forms of interaction in conflict with the intentions of the HLT.

Formulating a HLT that integrates technologies requires knowledge about the affordances provided by the tool and also knowledge of how these affordances are perceived and used by teachers and students in a learning activity [1] [6]. Addressing these kinds of issues with a collaborative approach challenges the researcher to create conditions for the teachers to discuss and consider different affordances provided by technology as well as create awareness among the teachers on how digital tools might affect their educational settings [1] [5].

2. Key Idea

Our goal is to develop a HTL that is grounded in theory and attuned to the various prerequisites imposed by different stakeholders, including the possibilities and constraints that may rise when using technologies in mathematics instruction. The collaborative approach challenges the researcher to create appropriate conditions for the teachers to be able to make informed decisions. Therefore, we also seek to explore how to develop, provide and evaluate different forms of scaffold for teachers' participation in the design process. Our strategy is to monitor and qualitatively analyze the outcomes from the discussions held with the teachers and, based on the analyses, provide support for enhancing the teachers' knowledge base. So far, our efforts include two meetings with the teachers.

3. Preliminary Results

Two teachers from the current school volunteered to participate and the purpose of the first meeting was to discuss the goals of the project. At this meeting, the teachers brought forward that they were interested in addressing some of the difficulties their students had concerning algebra, e.g. the students' inability to make sense of the distributive law. The 23 analysis of the discussions rendered the following research question: "What mathematical knowledge requirements does a teacher need in order to participate in the co-design of a mathematical learning activity supported by ICT?"

A synthesis of two complementary models was used suggest that "teachers' mathematical knowledge requirement would be to consider and be able to judge and compare the didactical value of various mathematical representations" [7]. This requirement includes also the use of technologies in the sense that technologies provide affordances for multiple and multi-modal representations, simulations, manipulation of data, and conversions of representations [5]. Furthermore, the analysis of the discussion indicated that there was a need for competence development among the teachers regarding mathematical representations. For this purpose a second meeting was held where the teachers where shown some activities, implemented in GeoGebra, where numerical expressions are connected with their corresponding geometrical representations (Figure 1).

Figure 1: The activities implemented in GeoGebra

The dynamics of GeoGebra provides possibilities to move and rearrange geometrical figures with ease. This affordance is used in the activities to illustrate how algebraic treatments of a numerical expression can be interpreted and represented geometrically. The possibility to display and hide text and figures in Geogebra is used to create freedom of choice to display the two different mathematical representations either simultaneously or one at a time. Although figures and expressions are organized in a determined order in the activities, the teacher still needs to consider how the different representations should interact within the activities. The activities are designed to address students' conceptions of the distributive law by affording transformations of representations which can be regarded as a characteristic of mathematical proficiency [3]. The activities are also designed to provide affordances for different forms of interaction between the teacher, the students and the activities.

4. Reflections on the Outcomes of the Meetings

The teachers had never used GeoGebra before the second meeting and they became interested in the features of this software and in the activities presented. Furthermore, they 24 wanted immediately access to the activities in order to use them with their students. During this meeting the teachers adopted the mathematical ideas presented in the activities and they came to realize the didactical potential in interpreting and representing algebraic laws geometrically. This was clearly a new insight for them and they recognized the limitations of alternative explanations that they normally used that where exclusively based on instructions on how to manipulate different variables.

The teachers were encouraged to use the activities with their students but they were not provided any details on how to create conditions for using the activities in instruction. Instead they were invited to modify and use the activities in GeoGebra in any preferable way and thereby challenging the teachers to create their own HLT. This last meeting has not yet been followed up and the outcome of these efforts has therefore not been analyzed yet.

5. Future Work

The next step is to discuss with the teachers how they have used the activities and also attend lessons where the teachers have implemented the activities as part of their daily work. The analysis of these sessions has two objectives. First we are interested in understanding and discussing how the teachers coordinate the different parts of the hypothetical learning trajectory when using GeoGebra. Secondly, we are interested in evaluating our efforts of providing competence development in terms of mathematical representation. We want to see if and how the teachers perceive and make use of affordances for representation and communication provided in the specific activities implemented in GeoGebra.

Towards Improving Reading Comprehension
Skills in Third Graders with a Serious Game

Abstract: The results of different evaluations about reading comprehension in Mexico are not positive. Different methods or techniques have been implemented to counteract such numbers, and the support of information technologies (IT) in reading comprehension, is one of them. During the last years, video games demand increased in Mexico, which indicates that they are already part of the culture, and consequently, those must be harness to obtain better results. The purpose of this research is to improve reading comprehension skills of third graders through a serious game.
Keywords: Reading comprehension, serious games, third graders

Introduction

Reading is a process that each person does by themselves and it allows to examine the content of what is being read, analyze each of its parts to stress the essential and compare already existing knowledge with the one that has been just acquired [1]. A wide range of reading skills, including digital reading, are essential for an individual's personal and social fulfillment. In essence, acquiring the ability to read and understand well is a basic requirement for the social and economic demands in the society. Proficiency in reading literacy is not only one of the principal goals of schooling, but is also one of the principal means of learning [2].

A report made by Entertainment Software Association [3] explains that many children, teenagers and young people, spend part of their free time playing video games, which suggests that most of such groups enjoy using and interacting with such technologies [4]. New generations show the impact of growing inside this digital wave; technologies are an integrated aspect in their lives [5]. Students in this group use technologies to learn, and to communicate in new ways.

1. Theoretical Background

1.1 Reading Comprehension

Reading comprehension evolves due to the social, cultural and economic changes that society experiences day by day. Reading comprehension is not just the mere decoding of meanings of a text, but the construction of meanings that result from the interaction of the reader with the text [6]. Reading competence is defined as the ability of a person to understand, use, reflect and gain interest in texts written with the purpose to achieve their own goals, develop their knowledge and their personal potential, and participate in the society [7]. However, according to Nation, Cocksey, Taylor, and Bishop [8], students at 26 young age need to be competent in two specific abilities in order for them to become good readers. They need to learn how to recognize and decipher words from a piece of writing, and also understand the message that each word transmits. Reading comprehension is an act that takes time to develop, it is impossible to demonstrate a lack of reading comprehension in children who have not yet learned to read with enough precision and fluency. Therefore, researches with greater load in reading comprehension report that children at the age of 8 and older are the ones that start suffering the lack of such activity.

1.2 Serious Games

One of the ways to support the development of reading and to encourage the reading in general, is through IT. Some authors [4] think that video games help to solve problems as the ones mentioned before, partly, because of the stories of success in the use of video games in the business and military training in some countries. The results of research studies show that video games encourage the acquisition of certain cognitive skills and improve the comprehension of students in the subjects presented [4]. According to Zapušek, Cerar, and Rugelj [9] serious games are video games used for training, publicity, simulation or education and they are designed to be executed in computers. They allow student to simulate and experiment with situations that are impossible or difficult in the real word for different reasons, such as security, cost or time. Results presented about learning show a positive impact in the development of new knowledge. Similarly, serious games are receiving interest from the researchers and the industry because of the advantages that education and formation present [10]. Besides, some pedagogues consider these types of games motivating and attractive, when the characteristics that make them convincing are incorporated, of quality and even addictive sometimes [11].

1.3 Video Games and Education

Brown [12] explains that as the adoption of video games by the military as devices of training and recruiting, the appearance of video games in classrooms represents an important institutional credit to the new media. Second Life, for example, a multiuser virtual environment, is used by many universities and institutions (e.g. Texas University, Hong Kong Polytechnic University, Harvard Law School, among others) as a virtual classroom or virtual campus, where professors and students interact online. Squire [13] states that video games encourage a way of learning that goes beyond the traditional disciplinary limits and emphasize the problem solving. For Brown and Squire, video games encourage achievements that are attained through the competence, cooperation and teamwork. Nowadays, there are new researches like Guillén-Nieto and Aleson-Carbonell [14] that explain advantages of the use of video game as an educational tool.

2. Problem Statement

Currently, there is a huge problem regarding reading comprehension in Mexico. It is been known that people do not have a reading habit, conclusions that emerged based on results which were obtained in the first survey about reading [15], in which it is revealed that the Mexican's reading average is 2.9 books per year. According to report [16], Mexico is in the 48th place among the 66 countries of the Organisation for Economic Co-operation and Development (OECD) in reading comprehension and analysis. This report places Mexico in Level 2 where there is a minimum and insufficient competence for the execution of complex cognitive activities. Meanwhile, in Spanish language in reading comprehension and 27 reflection on language at a national level, one of every four third graders is on the "Under basic" level, while the 56% is on the Basic level (See figure 1-A).

3. Niche Opportunities

The video game industry in Mexico had an average annual growth of 18.7% during 2007-2010 [17]. In 2010, the Mexican market was worth $757 million, placing the country among the top 15 markets worldwide video game being the first in Latin America (See figure 1-B). So, taking into consideration all this to think about the impact that video games will have in the field of reading comprehension, as proved by several studies on how they have been applied for education in different branches [4].

Figure 1. The first graphic (A) shows the percentage of students by level of educational achievement and school stratum in Spanish/Reading Comprehension and Reflection on laguange [16]. The second graphic (B) shows the distribution of the video game market in Latin America 2009-2013 [17].

Also, it is known that there is correlational evidence that students who read more have higher achievement [18]. An example of this is the correlation between the reading of elementary school students and their score on the Excale test. Excale are tests that measure the school achievement of students from preschool education, primary education and secondary education in different fields. In Gaytán-Lugo and Hernández-Gallardo [19] the results of their study shows that the number of books that an student of elementary school read is directly proportional to the score of Spanish in Excale, inasmuch as the correlation coefficient (r) was 0.608.

Based on the above, two research questions are generated: How to design and implement a methodology in a serious game to raise the level of third graders in reading comprehension? How a serious game promotes reading comprehension of third graders?

4. Method

We are going to use thinking aloud mixed with Solomon experiment. We have to design four groups. Two groups are going to be experimental samples and two groups are going to experience no experiment manipulation. Two groups are going to receive a pretest and posttest, and the other two are going to receive a posttest. This is because the control of the effects of the pretest [20]. In order to collect information and evidence about the progress of reading comprehension that third graders have at a specific moment, during the year they have to play with the serious game, every week we are going to go with the students to apply thinking aloud. This method allows students to speak about what they think and feel at the same time that, in this case, they play with the serious game. 28

5. Current Progress

Right now we are working in the story that will be fantasy genre as [11] recommended. At the same time, we are looking for techniques that improve reading comprehension. These ones have to be in the script and in the challenges of the serious game in an implicit way.

Development of Number Sense in Third Grade
of Elementary School Using Serious Game

Luis ARMERÍA-ZAVALA

Abstract: This research focuses on instrumentation of information technologies that become psychological tools, designed to develop number sense of third graders. The theoretical background is supported by the Cultural-Historical approach, and considers that, using a serious game; emphasize the student's attention and perception for constructing mathematical concepts. A preliminary outcome identifies numerical relationships and counting, as a field of opportunity to increase math skills associated with number sense.
Keywords: Number sense, serious game, artifact

Introduction

In early years at school is perceived the difficulty of students to build mathematical concepts and it is reflected in numeric skills. Different components of cognitive processes have been associated to a poor performance on that field. The aim of research is to identify new standards that foster cognitive processes of higher psychological functions of attention and perception, as a strategy to develop number sense in the third graders. To achieve this goal, we propose designing a serious game as psychological tool, that enables students relate the abstract operations of numerical entities with concrete objects, and navigate through different training paths, according student' cognitive level. It is hoped, from these mathematical learning experiences, that students develop their number sense.

1. Literature Review

1.1 Number Sense
The study of number sense is documented in several studies, which analyze the concepts and components of the skill needed to build mathematical concepts [1, 2, 3, 4, 5, 6]. Malofeeva et al. [3], establish that number sense is the ability to understand the meaning of numbers, relations between them and the ability to perform mental calculation, numerical estimation, and quantitative reasoning; furthermore, includes conceptual understanding of numbers, knowledge of place value, number relationships, counting and sequencing, understanding and meaning of addition, subtraction, multiplication and division.
1.2 Serious Games and Mathematics
Serious games (SGs), according Ling, Xiaoqiang and Dandan [7], are a category of video and computer games to train or educate users while giving them an enjoyable experience. SGs provides a simulated environment with experiential learning activities [8]. SGs can be 30 used as tools in schools to improve students' efficiency to learn [9], moreover, emphasize the student' attention and perception, to overcome the limits of their sensory field by doing a voluntary effort. The imaginary context of the game teaches the child to guide their conduct by the perception, situations that affect him, and the meaning of the situation. As result children learn to do, consciously, an activity, and acquire a development. Researches evidence the potential positive impacts of using games and serious games, with respect to learning, skills enhancement [10], therefore the advantages of use them in mathematics [11].
1.3 Artifacts as Psychological Tools
The Cultural-Historical approach of mediations, centered on the use of cultural artifacts, is widely used in mathematics learning [12, 13, 14, 15]. According to Vygotsky [12], the artifacts are cultural mediations, transformed as psychological tools, by the use of signs as language. The use of psychological tools promotes development of higher psychological processes as perception and attention, which are the source of a specifically human behavior [12, 16], necessaries to construct mathematical concepts [17]. The use of information technologies allow to exploit the potential of artifacts [14]. With SGs, the child could perceive its environment, and language help him to perceive objects immersed in it and the relationships between them. Through SGs and language, the child reorganizes its spatial and visual field, and creates a temporary field, which is real and perceptible for him. He captures changes and reconstructs the separate activities, therefore he develops his attention. These processes are necessary to construct mathematical concepts, and enables students relate the abstract operations of numerical entities with concrete objects [17].
2. Problem Statement
By the logical character and level of abstraction necessary to construct mathematical concepts, the students demonstrate cognitive difficulties, which are perceived by indicators of educative achievement [18, 19, 20]. In México, the problem is accentuated in third graders, whom must develop mathematical skills associated with number sense. However, statistics shows a score of 419 in math, when Organisation for Economic Co-operation and Development (OECD) countries has an average of 496 [20]; 52% of students are at levels considered unsatisfactory and show difficulty identifying numerical relationships, recognition of magnitudes and simple operations with numbers [19].
3. Contribution of the Proposed Research
Identifying new benchmarks in the transformation of higher psychological processes, for develop number sense, will be the major contribution of the proposed research. The incorporation of dynamic assessment and learning gradients, into a serious game, will be the second contribution. From these approaches it is expected to contribute to developing of skills of counting and numerical relationships as components of the number sense.
4. Proposed Research Methodology
4.1 Objective31
To design a serious game that develops number sense, through transforming of psychological processes of perception and attention in mathematical contexts, looking to improve the skills of counting and numerical relationships in third graders.
4.2 Research Questions
The research will address these questions: How to enhance the development of the psychological processes of perception and attention by an Instrumental approach? How a serious game develops number sense skills of third graders?
4.3 Hypothesis
The use of serious game transforms perception and attention, and develops the skills of counting and numerical relationships of number sense, in third graders.
4.4 Research design
The research will adopt a combination of qualitative and quantitative methods to explore the development of number sense. At the first stage, the transformation of the psychological functions of perception and attention will be studied by the Genetic method of Vytgotsky [12], whose function is to study these processes in its functionality. At the second stage, two classes of third grade, will be randomly selected and assigned to the experimental and control groups. Students of both the experimental and control groups will sit for identical pre-test [21]. For six months, control group will use the SGs designed. After that, both the experimental and control groups will be subject to post-test, to measure development of the skills of counting and numerical relationships [21].
5. Preliminary Outcomes
A pilot study was conducted to identify mathematical abilities of third graders. During first part of the study, a test was designed on the basis of number sense concept, and the Mexican curriculum. After applying test, Coefficient alpha was measure (α=0.8) and the test's structure was reviewed to improve internal consistency. The figure 1 shows results of the study. In the second part of the study (See Figure 2), same test was applied to different students, and they expressed difficulty in properly resolving the items associated with numerical relationships (36%), counting (38%) and exercises for applying basic concepts of arithmetic operations (46%). These findings allow to identify areas of opportunity associated to number sense's elements. This can lead to design of strategies to exercising these specific skills, to develop number sense, looking for increase mathematics learning in third graders.
Figure 2. Results of the number sense assessment.
Figure 1. Analysis of internal consistency, of the number sense test. 32
6. Conclusion and Future Work
Currently, we have been identifying areas of opportunity to improve mathematical skills, related with number sense. This allows designing strategies, for instance a serious game, to develop number sense. As future work of this study, the author is planning the following:
• Instructional design for SGs based on numerical relationships, counting and arithmetic operations, as categories of the number sense.
• Implementing a SGs with math problematizations, according student' cognitive level.
• Pre-test and post-test to measure skills of counting and numerical relationships.
From these processes it is expected to contribute to development of skills of counting and numerical relationships as components of the number sense of third graders.

Virtualmatriks: A Conceptual Mathematization Process in Virtual Learning Environment
Adi Nur Cahyono
Mathematics Department, Semarang State University, Indonesia
adinegara@staff.unnes.ac.id
Abstract: In the Virtual Learning Environment, students interact with the teacher and the other students. By interacting, students can enhance the understanding ofmathematical concepts and its application in the real life. This study aims to develop a model of virtual learning environment based on Realistic Mathematics Education. The research questions are how to develop and implement this model and its effect on the learning outcomes. The results of development in this study are the model and device of VirtualMATRIKS. Students simulate the conceptual mathematization process by create the movie about problem solving. Then students share and discuss it through virtual-learning device. After validated by experts, the model and device were implemented in Semarang Senior High School. And the result is the model and devices qualify the effectiveness and practicality. This model gives a positive impact on student learning outcomes, and students can reach the Upper Limit of Zone of Proximal Development. This model can be applied and developed further in learning mathematics by considering into environment, conditions and students interest.
Key words: RME ,Virtual-Learning Environment, Educational Movie, Conceptual Mathematization
Introduction
Teaching and learning mathematics are complex tasks. According to Freudenthal (1991), mathematics as human activity and mathematics must be connected to reality. Therefore, students should be able to understand the concepts of mathematics and and its application in the real world. But in fact, there are some problems in learning mathematics, such as some students are difficult to understand the concepts and problem solving, some students have low motivation in learning mathematics, and some students do not understand the application of mathematics in real life. By considering the expectations and problems, it is necesary to develop a model of learning environment that makes the learning activities become easier and more enjoyable so the students can reach the optimal learning outcomes. When referring to the Vygotskian perspective, learning outcomes and students' understanding can be increased as a result of interaction in learning. The interaction between teacher-student and student-student in learning, illustrates that social interaction in the form of discussion is able to provide students with opportunities to optimize the learning process. This interaction allows teachers and students to share and modify their ways of thinking. There is also a possibility for some students to showcase their own arguments as well as for other students the opportunity to try to capture the thought patterns of other students.
Activity is believed to be able to increase knowledge and understanding of the object was learned from the previous stage to a higher stage. Students can interact around the difficult task and share their effective problem-solving strategies, if there is an arrangement of classes and a form of learning environment. There are two forms of learning environment, namely physical learning environments and virtual learning environments. Virtual learning environment (VLE) developed by making the design of information spaces as learning environments. In the VLE, students interact with teacher and the other students, wherever and whenever. Teachers and students are familiar with the use of the system. Hardware and software that supports this system has been available. However, to achieve the purpose of learning mathematics, the development of the learning environment must be based on the characteristics and principles of mathematics and learning mathematics.
Theoretical Background
Vygotskian Perspective
According to Vygotsky (1978), there are two important concepts in the sociocultural theory, the Zone of Proximal Development (ZPD) and scaffolding. ZPD is the distance between the actual developmental level as determined by independent problem-solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers (Vygotsky, 1978). It is a dynamic developmental state. At the lower limit of the zone are the tasks that children can accomplish independently, while at the upper limit is the space where more complex tasks can be realized by children through interactions with more knowledgeable others. Learning can evoke a variety ofmental processes that can only be operated stored when a person interacts with an adult or collaborate with their peers. With these interactions, students can complete a complex task that can only be solved if students are given assistance by adults or

71collaborate with peers, the level is referred to as the upper limit of the ZPD. The process of giving assistance in this process is called scaffolding.
Scaffolding means providing large amounts ofaid to students during the early stages oflearning and then reducing the assistance and provide opportunities for children is to take over greater responsibility as soon as he can do it (Slavin, 1994). Vygotsky (in John and Thornton, 1993) explains that learning occurs in two stages: first stage occurs when collaborating with others, and the next phase done on an individual basis in which occurs the internalization process. During the process of interaction occurs (teacher-student and student-student), the following capabilities should be developed: mutual respect, to test

the truth ofthe statement of others, negotiate, and adopt the other opinion.
Virtual Learning Environment
A Virtual Learning Environment is a collection of integrated tools enabling the management of online learning,
providing a delivery mechanism, student tracking, assessment and access to resources (Dillenbour & al, 1999). In a virtual
learning environment, students and teacher can interact anywhere, anytime and easy to find and share informations. Interaction
can take many forms, including synchronous or asynchronous communication, one-to-one or one-to-many or many-to-many,
text-based or audio and video, or even indirect communication such as sharing objects. Researchers have introduced the notion
of "place" (Dourish & Chalmers in Dillenbour & al, 1999) to emphasize that space has a social impact. Places are settings in
which people interact. (Munro, Höök & Benyon in Dillenbour & al, 1999). The representation of the learning environment
ranges from text-based interfaces to the most complex 3D graphical output. 3D graphical representation is often used, because
it can increase motivation, and triggering a positive attitude towards the environment. Dillenbour & al (1999) observed that
virtual space imparts on users behaviour even when space is only described by text. In virtual environments, learning activities
ranging from multiple-choice questionnaire for simulation and problem solving. The idea of learning activities in a virtual
learning environment refers to something richer than the individual, closer to the idea of the project.
The difference between other constructivist environments and what virtual environments potentially offer can be
described as making students not only active, but also actors, i.e. members and contributors of the social and information
space. (Dillenbour & al, 1999). A virtual learning environment integrates a variety of tools supporting multiple functions:
information, communication, collaboration, learning and management (Peraya & al. in Dillenbour & al, 1999). Virtual learning
environments do not only integrate a variety of software tools but also integrate all the physical tools that can be found in a
classroom. According Carabaneanu (2006), a learning environment is considered adaptive if it is capable of: monitoring the
activities of its users; interpreting these on the basis of domain-specific models; inferring user requirements and preferences
out of the interpreted activities, appropriately representing these in associated models; and, finally, acting upon the available
knowledge on its users and the subject matter at hand, to dynamically facilitate the learning process.
Realistic Mathematics Education
Mathematics as human activity and mathematics must be connected to reality. These statements are the root of the
Realistic Mathematics Education (RME). RME refers to the mathematics education approach which has been developed and
applied in the Netherlands since 1971. Mathematics should be undertaken as an activity in the students experience mathematics
as a meaningful subject and can better understand it (Freudenthal, 1991). Freudenthal emphasizes real activity in mathematical
activities. Activities under consideration should consist largely of organizing or mathematization of subject matter and is taken
from reality. Learners must learn mathematics with mathematization of subject matter from the real context and activity of
mathematics, not learning from the traditional presentation of mathematics to the students as a ready-use system that is
generalized. Real situations can include contextual problems or authentic Mathematically Contexts for students where they're
having problems which are presented in relevant and real. The process of developing mathematical concepts and ideas that
started from the real world called conceptual mathematization (de Lange, 1993). Schematic model of learning is described as
follows.
Picture 1. Conceptual Mathematization(de Lange, 1993)
Through a process of progressive matematization, learners are given the opportunity to rediscover the insight,
knowledge and mathematical procedures. Thus learners do the stages which in RME called horizontal and vertical
mathematization. Gravemeijer (in Sembiring & al., 2008), suggests that there are three main principles of RME, namely: (a)
Guided reinvention / progressive mathematizing, (b) the didactical phenomenology and (c) self-developed models. For the
operationalization of the three main principles of RME, according Panhuizen (in Gravemeijer, 1994: 114-115), RME has five
characteristics, namely: a) The use of contextual problems, b) The use of various models, c) Student contributions, d)
interactivity, and e) intertwining (integrated). Strategy, which could be applied in the implementation of RME by LoucksHorsley (1998): (1) a short learning process, (2) curriculum development, and (3) the use of technology. The results of research
in the Netherlands showed that the RME has shown satisfactory results. RME has the potential to improve students'
understanding of mathematics (Streefland, 1991).

All human actions are called activities. An activity involves an object. The object is to be transferred to the output of
the activity. A subject performs an activity using a tool. The tool can be a physical or an abstract tool. The interactions between
subject, object and community can all be mediated. Rules mediate the activity between the community and a subject. The
activity may be collaborative, i.e. several subjects jointly do the activity using tools and dividing the work between each
subject (Multisilta, 2008). In general, tools, rules and division of work mediate the relationship between the subject,
community and object. Tools, rules and division of work are artefacts that are used to achieve the outcome. Experiences and
attitudes that influence one another (Uden, 2007). Activity can furthermore be divided into actions and an action on operations.
In general, activities are based on high-level goals (for example, documenting a work process with images and video clips).
The Shared Activities and Experiences framework originates from a need to describe sharing and experiences in social media
in theoretical terms (Multisilta, 2008).
Figure 2. The Shared Experience and Activities Framework (Multisilta, J., 2008)
Conceptual Framework and Research Question
Mathematics as human activity and mathematics must be connected to reality. Therefore, students shoud be able to
understand mathematics concepts and its application in the real world. Students' understanding can be optimized through social
interaction in the learning environment. There are two forms of learning environment, namely physical learning environments
and virtual learning environments. In a Virtual Learning Environment (VLE), students can interact with the other wherever and
whenever. In this learning environment, students do activities to learn and gain new knowledge and experience with solving
problems, sharing information, and discuss. Thus, students are expected to reach the upper limit of the zone of proximal
development (ZPD). Activities should be adapted to the characteristics of mathematics. Mathematical activity of solving
contextual problem starts from the real world problem, mathematizing and reflecting the problem, abstraction and
formalization, mathematizing in application and then bring back to the real world at the end process. In Realistic Mathematics
Education (RME) approach, this process is called Conceptual Mathematization
This research questions are (1) how to develop and implement the model of VLE based on RME in Semarang Senior
High Schools? and (2) Is the implementation of the model has a positive effect on student learning outcomes?
Research Method and Procedures
This research is a development research that continued from previous research, MATRIKSMovie: building the nation
character through movie-based RME (See also Cahyono, 2011). The purposes of this research is to develop the model of VLE
based on RME in Semarang Senior High School. According to Cahyono (2006), model is defined as a conceptual framework
used as guidance to do certain activity. Pouwer (1974: 243) explain about model as assumption like metaphor formulized
explicitly containing unsures which depends each other. As a metaphor, model has never been seen as part of data represented.
Model explains phenomena in a form which is not usual. Every model is needed to explain something more or different from
data. This requirement is fulfilled by presenting data in forms of summary (type, diagram), configuration (structures),
correlation (pattern), idealization and the combination of the four. Thus, model is metaphor which is solid and useful for the
comparation of relation between the choosen data and the relation among the choosen unsures of a logical construction.
In this study, validity, practicality and effectiveness criteria are defined as follows: validity refers to the extent that the
design of the intervention should include "state of the art knowledge" (content validity) and the various components of the
intervention are consistently linked to each other (construct validity), practicality refers to the extent that users (teachers and
pupils) and other experts consider the intervention as appealing and usable in normal conditions, effectiveness refers to the
extent that the experiences and outcomes from the intervention are consistent with the intended aims.
Following the work of Nieveen (1997) and Ottevanger (2001), the development and research activities in this research
were conducted in three stages. The first stage is called the front-end analysis, the current situation of mathematics learning in
Semarang Senior High School were analyzed. The second stage of the study is called the prototyping stage. This stage
consisted to develop and validate the prototype, namely virtual-learning device, the lesson kit and formative evaluation. The

implemented in Senior High School, and then the learning process and result are reflected and evaluated with the instrument.
Results and Discussion
The first stage is called preliminary stage or front-end analysis, that the current situation of mathematics learning in
Semarang senior high schools was analyzed. Result of the analysis in this stage are used as the basic for the development of
model with valid, practical, and effective criteria. There are some problems in learning mathematics, such as some students are
difficult to understand the concepts and problem solving, some students have low motivation in learning mathematics, and
some students do not understand the application of mathematics in real life. Students and teachers need a medium to interact
with easier, more enjoyable, and adjust to the development of information and communication technology. The results of the
analysis indicate that some of the high school students still require visualization of abstract concepts and application of
concepts in the real world. One material that is considered difficult by students is a matter of trigonometry. Student difficulties
understanding the concepts and solving problems related to trigonometry, including equations and trigonometric functions and
applications of trigonometry in real life. Students at this age also tend to be less motivated in carrying out learning activities in
mathematics and more interested in the entertainment and social networking because of the influence of age, social,
environmental, facilities, and technology. Technological development encourages innovation in teaching and learning of
mathematics by adjusting to conditions. By considering the expectations and problems, it is necessary to develop a model of
learning environment that makes the learning activities become easier and more enjoyable so the students can reach the
optimal learning outcomes. Learning outcomes and students' understanding can be increased as a result of interaction in
learning.
In the second phase (prototyping stage), the result of analysis in first stage used to develop the prototype. Based on
the preliminary analysis, the prototype being developed is a model and device of virtual learning mathematics based on RME,
called VirtualMATRIKS. The prototype that need to develop, i.e virtual-learning device, lesson plan, teachers guide, students
workbook, and the evaluation sheet. Preliminary description of the learning process is the students simulate of the conceptual
mathematization process by creating the movie about problem solving. Then students experiencing by share and discuss the
movie with other through virtual-learning device. It is based on the fact that mathematical activity of solving contextual
problem starts from the real world problem, mathematizing and reflecting the problem, abstraction and formalization,
mathematizing in application and then bring back to the real world at the end process. The activities of students in these
activities is to demonstrate the process of solving problems related to the rediscovery of the mathematical concepts and
applications of mathematical concepts in real life. Process in the production of educational films starting from a given theme as
a problem (in the form of the rediscovery of the concept of mathematics, or mathematical applications), then the students
discuss in a production team to develop problem-solving scenarios to be presented in the drama of human activity in problem
solving, setting up properties which is needed in problem solving and presentation, to present the steps solving the problem by
acting in front of the camera (as actrist or as a presenter), the product is presented in real video and/ or graphic animation
according to student creativity and made simple with simple tools, so implementation of these activities in accordance with the
allocation of time that has been planned in the lesson plan. The results of this learning process are portofolios and movie. Each
team share the learning experience by uploading the movie in the Virtual Learning Environment device, then students discuss
together about material with the guidance of teachers in the virtual learning environment. This activity can be done anywhere
and anytime, with rules specified by the teacher.
Draft of prototype validated by experts (education, mathematics, media, evaluation) to obtain a valid prototype and
ready to be implemented in learning process on the third stage. After validated, the prototype is corrected based on the
suggestions given by experts, so getting a second prototype that is better than ever. Then the second prototype was simulated in
the learning process. Simulation is used to obtain data on the implementation of models and tools in learning. The data come
from teachers, students, and the observer. Simulation concludes with discussion and reflection to obtain feedback and know the
lack of model and device as the basis for subsequent improvement. After repair and produce the final version of the prototype,
and ready for use, then executed the third stage. The result of prototyping are the model of virtual learning environment and
device of VLE. Learning environment that developed through this research is a hybrid learning environment (face-to-face
learning and learning through elearning devices). Learning processes and devices were developed based on the philosophy,
principles, and characteristics of RME and using IT-tools in the form of e-learning device that focus on providing support for
teacher(s) and students in the learning process. E-learning device was developed with the software and computer networks.
Syntax of the model are (1) Teachers provide instruction, convey learning goals, students in the class divides into groups,
distribute the student activity sheet, (2) The teacher gives problems to be solved by the students, so students are able to
construct the concept of matter being studied and/ or apply the concepts in real life, (3) Students discussing with his team to
share tasks and create problem-solving scenarios in accordance with the creativity of each. (with teacher guidance). (4)
Accordance with their respective duties, students creating a simple short film production process of solving the problem (the
construction of concepts and/ or application of concepts). (5) Each team sharing the learning experience by uploading a movie
in the VLE device (6) Students discuss their work together with the guidance of teachers in the virtual learning environment.
This activity can be done anywhere and anytime, with rules specified by the teacher, (7) Each student gives a conclusion. (8)
Teachers give clear, straighten the concept (if there is a less precise), and give final task of learning (projects, pop quizzes and/
or homework) using VLE device. Virtual learning device was developed and implemented by using software, hardware, and
computer network, that supports text files, images, interactive media, mathematical formulas and video. The device also
provides both synchronization and asynchronization communication feature.

share and discuss in VLE device
The third stage of the research is called the assessment stage. In this stage the final version of the VirtualMATRIKS
model and device are implemented in Senior High School, and then the learning process and result are reflected and evaluated
with the instrument.VirtualMATRIKS was implemented in a Semarang Senior High School class 10 in 2008 in the subject
matter of Trigonometry.
The research result suggest that the average of reliability of learning equipment (virtual-learning device, lesson plan,
teachers guide, students workbook, and the evaluation sheet) is 95,30%, that is a high reliability category, the capability of
teacher in organizing the learning could be categorized as very good, with average score 3,52. The average of teacher's
activities in the learning process is 3,54 or it reaches 88,48 % (category of very good). The average of students' activities in the
learning process is 3,54 or it reaches 88,57 % (category of very good). Seeing the average of students' involvement of each
meeting, it shows that there is an increase of students' involvement from 3.45 to 3.54 at the last meeting. The average of
students' skill of process in the learning is 3.57 or it reaches 89.26% (category of very good).
According the calculation,
2
x
calculation
= 1,296 which is significant at 0,069 > 0,05 , thus, Ho is accepted which
means the data has normal distribution. Therefore, the statistic used is statistic of parametric. The result shows that the
mathematics learning result data coming from upper, middle and lower groups in the experiment class and control class are
normally distributed and are homogenous. By using Univariate One Way Anova to test the difference of averages between the
upper, middle and lower groups. Based on the calculation, at the row group, the significant value is 0,020 < 5%, it means that
the learning outcomes between experiment class and control class is different. At the column group, the significant value is
0,000 < 5%, it means that there is no difference of the learning outcomes among the three groups (upper, middle, lower). Then,
there is no interaction because the value of significant is 0,091 > 5%.
By using Regression Analysis, F
calculation
= 25,643 with significant rate is 0,000. It shows that there is strong effect of
skill of process toward the learning outcomes or Ho is rejected which means there is influence between skill of process and
learning outcomes. From the calculation, the correlation between skill of process and learning outcomes is 63,5 % and the skill
of process gives contribution toward learning outcomes 40,3%. Therefore, the skill of process strongly correlates with the
learning outcomes. The regression equation between skill of process and learning outcomes is
^
Y = 32,371 + 2,657 X , where Y
= learning outcomes, and X = skill of process. From the calculation, F
calculation
= 27,616 with significant rate is. It shows
that there is strong effect of students' activity toward the learning outcomes or Ho is rejected which means there is influence
between students' activity and learning outcomes. The correlation between students' activity and learning outcomes is 64,9 %
and the students' activity gives contribution toward learning outcomes 42,1%. Therefore, the students' activity strongly
correlates with the learning outcomes. The regression equation between students' activity and learning outcomes is
^
Y = 13,968
+ 1,987 X , where Y = learning outcomes, dan X = students' activity.
From Compare Mean One Sample t Test , we find that t
calculation
= 2,963. By using right side test, for α = 5% and df
= n - 1 = 39-1 = 38 we gain t
1(α)(n--)1
= 2,021. Because t
calculation
> t
table
, then Ho is rejected. Therefore, it can be
concluded that the average of learning outcomes ≥ 65,0, thus, the students have mastered the material because they reach
material comprehension. Therefore, learning process using this model can reach the purposes of learning (reach the material

comprehension) with the average of learning result is 80,57.
The results of implementation show that the learning of mathematics through VirtualMATRIKS showed the good results. Activities and process skills of students in this learning is making a positive impact on student learning outcomes. The learning outcomes in this study referred to three aspects: cognitive, affective, and psychomotor. The cognitive aspect included pupils' achievement and reasoning, the affective aspect involved pupils' motivation, activity, and creativity, while the psychomotor included skills in problem-solving process. Scaffolding for students to reach the ZPD occurs when students interact with each other in processing of problem solving.
In the activities, students are trained to be creative and caring in problems solving, both social and environmental problems. Students work together in solving the problem. Students are able to communicate their ideas and dare to be responsible. This learning can build motivation, appreciation, contribution, interest, beliefs, creativity, confidence and
TOJSAT : The Online Journal of Science and Technology- July 2012, Volume 2, Issue 3
www.tojsat.net
75perseverance and a sense of responsibility and communication skills. RME approach can build self-reliance, democracy, tolerance, humanism and honesty. Mathematical learning occurs during the film production process and during the discussion and interact with teacher or the others using VLE device. Activities and process skills of students in mathematics learning through VirtualMATRIKS in the high school has provided a positive effect on the results student learning (cognitive, affective, and psychomotor). Students learning outcomes in this learning environment are better than students learning outcomes in the conventional leagrning environment. There is a difference between understanding and student learning outcomes between before and after the learning process in that environment. After interacting via the VLE devices, understanding and student learning outcomes are higher than ever. Students can reach the upper limit of the ZPD.
Conclusion and Suggestion
Based on the results from the three stages of this study, it has been concluded that: The result of this research is a VLE model based on RME, namely VirtualMATRIKS. In this learning environment, the students simulate of the conceptual mathematization process by creating the movie about problem solving. Then students experiencing by share and discuss the movie with other through virtual-learning device.Model and device are effectively implemented in mathematics learning in Senior High School, and this model gives a positive impact on student learning outcomes (cognitive, affective, and psychomotor). Students can reach the Upper Limit of Zone of Proximal Development.
Based on the conclusions of this study, it can be suggested that this model can be applied and developed further in learning mathematics by considering into environment, conditions and students interest.

Abstract
More sophisticated technology tools from laptops, smartphones, tabs and others make students dependence to use them and bring it everywhere they are. It would be better if they are used by the students to learn, not just for social networks such as Facebook, Twitter and others, but can be used for student's learning. The purpose of this research is to develop a blog based on the Realistic Mathematics Education (RME) in Algebra courses so that the students can access courses they need anywhere and at any time, review the effectiveness of blogs in supporting learning process algebra, review the practicality blog to use by students to have lecturing processes, use of sophisticated technology tools to support the learning process.
The development model employed the model of Dick and Carey (2009). This development model steps was started by writing targetted competences, to analyze learning, to identify basic ability, to write performance objectives, develop instrument assessment, to select and develop learning materials, to design and conduct formative evaluation, to revise, and design and develop summative evaluation.
The research results showed that validation of Educational Technology Expert of 88.7% and 89.71% by Mathematics Content Expert stated that the blocks with the RME approach was effective and practical, and could make the students understand the concepts of Algebra related to the real world. The results of testing a small group was 83.25%, and 85.50% for test large groups. From the tests that were done through pre-test and post-test, through the test of t> t table, it was obtained calculation results of t count = 6.48, while the values of the t table with significant levels of 5% and 1% were 2.09 and 2.84 respectively. Thus there were differences in the average value of learning achievements prior to and after the use of the blog-based learning (RME). In other words, the development of RME-based blog was effective to be used as a learning media and source to improve students' understanding of the Algebra materials.
Key Words : Blogs, Algebra, Realistics Mathematics Education (RME)
A. Introduction
As the times growing and more sophistication of technology tools from laptops, smart phones, Tab and others make students dependence to use and always bring them everywhere they are. The existences of these technological tools have a lot of benefits, ranging from as a means of communication and social networking, up to as a learning medium.
Math learning is not quite with learning process begins with lecturers to explain the algorithm with some examples, and then students do the exercises in accordance with the

example given by lecturers. The students are almost never given the opportunity by the lecturers to understand the rationale behind the algorithms that are taught to them. Lecturer focused the students to remember "the ways" they teach in solving the problem rather than to stimulate them to construct knowledge, so that the knowledge gained by the students is less meaningful and quickly forgotten .
In mathematics learning in higher education, there are a few things that tend to be ignored by the lecturers, which is characteristic of the topic being taught and student characteristics. From many mathematical topics that are taught, there is an easy one, so that the subject can be understood by the students just by listening to the explanation from the lecturer. Most of other topics will be understood if the presentation is accompanied by illustrations and drawings. Meanwhile, there are also topics to understand that requires hands-on activities or learning by doing. These conditions indicate that lecturers "should not" use the same learning methods from time to time. Lecturers need to select and use models, approaches, methods, or various media, making it easier for students to study a topic, and make the students actively in learning.
In addition, in terms of media usage, lecturer should use a simple, attractive, easily accessible media and close to the student life. Additional tools biasly used by lecturers as media are computer technology. Because through a computer program (internet), the users allows to save, organize and manipulate information, including text data and numerics (Eggen & Kauchak, 2012). In this modern era, the students are not strange with the internet. With the Internet, students can access a variety of information, ranging from the world of entertainment, social networking sites, even learning materials. However, many students today who prefer to use the internet to chat on social networks such as facebook, twitter, and others . It would be nice if they are used by the students to learn, not just on social networks such as Facebook, Twitter and others, but can be used for students' learning, such as Linear Algebra material.
Linear algebra is one of the mathematical material that is easy to understand if the presentation is accompanied by illustrations and drawings. In addition, many Linear Algebra material that can be associated with contextual problems. Therefore, researchers are interested in creating a Realistic Mathematic Education-based blog on Linear Algebra in UIN Riau Suska.
Realistic Mathematics Education (RME) approach is one approach that uses real-world context in the delivery of learning, where students are expected to be more motivated because they feel that math is very close to the real world. It's the real thing will be easier to remember than abstract ideas. Math will be easy to learn if you can see its application in the real world.
According to John Dewey (Uno, 2012), linking learning to one's life makes more meaningful learning, can learn something through experience, attention, and change; find it easier to run other activities conducted by a real and meaningful situations, so that students feel that learning mathematics has a great advantage because it can be applied in everyday life. Beside it with the blog Linear Algebra courses, students can access courses they need where anytime and anywhere, review the effectiveness of blogs in supporting learning process algebra, review the practicality of use student blogs to conduct the lecture, as well as the use of sophisticated technology tools to support the learning process. According to Sukiman (2012) through blogs bring significant benefits for students. Lecturers can lead the student to focus on the ideas or writing, or both. Thus, students can develop analytical abilities and faculty can learn to be a better writer and communicator.
Based on the background of the problem, this study focused on answering several questions as follows : 1) how is the expert response to the development of an EMR-based blog on Algebra course? 2) how is the media expert response to the development of an EMR-based blog on Algebra course? 3) how the test responses of learners in small groups towards the development of an EMR-based blog on Algebra course? 4) how the user response (educators) in field tests against the development of an EMR-based blog on Algebra course? 5) how is the Proceeding of International Conference On Research, Implementation And Education
Of Mathematics And Sciences 2014, Yogyakarta State University, 18-20 May 2014

ME-429
effectiveness of research products, which can be measured by looking at the difference between the scores of pre-test and post-test learners in the learning achieved by using RME-based blog ?
B. Method
This type of research used is the development (research and development/R & D). The use of this development research is based on the opinions Richey (Richey & Nelson, 2000) that facilitates the development of a research study of new models, equipment, and procedures that can reliably anticipate their effectiveness and efficiency. In this way, it can be determined the relevance from specific-context of the findings to other teaching and learning environment as well as to identify new general principles of design, development, and evaluation. When associated with this research that wants to create a blog based on the RME Linear Algebra courses that meet the valid, practical and effective criterias.
The design and procedures used in this study is a model of Dick and Carey (2009) with system oriented This model has ten following steps (Dick and Carey, 2000) . Picture 1
Figure 4.
The first step, second and third model of Dick and Carey are categorized into preliminary research activities. These activities include the identification of competencies to be achieved in a Linear Algebra course, learning analysis, and analyze the basic skills of students. The fourth, fifth, sixth, seventh steps are to write the specific purpose of learning or better known as the indicators of achievement of learning achievements of Linear Algebra course, the development of standard reference tests the development of learning strategies, and developing and selecting instructional materials is a further blog development steps. The next activities of development steps are evaluated in the eighth step which was to develop formative evaluation. Formative evaluation is done to see the advantages and disadvantages of the development of the

blog.
Picture 1. Development Model of Dick and Carey (2009)
Formative evaluations are conducted with the mechanism of one to one evaluation,
small group evaluation, and field trial evaluation. One to one is done by experts of Educational
Technology and Mathematics. After technology and maths experts provided materials'
improvement and certain considerations, and put them in a blog to be tested by the user as much
as 3 people from each of the different levels of ability and small group evaluation was
conducted to 6-9 users, as well as field trial evaluation conducted on 20 - 30 users. Field Risnawati, Annisa & Elviza /The Development of ... ISBN.978-979-99314-8-1
ME-430
evaluation or referred to by the term field trials was conducted on students of Mathematics
Education Program. Data collection instrument used in this study was a questionnaire and
observation sheet. Questionnaire was designed for experts and for field trials. Meanwhile, the
observation sheet was designed and used when we conducted field trials . Revisions were made
at each step .
In this study, it was used two data analysis techniques : 1) a qualitative descriptive
analysis techniques, 2) quantitative analysis techniques. Descriptive analysis techniques are
used to process data from the test results matter experts, media specialists, and educators a small
group of participants in the field test, whereas quantitative analysis is used to process the data
obtained from the questionnaire in the form of descriptive percent.
The data was processed on the field test data from the pre-test and post-test. Pre-test
achievements were given to students before the lecture with a problem-based learning blog,
while the post-test was given after they understood the blog with the problem-based learning.
C. Discussion
Based on the steps undertaken, EMR-based blog development product, the blog can be
unlocked through http://risna-wati-math.blogspot.com. Product development of the blog was
further validated and tested. The results were as described as follows :
1. Data of Validation Results from Educational Technology Specialists.
As a whole based on the indicators assessed by the Expert Technology from design blog, as well
as the suitability of the content of the expected performance, experts recommended that the
development of an EMR-based blog was well categorized, and it deserved to be used with the
percentage of 88.7%.
2 . Data of Validation Results from Matter Expert.
Validation that was performed by material experts recommended that RM -based blog deserved
to be used. Indicators of material truth and relevance to the basic competences and learning
indicator reaches 100% accuracy rate. This means that the competency has been referred to the
necessity of learning. Ease of understanding the material on blogs, attractiveness, clarity of
material, systematic presentation of the material presented had been very good. Matter expert
assessment of the components related to the design of the blog; subject's contents that include
affective, cognitive and psychomotoric, which means it has to meet several capabilities; quality
of the learning interaction; appropriateness of instructional media learning of life skills. Overall
data that was obtained from validation results of matter experts on a blog based on the category
of RME were very good around 89.71%.
3 . Results Data of Small Group Test.
Small group trials of 3-6 people as a whole was obtained a percentage rate of users reached
86.56 %. This quality means developing an EMR-based blog was in the category of fit for use.
Users expressed that blog can be studied either independently or in groups, anytime and
anywhere. This approach can make the students learn to understand and meaningful.
4 . Result Data of Field Test
The next test is to lecturers, before being tested, it was priorly socialized to lecturers of Linear
Algebra course, this blog was being piloted to two lecturers, field trial data on lecturers of
Linear Algebra course, the lecturer stated that this blog was easily understood by the students,
because it is directly related to their real life. Then the blog was directly tested on a large group
of about 20 people, from the processed data it was obtained the percentage of 85.50 % with
good qualifications. Based on the results of the assessment and expert reviews on both media
and materials, as well as individual testing, both small groups, to field test, the problem-based
learning-based blog was with good category.
5 . Different test of Pre-test and Post-test
Based on the tests that were tested through pre-test and post-test, through the test of t
count> t
table
, Proceeding of International Conference On Research, Implementation And Education
Of Mathematics And Sciences 2014, Yogyakarta State University, 18-20 May 2014

ME-431
it was obtained the calculation resultsof t = 6.48, while the value of the t
table with significant
levels of 5 % and 1 % were 2.09 and 2.84 respectively. Thus, there are differences in the
average value of learning achievements before and after using blogs based on problem-based
learning. In other words, the development of RME-based blog was effective to be used as a
media source and learning to improve students' understanding of the material Algebra.
Of the overall aspects evaluated and tested, it can be said that the development of this
blog was well categorized, in terms of fit to use as a medium of learning. Blog is a website that
is easy to use. This facility can quickly post thoughts of someone, interact with others, to
publish the papers, announcements and other much more advantages. Because it is easy and
practical, blogs can be used not only for communication but also used as a medium of learning
that allows everyone toaccess. Huette (2006) also described the benefits of using blogs in the
classroom, among other things : 1) to promote critical thinking and analytical, 2) to encourage
creative thinking, intuitive and associational thinking, 3) can encourage analogical thinking, 4)
has the potential to increase access and exposure to quality information, and 5) combining
solitary and social interaction .
RME incorporates the views of "what is mathematics, how students learn and how
mathematics should be taught. Mathematics education should lead students to use a variety of
situations and the opportunity to re-invent mathematics in their own way (Sutarto Hadi, 2005).
Through the blog, combined with real objects to make students learn more relaxed, less anxious,
because students can adjust the problem or understand an answer discovery materials at the time
the ability to think and learn. Wang, Haertel, and Walberg (1992) emphasized the importance of
reducing the anxiety of learning, particularly fear to do wrong, and to make students confident
(Harmin and Toth, 2012:68). Furthermore Harmin and Toth stated that all students have
individual learning styles, so the student can do and learn in accordance with the time he needs,
without any pressure. Learning without the pressure will be more meaningful.
Other advantages of developing blogs with RME based are as follows : 1) the student
can ask for the help of people who preferred to give understanding to those who are less
problems when they understand ; 2) can evoke the spirit of learning, because it is followed by
an attractive display, good presentation of the material, in fact the problem. 3) make it easier for
students to reinvent mathematics concepts in accordance with the characteristics of realistic
mathematics ; 4) to train students to solve math problems, with the understanding that has been
obtained in advance ; 5) makes it easy for lecturers to check student understanding
authentically, in accordance with the instructions in the blog. In addition to advantages also has
its limitations include 1) not all students have an internet connection ; 2) material developed is
limited to materials related to the real world.
D. Summary
Based on the formulation of the problem, the results of the data analysis and discussion
in this study, conclusions can be drawn. 1) learning technology experts responded that the
development blog RME -based learning was very good and it deserved to be used; 2) learning
materials experts responded that the block-based EMR was appropriate and feasible for use in
learning. 3) students as subjects for a small group test commented that the -based math blog
was good, because it could improve our understanding of Linear Algebra subjects; 4) lecturers
of Linear Algebra course in field tests provide a response that blocks mathematics through
problem-based learning was good and fit for use in the learning process; 5) based on the t test
conducted got the results of t
count (6.46), thus it can be said that t
count > t
table either on
significance levels of 1% (2.84) and 5 % (2.09). This means that there were differences in the
average value of student results after using blog trough RME-based learning.Risnawati, Annisa & Elviza /The Development of ... ISBN.978-979-99314-8-1
ME-432
Based on the research results, discussion and conclusions can be recommended : 1)
educators ought to have a strong desire and willingness to learn and make creative design that is
appropriate with learning system as learning needs in the classroom, in addition to the educators
also need to have creativity using ICT, both in the individual learning condition and study
group. 2) based on the data obtained, this study is limited to the pre-experimental phase with a
significant t-test results, the research can be carried out by quasi-experiments involving the
control group.

Does the use of technology make a difference in
the geometric cognitive growth of pre-service
mathematics teachers?
Gerrit Stols
University of Pretoria
This study investigated the geometric cognitive growth of pre-service mathematics
teachers in terms of the Van Hiele levels in a technology-enriched environment, as
opposed to that of students in a learning environment without any technological
enhancements. In order to investigate this, a quasi-experimental non-equivalent
comparison group design was used. Similar course content was used for both the
control and experimental groups. The students worked through a series of geometry
activities and problems. The difference between the groups was that dynamic
geometry software was integrated into the teaching of the experimental group. The
Cognitive Development and Achievement in Secondary School Geometry (CDASSG) Van
Hiele geometry test was used to determine all the students' level of geometric thinking
before and after the course. The study found that the use of dynamic geometry
software enhanced student teachers' geometric visualisation, analysis and deduction,
but not their ability to informally justify their reasoning and to understand the formal
aspects of deduction.
Background and literature study
Despite large amounts of money having been invested in equipping schools with
technology, there is limited evidence of positive effects on student achievement
(Wenglinsky, 1998; Zhao, Pugh, Sheldon & Byers, 2002). The assumption was that
increased availability of technology in the classroom would lead to increased use, and
increased use would then lead to not only efficient teaching and better learning, but
also better student achievement (Cuban, 2001). According to Brown-L'Bahy (2005),
researchers voiced uncertainty about the benefits of school technology use as early as
in 1987. In fact, Myhre, Popejoy and Carney (2006, p. 1002) pointed out that there is
"considerable uncertainty within the educational community regarding the value of
technology in teaching and learning". From these different arguments it is clear that
researchers themselves struggle with the question of whether and how technology can
improve teaching and learning. There are however researchers who believe that
technology, if correctly used, can enhance teaching and learning. Ching, Basham and
Planfetti (2005, p. 226) found from research that "student-centered, technologyintegrated learning environments help to produce students who are better able to
think critically, solve problems, collaborate with others, and engage deeply in the
learning process". According to Sanders (1998), the appropriate use of dynamic
geometry software can enhance mathematics teaching and conceptual development,
and enrich visualisation, while also laying a foundation for deductive proof.1234 Australasian Journal of Educational Technology, 2012, 28(7)
Wong (1998) contended that the instructional objective with graphing software is to
develop and reinforce concepts, to rectify common errors, to check graphical solutions,
to solve equations graphically, to test conjectures through problem posing, to
encourage users to become metacognitive, to help users to acquire information
technology skills, and to enhance the desire to learn. A study by Usun (2007) suggested
that if technology is used for higher-order learning, it can result in increased
mathematical achievement. Wang (2008) also argued that technology-supported
collaborative learning has a positive effect on students' performance in problem-based
tasks.
Guven (2012) explained that the contribution of technology to the teaching and
learning of geometry has been associated with the dynamic nature of software such as
Cabri, GeoGebra and Geometer's Sketchpad. The power of the dynamic software does not
stem only from the possibility of making constructing, it also allows interactive
explorations by the dragging of points, vertices and objects:

Once a construction is completed, the user can drag certain elements of it, and the whole construction behaves in such a way that specified constraints are maintained, providing an environment in which students can experiment freely. They can easily test their intuitions and conjectures in the process of looking for patterns … (Guven, 2012)
The current research aims to investigate whether and how the use of dynamic geometry software, such as Cabri 3D, GeoGebra and Geometer's Sketchpad, influences the cognitive growth of geometry students. The Van Hiele theory was used to measure the cognitive growth of these students. Idris (2009) also used the Van Hiele theory in a study among Form 3 students in one of the secondary schools in Malaysia and found that using Geometer's Sketchpad has promising implications for the potential for teaching geometry at the secondary school. This study, however, did not explain to what extent and how the use of the dynamic software influences the specific Van Hiele levels.
Theoretical framework
The Van Hiele theory was used to measure the cognitive growth of these students. This theory has made a significant impact upon geometry education, particularly after it became known internationally what its impact had been on Russian mathematics education. Following in the footsteps of Piaget, Pierre and Dina Van Hiele identified five hierarchical, sequential and discrete levels of geometric development that are dependent on a learner's experience. In contrast with Piaget's theory, development is not dependant on age but rather on experience and the quality of instruction. In this context, it is useful momentarily to consider the basic tenets of both Piaget and Van Hiele. Battista and Clements (1995, p. 50) summarised the two theories as follows: Piaget's theory, on the one hand, describes how thinking in general progresses from being non-reflective and unsystematic, to empirical, and finally to logical-deductive. The theory of Van Hiele, on the other hand, deals specifically with geometric thought as it develops through several levels of sophistication under the influence of a school curriculum.
According to Kotze (2007, p. 22), Piaget's argument can be put like this: there is a "maturation process" that takes a learner through acquisition, representation and characterisation of spatial concepts. Van Hiele, however, suggested progress throughStols 1235 thinking on sequential levels as a result of experience. This experience is almost entirely dependent on instruction (Larew, 1999). According to their model, learners have to master a level to be able move to a higher level. The levels, as described by Mason (2009, pp. 4-5) are as follows:
Level 1 (Visualisation): Students recognise figures by appearance alone, often by comparing them to a known prototype. The properties of a figure are not perceived. At this level, students make decisions based on perception, not reasoning.
Level 2 (Analysis): Students see figures as collections of properties. They can recognise and name properties of geometric figures, but they do not see relationships between these properties. When describing an object, a student operating at this level might list all the properties he/she knows, but may not discern which properties are necessary and which are sufficient to describe the object.
Level 3 (Abstraction): Students perceive relationships between properties and between figures. At this level, students can create meaningful definitions and give informal arguments to justify their reasoning. Logical implications and class inclusions, such as squares being a type of rectangle, are understood. The role and significance of formal deduction are, however, not understood.
Level 4 (Deduction): Students can construct proofs, understand the role of axioms and definitions, and know the meaning of necessary and sufficient conditions. At this level, students should be able to construct proofs such as those typically found in a high school geometry class.
Level 5 (Rigor): Students at this level understand the formal aspects of deduction, such as establishing and comparing mathematical systems. Students at this level can understand the use of indirect proof and proof by contrapositive, and can understand non-Euclidean systems.
The Van Hieles considered the levels to be discrete, but other researchers (Clements & Battista, 1992; Burger & Shaughnessy, 1986; Crowley, 1987) argue that since learners develop several Van Hiele levels simultaneously and continuously, it is problematic to assign a learner to a particular level. This is an important reason why this research focuses on the mean scores of the students per level, rather than to assigning students to particular levels.
Research question
The current study investigates whether the use of dynamic geometry software as an integrated part of instruction is beneficial in increasing students' geometric cognitive growth, measured in terms of the Van Hiele levels.
Research design
In order to address the above question, a quasi-experimental, non-equivalent comparison group design was used. The reason for this decision was that practically it was not possible to assign the students randomly into two groups because of their timetables. Two geometry classes of a one semester geometry module were used (Table 1).1236 Australasian Journal of Educational Technology, 2012, 28(7)
Table 1: Non-equivalent comparison group design

Group	Pre-test	Treatment	Post-test
Experimental/ technologyenriched group	CDASSG Van Hiele Test	Geometry course and tablet PC GeoGebra and Cabri 3D	CDASSG Van Hiele Test
Control group	CDASSG Van Hiele Test	Geometry course and tablet PC	CDASSG Van Hiele Test

The study used descriptive statistics, a McNemar Test on each individual test item, and independent t-tests to investigate whether the use of dynamic geometry software as an integrated part of instruction was beneficial in increasing students' level of understanding, as measured in terms of the Van Hiele levels.
Intervention
The researcher offered a six-month geometry module to two groups of third-year preservice student teachers at the University of Pretoria, South Africa. This module dealt with various aspects of geometry, including Euclidean. Problems and activities were presented and discussed in class, thereby gradually and almost imperceptibly taking students from one level to the next in terms of the development of their thinking. The idea was to start with activities on Level 2 and gradually increase the level of thinking so as to reinforce Levels 3 to 5. The design of the geometry course was loosely based on the five tenets developed by the Realistic Mathematics Education (RME) movement, as described by Treffers (1987, cited in Bakker, 2004). The first tenet states that "[a] rich and meaningful context or phenomenon, concrete or abstract, should be explored to develop intuitive notions that can be the basis for concept formation" (p. 6). These activities were meant to develop the students' understanding of geometry while solving real-world and theoretical problems. Although there was ample opportunity to integrate and use dynamic geometry software in this course, the course was not designed specifically for a technology-enriched environment. Both the control and experimental groups were taught by the researcher/lecturer with the same amount of contact time.
The researcher used GeoGebra and Cabri 3D in class when teaching the experimental group. These programs allow users to drag vertices and points to investigate and explore mathematical relationships. GeoGebra is an open-source dynamic mathematics software that combines arithmetic, geometry, algebra, statistics and calculus. Cabri 3D enables students and teachers to construct and investigate three-dimensional geometry. It encompasses the benefits of interactive geometry and enables the user to construct, measure, unfold and rotate objects. The experimental group also spent two weeks using GeoGebra in the computer lab. The students in the control group were not exposed in class to either of these software programs. It is however possible that some of the students in the control group had 'informal' access to GeoGebra outside the classroom because it could be downloaded for free.
Examples of activities and how GeoGebra and Cabri 3D were used
• Activity: If you have a piece of land that is a quadrilateral, what kind of quadrilateral will be formed if you take the midpoint of each of its four sides and join these midpoints? Explain and justify your answer.Stols 1237
The idea of the activity was firstly to explore and discover that the new quadrilateral EFGH is a parallelogram. The experimental group used GeoGebra to make the construction. The advantage of using GeoGebra is that the mouse could be used to drag the quadrilateral vertices A, B, C, and D in order to observe the behaviour of quadrilateral EFGH.
• Activity: If a line is drawn parallel from one side of a triangle, it will divide the other two sides proportionally.
GeoGebra was used by the experimental group to make the construction and to measure the segments accurately. The advantage of using GeoGebra is that the mouse could be used to drag the vertices A, B and C to create more special cases. GeoGebra will measure the segments immediately and also update any calculations.
• Activity: Calculate the surface area of the rectangular pyramid with a perpendicular height of 5 cm and base of 8 cm by 6 cm.
The idea of the activity was to unfold the pyramid and to draw the net and use Pythagoras Theorem to determine the height of the different triangles. This unfolding was also illustrated in the class of the experimental group by using Cabri 3D.1238 Australasian Journal of Educational Technology, 2012, 28(7)
• Activity: What is the sum of the measures of the interior angles of a 1000-gon (a triangle is a 3-gon)?
The idea of the activity was to force students to use inductive thinking. The students could find the pattern for a 3-gon (1 triangle), 4-gon (2 triangles), and 5-gon (3 triangles) and generalise the pattern. GeoGebra was used by the experimental group to sketch the quadrilaterals and to measure the interior angles.
A typical lesson consisted of a short introduction, after which students worked on a series of problems and spontaneously bounced ideas off their classmates. When the majority struggled too much, the researcher intervened and worked with them on specific problems. The nature of the struggling was threefold, in some instances it was limited knowledge of the software, sometimes a lack of content knowledge, and in some instances, limited problem-solving skills. For example, some students struggled to solve the following problem: What is the sum of the measures of the interior angles of a 1000-gon (a triangle is a 3-gon)? Some students lack problem solving skills and tried to construct a 1000-gon using GeoGebra. This approach does not work because it is too tiresome and will take hours. Other students tried to use inductive reasoning but did know how to measure the interior angles in GeoGebra.
Participants
The students in both the control and experimental groups were third-year BEd preservice teachers who were enrolled for two geometry courses at the University of Pretoria, South Africa. The study used a control group of 55 pre-service teachers and an experimental group of 53 pre-service teachers who were enrolled for the geometry module. These students were selected for the sake of convenience.Stols 1239
Research instrument
The research instrument that was used was the Cognitive Development and Achievement in Secondary School Geometry (CDASSG) Van Hiele Geometry Test that forms part of the CDASSG project developed by Usiskin (1982). The Van Hiele Geometry Test consists of 25 multiple-choice test questions (five questions on each Van Hiele level). This instrument was selected because it was easy to analyse, well tested, and widely used (permission was obtained from Professor Usiskin to use the test). By using the KuderRichardson Formula 20 in his study (1982), he found that the pre-test reliability of this test was 0.31, 0.44, 0.49, 0.13, 0.10 and 0.39, 0.55, 0.56, 0.30, 0.26 in the post-test for the questions on Van Hiele levels 1, 2, 3, 4, and 5 respectively. According to Larew (1999, p. 37), the construct validity of the instrument was established by Senk in 1989: Senk found that achievement in writing geometry proofs was positively correlated with Van Hiele level (.50 in the fall and .60 in the spring). Senk also found that in spring the percentage of students who had mastered proof from each spring Van Hiele level was as follows: Level 0 –17%; Level 1 –22%; Level 2 – 57%; Level 3 – 85%; Level 4 – 100%. These data seem to support that Level 3 (as tested by the CDASSG test) is the level at which students master proof and that Level 2 is a transitional level … These results established the predictive validity of the CDASSG Van Hiele Geometry Test.
Data analysis procedure
Both the experimental and the control group wrote the same pre-test and post-test, namely the CDASSG Van Hiele Geometry Test, before and after their courses were presented. During the first and last contact session students were given 30 minutes to complete the five multiple-choice questions on each of the five Van Hiele levels, thus in total 25 questions.
As a first step, descriptive statistics were used to determine the average scores of students in both the control and experimental groups on each Van Hiele level before and after the course. Secondly, the study employed an independent t-test for each Van Hiele level, to investigate whether the difference between the pre- and post-test was as a result of the use of GeoGebra and Cabri 3D during instruction.
Results and discussion
The results of the study suggest that the pre-service mathematics teachers did not have a sound understanding of more advanced Euclidian geometry. The most problematic areas were the construction of proofs, understanding the role of axioms and definitions, and an understanding of non-Euclidean systems. There was a definite descending trend from Level 1 (Q1 to Q5) through to Level 4 (Q16 to Q20), as predicted by the literature (see Figure 1). This was, however, not the case with the Level 5 (Q21 to Q25) questions. The students performed slightly better on the Level 5 questions compared to the Level 4 questions. This was contrary to the Van Hiele model, which suggests that mastering on one level is a prerequisite for mastering on the next level.1240 Australasian Journal of Educational Technology, 2012, 28(7)

Figure 1: Percentage of students who answered the questions correctly
Although Question 4 was poorly answered compared to the other Level 1 questions
(Q1 to Q5), the experimental group did perform slightly better than the control group.
The use of dynamic geometry software probably improved students' understanding of
the basic definitions and properties of the different quadrilaterals. Question 4 was
"Which of these are squares?"
A) None of these are squares
B) G only
C) F and G only
D) G and I only
E) All are squares
Figure 2 analyses the selection of distracters as selected by the students. Although only
a few students selected distracters A and C, distracters D and E attracted quite a
number of students. A possible reason for selecting options D and E could be that
some students were under the impression that the inclusion property works in two
directions. Students who selected option D defined a square as a quadrilateral with
four equal sides.
Students found it difficult to grasp the idea of class inclusion or hierarchical
classification, such as a rectangle being a type of a parallelogram. The idea of class
inclusion falls typically in the abstraction level of geometrical thought, which is Level
3. This may be the reason why Question 14 was also poorly answered, compared to the
other questions (Q11-Q15) on Level 3.

Figure 2: Percentage of students who selected the different distracters (Question 4).
Which of these can be called rectangles?
A) All can.
B) Q only
C) R only
D) P and Q only
E) Q and R only
The same phenomenon has been identified by other researchers. A study done by
Smith (1987) revealed that students find these questions about class inclusion or
hierarchical classification consistently more difficult than some higher-level questions
(on Levels 4 and 5).
Other outlier questions that were poorly answered compared to other questions on the
same level are 10, 19, 21 and 22. These questions will be discussed briefly. Question 10
(Van Hiele Level 2) concerned diagonals, sides and the angle properties of a rhombus.
Question 19 (Van Hiele Level 4) focused on the properties of an axiomatic system
while questions 21 and 22 (Van Hiele Level 5) dealt with non-Euclidean geometry:
P Q R1242 Australasian Journal of Educational Technology, 2012, 28(7)
In F-geometry, which is different from the geometry
you are used to, there are exactly four points and six
lines. Every line contains exactly two points. If the
points are P, Q, R and S, and the lines are {P,Q}, {P,R},
{P,S}, {Q,R}, {Q,S}, and {R,S}. Here is how the words
"intersect" and "parallel" are used in F-geometry. The
lines {P,Q} and {P,R} intersect at P because {P,Q} and
{P,R} have P in common. The lines {P,Q} and {R,S} are
parallel because they have no points in common. From
this information, which is correct?
A) {P,R} and {Q,S} intersect.
B) {P,R} and {Q,S} are parallel.
C) {Q,R} and {R,S} are parallel.
D) {P,S} and {Q,R} intersect.
E) None of the above answers (A–D) is correct.
In order to determine the impact of the use and non use of dynamic geometry software
on students' understanding of individual questionnaire items, a McNemar test was
applied (see Table 2).
Table 2: McNemar Test applied to each individual questionnaire item

Only two items showed that the use of technology has a statistically significant (below
the 5% confidence level) impact on students' conceptual understanding. That was Q6,
which is about the properties of quadrilaterals, and Q11, which is about mathematical
logic. Three items in the control group showed that the non-technological intervention
had a statistically significant (below the 5% level) impact on students' conceptual
Q
R
P
SStols 1243
understanding. These questions were Q13, Q23 and Q25. Both Q23 and Q25 focused on
mathematical rigor and the students' understanding of formal aspects of deduction.
The means were computed to summarise the scores (out of 5) for each Van Hiele level
for both the pre- and post-tests (see Table 3). The majority of students did not reach the
Van Hiele levels 4 or 5 in both groups and only about half reached Van Hiele level 3. It
came as a surprise that not all pre-service students scored full marks on Van Hiele
levels 1, 2 and 3 in both the control and experimental groups – not even after the
course had been presented.

Comparing the mean improvements of the control and experimental groups in Table 3,
it appears that the technology-enriched environment improved the conceptual
geometric growth of students in the experimental group on Van Hiele levels 1, 2 and 4.
However, there was also evidence of cognitive growth when technology was not used
on Van Hiele levels 1, 3, 4 and 5. The negative mean improvement score on Van Hiele
level 5 suggests that the technology-enriched environment did not enhance students'
understanding of the formal aspects of deduction, such as proofs. In the "rigor" (Level
5) category (questions that covered the more formal aspects of deduction), the score of
the experimental group declined, while the control group improved on average by 0.93
(out of 5) on Van Hiele level 5 questions.
An independent samples t-test was conducted to compare the improvement in scores
of the control and the experimental groups for each Van Hiele level. The results of the
mean (maximum 5) improvement on each level are presented in Table 3. The results of
the independent t-test show that the only statistically significant difference in the preand post-test scores of the control group was on Van Hiele levels 3 and 5 at $p < .05$ (see
Table 4). In the case of the experimental group (technology-enriched) there was a
significant difference in the pre- and post-test scores on Van Hiele levels 1, 2, 3 and 4 at
$p < .05$.
Conclusion
This study sought to use the Van Hiele theory to investigate the geometric cognitive
development of students in a technology (dynamic geometry software) enriched
environment, compared with students in a learning environment without any
technological enhancement. The results suggest that the technology enriched
environment helped to improve the conceptual geometric growth of students on Van1244 Australasian Journal of Educational Technology, 2012, 28(7)
Hiele levels 1, 2 and 4 which is about geometric visualisation, recognition of properties
of geometric figures, and the construction of proofs. This finding about the
improvements on Van Hiele levels 1 and 2 resonates well with the literature, which
suggests that technology can help to create an active learning environment in which
students can discover, explore, conjecture and visualise.

* indicates a significance at the 0.05 level (two-tailed)
Dynamic geometry software cannot improve Van Hiele level 4 reasoning directly
because deductive reasoning is about the understanding of axioms and the
construction of proofs. The question then is why this improvement on Van Hiele level
4? According to the Van Hiele theory the use of dynamic geometry software is not
rendered worthless on this level. Larew (1999) argues that in order for students to
reason at the higher levels, there must be sufficient mastery at the lower levels. De
Villiers (2007, p. 55) explained:
This is why I have frequently argued that it is far more meaningful to INTRODUCE
proof within a dynamic geometry context, NOT as a way of making sure, but rather as
a means of explanation, understanding, and discovery before dealing with the more
formal and abstract functions of verification and systematisation.
Although the experimental (technology-enriched) group outperformed the control
group on Van Hiele levels 4, this advantage did not materialise in terms of a better
understanding on Van Hiele level 5. The results also show that the use of dynamic
geometry software, as opposed to a traditional learning environment of the control
group, may have a negative impact on the geometric development on Van Hiele levels
3 and 5. These levels are about informal argumentation and the formal aspects of
deduction. This result suggests that geometric reasoning at the Van Hiele level 5
(deduction) differs in nature compared to the first 4 levels, which concern
visualisation, relationships between properties, informal justification, and proof.Stols 1245
In fact, several researchers found the last Van Hiele level problematic. Even Pierre Van
Hiele (1986, p. 64) himself, writing subsequent to the demise of his wife, admitted that:
"It takes nearly two years of continual education to have the pupils experience the
intrinsic value of deduction, and still more time is necessary to understand the intrinsic
meaning of this concept". Weber (2001, p. 102) found that: "While this research has
provided rich data, there is a large and important class of failed proof attempts that it
cannot explain. Students often fail to construct a proof because they reach an impasse
where they simply do not know what to do." The achievement or lack thereof cannot
be accounted for on the grounds of Van Hiele levels alone. Weber (2001, p. 116)
concluded that students also need strategic knowledge, but is fully aware of the
problematic consequence of the fact: "Since strategic knowledge is heuristic, designing
activities that will lead students to acquire this knowledge will be a formidable task."
De Villiers (1987, p. 24) pointed out that "two aspects of the Van Hiele theory need
clarification and further research, namely a refinement with regard to the levels at
which deduction (as justification, explanation and systematisation) is supposed to
occur, as well as the relationship between hierarchical thinking and deduction".
Against this background it is understandable that the use of dynamic geometry
software does not support the development of the formal aspects of deduction. The
results of this study therefore contradict some of the findings of other studies, as
mentioned in the literature review, which suggested that the use of technology always
supports the development of higher-order thinking.
Limitations
A limitation of the present study was the fact that the Van Hiele test that focuses on
Euclidean geometry was used. The course offered covered not only Euclidian
geometry, but also analytical geometry, transformation geometry, and volumes and
surface areas. However, this particular test still gave us insight into students'
understanding of one of these topics. A possible idea for future research is the
development of a new and more comprehensive geometry test.
Another possible limitation of this study in terms of the Van Hiele module is identified
by Salomon (2005, p. xvii), who warned that:
Related to this is the assumption that wisely integrating technology into instruction will
yield better learning outcomes assessed by the same yardsticks. But this totally ignores
the observation that the use of different instructional means afford different kinds of
learning activities which, in turn, facilitate the attainment of different kinds of outcomes.
Acknowledgments
The financial assistance of the Research and Development grant from the University of
Pretoria towards this research is hereby acknowledged. Opinions expressed and
conclusions arrived at, are those of the author. I want to thank Prof. Z. Usiskin from
the University of Chicago for permission to use and copy the CDASSG Van Hiele
Geometry Test, and also Prof. F. Steffens for the statistical analyses made.

(Received 11 November 2009;final version received 26 February 2010)

A large body of research has shown that for novice learners, instruction that relies
more heavily on worked examples than on problem solving, is more effective for
learning as shown by higher test performance. Moreover, this beneficial effect is
often obtained with less acquisition time and lower cognitive load during acquisition
and test phase. However, most of this research has been conducted in laboratory
settings with college or university students and a control condition consisting of
problem solving without any additional support. The present study, using a quasiexperimental design, investigated the effects ofimplementing worked examples in an
existing primary school mathematics curriculum in which a realistic mathematics
teaching method is used, during a 3-week period. The results showed no significant
differences in test performance or cognitive load; however, the worked examples
group attained this level of performance with significantly less acquisition time.

Keywords: worked examples; problem solving; cognitive load; mathematics;
primary education

Introduction

The present study investigated the effects of implementing worked examples in an
existing primary school mathematics curriculum in which a realistic mathematics
method is used, over a 3-week period. Despite the popularity of ''learning by doing''
in contemporary education, a large body of research has shown that for students
who lack prior knowledge of a task, self-directed problem solving is not the most
efficient way to acquire knowledge. It is far more effective and efficient for novice
learners to study a good example (see Atkinson, Derry, Renkl, & Wortham, 2000;
Sweller, 2006; Sweller, Van Merrie¨nboer, & Paas, 1998). This has become known as
''the worked example effect'', which cognitive load theory has explained as the
effectiveness of worked examples in terms of reduced ineffective load on working
memory (Sweller, 1988; Sweller et al., 1998).

Cognitive load theory

Cognitive load theory (Sweller, 1988; Sweller et al., 1998) is concerned with the
design of instructional methods that efficiently use people's limited cognitive

Downloaded by [North West University] at 00:46 28 May 2015 processing capacity. The theory distinguishes three types of cognitive load: Intrinsic,
extraneous, and germane load. Intrinsic load depends on the complexity of a task,
that is, on the number of interacting information elements the task contains
(Chandler & Sweller, 1991). These elements have to be processed simultaneously in
order to successfully learn to perform that kind of task. Because working memory
capacity is limited to seven plus or minus two elements (or chunks) of information
when merely holding information (Miller, 1956) and even fewer (ca. four) when
processing information (Cowan, 2001), the higher this number of interacting
information elements is, the higher the intrinsic load imposed on working memory is.
However, intrinsic load does not only solely depend on the nature of the task but
also on the level of expertise of the learner. As expertise increases, information
elements contained in the task become incorporated into cognitive schemata stored
in long-term memory. Because a schema retrieved from long-term memory can be
handled in working memory as a single element, the number of interacting
information elements a task contains, and hence, the intrinsic load it imposes,
decreases for more knowledgeable learners. With extended practice, certain
schemata can be automated and no longer require controlled, effortful processing,
which further reduces the load on working memory (Schneider & Shiffrin, 1977).
Extraneous and germane load both depend on the way the task is designed, with
extraneous load being imposed by processes that are evoked by the design of the task
that are ineffective for learning (e.g. unnecessary visual or mental search processes)
(Chandler & Sweller, 1991) and germane load being imposed by processes evoked by
the design of the task that do contribute to learning (e.g. imagining a solution
procedure) (Cooper, Tindall-Ford, Chandler, & Sweller, 2001). The central tenet of
cognitive load theory is that in order to be effective and efficient, instruction should
be designed in such a way that intrinsic load is optimized, that is, tasks should be at
an appropriate level of complexity for trainees (i.e. challenging, but feasible; cf.
Vygotsky's (1978) concept ofthe Zone ofProximal Development), extraneous load is
minimized, and germane load is optimized so that the available cognitive capacity is
optimally used (Sweller et al., 1998). An effective instructional technique to
accomplish this is to implement a heavier reliance on worked example study rather
than problem solving.

Effectiveness of worked examples

Conventional problems contain only a description of some ''givens'' (e.g. how fast a
car accelerates and its average velocity) along with a goal statement (e.g. ''calculate
how far the car has traveled''). Instruction that consists mainly of solving
conventional problems forces novices to resort to weak problem-solving strategies
such as means-ends analysis, which impose a high cognitive load but are not effective
for learning: even though such weak strategies may allow learners to succeed in
solving the problem eventually (i.e. performance), they have been shown to
contribute very little to learning (Sweller, 1988), that is, to building a cognitive
schema ofhow such problems should be solved. Worked examples prevent the use of
such weak problem-solving strategies, by presenting the learner not only with the
givens and a goal statement but also with the worked-out solution steps that are to
be taken to reach the goal state. The learner can devote all his or her available
cognitive capacity to studying the given solution and constructing a cognitive schema
for solving such problems. As such, compared to instruction consisting of

Downloaded by [North West University] at 00:46 28 May 2015 conventional problem solving, instruction that relies more heavily on studying
worked examples reduces ineffective cognitive load on working memory, and
enhances learning, as well as transfer. That is, students not only learn how to solve
identical problems but also (partly) novel problems, for which they have to flexibly
adapt the learned solution procedure (see Sweller et al., 1998). In addition to
enhanced learning and transfer (i.e. higher test performance), a heavier reliance on
worked examples has also been shown to have beneficial effects on required
acquisition time (i.e. lower) (see e.g. Sweller & Cooper, 1985; Van Gog, Paas, & Van
Merrie¨nboer, 2006; Zhu & Simon, 1987) and cognitive load experienced by students
during acquisition (i.e. lower) (see e.g. Paas & Van Merrie¨nboer, 1994; Van Gog
et al., 2006) as well as during the test (i.e. lower) (see e.g. Paas, 1992; Paas & Van
Merrie¨nboer, 1994).

It should be noted though, that these beneficial effects of worked examples on
learning, acquisition time, and cognitive load, seem to apply primarily to novice
learners, and only when the examples are well-designed. To start with the latter,
following the early studies on worked examples by Sweller and Cooper (1985) and
Cooper and Sweller (1987), it was soon discovered that studying worked examples
was not always more effective for learning than problem solving. Rather, the design
of the examples played a crucial role in their effectiveness (Tarmizi & Sweller, 1988).
If worked examples induced split attention, by presenting mutually referring
information sources such as text and picture/diagram separately, a worked example
effect (i.e. benefit over learning by problem solving) was not obtained. Presumably,
this was due to extraneous cognitive load imposed by the processes of dividing
attention (i.e. visual search) and mental integration that were required in order to
learn from the separate sources of information. When these information sources
were presented in an integrated manner, the worked example effect was again
obtained (Tarmizi & Sweller, 1988); reduction of extraneous load due to split
attention can also be done by providing spoken rather than written text with the
pictorial information in the example (Mousavi, Low, & Sweller (1995). On the
other hand, when information sources are not mutually referring and can be
easily understood in isolation, extraneous cognitive load is imposed by the need
to process redundant information. In this case, one of the information sources
should be left out (see Chandler & Sweller, 1991). Next to these basic
requirements for the design of worked examples, there are some design measures
that can be applied to enhance the effectiveness of examples even further, by
stimulating more active processing of the examples or emphasizing important
aspects of the procedure (i.e. increase germane load) (Paas & Van Gog, 2006),
such as making subgoals explicit through labeling or visually isolating sets of
steps (e.g. Catrambone, 1995), requiring students to complete steps in partially
worked-out examples (e.g. Paas, 1992), asking students to explain the principles
behind the worked-out solution steps for themselves (e.g. Chi, Bassok, Lewis,
Reimann, & Glaser, 1989; Renkl, 1997), or providing them with instructional
explanations (e.g. Lovett, 1992; Renkl, 2002) or problem-solving process
information (e.g. Van Gog, Paas, & Van Merrie¨nboer, 2008) that help them
understand the principles behind the solution steps.

Next to design, prior knowledge also plays a role in the effectiveness of worked
examples. As mentioned above, with increasing expertise, the intrinsic load imposed
by the task becomes lower. As a consequence, extraneous load might no longer have
negative effects, as enough cognitive capacity is available to deal with the task

Downloaded by [North West University] at 00:46 28 May 2015 aspects that impose extraneous load. Moreover, techniques that may successfully
reduce extraneous load for novice learners, such as studying worked examples, may
increase extraneous load for more knowledgeable learners. That is, because of their
prior knowledge, studying the worked-out solution is a redundant, unnecessary
cognitive activity. As a consequence, for advanced learners, worked examples may
no longer be effective, or may even start to hamper learning (e.g. Kalyuga, Chandler,
Tuovinen, & Sweller, 2001). This is an example of what is known as the ''expertise
reversal effect'' (for a review, see Kalyuga, 2007; Kalyuga, Ayres, Chandler, &
Sweller, 2003).

In sum, the worked example effect indicates that when examples are well-designed,
instruction that relies more heavily on example study is more effective, efficient, or
both, for novices than instruction consisting of problem solving. A ''heavier reliance''
on example study has been implemented differently in different studies, though. Some
authors have compared instruction consisting only of studying examples to instruction
consisting of problem solving (e.g. Van Gerven, Paas, Van Merrie¨nboer, & Schmidt,
2002; Van Gog et al., 2006, 2008), whereas others have used example-problem pairs,
arguing that this would be more motivating for students (e.g. Cooper & Sweller, 1987;
Sweller & Cooper, 1985), or two examples-one problem triplets (Paas, 1992). Others
have used problem-example pairs, arguing that this allows students to experience where
their difficulties with problem solving occur, so that they would subsequently study the
example more closely (e.g. Stark, Gruber, Renkl, & Mandl, 2000; for a discussion of
their study in English see Stark, Gruber, Hinkofer, & Mandl, 2004). Finally, a heavier
reliance on example study has been implemented by providing students with examples
that are available for students to use as an analogy while they are solving a problem
(e.g. Reed, Dempster, & Ettinger, 1985), which is also the approach taken in this study.

The present study

Although the effects of worked examples on mathematics learning have been widely
studied (e.g. Carroll, 1994; Cooper & Sweller, 1987; Mwangi & Sweller, 1998; Reed
et al., 1985; Sweller & Cooper, 1985; Zhu & Simon, 1987), research consists mostly of
short-term experimental studies (i.e. conducted in one or two sessions); there are very
few studies done in actual school curricula over a longer period of time (for an
exception, see e.g. Zhu & Simon, 1987). Moreover, most of the research on learning
from worked examples has been conducted with college or university students, and very
little with primary school age children (for an exception, see e.g. Mwangi & Sweller,
1998). Finally, the control condition in previous research usually consisted of problem
solving by oneself without any additional instructional support or guidance, not of the
teaching methods regularly used in schools, which might be a stronger control
condition (cf. Schwonke et al., 2009).

Therefore, the present study investigated the effects of implementing a heavier
reliance on worked examples by providing them as analogies for problem solving in
an existing primary school mathematics curriculum in which a realistic mathematics
teaching method is used, over a 3-week period. The focus during this period was on
subtraction problems with borrowing 10s and 100s. Such problems contain many
interacting information elements, so they impose a high intrinsic cognitive load for
students, and – probably as a consequence – many errors may occur, such as
subtracting digits in the wrong order, trying to borrow from zero rather than
the column to the left, not carrying 10s or 100s, etc. (see Peltenburg, Van den

Downloaded by [North West University] at 00:46 28 May 2015 Heuvel-Panhuizen, & Doig, 2009). Based on previous research, it is hypothesized
that the availability of worked examples as an analogy for problem solving, will lead
to lower acquisition time, lower cognitive load during acquisition and test phase, and
higher test performance.

Method

Participants and design

Participants were 45 fourth-grade Dutch primary school students (age M ¼ 9.9
years; SD ¼ 0.34). They were students from two existing classes of the same school.
A quasi-experimental design was used in which one class (n ¼ 23) was assigned as
experimental group and one class (n ¼ 22) as control group.

Materials

Subtraction instruction

This primary school uses a realistic mathematics teaching method called ''RekenRijk''

(Bokhove, Kuipers, & Postema, 2003). This method consists of 12 blocks per year. This study focused on block 6, in which subtracting with borrowing 10s and 100s is taught. This block consists of 12 lessons (four teaching lessons, six self-study lessons, one repetition lesson, and one ''deepening understanding'' lesson). Six of those lessons were devoted to subtracting with borrowing 10s and 100s according to the problem format 787 7 492 ¼ . . . (i.e. in the other lessons, other problem types such as word problems were used), so data from these lessons are used in the analyses.
The control group engaged in their regular instruction and self-study using the RekenRijk method materials. The experimental group also engaged in their regular instruction and self-study with the RekenRijk method and materials, but additionally received two worked examples on subtracting with borrowing (one on borrowing 10s and one on borrowing 100s), which were explained by the teacher in the first lesson and were handed out to each student so that they could consult these examples as an analogy for problem solving throughout the acquisition phase.
Cognitive load rating scale
The most common method ofmeasuring cognitive load in educational research is via subjective rating scales (Paas, Tuovinen, Tabbers, & Van Gerven, 2003). An illustrated 4-point cognitive load rating scale was developed for this age group, asking students to indicate how ''heavy'' they found the tasks they just completed, ranging from (1) not at all (a drawing of a child carrying one block above her head and smiling), to (4) very heavy (a drawing of a child carrying four blocks above her head looking sad).
Time-on-task
Students were asked to write down their start and end times on the pretest and posttest and for each lesson according to a digital alarm clock that was placed in such a way that it was clearly visible for all students.

Downloaded by [North West University] at 00:46 28 May 2015
Pretest andposttest
To measure participants' knowledge gain, the regular ''Block Test'' for Block 6 from the ''RekenRijk'' method (Bokhove et al., 2003) was used. Twenty items from this test concerned subtracting with borrowing 10s and 100s similar to the problems that were worked out in the examples, so these 20 items were used to determine test performance in the context of this study.
Example experience questionnaire
To get an impression of how students in the worked examples condition experienced working with the examples, a short self-report questionnaire was used, with answer options ''no'', ''don't know'' or ''yes'', that asked students: (1) whether the examples were clear, (2) whether they felt problem solving was easier when using the examples, (3) whether they felt they required less assistance during problem solving when using the examples, (4) whether they used the examples with every problem, (5) whether they would want to use examples also with other types of problems.
Procedure
Prior to the study, the teachers received information about how to proceed in their respective condition. In the control group, this meant engaging in instruction as usual, except for the pretest and the cognitive load and time on task measures that were added for this study. In the experimental group, this additionally included information for the teachers on how to implement the examples. Students were also acquainted with the cognitive load and time on task measurement procedure prior to the study, and they were informed that the pretest (which was added for this study) would not be taken into account in determining their progress report scores. At the start of the 3-week period, participants first completed the pretest, indicating their perceived cognitive load immediately after completing the test. Then, for 3 weeks, they engaged in the learning activities of Block 6 of the RekenRijk method, either with or without the additional worked examples depending on their assigned condition. For each lesson, students indicated their start and end time according to the digital clock, and at the end of each lesson rated their perceived cognitive load. Finally, all students completed the posttest, again indicating their perceived cognitive load immediately after completing the test. In the week after the posttest, the students in the worked examples condition completed a short questionnaire about their experience working with the examples.
Results
Means and standard deviations of performance, cognitive load, and acquisition time are presented in Table 1. A repeated measures analysis on pretest and posttest performance showed - as one would expect - a significant reduction in the amount of errors made (max. ¼ 20) from pretest (M ¼ 15.98, SD ¼ 6.26) to posttest (M ¼ 5.91, SD ¼ 4.85), $F(1,42)$ ¼ 101.94, MSE ¼ 21.89, p 5 .001; however, there was no significant interaction with group $F(1,42)$ 51, ns. That is, in contrast to our hypothesis, the worked examples group did not outperform the control group on the posttest.

Downloaded by [North West University] at 00:46 28 May 2015
A repeated measures analysis on perceived cognitive load during pretest and posttest showed - as one would expect given the increase in knowledge - a significant reduction in the perceived cognitive load from pretest (M ¼ 2.70, SD ¼ 1.03) to posttest (M ¼ 1.61, SD ¼ .78), $F(1,42)$ ¼ 39.69, MSE ¼ .66, p 5 .001; however, there was no significant interaction with group $F(1,42)$ 51, ns. That is, in contrast to our hypothesis, the worked examples group did not experience lower cognitive load than the control group on the posttest.
An ANOVA showed that in contrast to our hypothesis, perceived cognitive load during the acquisition phase in the six lessons on subtraction with borrowing did not dijer between the experimental group and the control group, $F(1,38)$ 5 1, ns (four participants were excluded from this analysis due to missing data on one or more of the lessons). However, in line with our hypothesis, there was a significant dijerence in acquisition time during those lessons (five participants were excluded from this analysis due to missing data on one or more of the lessons), with acquisition time in the experimental group being lower than in the control group, $F(1,37)$ ¼ 6.28, p ¼ 0.017.
Descriptive statistics of the examples experience questionnaire data are provided in Table 2. Not taking into account the ''don't know'' answers, it can be concluded that all students found the examples clear, and the majority of students reported they found problem solving easier when using the examples, felt they required less assistance from a teacher or peer when using the examples, would like to work with examples also with other types of math problems, and that they had not used the examples as an analogy with every problem they solved.
Table 1. Means and standard deviations of performance, cognitive load, and acquisition time.

	Control		Worked examples	
	M	SD	M	SD
Pretest performance (number of errors, max. ¼ 20; lower ¼ better)	15.90	6.43	16.04	6.24
Pretest cognitive load (max. ¼ 4)	2.76	1.00	2.65	1.07
Cognitive load acquisition (max. ¼ 4)	1.62	0.50	1.66	0.52
Acquisition time (min.)	33.80	5.40	29.44	5.43
Posttest performance (number of errors, max. ¼ 20; lower ¼ better)	5.52	4.43	6.26	5.27
Posttest cognitive load (max. ¼ 4)	1.62	0.87	1.61	0.72

Table 2. Answers to example study experience questionnaire (n ¼ 22, data from 1 participant missing due to absence).

Question No	Don't know	Yes	Proportion Yes/Yes þ No (%)
Were examples clear?	0	2	20 100.00
Problem solving easier when using examples?	4	5	13 76.47
Less assistance required when using examples?	5	5	12 70.59
Examples used with every problem?	10	10	2 16.67
Want examples also with other problems?	3	7	12 80.00

Discussion
This study aimed to investigate the ejects of implementing a heavier reliance on worked examples in an existing primary school mathematics curriculum over a 3-week period. It was hypothesized that a heavier reliance on worked examples would lead to lower acquisition time, lower cognitive load during acquisition and test phase, and higher knowledge gains (i.e. dijerence between pretest and posttest scores). This hypothesis was only partially confirmed: No dijerences in test performance or cognitive load were found between the groups, but the worked examples group did require less acquisition time.
Even though there were no dijerences in perceived cognitive load between the two groups, the measure that was developed for this study seems to be adequate for use with relatively young children, and seems to show construct validity. That is, for people without any prior knowledge, as was the case at the time of the pretest, problem solving tasks impose a much higher intrinsic load than for people who do have prior knowledge of the tasks, as was the case at the time of the posttest. As indicated in the introduction, with increasing practice, interacting information elements that a task contains are combined into cognitive schemata that can be handled in working memory as a single element, which reduces the amount of intrinsic load imposed by a task. Moreover, with increasing practice, problemsolving procedures can become automated, which further reduces working memory load. The measures of perceived cognitive load used in this study reflect the decrease in cognitive load one would expect with increasing knowledge/practice. However, a scale with more answer options might have provided more sensitivity to detect potential subtle dijerences in cognitive load during the acquisition phase.
There are several possible explanations for the finding that the only dijerence between the groups lay in the required acquisition time, whereas a lot of previous studies have also shown beneficial ejects on learning. First of all, the realistic mathematics teaching method used by this school as well as the ecologically valid setting of this study which included not only self-study but also teacher instruction may have provided a stronger control group than normally used in studies on the ejectiveness of worked examples. That is, in most studies, the control condition usually consists of solving problems by oneself without any additional instruction or guidance for students. The study by Schwonke et al. (2009) which also used a stronger control condition, that is, problem solving guided by a cognitive tutoring system, also showed positive ejects of worked examples mainly in terms of lower acquisition time. Secondly, students were given only two worked examples to use as analogies for problem solving and even though these two examples were illustrative for both problem categories (i.e. borrowing 10s and borrowing 100s), the fact that they were always the same may have reduced their motivation to actively process them over the course of the 3 weeks. Finally, and this is a limitation of this study, we do not have any data on the extent to which the students used the examples and when they used them. The self-report data on the questionnaire suggest that students did not use them with every problem they solved. Given that we know that worked examples are more ejective in the initial stages of skill acquisition, and tend to become redundant when students have gained prior knowledge of the task (the expertise reversal eject) (Kalyuga, 2007; Kalyuga et al., 2003), and that our students' knowledge levels did increase in the course of this study, as shown by the performance and cognitive load data on the pretest and posttest, it would have been

Downloaded by [North West University] at 00:46 28 May 2015
interesting to have data on whether students indeed consulted the examples more in the beginning ofthe study. It would be interesting to complement the self-report data with observation data in future studies, to get information on when and how students use worked examples as an analogy for problem solving.
Nonetheless, the finding that providing worked examples as an analogy for problem solving in an ecologically valid setting reduces the time required for attaining the same level of performance is interesting for educational practice: By implementing examples, time can be gained that can be used for repetition or other activities. Moreover, providing some examples as analogies for problem solving is very easy to implement and does not require a lot of development time from the teachers; indeed, if students' self-report data on their reduced need for assistance are accurate, providing students with worked examples might even save teachers some time. As mentioned in the introduction, there are other ways of implementing a heavier reliance of worked examples than providing them to be used as an analogy during problem solving (in which case they are an addition to problem solving). An interesting question for future research would be whether replacing part of the problems from the teaching method with worked examples would enhance learning. Research suggests that a completion or fading strategy (Renkl & Atkinson, 2003) might be a good way of doing this. In a completion or fading strategy, completion problems (i.e. partially worked-out examples that leave some solution steps open for the learner to complete) (Paas, 1992) provide a bridge between studying fully worked-out examples and solving the entire problem oneself. So, this strategy takes into account the learners' developing expertise, by starting instruction with studying worked examples, and proceeding via completion problems with increasingly more steps to be completed by the learner, to having learners solve problems on their own.
Acknowledgments
During the realization ofthis work, Tamara van Gog was supported by a Veni Grant from the Netherlands Organization for Scientific Research (# 451-08-003). The authors thank the teachers involved in this study for their cooperation.

How a Realistic Mathematics Education Approach and
Microcomputer-Based Laboratory Worked in Lessons on Graphing
at an Indonesian Junior High School
Yenni B. Widjaja
and
André Heck
AMSTEL Institute, University of Amsterdam,
Amsterdam, The Netherlands
This study focuses on the applicability of ICT-supported lessons based on a Realistic
Mathematics Education (RME) approach in an Indonesian classroom context. The topic chosen
for the research experiment was pupils' graphing skills with emphasis on graph interpretation
and with application especially to kinematics. One class was involved in this study and 13 – 14
years old pupils used the specially designed materials and activities. This included the use of
motion detectors in pupils' experimental work. The authors investigated the expectations,
performances, and opinions of the pupils and the teacher with respect to the activities and
analyzed pupils' thinking and understanding in the reformed setting. The results of the classroom
experiment indicated that the pupils made remarkable progress in their performances that can
be attributed to the chosen approach. The pupils' and the teacher's opinions on the teaching and
learning activities in general also tended to be positive.
Introduction
Although mathematics is considered important in all stages of education, Indonesian pupils'
performances in this subject is generally still poor: for instance, Indonesian 8
th
graders ranked
34
th
among 38 participating countries in the TIMMS-R assessment (Mullins et al., 1999). The
poor performance on the international stage also held for science and technology. It does not
seem likely that the intelligence and capacity of Indonesian children are worse than those of
children from other countries. We are of the opinion that the main cause lies in the current
instructional setting.
Indonesian mathematics education faces another problem: most pupils' attitudes towards
mathematics are negative. Most of them perceive mathematics as difficult and boring. This is not
surprising when we look closely at the common practice of teaching and learning mathematics in
Indonesian classrooms. A diagnostic survey conducted by the Ministry of Education and Culture
in 1996 revealed that despite many reform efforts, teacher-centered learning focusing on
procedural knowledge is still the norm. Teachers actively explain materials and provide
examples and exercises, while pupils only listen, write, and perform the tasks initiated by the
teachers. Discussion, interaction, and communication are seldom conducted. Mathematical goals
and curriculum materials are still based on the mathematics of mathematicians, and they lack real
life application. More recent research that was conducted to identify Indonesian problems
(Zulkardi, Nieveen, van den Akker, & de Lange, 2002) confirms this educational picture and
mentions various causes, including inaccurate learning materials, inadequate mechanistic
teaching methods, poor forms of assessment, and pupils' anxiety about mathematics.Published in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 2
Another problem of Indonesian mathematics education is its lack of touch with Information
and Communication Technology (ICT). This is a pity because research indicates that ICT is a
good catalyst for the realization of alternative setups such as an activity-based approach or a
realistic approach to mathematics and science instruction.
One of the ongoing developmental research efforts is to adapt the instructional design
perspective of RME to the teaching and learning of mathematics in Indonesia (Fauzan,
Slettenhaar, & Plomp, 2002; Hadi, Plomp, & Suryanto, 2002). In the concept of RME,
mathematics is a human activity connected with reality. Context problems, i.e. problems in
which the problem situation is experientially real to the pupils, are used as starting point in
learning. By giving pupils opportunity to use their own informal strategies in solving the
problems and to discuss with teacher and fellow pupils, the process of understanding is
stimulated. RME seemed to us a promising approach to tackle some problems of mathematics
education in Indonesia. The authors also thought that ICT tools could be used to support the
process for pupils of coming to grips with mathematics.
The authors decided to design and test ICT-supported teaching and learning activities that
were based on the RME approach. The design was used as a replacement of part of the chapter
'Time, Distance, and Velocity' in a popular Indonesian mathematics textbook. The focus was on
graphing skills with emphasis on graph interpretation and with application especially to
kinematics. One of the main reasons for choosing this topic is the frequent complaint of teachers
in various fields about the lack of pupils' competence in interpreting graphs. The instructional
design concerned some characteristics of the RME approach and used a Microcomputer-Based
Laboratory (MBL) environment – in our case, the "Coach computer learning environment"
(Heck, 2002) – in the teaching and learning activities. Besides the focus on enhancing students'
learning, the design was also tested for the purpose of ascertaining how this teaching and
learning model worked in an Indonesian classroom context. This included organizational
aspects, teacher and pupil classroom behavior, and teacher and pupil opinions of the activities.
Moreover, the teaching and learning activities and the materials designed and developed in this
study might become a model for later use by teachers. Results of the study might also reveal
some aspects that should be considered when implementing RME based and/or technology
supported lessons.
The Research Project
The major concern in this research study is the applicability of the designed teaching and
learning activities. The research questions are:
a) How applicable is the teaching and learning activity based on an RME approach to a
graphing topic with application to kinematics in an Indonesian second grade junior high
school classroom? In particular, The authors were interested in the way the pupils and the
teacher behaved during the activity and in their opinions about the RME approach.
b) How does the implementation of MBL-based instruction work in lessons on kinematics
graphs in an Indonesian second grade junior high school classroom? In particular, The
authors wanted to find answers to the following questions about the MBL approach: Does it
help to correct pupils' alternative conceptions in graphing? How do the pupils and the teacher
behave in the MBL environment and what difficulties do they experience? What are their
opinions about the MBL approach?Published in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 3
Regarding the research questions, The authors expected the following to occur during the
teaching and learning activities:
a) Concerning the RME approach: Pupils will talk more actively and become more aware of
their mathematical thinking. The situational problem as the starting point helps pupils to
relate what they learn to problems in daily life. The class environment becomes livelier. The
teacher might have difficulty in the beginning to adjust to his new role in the activities; e.g.,
he might have problems with guiding the class discussion because this is new to him.
b) Concerning MBL: It enables pupils themselves to construct and interpret graphs that are
related to real situations, and this helps to correct their alternative conceptions in graphing.
The laboratory set-up encourages pupils to become engaged and to be more enthusiastic in
the work. There might be technical problems related to the MBL environment or to the
teacher's capability to master it in a short time.
Previous Research and Theoretical Framework

The research background of this study consists of three elements: results of research on graphing, the philosophy of Realistic Mathematics Education, and the theory and practice of the use of Microcomputer-Based Laboratory in mathematics and science education.

Graphing

In the world where fast, accurate, effective, and efficient exchange of data and information is needed, methods of displaying trends and relationships between variables are very important. Weintraub (as cited in McKenzie & Padilla, 1986) stated, "Graphs present concepts in a concise manner or give at a glance information, which would require a great deal of descriptive writing. They often distill a wealth of information into a small amount of space" (pp. 571 - 572).

Graphing skills are also thought to be one of the critical topics that are important and fundamental to other more sophisticated parts of mathematics as well as to other disciplines (e.g., see Beichner, 1994; Clement, 1985; Lenton, Stevens, & Illes, 2000; McKenzie & Padilla, 1986). Of these skills, graph construction and interpretation have been identified as important. However, pupils are likely to have difficulties in graphing, especially when dealing with interpretation tasks. Research conducted by Lenton et al. (2000) on 14-15 year old pupils showed that construction of graphs was generally done well by this year group, but that interpretation of data was often less accurate. There have been many similar findings, most of which deal with kinematics, i.e., the motion of objects (e.g., Beichner, 1994; Clement, 1985; McDermott, Rosenquist, & van Zee, 1987; Mokros & Tinker, 1987).

Research has identified the following alternative interpretations and conceptions that pupils have in graphing:

• Variable confusion. Pupils do not distinguish among variables. They often believe that graphs of these variables should be identical; they appear to readily switch labels on axes from one variable to another without recognizing that the graphed line should also change (Beichner, 1994).

• Interval/point confusion. In interpreting graphs, pupils often narrow their focus to a single point, even though a range of points (an interval) is more appropriate. This is most apt to occur if the wording of a question is ambiguous, especially concerning use of the wordPublished in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 4 "when". Nevertheless, their focus on a single point seems to be part of an overall tendency to interpret graphs point-wise (Leinhardt, Zaslavsky, & Stein, 1990).

• Height/slope confusion. Pupils have been found to confound these two graphical features on both interpretation and construction tasks (Leinhardt et al., 1990). They often confuse gradients with maximum (or minimum) values – reading values off the axis and directly assigning them to the slope. An example of such an error is the use of graphical feature of height instead of slope to represent speed in a distance-time graph.

• Iconic interpretation ('graph as a picture' error). Pupils sometimes interpret a graph of a situation as a literal picture of that situation. A frequently cited finding in this regard is pupils' interpretation of travel graphs as the paths of actual journeys. Clement (1985) divided it into two categories:

1. Global correspondence: when the shape of an entire problem scene is matched to the shape of the entire graph in a global manner.
2. Feature correspondence: when a specific visual feature of the problem scene is matched to a specific feature of the graph.

Realistic Mathematics Education (RME)

Realistic Mathematics Education was first introduced and developed by the Freudenthal Institute in the Netherlands where it is still under active development. It is based on the view of Freudenthal (1991) that mathematics is a human activity and that reality can be used as a source for mathematization. Zulkardi (2002; after Treffers, 1987) provides the following characteristics of RME:

• Use of contextual problems. It is important to use real contexts that are meaningful and natural to pupils as a starting point for their learning, allowing them to become immediately engaged in the situation. Instruction should not start with the formal mathematical system and end with an application or related context problem as a kind of add-on to be studied after the appropriate mathematics has been learned, perhaps in order to conclude the learning process. On the contrary, the phenomena in which the concepts appear in reality can be taken as anchoring points for concept formation. Also, 'real contexts' and 'reality' should not be understood primarily as problem situations from real life or the real world; rather, they refer more to situations that are experientially real to pupils and/or something real in their minds.

• Use of models or bridging by vertical instruments. In solving problems, pupils develop and use models as a bridge between abstract and real. At first it is a model of a situation that is familiar to the pupils. By a process of generalizing and formalizing, the model eventually becomes an entity on its own and is used as a model for mathematical reasoning.

• Use of pupils' contributions. Pupils should have the opportunity to produce more concrete things themselves and to develop their own informal problem solving strategies. The teacher and the instructional materials guide a bottom-up reinvention process of the pupils. The process by which a given piece was invented in the history of mathematics may be a source of inspiration for the teacher and for the designer of the instructional materials.

• Interactivity. Interaction among pupils and between pupils and teacher is an essential part in RME because discussion and collaboration enhance reflection on the work (Gravemeijer, 1994; de Lange, 1995). In an interactive instruction pupils are engaged in explaining, justifying, agreeing and disagreeing, questioning alternatives, and reflecting.Published in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 5

• Intertwining of learning strands. In the philosophy of RME, various mathematical topics should be integrated in one curriculum. Pupils should develop an integrated view of mathematics as well as the flexibility to connect to different sub-domains and/or to other disciplines. This demands connection among strands, to other disciplines and to meaningful problems in the real world.

Thus, RME is more than "using real life contexts in mathematics education". Its main points are guided reinvention, didactical phenomenology, and emergent models (Gravemeijer, 1998). We restrict the further discussion of RME here to two aspects, viz., the mathematization and the use of pupils' informal strategies and own productions. More detailed descriptions of RME can be found in Freudenthal (1973, 1991), Gravemeijer (1994, 1998), Treffers (1987), and at the website www.fi.uu.nl/en/rme.

In mathematics education the focus is quite often on mathematics as a closed system. But organizing phenomena by means of progressive mathematization, i.e., by considering mathematics as a human activity, seems more important in the learning of mathematics. Treffers (1987) distinguished two kinds of mathematization: horizontal mathematization refers to modeling experientially real situations into mathematics and vice versa, whereas vertical mathematization refers to the process of attaining a higher level of abstraction within mathematics. In other words, horizontal mathematization is a process in which pupils translate problem situations that they perceive as real or realistic into some mathematical system. They invent or use mathematical tools to organize and solve their mathematical problems. In the end they translate mathematical results back into underlying statements of the problem situation, and they reflect on the work they have done. Vertical mathematization, on the other hand, concerns reorganization within the mathematical system itself like, for example, finding shortcuts, generalizing methods, and making connections between concepts and strategies. Freudenthal (1991) stated it in the following way: "horizontal mathematization involves going from the world of life into the world of symbols, while vertical mathematization means moving within the world of symbols". In RME mathematization takes place in both directions by means of a reinvention process that is guided by the teacher and by the instructional materials.

Treffers (1987) classified mathematics education into four types with regard to the presence (showed by a checkmark) of horizontal and vertical mathematization, as presented in Table 1.

Type	Horizontal mathematization	Vertical mathematization
Mechanistic	-	-
Empiric	Y	-
Structural	-	
Realistic		

Table 1. Classification of Mathematics Education Type According to Treffers (1987)

The mechanistic approach is based on drill practice. Mathematics is seen as a system of rules and algorithms; doing mathematics is analogized with machinery works which means verifying and applying these rules to problems that are similar to previous problems (Wubbels, Korthagen, & Broekman, 1997). This approach is dominant in Indonesian schools. The empiric approach sees the world as reality. Pupils are confronted with materials from the real world in which they have to do horizontal mathematization, but they are not prompted to extend a situation in order to come up with a formula or model. According to the structural point of view, mathematics is anPublished in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 6 organized, deductive system. The learning process in mathematics education is guided by the structure of this system and has nothing in common with the learner's living world.

The realistic mathematics education approach is based on a different point of view of mathematics education. The main difference with the mechanistic and structural approaches is that RME does not start from abstract principles or rules with the aim to learn to apply these in concrete situations (Wubbels et al., 1997). On the contrary, much importance is attributed to informal strategies and constructions that pupils develop themselves. They form the most natural way for pupils to attack problems and RME makes use of this in the instructional design of lessons. The art of teaching according to RME is to give pupils the opportunity to produce more concrete things themselves and to take their own productions as starting points for the mathematization and the gradual formalization of the informal strategies. The general idea behind this is that by making free productions, pupils are forced to reflect on the path they themselves have taken in their learning process and, at the same time, to anticipate its continuation (de Lange, 1995). Thus, in lesson work pupils are encouraged to realize and identify mathematical aspects in their daily life and to give meaning to problems from a real world context. They are challenged to develop their own strategies and approaches for solving the problems and to discuss them with fellow pupils. The teacher's role here is more one of facilitating pupils' learning through the so-called "guided reinvention" process in which pupils reflect on their own strategies in a follow-up discussion facilitated by questions from the teacher. In essence, the pupils are in a RME approach very actively involved in the development of their relational networks of mathematical concepts.

Microcomputer-Based Laboratory (MBL)

Microcomputer-Based Laboratory is equivalent to the UK English term "computer-based data logging". Computer-based data logging consists of computer tools for measuring data in practical work. One needs sensors, an interface, and a computer with an application that can present the data as tables and graphs. Physical quantities such temperature, force, current, voltage, light intensity, motion, sound, pressure, and so on, are measured with sensors whose signals are digitised and fed into the computer through an interface. After data are collected and stored in the computer, they can be processed, analyzed and presented in tables and graphs. One major goal of this data manipulation is to aid in the interpretation of graphs. Data processing and data analyses are often considered as a part of MBL.

[1]

Many researchers have already done research studies on using MBL-based instruction to enhance pupils' graph interpretation skills in various contexts. According to reviews done by Lapp and Cyrus (2000) and Lapp and Moenk (2001), some research has suggested positive results in this respect. Various contexts were used in the research projects including chemical concepts (Nakhleh & Krajcik, 1991), heat energy and temperature (Linn, Layman, & Nachmias, 1987), and kinematics (Brasell, 1987; Mokros, 1985; Thornton, 1996; Thornton & Sokoloff, 1990; Svec, 1999). Mokros and Tinker (1987) identified the following characteristics of the MBL-tools that are important to enhance pupils' interpretation of graphs:

• MBL uses multiple modalities. In learning through MBL pupils experience the materials in many different ways. They have kinesthetic experience by manipulating physical lab materials and probes and sometimes using their own physical features or movements as data. These are reinforced by visual (and sometimes audio) as well as analytical experience. The

[1]

We refer to Tinker (1996) for a broad overview of the use of MBL in science education.Published in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 7 multi-modal approach enables pupils to use their strong intelligence or learning styles and encourages them to build up learning modalities that are weak.

• MBL provides a real-time link between a concrete experience and the symbolic representation of that experience. It may form a bridge between concrete and formal operations. Barclay (1985) mentioned that the fast feedback allows pupils to relate immediately the graph to the event. Linn et al. (1987) and Thornton and Sokoloff (1990) made similar statements.

• MBL provides a genuine scientific experience for pupils. For instance, pupils gather and analyze real data. Mokros and Tinker (1987) viewed learning about graphing within real contexts and pupil-controlled experiments as analogous to learning about grammar by writing.

• MBL eliminates the drudgery of graph production. This advantage allows pupils to focus more on exploring the data and its representations. Rather than doing time-consuming tasks associated with data collection and display, pupils can spend more of their laboratory time in observing physical phenomena and interpreting, discussing, and analyzing data. Thornton and Sokoloff (1990) also supported this point.

Especially in a kinematics context it appears that the immediate display of the real-time graph production, along with pupils' ability to control the environment and the kinesthetic experience, play a vital role (Lapp & Moenk, 2001). It is speculated that experiencing the movement while watching the graph helps pupils to form a link between the two.

The computer application used in the activity design of this research was Coach 5,

[2]

which is

under continuous development at the AMSTEL Institute in the Netherlands. This computer learning environment provides several possibilities for active, self-responsible study of natural and mathematical phenomena by pupils, such as:

• carrying out measurements, immediately displaying results of measurements, processing data;
• controlling apparatus (e.g., a lamp or a motor);
• setting up computer models, investigating relationships between physical quantities, making predictions and comparing these to real life data;
• collecting position-time data from moving objects in digital video clips or in a sequence of pictures

The sensor used by the pupils in this study was the Ultrasonic Motion Detector (UMD) which measures distance by emitting ultrasonic pulses and by determining the length of time it takes for the reflected pulses to return. It was connected to the computer via the Coach Lab II interface.

Design of Classroom Activities

Before developing the instructional unit we analyzed the chapter "Time, Distance, and Velocity" of the mathematics textbook (Adinawan & Sugijono, 2000) that teacher and pupils used in class. We restricted ourselves to the part that discusses motion graphs, i.e., the section on drawing distance-time graphs and the section on graph reading. We identified the following graphing skills regarding distance-time graphs:

[2]

For further details about the Coach 5 environment see: http://www.science.uva.nl/research/amstel/ or http://www.cma.science.uva.nlPublished in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 8

• Skills required for creating graphs:

1. choosing scales;
2. drawing and labeling axes;
3. plotting points (from table or context) in a coordinate system;
4. understanding the connection between a graph and a table

• Skills required for analyzing and interpreting graphs:
5. point reading and the meaning of coordinates;
6. interval reading and what it means;
7. knowing the meaning of zero slope;
8. interpreting the steepness of parts of a graph;
9. determining the slope of a straight line and relating it to average velocity;
10. determining the intersection of graphs and relating it to the situational context
The textbook supports the teaching of these skills through drill and practice.
The authors also applied the classification of tasks on graphing of Leinhardt et al. (1990). For each task found in the examples and exercises we wrote down its type (prediction, classification, translation, or scaling), its category (construction or interpretation), its perspective (local or global), its character (quantitative or qualitative), and its focus (e.g., point reading, interval reading, graph feature, and so on). Our conclusions were:
• All tasks in the section on drawing distance-time graphs are combinations of translation and scaling, belong to the construction category, have local perspective and quantitative character, and focus mainly on the coordinate system.
• All tasks in the section on graph reading are translations of interpretation type and quantitative character. Two-thirds of these tasks relate to local properties and focus on one quantity through point reading. The other tasks mostly focus on interval-reading and deal with global properties such as stopping time and average velocity on a certain time interval, i.e., involve the use of two or more values extracted from the graph.
So, tasks of prediction or classification type and tasks of qualitative character were not present in the textbook. The findings from the analysis also indicated some omissions in this widely used textbook that we consider as important aspects of creating and viewing a graph:
• sketching a graph, e.g., from a narrative description of the situational context;
• describing a given graph in simple words, e.g., using a graph for communication purposes;
• global understanding of a graph and connecting it to the situational context, i.e., seeing a graph not as just a nice picture, but realizing that it is a concise representation of information and a useful mathematical tool;
• relating a distance-time graph to a velocity-time graph (as a first example of different types of graphs that describe the same phenomenon)
A teaching and learning activity was then designed to take into account the instructional goals already found in the textbook (skills 1 to 10) and the extra skills listed below:
11. sketching a graph, given a textual situational context;
12. making a textual description of a given graph in a related real situation;
3
13. knowing that in reality time cannot move backward to zero and that actions do not happen instantaneously;
14. drawing a graph related to a given graph, in particular, making the connection between a distance-time graph and a velocity-time graph

3
This is supposed to be achieved by giving a predicted graph of motion and asking pupils to describe the motion.Published in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 9
With the instructional goals in mind and guided by the theory of RME we developed an instructional unit on motion graphs. In the lessons pupils would start with practical works using their own movements as a source of data (made possible by the MBL environment) and as a starting point in their learning. This experimental set-up was chosen to allow pupils to become engaged immediately in the situation that connects "real life" to mathematical concepts. It involves horizontal mathematization. The practical works were meant to be done in-groups of two or three pupils and to be followed by classroom discussion to ensure interaction among pupils and between teacher and pupils in order to encourage talking about mathematics and mathematical thinking. For the same reason, the pupils were asked to write lab reports of their practical works. All this reflects the RME ideas of "interactivity", "guided reinvention", and "use of pupils' own contributions". The end point of the unit was a small investigation task for which pupils were asked to give a presentation of their results. This reflects the RME idea that pupils need to have room for exploration and for construction of their own products and strategies in order to build up their own theory. The intertwining of learning strands was taken into account in the instructional unit by making connections to other disciplines and to meaningful problems from the pupils' real world.
The instructional unit was designed for four classroom meetings of two hours. In the first meeting the teacher would introduce the pupils to the MBL-environment Coach and to the ultrasonic motion detector (UMD). The idea was to actually invite the pupils to get involved in the introductory experiments, thus giving them the opportunity to become acquainted with the hardware and software. Classroom discussions about the way things work and about the meaning of the graphs produced would play a key role in the first meeting. Pupils would practice in this introductory meeting the already taught skills required for creating graphs. The experiments would also serve the purpose of preparing the pupils for their practical works in the next two meetings. The compulsory practical works in these meetings are listed below, together with the graphing skills that are addressed in them (using the above numbered list of skills).
1. Investigate the difference of the appearance of the distance-time graph and of the velocitytime graph while you walk steadily and while you walk with changing speed (faster, slower, and at random). Skills: 5, 8, 11, 14.
2. Find the characteristics of the distance-time graph and velocity-time graph when you walk fast, slow, and when you stop. Skills: 6, 7, 8, 14.
3. Walk the graph, i.e., simulate a motion that produces (as similar as possible) some given graph. Skills: 5, 6, 7, 8, 9, 12, 14.
4. Walk the graph (continued) or explain why the given graph cannot be a motion graph. Skills: 12, 13.
5. Explore (with Z UMD) how the diagrams will look if you record the simultaneous motion of two objects and plot their distance-time graph in one picture. Skills: 5, 10.
Pupils would conclude their practical work with a short investigation task that they could choose from a list of five:
1. Investigate the motion graph of a bouncing ball.
2. Draw and describe the distance-time graph of your trip from home to school.
3. Compare the distance-time graph of a boy and girl in a walking race.
4. Compare the height vs. age diagram of East-Asian boys and girls (Internet data).
5. Compare graphs of temperature in two different regions during a week (Internet data).Published in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 10
Pupils would be asked to prepare a presentation of their results for the final classroom meeting in which their lab notes would be discussed and the results of the investigation tasks would be presented.
To support the teacher and pupils during the teaching and learning activities, we developed a Teacher's Guide and a Pupils' Guide. The section in the Pupils' Guide for Practical Work 3 is shown below and is representative of the kind of tasks given. Note that this text was also made electronically available to the pupils in the form of a Coach activity, which allowed us to prepare the graphs to be matched beforehand.
Goal of Practical Work 3:
In this activity, you are asked to simulate the motion to
produce (as similar as possible) the graph to the right:
Steps of Practical Work 3:
First, describe what you think you should do by
answering the following questions:
1. How far from the detector should you start?
2. How far from the detector should you finish?
3. How many times should you stop and how long each time?
4. How long should you walk before the first stop?
5. When (in which time interval) do you walk at highest speed?
6. Determine the velocity in each time interval (0 to 3, 3 to 6, 6 to 9, 9 to 13, 13 to 18)
Now, try to walk that way. Is your prediction correct? Try several times until you get the best result. Copy down the resulting x-t and v-t graph on the experiment worksheet or save it in Word.
Have a look on the v-t graph. Compare the result with your answer to question 6.
7. If there is any difference, why do you think that is?
8. If you continue to walk with the same velocity as the last time interval, when do you think you will be 6 meters away from the motion detector?
Research Design and Methodology
Participants
The research took place from January to March 2002 at SLTP Ciputra,
4
a junior high school
located in Surabaya, East Java, Indonesia. One of the reasons for choosing this school was that it is well equipped for conducting the classroom experiment. It has a computer laboratory with enough computers for a complete class and with a beamer that can be used for demonstrations and for pupils' presentations of their results.
One class of the second grade level of junior high school with 23 pupils (13 males and 10 females, all between 13 and 14 years of age) was involved in the study. There were four parallel classes at this grade level, but the grouping of these classes was not based on the pupils' performance level. So, in the particular class, pupils' performance varied from low, middle, to high achievement level.
The class had one mathematics teacher who was also the mentor of this class. He was and is a young teacher, who at the time of the research was in his second year of teaching at the school. Before that, during his teaching training period, he had given private mathematics tutorials to

4

high school pupils. At the time of the research study, he taught mathematics in four classes, two classes at the first grade level and two classes at the second grade level, and he taught the particular topic for the second time in a school setting. The teacher was acquainted with the RME idea, but he admitted that the notion was still not clear to him and his other colleagues. There were some differences in their understanding of the RME idea. For the ICT aspect, he reported that he was quite familiar with it, but seldom used it in his mathematics lessons. The only time he used ICT was by asking his pupils to search for some information about a particular mathematical topic on the Internet.
Methods and Instrumentation
The research experiment was set up in a classroom situation. The pupils made use of the designed classroom activities. The validity of these activities (e.g., whether their contents indeed reflect the school curriculum) was discussed one month before with Indonesian mathematics teachers. The activities were also tried out with some mathematics and science teachers at SLTP Ciputra shortly before the experiment took place. This led to some changes in the Pupils' Guide to make it less difficult and more suitable for the pupils.
The authors gave pre- and post-tests to the pupils to investigate the effect of the ICT-rich RME-based instructions on the pupils' graphing skills. The designing of the pre- and post-tests was based on some sources, e.g. Test of Graphing in Science (TOGS) developed by McKenzie and Padilla (1986) and some research papers by Mokros and Tinker (1987) and Lenton, Stevens, and Illes (2000). These tests contained 8 items and were scheduled for one hour. Answer sheets were prepared so that pupil would not only select an answer from various options but also explain the reasoning behind choosing or not choosing an option. The pre-test was tried out on some non-participating pupils of the same age in order to ascertain the understandability and the time aspect of the test. The pre- and post-test results were scored in terms of a percentage using a predetermined weighting scheme. It should be noted that the marks depended strongly on the reasoning given by the pupils and that, therefore, subjectivity in marking was unavoidable.
Since we were more interested in the improvement of graphing skills of individual pupils rather than in the comparison of pupils by their marks, we considered the pre- and post-tests as useful tools for finding out the effects of our teaching and learning design on the pupils' performance in graphing.
The authors selected three pupils, one each from low, middle and high achievement levels (according to the teacher), to do the pre- and post-test in a special setting in which they were invited to think aloud and were interviewed separately. In this way we hoped to obtain a better overview and understanding of the pupils' mathematical thinking.
The authors developed pre- and post-questionnaires to learn more about pupils' opinions on teaching and learning activities in mathematics before and after the actual classroom meetings. These questionnaires contained both Likert-type items and open-ended questions regarding RME and ICT aspects. Results of Likert-type items were reported in a percentage format, whereas open-ended items were analyzed and summarized.
The authors interviewed the teacher before and after the instructional unit had been used. We did this to ascertain his expectations before the pupils' activities and his evaluation and suggestions after the classroom meetings. We used the interviews with the teacher in our assessment of the applicability of the teaching and learning design.Published in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 12

Other sources of data were the pupils' reports of their practical works and the observations made during the classroom meetings and the pupils' presentation sessions. The observation protocol consisted of taking field notes about each group's method and progress in doing practical works, pupils' discussions, and interesting events in each meeting.
The Classroom Meetings
In this section The authors give a short impression of how the classroom meetings went. For a written meeting-by-meeting account we refer to the extended research report (Widjaja, 2002).
The very first meeting suffered severely from two things. Firstly, due to a school event, the teacher had found little time to prepare the lesson and to acquaint himself well enough with the software and equipment. Secondly, the computer lab could only be used for one lesson hour of 40 minutes, which was really too short for this introductory lesson. Although the pupils evinced some concern about this, they nevertheless showed great interest in the software and equipment as well as in the upcoming practical works. The first meeting was repeated one week later, but now for the full 80 minutes and with a better preparation by the teacher. This time everything went well with one exception: it turned out that the computer laboratory was not spacious enough for 8 groups of 23 pupils in total and 3 adults to work simultaneously in an effective way. The motion detector was limited to short distances, the surrounding tables and computers were in the way, and the groups could not avoid hindering each other during motion experiments. We made a design for optimal use of the space in the computer lab (see Figure 1), but after trying this out the following class meeting, it became clear that the only viable solution was to split the class into two.
Figure 1. Set up of the computer laboratory (dimension: 9m × 8m). The rectangles represent computers (Coach 5 was installed in the shadowed ones) and the dashed lines represent the

pupils' walk paths. The numbers indicate which group was assigned to which computer and
which walk path.Published in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 13
While doing their practical works, some groups took measurements by placing the ultrasonic
motion detector (UMD) on top of a stool, table, or monitor. Others did them by asking one of
their group members to hold the UMD while another member walked in front of it. The difficulty
most pupils faced in the beginning was how to adjust their movement so that they could produce
a good and smooth graph. In the beginning they tended to walk too fast. Then they realized that
by doing so, either they could not walk any further even though the preset measuring time was
not over, or that they moved too far from the detector so that it could not detect them anymore.
Some pupils changed the experiment setting and shortened the measuring time; others just
walked more slowly. One unexpected problem remained; the UMD seemed to function only with
a pupil whose body was broad enough to be detected easily. This forced groups with only skinny
members to 'borrow' a fatter person from another group to do the motion.
The teacher usually walked around in the classroom, observing the groups and having
discussions with them. Almost every time he came to a group, questions arose from group
members, mostly about what had to be done. This indicated that pupils still were not used to, or
felt a bit insecure about, the new role of active, investigative learners. They still seemed to prefer
that the teacher instruct them on what to do, rather than to read the Pupils Guide and find out by
themselves. The teacher tried to refrain from intervening in pupils' experiments, giving
instructions, or giving hints and answers to questions too easily.
The activity which pupils found most difficult was Practical Work 3: "Walk the Graph"
(shown on the example of practical work). There were two reasons for this: First, before going
on to this particular activity, pupils got a separate text explaining the velocity concept. After
studying this text, they could continue with the Pupils' Guide and do another experiment. Here
we made too strong an appeal to pupils' ability to read theory and the practical guide
independently and to link them with one another. As a result, pupils felt insecure and tended to
ask what to do, what the meaning of something was, and so on. Second, producing a graph
similar to a given one is not easy. One has to pay attention to many things, like whether to move
forward or backward, whether to move slow or fast, and in the meantime, has to pay attention to
the distance. Our pupils had the same expected difficulties, even more so because of lack of
space and, sometimes, technical problems with the equipment.
During the practical works, pupils not only collaborated with members of their group but also
with members of other groups. Encouraged by the fact that one group had finished, some groups
asked for extra hours to complete their own tasks. This interest in other pupils' work was also
revealed when some groups did their practical work in the Internet corner of the school library
because of scheduling problems for the computer lab. Hence pupils from other classes and even
from senior high school were very interested in what happened, had a look, and commented that
they would very much like it if they also got that kind of activity in their mathematics lessons.
Because of a shortage of time, the tight school schedule, and pupils' various stages of work,
the teacher and the first author decided to modify the last part of the teaching and learning
design. As an assessment, the groups would do their presentation of the 6th task in pairs instead
of in a class discussion format. Two groups would be assessed at a time, one of them presenting
their results and the other giving comments, and vice versa. The presentation session was held in
the computer laboratory. The teacher assessed all presentations, and the researchers were present
merely as observers. Some groups gave good presentations and were quite confident when
reporting their results. They also made good comments that showed their understanding of
features of graphs. Others were a little clumsy when making their presentation and had some
confusing discussions with the teacher because of misunderstandings. These pupils used quite aPublished in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 14
lot of improper terms when presenting results and answering questions. In general, the teacher's
questions to pupils during the presentation session were mainly asking them to describe what
they had been doing in the activity and how they had gotten the required data for the tasks. Then
he would inquire about some details, and based on the question in the activity, he would demand
explanations on how they found the answers. During the presentation, sometimes it seemed that
the teacher asked unrelated questions, and unfocused discussion followed as a result. In spite of
this, in general the assessment ran smoothly.
Findings and Analysis
Information from all data sources was examined in relation to the concerns and questions of the
study. Results are presented in this section. Readers interested in more details can find them in
the extended research report (Widjaja, 2002).
Pupils' and Teacher's Behavior in the RME-Based and MBL-Supported Activities
The most noticeable new aspect in the classroom setting was its interactivity, one of the main
RME characteristics. It was no longer the teacher who actively took control of everything and
determined what to do, but it was the pupils who in doing this became more responsible for their
own learning process. Nevertheless, this was new for pupils and they were not yet accustomed to
it. They tried to read and follow the Pupils' Guide, but most of the time they tended to ask for
exact guidance on what to do. Instead of inquiring and finding out by themselves, they asked the
teacher what some things were meant to be, what the answers were for the questions, and so on.
That they were accustomed to teacher-centered learning was also seen from comments made in
the open-ended items of the post-questionnaire: some pupils expected the teacher to explain the
topic to them in a detailed way.
When working on their tasks, some pupils were more persistent than others. They insisted on
doing several trials again and again until they got satisfactory results, whereas others tried to
manipulate the situation to get expected results. Nevertheless, it is of interest that, when given
more self-responsibility, pupils were more concerned to do their tasks well. The pupils were
actually the ones who proposed extra time to continue and finish their work.
In group-work, most pupils could collaborate well and were willing to do so. At the least,
they divided the tasks and did their own favorite part, but mostly they did all the tasks together
and took turns in doing the motion, handling the software, and typing the report. When giving
the presentation, they also divided the duties (who would give the introduction, who would
present the graphs, and so on), and they assigned a fair time for each member to present his/her
part. There was a sort of competition between some of the groups, but not in a negative manner.
They just liked to do the tasks faster and better than the others did. On the other hand,
cooperation not only happened within groups, but it also happened between members of different
groups. This consisted of helping other groups with their tasks when necessary, of discussing
among one another, and debating answers to the questions.
The discussion and debate between pupils and the teacher was also something noticeable.
Not only during the practical work sessions, but also during the presentation session, pupils did
not hesitate to express their own views or their own thinking, even when they differed in opinion
with the teacher. On the other hand, discussion between the teacher and pupils was not as intense
as we expected beforehand.Published in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 15
Pupils were quite comfortable with using the software and equipment. In the beginning they
asked a lot of questions and demanded explanations on how to do things. Because of limited
answers from the teacher (partly on purpose, partly because there were too many pupils asking
questions at the same time), they tried out the hard- and software themselves. In quite a short
time, they could already find useful tools and commands on their own. They were able to make
changes in measurement settings or in the graphical format to fulfill their intentions. During the
last classroom meetings, some pupils could set up the whole equipment by themselves.
Pupils' and Teacher's Difficulties in the Activities
In the open-ended post-questionnaire results, the pupils reported mostly technical problems.
They had difficulties with the motion detector, the software, and the computers. These were
revealed in many different ways by pupils, e.g., "not reaching the furthest distance", "not
working", "not measuring" (for the UMD), and "malfunctioning", "broken", "not satisfactory",
"out of date", "not saving well" (for the computers). Another problem mentioned by pupils was
the lack of space to work on the practical tasks. Concerning the RME approach, some pupils
mentioned difficulties in preparing and conducting the presentation and in the cooperation within
the group.
The teacher's difficulties were also mostly related to technical issues such as mastering the
software in time and his knowledge limitation in technical matters. This was revealed during the
post-interview:

According to the teacher, he did not have problems in conducting the discussions in the
introductory activities or during the pupils' presentation. The problems in the first lesson were
mainly because the material was new for him and for the pupils, so that sometimes the
explanation and communication during introductory activities did not run smoothly. Another
problem that he mentioned was about encouraging pupils' collaboration during group work.
When asked about this matter, he stated:

!

Pupil Performance
Pupils' performances were evaluated by their results on the pre- and post-tests, their report on the
practical works, and by the teacher's judgement.
Question No. 1 2 3 4 5 6 7 8

time
B. Distance
from mark
In general, pupils showed good progress on the post-test. Table 2 shows that the mean value
for each question's mark increased between the pre- and post-test. This means that in the posttest session more pupils gave more satisfactory answers to the questions. Not only could they
give more correct answers, but they also could reason better in their answers. The mean value of
scores of each individual increased from pre-test to post-test up to an increase of 40%.
Comparison of the pre- and post-test results also revealed that pupils who got lower marks on the
pre-test made greater progress in their post-test scores compared to their fellow pupils who got
higher marks on the pre-test.
The pre- and post-test results indicate that pupils made progress mostly on items that were
related to the distance-time graph (numbers 3, 5, 6) and to the graph with a similar conception in
a different context (number 8). In particular, pupils showed more confidence in giving reasons
for their answers. They were more to the point and clearer in stating their explanations, not
circling around giving unclear and confusing reasons. Apparent improvements dealt with the
graph as picture error that many pupils revealed on the pre-test and with the correspondence
between a zero slope in the distance-time graph and cease in motion. These misconceptions did
not show up in the post-test anymore. This increase of performance in pre- and post-test is
illustrated by two examples:
In question 3 in the pre-test, pupils were given a description of motion:
Adit walks away from a mark on the floor at a steady rate and then directly walks
back toward it.
Some options of graphs were given and pupils were asked to answer and give their reason
for each graph whether or not it could describe the motion. One of the options was:
Kendy's answer and reasoning for the particular item in the pre-test:
Wrong, because the graph displays that Adit from where he started was back by turning
around but not going back on the same path.
Kendy's reasoning for the associated question and option in the post-test:
Impossible, because in the graph, the time goes back. It is impossible that the time is
repeated or back and a person cannot be at a different place or distance at the same time.
In question 5 in the pre-test, pupils were given a description of trips done by three people
and six options of graphs. One of the persons (Valentina) described her trip by:
I take the train every day to go to school. On the way, the train stops twice.
Stefanus assigned option B for Valentina's graph (graph on the left).
Distance
from
time
Distance
from
time
Distance
fromPublished in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 17
His reason was:
Valentina, because it stops twice.
The associated question in the post-test was a trip description made by a person, Victor:
I take the bus every day to school. There are three bus stops on the way.
Stefanus' answer for the associated option (graph in the middle) in the post-test:
Wrong, because in this graph, it's back to initial place three times with constant velocity.
He assigned the correct graph for Victor instead (graph on the right) and gave reason:
Victor, because there are three flat lines which means he stopped.
Pupils still revealed difficulties dealing with velocity, either in determining velocity from a
distance-time graph or in interpreting a velocity-time graph (Questions 4 and 7 in the pre- and
post-tests). The teacher also mentioned this in the post-interview. This came to no surprise:
pupils were only asked in Practical Work 3 to determine a velocity from a distance-time graph.
Nowhere else in the teaching and learning activity were they asked to derive a velocity-time
graph from a distance-time graph (it was just implicitly done in some of the practical works).
Velocity-time graphs were not covered in the textbook, either. So, the limited discussion of this
topic during the classroom activities was clearly not enough for pupils to fully understand the
concept. This is also supported by the fact that there were pupils who showed confusion between
the distance-time and velocity-time graphs in the post-test. This could well be because they dealt
mostly with distance-time graphs during the teaching and learning activity. So they mixed them
up, especially in certain features of graphs. To describe this confusion, consider question 4 in the
post-test (see Figure 2).
A ball was rolled by somebody on a flat surface. It moved along the surface, went up a small bump and
finally glided down. See the picture below:
Which graph best describes the speed of the ball? Explain your reason (for instance, why you chose or do
not chose a certain graph)!
Figure 2. Question 4 in the Post-test
time
C
Speed
time
D
Speed
time
B
Speed
A
Speed
timePublished in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 18
Olivia's answers for option A and B were:
Wrong, because there is a flat line which shows that the ball stopped.
Nevertheless, there was still progress in pupils' reasoning when dealing with a velocity-time
graph. Remarkable progress on the item concerning the transformation of a given distance-time
graph to a velocity-time graph (see related question from the post-test in Figure 3) was shown by
Shanty, as described below.
Below is a distance – time graph of a trip.

Which of the four graphs below most likely represents the velocity - time graph of the trip? Explain your reason!
A B.
C. D.
Figure 3. Question about graph transformation in the post-test.
Shanty's answer and reasoning for each option of question 7 in the pre-test:
Option A, B, D: Wrong, because the graph is not suitable with a distance-time graph of a
trip.
Option C: True, because the graph is suitable with a distance-time graph of a trip.
Her answer for the associated question in the post-test were:
Option A: Wrong, because in the beginning, the vehicle was not moving in a velocity of
12 km/hour, but it actually stopped.Published in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 19
Option B: Wrong, because the graph shows changing velocity but increasing distance,
the distance continuously increased from the initial position.
Option C: Wrong, because the velocity of 10 km/hour should be negative, since the
numeral of its final position is smaller than the numeral of its initial position.
Option D: True, because the velocity-time graph shows 2 hours of stop, 2 hours of
moving nearer in a velocity of 10 km/hour, then stopped for 1 hour, and
moving further for 2 hour in a velocity of 5 km/hour and moving further for 2
hour in a velocity of 20 km/hour. (she also wrote her calculation of the
velocities)
This progress was shown not only in the written post-test, but also during the interview with
some pupils. For example, Welim suffered with the graph-as-a-picture error and did not reason
well during the pre-test. In the post-test however, Welim (W) could interpret the velocity-time
graph in question 4 (see Figure 2) correctly and he could reason meaningfully, as shown in the
discussion with the first author (Y) below.
Y: Which one is correct?
W: B
Y: B? And the reason?
W: Yeah, at first the surface was flat, it moved fast. After that ascending (pause) it ascended then
(pause) it was a bit slow, wasn't it? Nah, a bit slow means a bit down (pointing at the part
where the graph descends). Then, the ball descended (pause) descended (pause) nah,
descending means fast (pointing at the part where the graph ascends). After descending, the
surface is flat again, yeah ... a bit normal again.
Y: Why didn't you choose C?
W: (he thought and mumbled for a while). Eh, C (pause) in C the first motion was directly fast.
Here (pointing at the picture in the question) it was not fast, was it? First it should be
normal. Here it's suddenly fast. After moving fast, then slow, and then fast again. It was not
the case, was it? In my opinion, the velocity is the same. So (pause) not directly fast.
Y: If, for instance, when rolling the ball, I pushed it like this? (I made a gesture of pushing with
my palm)
W: Yeah, that is C.
Y: So, that is now C. Why didn't you choose A and B, either ?
W: Ehm ... firstly, A here (pointing at the part where the graph ascends) is bulging. When it
bulges, it means faster, doesn't it? It should be slower, though. And B here (pause) it is
suddenly fast (pause) drastically fast.
In general, pupils' answers to questions in the practical works were as expected. Some
groups seemed to be imprecise when answering questions although they actually could have
done better on this. For instance, pupils were often imprecise when doing point reading. Another
prominent point was the use of improper terms in answers. For instance, one group stated, "when
walking fast, the graph yields a sloppy line 45 degrees up, and when walking slowly, the graph
yields a sloppy line less than 45 degrees". Some groups described intersection as: "crossing likePublished in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 20
a multiplication sign", "yielding the letter X", "meeting each other". This may be due to the fact
that pupils lacked guidance from teacher when doing group discussions.
According to the teacher, the performance difference between pupils taught by this method
and the traditional method was not really sharp. However, he admitted that the difference might
be greater if the approach was applied to more complicated contextual problems. He believed
that those pupils who had the opportunity to apply the topic to practical problems must have
more experience in solving them, compared to pupils who only imagined and solved paper and
pencil exercises. The teacher also mentioned the fact that in the school's final assessment, the
pupils involved in this research outscored those in the other class who he had taught the same
topic in the traditional way and who he considered to be stronger in mathematics. This is an
interesting side outcome, despite the fact that we could not validate it in this research.
Pupils' Opinions on RME-Based and MBL-Supported Activities
It seemed that pupils of this age enjoy very much being able to carry out experiments during
lessons instead of just listening to the teacher and solving written exercises in the classroom.
This could be seen from their involvement and their willingness to try out new things during the
practical works. On the one hand it resulted in a messy and noisy classroom, but on the other
hand everyone seemed to enjoy the work. The teacher supported this view and said that the
pupils tended to follow the lessons more enthusiastically and that they were not easily bored. The
classroom work seemed to interest them more.
Pupils' expectations about the teaching and learning activity in general tended to be positive.
As much as 61% of the pupils had positive or very positive opinions about RME aspects, only
14% were negative or very negative beforehand. This positive tendency was seen in almost every
item, except the ones concerning the presentation of one's work. It seems that many pupils did
not think that doing a presentation would improve their understanding. They did not feel ready
for the presentation and feared that they might face difficulties. Most pupils' opinions about the
usage of ICT in the lessons were positive beforehand, too (54% of pupils). However, somehow
they were not really sure whether they would have problems with the software and the
equipment, or not.
After the classroom meetings, it seemed that fewer pupils (47%) had positive opinions about
the RME approach. Among all items related to RME, pupils still did not seem to think that the
presentation encouraged them to understand the material thoroughly and more deeply, and they
seemed to think that the tasks and the workload might not have been divided fairly amongst
group members.
On the other hand, pupils were still positive about the ICT usage. This was especially shown
by the fact that 77% agreed or strongly agreed that doing activities using a computer in the
lesson was interesting and exciting, and that 73% of them looked forward to more use of ICT in
the next mathematics lessons.
In the analysis of individual pupils, they generally tended to be positive before the classroom
meetings, but their opinions afterwards were more variable and had mostly moved towards the
less positive. This might be due to difficulties they faced during their work: further analysis
revealed that pupils whose opinions afterwards were less positive than before were the ones who
had suffered from many problems and troubles in doing their tasks. Another reason might be that
the expectations of some pupils were too high in the beginning and just became more realistic
afterwards.Published in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 21
The Teacher's Opinion
During the post-interview, the teacher revealed his opinions about the teaching and learning
process in ICT-supported and RME-based activities and about his new role. In general, the tone
of the interview was positive. The instructional unit had made a good impression on the teacher,
in the sense that he liked his new role and would like to have more teaching and learning
activities designed in this way.
According to the teacher, the chosen approach offers both parties (teacher and pupils)
advantages. Pupils obtain results more by their own efforts. They experience the process of
achieving results by themselves, instead of receiving descriptive materials from the teacher.
Moreover, pupils become acquainted with new technology, which is an advantage for them.
Their abilities and skills are explored and encouraged more in an open computer-learning
environment. They are also trained in doing presentations, speaking in front of an audience, and
so on. For the teacher it is an advantage that he or she does not have to spend too much energy
on explaining things all the time. It should be noted that this last comment was tentative. If there
are ready materials and a fixed arrangement or scheduling of lessons, the teacher might indeed
not face many difficulties, but this would certainly not be the case in every situation. The
teacher found that the assessment method was appropriate. It matched his idea that the pupils'
capacity should not be measured only by written tests.
Discussion and Recommendations
This study focussed on the applicability of ICT-supported lessons based on a RME approach in
an Indonesian classroom context. In this section we summarize and discuss our findings. This
leads to recommendations to teachers who want to apply this approach in their own lessons.
Discussion
Many of the findings obtained from the research experiment were in accordance with what we
had expected before. Interactivity is the keyword to describe the classroom setting. The
classroom became livelier with pupils' experimental work as well as with discussions and
debates among the pupils and between the pupils and the teacher. Encouraged by the open
computer-learning environment, pupils tried to find out things themselves, talked more actively,
and they seemed to become more aware of their own mathematical thinking. Pupils were also
more involved and more enthusiastic in doing the lesson work. The experimental set-up
encouraged them to explore more phenomena. They made predictions and were quite persistent
in proving their hypotheses. We would like to state that one of the most important changes in the
RME-based and ICT-supported instructional unit was the way pupils were stimulated to think, to
question, and to wonder about phenomena. Given a chance to explore their ideas and to discuss
them freely, they became more critical and more involved in the learning process, and they were
more willing to understand things better. But also unexpected things happened. For example,
pupils appeared to be concerned more about their tasks when given more self-responsibility.
The technical problems that occurred were also expected beforehand, including the extra
time needed by the teacher to master the software. Only the lack of space was not foreseen.
Nevertheless, pupils' ability to cope with the software and the equipment was quite admirable.Published in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 22
On the other hand, pupils did feel that they had problems in collaborating within their own group
and in conducting the presentation of their work.
The teacher had fewer difficulties during the lessons than expected. He did not have crucial
problems either in adjusting to his new role or in conducting class discussions. He felt
comfortable with the different role that he took, with the teaching and learning activities, and
with the assessment. This might have been due to his nature and attitude in teaching, which was
quite progressive, and the fact that he as a mentor of the class had a good relationship with the
pupils. His problem, however, lay more in encouraging good cooperation among pupils during
their group work.
Pupils showed progress in their performance between the pre- and the post-tests. On the posttest they could give a greater number of correct answers and they could reason better in their
answers. Some concepts were mastered and some alternative conceptions were corrected. The
topic related to velocity-time graphs had not been mastered well enough, but this might be due to
the lack of discussion concerning this topic in the teaching and learning activities.
Evidence was not sufficient to verify some expectations very strongly. Did the materials and
activities help pupils to relate what they had learned to problems in daily life? However, by using
real situational contexts such as a bouncing ball, the trip from home to school, and human
growth, it is hoped that pupils' realizations of mathematical aspects in daily life were
encouraged. Although the results from this research experiment do not reveal great differences in
pupils' understanding of the mathematical concepts between the traditional lessons and the RME
approach, it is the pupils' learning process that might make a difference in the time ahead. It
seems logical to expect that pupils who obtain understanding of a concept by their own struggle
and through their own way-of-thinking process will stay with it much longer than pupils who
receive ready lesson materials, formulas, and so on, without going through the process of
deriving and manipulating them. It is our strong belief that pupils should not only receive, but
also should be given a chance to question and process the information they get. This is one of the
corner stones of the RME approach.
The use of the MBL environment also helped pupils to elaborate their ideas to their own
satisfaction and at their own pace. It served as an open learning environment in which pupils
could do trials and experiments, and test their own hypotheses. All of these would otherwise
have been more difficult to realize. The MBL environment also enabled the development of
materials using daily problems, which were real and meaningful to pupils, and which encouraged
them to realize mathematical aspects in nature and in their daily life. Hence, we can see
indications that technology might serve as a catalyst for a realistic approach to mathematics
education.
It should be noted that starting with real situations and real data is not at all easy. This might
even look more complicated as far as real phenomena are concerned. For instance, the graphs
produced in the activities in this research were messier and not as ideal as the ones pupils usually
are introduced to in their mathematics textbook. This is something to be taken into consideration
by teachers. This is just one of the many things that must be paid attention to when adopting the
approach. But most important, the teacher must be willing to change his/her role in the
classroom. The teacher must allocate the more active parts of the learning activities to pupils and
must be able to design materials and activities that can stimulate pupils to think, to dare to draw
their own conclusions and to express their opinions about the topics they are learning. A teacher
also needs to be prepared in technological literacy - at least in basic technical things. On the
other hand, pupils should also be prepared, e.g., for more independent self-responsible learning.Published in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 23
The roles of policymakers in education and of the school's management are not less important.
The progressive changes in pupils' and teachers' roles, and in the educational approach, crucially
need the support and openness of both policymakers and school management. Provision of
facilities and access to technology are also things to be taken into consideration nationwide by
schools and the government.
Limitation of the Study and Suggestions for Further Research
One of the limitations in the research experiment was the size of observational data and the lack
of comparative data. One experiment in one class is a weak basis for making generalized
conclusions.
The problem of lack of space in the computer lab forced the teacher and us to split the class
in two for most of the classroom meetings. As a consequence, the teacher was not always present
during all practical works. This and also the changes to some parts of the lesson design caused
weakening of some characteristics of RME that were actually supposed to be a highlight, i.e., the
guided discussions.
In further research concerning RME-based materials and also in the implementation of an
RME-based lesson, this matter should be given more attention. In retrospect, we would like to
pay more attention in the learning materials to understanding velocity-time graphs and to
transformations from a distance-time graph to a velocity-time graph and vice versa.
Another limitation is the fact that the school was not representative of Indonesian schools in
general. At the moment, most schools do not have their own computer laboratories and other
sophisticated facilities. Pupils' and teachers' familiarity with technology is also not something
that can be presupposed for Indonesian pupils and teachers in general. Further research done in
this area would be very useful if it involved more representative Indonesian schools and also
teacher training faculties. Development of materials in other topics that use the RME approach
and that are supported by ICT also must be considered.
There were some questions still left to be explored, to which the limited data gained in this
research and the restricted time have obscured finding answers to them. One of them is the
indication that low achievement pupils might benefit more than high achievement pupils (see the
section on pupils' performance). Pupils' and the teacher's changing roles would also have been
interesting research topic and could have been given more attention. The concepts of distance
and velocity might also be addressed more in further research. Distance and velocity are known
to be difficult concepts for pupils, and more attention to these concepts would have been

valuable to them.
Recommendation for Teachers
Our research experiment leads us to the following list of recommendations for teachers who want
to implement RME-based and ICT-supported lessons:
• In general, teachers must be willing to change their role in the classroom towards more pupilcentered learning.
• Activities and tasks should be chosen properly and carefully. Completion of tasks should
guide pupils to acquire the concepts they are supposed to master. Too few activities might
hinder the process, but too many activities might result in bored and exhausted pupils.Published in: Journal of Science and Mathematics Education in Southeast Asia, 2003, Vol. 26, No 2, pp. 1-51. 24
• The organizational things should be paid much attention. It is always better to make sure far
in advance the availability of laboratories, other facilities, and so on.
• Especially from the implementation of our instructional unit, we can learn that it is useful to
prepare enough laboratory space for pupils to do their practical works, for instance, by a
good set up of the laboratory or a good arrangement of groups.
• Teachers should sharpen their skills in conducting class discussions, and in addressing
questions that challenge pupils and encourage them to think critically. This might need some
practice, training, and customization of teachers' behavior.
Final Remarks
From what happened during the research experiment in an Indonesian classroom, it seems that in
practice many things still have to be worked out. It was still difficult, in this case especially for
pupils, to adjust to the pupils' more active role in learning. We suppose that encouraging pupils
to be more active will be even more difficult in a typical Indonesian school, less progressive than
the one involved in the research. It will be more difficult, as well, to change traditional-minded
teachers' attitudes. But, this surely can be done. Some Indonesian mathematics educators have
already begun such efforts by conducting research, by introducing the RME idea at every
opportunity, and by influencing policymakers in education. Developing the idea within teacher
training institutes, providing more material for teachers, and establishing good networks among
teachers, student teachers, and teacher educators are also efforts in progress.
Acknowledgement
The authors would like to thank Martin Goedhart and Mary Beth Key for their critical comments
and encouragement during the research project. Thanks are also due to Ton Ellermeijer and Y.
Marpaung for their invaluable assistance that made the research experiment feasible. And last but
not least, the authors would like to thank the mathematics teacher Eko Sumarsono at the Ciputra
Junior High School for allowing the experiment in his class and the pupils for their enthusiasm at
work.
Note
The first author conducted this research study as her final project in the International Master
Program in Mathematics and Science Education at the AMSTEL Institute, University of
Amsterdam.

The use of Information and Communication Technologies in the first grade of primary
school for teaching rectangles based in Realistic Mathematics Education
Zaranis Nicholas
Department of Preschool Education
University of Crete
Rethymno, Greece
e-mail: nzaranis@edc.uoc.gr
Abstract—The aim of this study is to investigate the question:
"Can Information and Communications Technology (ICT)
helps to improve primary school students' geometry
achievements for rectangles?" The applied educational
software consisted of a story and several activities with and
without the use of computers which were designed following
the background of Realistic Mathematics Education for
geometry concepts; referred to as the 'Primary Shape Model'
(PSM). In addition, we use a mathematical test referred to as
the 'Primary Shape Test' (PST) to explore the use of ICT in
the primary classroom for teaching basic geometrical concepts.
It is a task orientated test which attends to measure the level of
geometry competence developed for students of the first grade.
The study dealt with students in the first grade of primary
school of Athens and Crete, who were divided into two teams
(experimental and control). The experimental group consisted
of 113 students, who were taught of rectangles by the support
of computers. There were 121 students in the control group,
which received only the traditional science instruction for
rectangles. Students in both groups were pre-tested and posttested for their geometry performance for rectangles. The
results of the study indicated that teaching and learning
through ICT is an interactive process for children at primary
school level and has a positive effect for geometry education of
rectangles.
Keywords - ICT; educational software; geometry teaching;
realistic mathematics; primary school; rectangle.
I. INTRODUCTION
The innovations which have been occurring through recent
decades in Information and Communications Technology
(ICT) have awakened the interest of the educational
community which in turn has felt the need to evolve in its
theoretical areas and pedagogic practices. Especially the
integration of ICT into primary education has become a high
priority for everybody involved in the learning process.
Educational researches, which have been occurring through
recent decades, suggest that the mathematical difficulties
students encounter later are connected with insufficient
development of mathematical thinking in the early years [1],
[2].
Moreover, various research results relate the appropriate
use of computers with the ability of students to more
efficiently understand the different mathematical notions [3],
[4], [5], [6]. Thus it becomes obvious that primary school
emerges as a very attractive environment of investigating the
computer use in education of mathematics. Indeed, a vast
number of studies show a positive correlation between the
use of computers and the development of mathematical
thinking in school [7], [8], [9].
II. THE LEVELS OF UNDERSTANDING GEOMETRY
Realistic Mathematics Education (RME) is a theory of

teaching and learning mathematics which started as a movement in the late 60s in the Netherlands in an effort of reconsidering mathematics education, where the mechanistic approach was dominant until then. Starting in 1968 with Wiskobas [10], a program initiated by the Dutch government, a new approach on mathematics education made its first steps offering an alternative to the American "New Mathematics," threatening at the time to invade the Dutch mathematics education [11]. RME is an active and constantly evolving theory of teaching and learning mathematics [12]. Indicative of this is the learning teaching trajectories with intermediate attainment targets which was first conducted for calculation with whole numbers in primary school and then extended to measurement and geometry [13], [14].

In the whole trajectory, four levels of understanding geometry concepts are involved. These should be the main focus of the learning and teaching procedure concerning geometry in primary school. The four levels were developed from the van Hiele theory, which is one of the basic axis of RME. The theory of van Hiele model deals specifically with geometric thought as it develops through several levels of sophistication under the influence of a school curriculum [15]. The van Hiele model uses five levels, however, for the first grade students only the first two levels were used. In the Visual Level, students were to identify figures such as squares and triangles as visual gestalts, for instance, they might say that a figure is a rectangle because 'it looks like a door.' In the Descriptive/Analytic Level, students were to identify shapes from their properties, for example, a student shows a rhombus as a figure with four equal sides [2].

Following the above model, the four level model designed for this research was inspired by the framework of the levels of van Hiele model for geometrical concepts, referred to as the 'Primary Shape Model' (PSM). In the first level, young students were introduced to visual recognition, verbal presentation and drawing skills of the shapes. They were also implicated with problem situations in which questions of comparisons or 'what is this' questions were posed in a way to be meaningful for students. Examples of such activities could be as follows: 'Draw a rectangle.' 'Bring me something that is a rectangle from the classroom.' 'What is the shape of the door?' etc.

In the second level, students should be able distinguish shapes from their figure, separating them from a set of objects and fitting together several figures under certain conditions. This can be realized by performing activities such as playing with constructing blocks, working with cutouts and tangram. Examples of such questions could be 'make a dog from these rectangles', 'find the shape by touching it', 'find the correct shape' etc.

In the third level, students should be able to face direct questions such as 'find the properties of rectangle' and 'find the shape with four sides' and answer them. Attention is focused to quantificatıon where the involvement of properties is immediate. As a result, questions should relate to distinctive objects or quantities such as 'how many angles does a rectangle have' or 'which shape has four sides'. At this level students should be able to organize the properties of objects using clear patterns as to avoid mistakes.

In the last level students do not need the physical presence of objects any more, but the 'mental representations,' of the objects like their properties. Also they understand the concept of shared properties, like 'the square is a rectangle' etc.

III. METHODOLOGY

The study was carried out during the 2011-12 school year in ten public primary schools located in the cities of Rethymno (Crete - Greece) and Athens. The sample consisted of 234 first graders (123 girls and 111 boys). There were two groups in the study, one control and one experimental. Five schools were selected as the control group (n=121) and the others as the experimental group (n=113). In the control group there was not a computer available for the students' use, while in the experimental there was one computer in the class and a video projector, which were used from children as part of the teaching procedure.

The present research was conducted in three phases. In the first phase the pre-test was given to the class during the beginning of December 2011 to isolate the effects of the treatment by looking for inherent inequities in the geometry achievement potential of the two groups. The first twenty questions of the test were based on the first level of the Van Hiele model and the last twenty two questions were from the test that was used in the research by Clements et al. [16]. The whole test is referred to as the 'Primary Shape Test' (PST). Due to the young age of the students the pre-tests were administrated in the class with explicit and detailed instructions of the teacher. These were pencil-and-paper tasks in which the children were asked to mark the shapes that are rectangles, squares, triangles, and circles on an page with various geometric figures "Fig. 1". The test lasted about 25 minutes. The responses were scored and coded and the data set was created by scoring the students' selections for correctness.

In the second phase the control group coordinated with traditional teaching. Group and individual activities were given to children every day. The experimental group covered the same material at roughly the same time, according to the PSM. The content of the four week syllabus was about shapes including a variety of topics concerning fundamental geometry concepts and focus on rectangles.

The first level of the PSM started with the educational software which was designed using Flash CS3 Professional Edition. It was a story about 'The Family of Shapes.' In this story Miss Circle met Mr. Rectangle "Fig. 2", they got married and had many children that looked like their parents. Then a drawing activity was performed by the children in which the students drew the 'The Family of Shapes' "Fig. 3". Next the teacher asked the children to bring things which look like rectangles and asked questions like the following: 'What is the shape of this door?', 'What is the shape of the clock?' etc.

The second level of the PSM included an activity where a child had to draw a shape from a bag and to find out the name of the shape without seeing it. Then, the students split in groups and each group had to construct a dog or a man from a set of shapes. At the end of this level a computer activity followed where the student had to recognize shapes and to choose the correct shape among triangles, circles, squares or rectangles "Fig. 4".

Figure 1. Student marks rectangles. The third level of the PSM had a software activity in which the properties of each shape are represented "Fig. 5". Next, the children were separated into groups and made a shape with their bodies on the floor "Fig. 6". In addition, they were given cut-outs with all kinds of shapes and shared them to the rest of the children.

In the last level of the PSM the students played card games "Fig. 7". There were two kinds of card games: the white cards with the properties of sides and the yellow cards with the properties of angles. The cards had shapes on them and at the end the child who had the majority of cards was the winner. Afterwards, there were computer activities where the children had to recognize the shapes from their properties "Fig. 8".

Figure 2. First level, student saw the 'The Family of Shapes'.
Figure 3. First level, student drew the 'The Family of Shapes'.
Figure 4. Second level, the student had to recognize shapes.
Figure 5. Third level, rectangle with its properties.
Figure 6. Third level, the students made a shape with their bodies.

Regarding the educational software represented above, once an activity is selected, the problem is announced and directions are given to the user through a recorded message. The feedback users get after following these directions is represented by two different screens, one positive and one negative, followed by corresponding audio messages from which the user can navigate out of by clicking on the arrow at the bottom right side of the screen. In the first case the user gets a 'well-done' message and on the second a 'try it again' one. In both cases, though, an effort was made to keep these messages to be as little emphatic as possible, so that children's interest is focused more on the mathematical procedure of the application rather than their result or the competition. However, drill and practice applications, as the described software, can be beneficial on promoting competence on certain mathematical skills while they encourage taking turns and competition [17], [18].

During the third phase of the study after the teaching intervention, the same test (post-test) was given to all students to measure their improvement at the beginning of March 2012. This was used to test the geometry achievements for the experimental and control groups. The independent variable was the use of educational software. Figure 7. Fourth level, the students played card games.
Figure 8. Fourth level, the educational software.

The main purpose of the software is to foster the first grade students' geometry concepts and to engage them in self-regulated learning. The dependent variable was the students' PST scores.

IV. RESULTS

The PST was taken by 234 students. One hundred and eleven of the students were male and 123 were female. Analysis of the data was carried out using the SPSS (ver. 19) statistical analysis computer program. An independent sample t-test was conducted. The independent variable had two levels: exposure to educational software (experimental group) and no exposure (control group).

The dependent variable was the student's pre-PST score. Levene's Test for equality of variances was not significant ($F = 0.521$, $p = 0.471$). The t-test for equality of means was also not significant ($t = 0.035$, $p = 0.972$), indicating no significant differences initially, in numeracy achievement between the experimental and control groups. Though the experimental group had a mean score slightly higher than the control group, the mean difference in the pre-PST scores was 0.01887. The results of this test are summarized in Table I and Table II.

In order to determine if the performance of the experimental group is significant, a paired t-test was performed using the grades of this group for a comparison between pre and post-PST scores. The mean grade for the pre-test in the study was 35.0354 (SD=3.93457) compared to 38.3451 (SD=4.66708) for the post-test. At $a = 0.05$ and $df = 112$, the critical value of the t ratio ($t=-12.954$) was less than 0.001. Therefore, the post-PST score was significantly different from the pre-PST score in the experimental group, as represented by Table III and Table IV.

Similarly, to determine if the performance of control group is significant, a paired t-test was performed using the grades of this group for a comparison between pre-test and post-test scores. The mean grade for the pre-test in the study was 35.0165 (SD=4.19917) compared to 35.5868 (SD=3.95110) for the post-test. At $a = 0.05$ and $df=120$, the critical value of the t ratio ($t=-2.743$) was 0.007. Therefore, the post-PST score was significantly different from the prePST score in the control group, as depicted in Table V and Table VI.

Finally, an independent sample t-test was conducted. The independent variable had the same two levels as in the previous test: experimental and control. The dependent variable was the student's post-PST score. Levene's Test for equality of variances was not significant ($F = 2.594$, $p = 0.109$). The t-test for equality of means was not significant ($t = 4.890$, $p = 0.000$) indicating significant differences, in post-PST scores between the experimental and control groups, as summarized in Table VII and Table VIII.

Results of this study expand the research on the effects
of appropriate educational programs embedded in a
computerized environment as a tool for visualization and
mathematical reasoning [6], [14], [18].

V. CONCLUSIONS
The purpose of the study was to investigate the impact of the
intervention of PSM in regards to the geometry competence
of the first grade students. The results obtained from the
statistical analysis support our initial hypothesis, considering
that students of the experimental group as opposed to those
of the control one, displayed a greater improvement on the
post-test measurement.
During the study observational notes were taken by the
teacher who reported that students in experimental group
were eager to take their turn at computer and all of the
children were generally attentive. The students in the
computer group were able to use the computer with relative
ease and exhibited mutual consulting, cooperation, and
collaboration. Moreover, the computer may not be as
effective with students who were just at the first van Hiele
level but may of greater value with children who have a
better understanding of geometric concept at the second level
van Hiele model. The observations suggest that these
students are more comfortable with the computer than
children with less geometrical understanding. These results
tend to support the conclusion that computers may not be
equally beneficial to all students. For the students with less
representational competence concrete instructional activities
may be more appropriate.
The current findings add to a growing body of literature
supporting the effective role of educational software in
education and more specifically in mathematics [2], [6], [4],
[18]. Furthermore, the undertaken computer assisted
educational procedure revealed an extended interest for the
tasks involved from the part of the students which
transformed the whole procedure into a thorough, focused,
quiet, independent learning environment reinforcing
previous research conclusions [2], [3], [4]. Our findings in
this report are subject to certain limitations though. We have
to acknowledge that a larger and more representative sample
across all of Greece would have provided us with more solid
results.
Considering the above limitations of this work and the
fact that a research trend of developing and implementing
specific, theory-based and effective software tools, a
necessity to expand research towards this direction emerges.
The results of our research show that teaching and learning
through ICT is an interactive process for of the first graders
and has a positive effect for the teaching of rectangles.

ABSTRACT
The purpose of this study is to investigate if information and communications technology (ICT) helps to improve first grade students' basic geometry achievement regarding circles, triangles, rectangles and squares. Our research compares the level of geometrical competence of the students taught using our ICT oriented learning method specifically targeting 'Realistic Mathematics Education' (RME) for geometry concepts, as opposed to traditional teaching methodology. The designed software consisted of a story and several activities with and without the use of computers for circles, triangles, rectangles and squares. It was designed following the background of RME theory for geometry concepts. The study dealt with first grade students in Crete and Athens, who were divided into two groups (experimental and control). The experimental group consisted of 113 students who were taught about circles, triangles, rectangles and squares with the support of computers. There were 121 students in the control group which were not exposed to the computer oriented curriculum. Students in both groups were pretested and post-tested for their geometry performance. The results of the study indicated that teaching and learning through ICT is an interactive process for students at the first grade level and has a positive effect for the learning of circles, triangles, rectangles and squares using the background of RME theory. Also, the most important outcome of this study was that this teaching intervention seemed to be more effective for triangles and rectangles than for circles and squares.

Keywords
ICT, Realistic Mathematics, geometry, circles, triangles, rectangles, squares, primary education.

1. INTRODUCTION

Nowadays, it is widely accepted that information and communication technologies are used in every steps of education [1], [2], [3]. Technology acts as a catalyst in children, provides social interaction and moreover provides additional opportunities for a rich learning environment that is consistent with modern times [4]. Although concerns about developmental convenience of technology have been announced, many studies have determined that technology has had positive influences on children cognitive and sensual developments [5], [6].

A growing body of literature provides increasing evidence of the effectiveness of using computer technologies to facilitate instruction and learning across a variety of school subjects [7], [8], [9], [10]. Particularly, studies have demonstrated that computers have supported the development of the abilities in children's memory, problem-solving, literacy and math [11], [12], [13], [14], [15], [16]. Indeed, ICT can play an essential role in achieving the objectives of the kindergarten curriculum if supported by appropriate software applications embedded in appropriate educational scenarios [17], [18], [19].

2. ICT AND MATHEMATICS

In the most ideal setting, information communication technologies are treated as a tool for teaching and learning [20], [21], [22]. They are used as a tool for the students to become more familiar with new technology and to integrate investigation, communication and understanding across the full range of the curriculum. Particularly, in the cognitive field of mathematics an evaluation of learning outcomes regarding computer based mathematical teaching in students showed that computer-assisted learning can significantly help in developing proper mathematical skills and the cultivation of deeper conceptual thinking in comparison to the traditional mathematical teaching method [23], [24], [25].

Researchers suggest that the mathematical difficulties students encounter later are correlated with insufficient development of mathematical thinking in their early years [26], [27]. Various researches' results relate the appropriate use of computers with the ability of students to more efficiently understand the different mathematical notions [28], [29]. Thus, it becomes obvious that in the primary school level a very attractive environment of investigating the computer use in mathematics education emerges. Indeed, a vast number of studies show a positive interrelation between the use of computers and the development of mathematical thinking in school [8], [30]. Nonetheless, computer based activities should reflect the theoretical ideas behind them [31], [32].

Following this principle, the software designed and the students' activities developed and examined for the purposes of the current study were inspired by the framework of Realistic Mathematics Education (RME). RME was based and developed principally upon Freudenthal's [33] view of mathematics as a "human activity." According to his perspective, in order for mathematics to be of human value, it has to be taught so as to be useful, it has to be closely related to reality, close to children and relevant to the society [33], [34]. RME is an active and constantly evolving theory of teaching and learning mathematics [35]. Indicative of this, the learning and teaching trajectories with intermediate

DOI: http://dx.doi.org/10.1145/2643604.2643607attainment targets were first conducted for the subject of mathematical calculation at the primary school level and extended to the subject of geometry [36].

In the whole trajectory of the RME teaching theory, five main characteristics of understanding geometry concepts are involved: (a) introducing a problem using a realistic context; (b) identifying the main objects of the problem; (c) using appropriate social interaction and teacher intervention to refine the models of the problem; (d) encouraging the process of reinvention with the development of the problem; and (e) focusing on the connections and aspects of mathematics in general [35]. These should be the main focuses of the learning and teaching procedure concerning geometry in primary school.

Following the theoretical framework that blends together Realistic Mathematics Education (RME) and the use of ICT in primary school, we designed a new model referred to as the First Class Primary Shape Model (FCPSM) which consisted of five levels.

The majority of previous studies aggregately examined the effects of various teaching on the geometric shapes. However, a small number of studies have found that in the first levels of primary school, various shapes are understood differently by students [16], [37]. These studies examined the impact of various teaching interventions on each shape distinctively. Specifically, in the case of circles and squares, only the thickness and size may be varied. Rectangles and triangles may also share differences in characteristics of thickness and size with the addition of other variable characteristics such as length of sides and orientation. Moreover, triangles may vary in the degree of their angles, resulting in a greater variety of shapes. Thus, from the perspective of characteristic features, circles and squares are the simplest. On the contrary, triangles are the most complex, and rectangles are of intermediate difficulty [38], [39].

Our study was based on the above mentioned international literature; we set out to investigate the following research question: Is the concept of triangles more difficult to understand than circles for the first grade students?

In addition, based on the previous studies, we set out to investigate the following hypotheses:

1. The students who will be taught circles with educational intervention based on FCPSM will have a significant improvement in comparison to those taught using the traditional teaching method according to the first grade curriculum.
2. The students who will be taught triangles with educational intervention based on FCPSM will have a significant improvement in comparison to those taught using the traditional teaching method according to the first grade curriculum.
3. The students who will be taught rectangles with educational intervention based on FCPSM will have a significant improvement in comparison to those taught using the traditional teaching method according to the first grade curriculum.
4. The students who will be taught squares with educational intervention based on FCPSM will have a significant improvement in comparison to those taught using the traditional teaching method according to the first grade curriculum.

The present study makes an important contribution to the literature; we examined and compared the effects of a new model which combines computer and non-computer activities for teaching circles, triangles, rectangles and squares separately.

3. METHODOLOGY

The present research was conducted in three phases. In the first and third phases, the pre-test and post-test were given to the classes respectively. In the second phase, the teaching intervention was performed.

3.1 Subjects

The study was carried out during the 2011-12 school year in ten public primary schools located in the cities of Rethymno in Crete (two classes) and Athens (eight classes). It was an experimental research which compared the FCPSM teaching process to traditional teaching based on first grade curriculum. The sample included 234 first graders consisting of 123 girls and 111 boys age six to seven years old. There were two groups in the study, one control (n=121) and one experimental (n=113). In the control group there was not a computer available for the students' use. The classes in the experimental group, in order to participate, were required to have a laptop computer and a video projector available for use by children as part of the teaching procedure. For the uniformity of the survey, instructions were given to the teachers who taught in the experimental or control groups. Teachers who participated in the study had university degrees in education. The teachers in the experimental group ranged from 40 to 50 years old with in-service teaching experience ranging from 18 to 28 years. The teachers in the control group were of ages 38 to 48 years old with in-service teaching experience ranging from 15 to 25 years.

3.2 Instructional Intervention

In the second phase the control group taught with traditional teaching according to first grade curriculum. Group and individual activities were given to children every day. The experimental group covered the same material at roughly the same time according to the FCPSM teaching. The content of the four week syllabus of the FCPSM divided in five levels. It comprised of shapes including a variety of topics concerning fundamental geometry as circles, triangles, rectangles and squares.

The first level of the teaching intervention was according to the first characteristic of the teaching theory of RME which introduces a problem using a realistic context. In this level a story called 'The Family of Shapes' was presented to the students. Various geometrical shapes including circles, triangles, rectangles and squares are presented in this story in a fictional family setting where each member of the family represents a particular shape. This story was designed using Flash CS3 Professional Edition and presented with the video projector in the classroom. In this story *Mrs.* Square and *Mr.* Triangle had a daughter *Miss* Circle. Later in the story, *Miss* Circle met *Mr.* Rectangle, they got married (see Figure 1) and had many children that looked like their parents and grandparents.

The second level started with an activity which identifies the main objects of the problem as underlined by the RME theory. According to the second characteristics of the RME theory, the students (a) identified various geometrical shapes by examining objects in their classrooms, (b) drew certain geometrical shapes

(see Figure 2) and (c) named the shape of a set of various objects presented to them by the teacher.
The third level of the teaching procedure included activities using appropriate social interaction to refine the models of the problem. Firstly, a child had to draw a shape from a bag and to find out the name of the shape without seeing it. Then, the students split into groups and each group had to construct a dog or a man using a set of shapes. The final part of this level involved a computer-based group activity in which the student had to recognize and choose the correct shape among other shapes (see Figure 3).
In the fourth level of the teaching procedure, according to the RME theory, we implemented a process of reinvention with the development of the shapes in a higher cognitive level where the properties of an object were presented in a software activity. Next, the children were separated into groups and cooperated with one another to make a shape with their bodies on the floor. Then, they divided into groups and each group was assigned a specific shape. Each of these groups was instructed to make fake cookies from plasticine in the form of the groups' assigned shape (see Figure 4). At the end of this activity, the students in each group shared their cookies with the other groups.
Figure 1. Students watched the story 'The Family of Shapes' (first level).
Figure 2. The student did a drawing activity (second level).
Figure 3. The student had to recognize shapes (third level).
Figure 4. Each student was instructed to make fake cookies from plasticine (fourth level).
In the last level of the teaching process, the students played card games with the properties of shapes. The goal of this card game is to focus on the connections and aspects of the properties of circles and triangles as implied by the fifth characteristic of the RME theory. There were two kinds of card games: the white cards with shapes and their properties of sides and the yellow cards with shapes and their properties of angles. The students are separated into groups and each student in a group starts with a number of cards in their hand. Each student takes his/her turn throwing a card on the table. The purpose of the game is to match cards with identical properties and to collect those cards. At the end of the game the child who had the majority of cards was the winner.
Afterwards, there were computer activities where the children had to recognize the shapes from using only the properties of the shapes. The computer presents a picture as a puzzle. The students then must drag and drop the corresponding shape, based the geometrical property displayed on the screen, into the box (see Figure 5).Figure 5. Students completed a software activity (fifth level).
In the software represented above, once an activity is selected, a problem is announced verbally and directions are given to the user through a recorded message. The feedback users get after following these directions is represented by two different screens, one positive and one negative. This feedback is accompanied with the corresponding audio messages. In the first case, the user receives a 'well-done' message (see Figure 6) and in the second case the user gets a 'try it again' message. In both cases, though, an effort was made to keep these messages to be as little emphatic as possible. This way, the children's interest is focused more on the mathematical procedure of the application rather than their result or the competition.
Figure 6. The user receives a 'well-done' message.
3.3 Educational Measures
In the first phase, the pre-test was given to the classes of the experimental and control groups during the beginning of December 2011 to isolate the effects of the treatment by looking for inherent inequities in the geometry achievement potential of the two groups. The pre-test was referred to as First Class Primary Shape Test (FCPST) and it contained thirty tasks in total. The first twenty tasks of the FCPST were based on the first level of the Van Hiele model and the last ten were from the test that was used in the research by Clements et al. [40] based on the second van Hiele level.
The theory of the van Hiele model deals specifically with geometric thought as it develops through several levels of sophistication under the influence of a school curriculum [41]. The van Hiele model uses five levels, however, for the first grade students only the first two levels were used. In the Visual Level, students were able to identify figures such as circles and triangles as visual gestalts. Conceptualization at this level includes being able to name, reproduce and group similar geometric objects by visual recognition. For instance, they might say that a figure is a rectangle because it looks like a door. In the Descriptive/Analytic Level, students were able to identify shapes from their properties. Conceptualization at this level includes identifying geometric objects according to their properties. For example, a student sees a rhombus as a figure with four equal sides [42].
Due to the young age of the students, the pre-tests were administrated in the class with explicit and detailed instructions of the teacher. These were pencil-and-paper tasks in which the children were asked to select shapes including rectangles, squares, triangles and circles on a page with various geometric figures (see Figure 7). Each task had a weighted grade that was computed from the student's answers. Particularly, for each correct answer the student was given one grade and lost one grade for each incorrect. Scores were computed for each of the individual geometrical tasks of the FCPST. Since the numbers of problems varied across tasks, a mean proportion of correct responses for each of the thirty tasks were produced by dividing the number of correct responses by the total number of problems on that task (possible range of standardized scores, 0-1.00). Moreover, for the purposes of the present study, we measured the score of circles and the score of the triangles separately. The scale used to measure the unstandardized scores for circles is based on a scale from 0 to 69 and for squares is from 0 to 67. The scale used to measure the unstandardized scores for triangles is based on a scale from 0 to 40 and for rectangles is from 0 to 41..
Figure 7. Student marks circles.Similarly, during the third and final phase of the study, after the teaching intervention, the same test (FCPST) was given to all students in both the experimental and control groups as a post-test at the beginning of March 2012 to measure their improvement on circles and triangles separately.
3.4 Research Design
The present study was a quasi-experimental design with one experimental and one control groups. Eight first grade classes from Athens and two from Rethymno participated in this study. From the eight classes located in Athens, we randomly assigned four classes to the control group and the remaining four classes were assigned to the experimental group. We then randomly assigned one of the two classes from Rethymno to the control group and the other class to the experimental group. Therefore, five classes were in the control group (n=121) and the remaining five classes were in the experimental group (n=113).
4. RESULTS
A set of analyses was conducted to determine the effects of the mathematics intervention on first grade students' geometry knowledge for circles and triangles. The pre-test and post-test were taken by 234 students. Analysis of the data was carried out using the SPSS (ver. 19) statistical analysis computer program.
The independent variables were the group (experimental group and control group) and the shape (circles, triangles, rectangles or squares). The dependent variable was the students' FCPST posttest score.
4.1 Comparing the difficulty of understanding among shapes
The first analysis was a paired t-test among the students' FCPST pre-test scores of circles, triangles, rectangles and squares. This was done in order to examine whether the concept of triangles is more difficult to understand than the other shapes. Also it was examined whether the concept of circles are more easy to understand than the other shapes. Moreover, the difficulty of squares is higher than circles and lower than rectangles. There were significant differences in the students' FCPST pre-test scores among circles (M =.951, SD =.035) and triangles (M=.837, SD = .057), t(233) = 29.033, p <. 001, rectangles (M=.859, SD = .100), t(233) = 15.067, p <. 001, and squares (M =.897, SD =.080), t(233) = 11.021, p <. 001. Also, there were significant differences in the students' FCPST pre-test scores among triangles (M=.837, SD = .057) and rectangles (M=.859, SD = .100), t(233) = -3.431, p <. 001, and squares (M =.897, SD =.080), t(233) = -11.653, p<.001. Moreover, there was a significant difference in the students' FCPST pre-test scores among rectangles (M=.859, SD = .100) and squares (M =.897, SD =.080), t(233) = -6.452, p<.001.
The descriptive statistics for students' scores for circles and triangles are presented in Table 1.
Table 1. Descriptive statistics for students' FCPST pre-test scores

Circles	Triangles	Rectangles	Squares
M, SD	M, SD	M, SD	M, SD
Control and Experimental	.951, .035	.837, .057	.859, .100	.897, .080

4.2 Evaluate the effectiveness of FCPSM for circles
Before conducting the analysis of ANCOVA on the students' FCPST post-test scores for circles to evaluate the effectiveness of the intervention, checks were performed to confirm that there were no violations of the assumptions of homogeneity of variances and homogeneity of regression slopes [43]. The result of Levene's test when pre-test for circles was included in the model as a covariate was not significant, indicating that the group variances were equal, F(1, 232) = .342, p = .559; hence the assumption of homogeneity of variance was not been violated.
Table 2. Comparison of student scores for circles in post-test:

ANCOVA analysis Sources	Type III Sum of Squares	df	Mean Squares	F	Sig.	η2
Pre-test	.069	1	.069	102.0	.000	.306
Group	.030	1	.030	44.38	.000	.161
Error	.156	231	.001			

After adjusting for FCPST scores for circles in the pre-test (covariate), the following results were obtained from the analysis of covariance (ANCOVA). A statistically significant main effect was found for type of intervention on the FCPST post-test scores for circles, F(1, 231) = 44.384, p = .001, η2 = .161 (Table 2); thus the experimental group performed significantly higher in the FCPST post-test for circles than the control group.
4.3 Evaluate the effectiveness of FCPSM for triangles
Then, the analysis of ANCOVA on the students' FCPST post-test scores for triangles was performed to evaluate the effectiveness of the intervention. The result of Levene's test when pre-test for triangles was included in the model as a covariate was not significant, indicating that the group variances were equal, F(1, 232) = 2.743, p = .099; hence the assumption of homogeneity of variance was not been violated.

After adjusting for FCPST scores for triangles in the pre-test (covariate), the following results were obtained from the analysis of covariance (ANCOVA). A statistically significant main effect was found for type of intervention on the FCPST post-test scores for triangles, F(1, 231) = 66.558, p < .001, η 2 = .224 (Table 3); thus the experimental group performed significantly higher in the FCPST post-test for triangles than the control group.

Table 3. Comparison of student scores for triangles in posttest: ANCOVA analysis

Sources	Type III Sum of Squares	df	Mean Squares	F	Sig.	η 2
Pre-test	.106	1	.106	30.05	.000	.115
Group	.234	1	.234	66.55	.000	.224
Error	.812	231	.0044.4			

Evaluate the effectiveness of FCPSM for rectangles

Then, the analysis of ANCOVA on the students' FCPST post-test scores for rectangles was performed to evaluate the effectiveness of the intervention.

After adjusting for FCPST scores for rectangles in the pre-test (covariate), the following results were obtained from the analysis of covariance (ANCOVA). A statistically significant main effect was found for type of intervention on the FCPST post-test scores for rectangles, F(1, 231) = 58.108, p < .001, η 2 = .201 (Table 4); thus the experimental group performed significantly higher in the FCPST post-test for rectangles than the control group.

Table 4. Comparison of student scores for rectangles in posttest: ANCOVA analysis

Sources	Type III Sum of Squares	df	Mean Squares	F	Sig.	η 2
Pre-test	1.869	1	1.869	565.1	.000	.710
Group	.192	1	.192	58.10	.000	.201
Error	.764	231	.003			

4.5 Evaluate the effectiveness of FCPSM for squares

Then, the analysis of ANCOVA on the students' FCPST post-test scores for squares was performed to evaluate the effectiveness of the intervention. The result of Levene's test when pre-test for squares was included in the model as a covariate was not significant, indicating that the group variances were equal, F(1, 232) = .044, p = .834; hence the assumption of homogeneity of variance was not been violated.

After adjusting for FCPST scores for squares in the pre-test (covariate), the following results were obtained from the analysis of covariance (ANCOVA). A statistically significant main effect was found for type of intervention on the FCPST post-test scores for squares, F(1, 231) = 3.367, p = .001, η2 = .068 (Table 3); thus the experimental group performed significantly higher in the FCPST post-test for squares than the control group.

Table 5. Comparison of student scores for squares in post-test: ANCOVA analysis

Sources	Type III Sum of Squares	df	Mean Squares	F	Sig.	η 2
Pre-test	.252	1	.252	115.6	.000	.334
Group	.120	1	.120	55.26	.000	.193
Error	.503	231	.002			

Results of this study expand the research on the effects of appropriate software embedded in a computerized environment as a tool for visualization and mathematical reasoning used alongside with specially designed activities [26], [23], [32], [27], [28], [44], [29], [37], [39], [42]. Also, the outcomes of the present study create a new teaching model with computer and non-computer activities based on the theoretical framework that blends together Realistic Mathematics Education of geometric thinking in primary school.

5. DISCUSSION

The general purpose of the study was to investigate the impact of instructional intervention using the First Class Primary Shape Model (specially designed mathematics activities and software based on Realistic Mathematics Education) for the purpose of teaching the basic geometrical concepts of circles, triangles, rectangles and squares in regards to the geometry competence of the first grade students of primary school. In this research, we found that it is more difficult for first grade students to understand the concept of triangles than the other shapes. These students carried a relatively great amount of geometric knowledge from kindergarten and as a result, it is possible that the students understand circles and their properties better than triangles, rectangles and squares because triangles are more complex shapes than the other shapes [26], [31]. Similar behavior we have with rectangles, which are more complex than squares and circles. Finally, squares are more complex than circles. Our findings agree with similar researches [38], [16], [37], [39] which implied that circles are simpler and triangles are most complex.

Moreover, we found that the students that were taught circles with educational intervention based on FCPSM had a significant improvement compared to those taught using the traditional teaching method according to the first grade curriculum (hypothesis 1). Therefore, the first hypothesis was confirmed. Also, our findings suggest that the students were taught triangles with educational intervention based on FCPSM had a significant improvement compared to those taught using the traditional teaching method (hypothesis 2). As a result, the second research question answered positively.

Moreover, we found that the students that were taught rerctangles with educational intervention based on FCPSM had a significant improvement compared to those taught using the traditional teaching method according to the first grade curriculum (hypothesis 3). Therefore, the third hypothesis was confirmed. In addition, we found that the students that were taught squares with educational intervention based on FCPSM had a significant improvement compared to those taught using the traditional teaching method according to the first grade curriculum (hypothesis 4). Therefore, the fourth hypothesis was confirmed. Our results overlap with the results of other analogous studies which indicate the positive effects of a computer based-model of teaching geometry [26], [32], [37], [42]. Also, our results tend to confirm that other similar studies which indicate the positive effects of a computer based teaching model for geometric shapes [23], [28], [44], [29], [39], [45].

Moreover, an important statistical outcome of the present study was that the partial eta squared for triangles (η2 = .224 - Table 3) is higher than it was for rectangles (η2 = .201 - Table 4). Also, the partial eta squared for rectangles (η2 = .201 - Table 4) is higher than it was for squares (η2 = .193 - Table 5). Finally, the partial eta squared for squares (η2 = . 193 - Table 5) is higher than it was for circles (η2 = . 161- Table 2).

This outcomes supports that, our teaching intervention had a somewhat greater impact in learning triangles than of learning circles for first grade students. Also, the present study demonstrates that our first grade teaching process, the noncomputer based mathematics activities and the computer based mathematics activities, may support the learning of both difficult and simple mathematics in the primary school level. Our findings agree with other similar researches supporting the effective role of ICT in education and more specifically in mathematical reasoning [31], [23], [45], [24], [28], [25], [30].

The above discussion should be referenced in light of some of the limitations of this study. The first limitation of the study is that the data collected was from the participants residing the cities of Athens and Rethymno. The second limitation was the generalizability of this study which was limited to participants attending public schools. Therefore, the results from this research can be generalized only to similar groups of students. The results may not adequately describe students from other regions of Greece. However, as the study was of small scale and context specific, any application of the findings should be done with caution.

Furthermore, the undertaken computer assisted educational procedure revealed an extended interest for the tasks involved from the part of the students. It is an ongoing challenge for the reflective teacher to decide how this technology can be best utilized in education; especially in light of the current researches on the effects of such an implementation. This study is simply one small piece in the puzzle of geometry education in primary schools.

Introduction
Nowadays, it is becoming increasingly accepted that various ICT applications are
developmentally appropriate technological resources for children of primary and
secondary school age (Druin & Fast, 2002 ; Passey, 2006 ; Plowman & Stephen,
2003 ; Zaranis, 2011). It is obvious now that the original "aphorism" and the ignoring of ICT are no longer effective strategies and are gradually replaced by more
realistic solutions as infl uenced by related research (Remtulla, 2010).
Technology, in this enlarged view, acts as a catalyst in their social interaction and
moreover provides additional opportunities for a rich learning environment that is
consistent with the modern era. International research confi rms that the implementation of computers in education can have positive results in different subjects (Chou
& Liu, 2005 ; Finegan & Austin, 2002 ; Livingstone, 2012). These technologies can
therefore play an essential role in achieving the objectives of the primary curriculum
in all sectors and subjects if supported by developmentally appropriate software
applications embedded in appropriate educational scenarios (Dwyer, 2007 ; Fisher,
Denning, Higgins, & Loveless, 2012 ; Lee, 2009 ; Zaranis & Oikonomidis 2009).
ICT and Mathematics
In the most ideal setting, information communication technologies are treated as a
tool for teaching and learning (Burnett, 2009 ; Sife, Lwoga, & Sanga, 2007 ;
Sutherland et al., 2004). They are used as a tool for the students to become more
Geometry Teaching Through ICT
in Primary School

familiar with new technology and to integrate investigation, communication, and
understanding across the full range of the curriculum. Particularly, in the cognitive
fi eld of mathematics an evaluation of learning outcomes regarding computer based
mathematical teaching in students showed that computer-assisted learning can signifi cantly help in developing proper mathematical skills and the cultivation of deeper
conceptual thinking in comparison to the traditional mathematical teaching method
(Dimakos & Zaranis 2010 ; Hardman, 2005 ; Keong, Horani, & Daniel, 2005).
Researchers suggest that the mathematical diffi culties students encounter later
are correlated with insuffi cient development of mathematical thinking in their early
years (Bobis et al., 2005 ; Gersten, Jordan, & Flojo, 2005). Various researches'
results relate the appropriate use of computers with the ability of students to more
effi ciently understand the different mathematical notions (Howie & Blignaut, 2009 ;
Trouche & Drijvers, 2010). Thus, it becomes obvious that in the primary school
level a very attractive environment of investigating the computer use in mathematics
education emerges. Indeed, a vast number of studies show a positive interrelation
between the use of computers and the development of mathematical thinking in
school (Clements, 2002 ; Vale & Leder, 2004). Nonetheless, computer based activities should refl ect the theoretical ideas behind them (Clements & Sarama, 2004 ;
Dissanayake, Karunananda, & Lekamge, 2007).
Following this principle, the software designed and the students' activities developed and examined for the purposes of the current study were inspired by the framework of Realistic Mathematics Education (RME) and the van Hiele model. RME
was based and developed principally upon Freudenthal's (1968) view of mathematics
as a "human activity." According to his perspective, in order for mathematics to be
of human value, it has to be taught so as to be useful, it has to be closely related to
reality, close to children and relevant to the society (Freudenthal, 1968 ; Van den
Heuvel-Panhuizen & Wijers, 2005). RME is an active and constantly evolving theory of teaching and learning mathematics (Van den Heuvel-Panhuizen, 2001).
Indicative of this, the learning and teaching trajectories with intermediate attainment targets were fi rst conducted for the subject of mathematical calculation at the
primary school level and extended to the subject of geometry (Van den Heuvel-
Panhuizen & Buys, 2008).
In the whole trajectory of the RME teaching theory, fi ve main characteristics of
understanding geometry concepts are involved: (a) introducing a problem using a
realistic context; (b) identifying the main objects of the problem; (c) using appropriate social interaction and teacher intervention to refi ne the models of the problem;
(d) encouraging the process of reinvention with the development of the problem;
and (e) focusing on the connections and aspects of mathematics in general (Van den
Heuvel-Panhuizen, 2001). These should be the main focuses of the learning and

teaching procedure concerning geometry in primary school.
Moreover, the theory of the van Hiele model deals specifi cally with geometric
thought as it develops through several levels of sophistication under the infl uence of
a school curriculum (Clements & Battista, 1992). The van Hiele model uses fi ve
levels, however, for the fi rst grade students only the fi rst two levels were used. In the
Visual Level, students were able to identify fi gures such as circles and triangles as
visual gestalts. Conceptualization at this level includes being able to name, reproduce
N. Zaranis61
and group similar geometric objects by visual recognition. For instance, they might
say that a fi gure is a rectangle because it looks like a door. In the Descriptive/
Analytic Level, students were able to identify shapes from their properties.
Conceptualization at this level includes identifying geometric objects according to
their properties. For example, a student sees a rhombus as a fi gure with four equal
sides (Zaranis, 2012). Following the theoretical framework that blends together
Realistic Mathematics Education (RME), the van Hiele model of geometric thinking and the use of ICT in primary school, we designed a new model referred to as
the First Class Primary Shape Model (FCPSM) which consisted of fi ve levels.
The majority of previous studies aggregately examined the effects of various
teaching on the geometric shapes. However, a small number of studies have found
that in the fi rst levels of primary school, various shapes are understood differently
by students (Walcott et al., 2009 ; Wong et al., 2007). These studies examined the
impact of various teaching interventions on each shape distinctively. Specifi cally, in
the case of circles, only the thickness and size may be varied. Rectangles and triangles may also share differences in characteristics of thickness and size with the
addition of other variable characteristics such as length of sides and orientation.
Moreover, triangles may vary in the degree of their angles, resulting in a greater
variety of shapes. Thus, from the perspective of characteristic features, circles are
the simplest. On the contrary, triangles are the most complex, and rectangles are of
intermediate diffi culty (Satlow & Newcombe, 1998 ; Wong et al., 2011).
Our study was based on the above mentioned international literature; we set out
to investigate the following research question: Is the concept of triangles more dif-
fi cult to understand than circles for the fi rst grade students?
In addition, based on the previous studies, we set out to investigate the following
hypotheses:
1. The students who will be taught circles with educational intervention based on
FCPSM will have a signifi cant improvement in comparison to those taught using
the traditional teaching method according to the fi rst grade curriculum.
2. The students who will be taught triangles with educational intervention based on
FCPSM will have a signifi cant improvement in comparison to those taught using
the traditional teaching method according to the fi rst grade curriculum.
The present study makes an important contribution to the literature; we examined and compared the effects of a new model which combines computer and non-
computer activities for teaching circles and triangles separately.
Methodology
Subjects
The study was carried out during the 2011-2012 school year in ten public primary
schools located in the cities of Rethymno in Crete (two classes) and Athens (eight
classes). It was an experimental research which compared the FCPSM teaching
Geometry Teaching Through ICT in Primary School62
process to traditional teaching based on fi rst grade curriculum. The sample included
234 fi rst graders consisting of 123 girls and 111 boys age 6-7 years old. There were
two groups in the study, one control (n = 121) and one experimental (n = 113). In the
control group there was not a computer available for the students' use. The classes
in the experimental group, in order to participate, were required to have a laptop
computer and a video projector available for use by children as part of the teaching
procedure. For the uniformity of the survey, instructions were given to the teachers
who taught in the experimental or control groups. Teachers who participated in the
study had university degrees in education. The teachers in the experimental group
ranged from 40 to 50-year-olds with in-service teaching experience ranging from 18
to 28 years. The teachers in the control group were of ages 38-48 years with in-
service teaching experience ranging from 15 to 25 years.
Instructional Intervention
In the second phase the control group taught with traditional teaching according to
kindergarten curriculum. Group and individual activities were given to children
every day. The experimental group covered the same material at roughly the same
time according to the FCPSM teaching. The content of the 4-week syllabus of the
FCPSM divided in fi ve levels. It comprised of shapes including a variety of topics
concerning fundamental geometry concepts and focus on circles and triangles.
The fi rst level of the teaching intervention was according to the fi rst characteristic of the teaching theory of RME which introduces a problem using a realistic
context. In this level a story called "The Family of Shapes" was presented to the
students. Various geometrical shapes including circles and triangles are presented in
this story in a fi ctional family setting where each member of the family represents a
particular shape. This story was designed using Flash CS3 Professional Edition and
presented with the video projector in the classroom. In this story Mrs. Square and
Mr. Triangle (Fig. 1 -left) had a daughter Miss Circle. Later in the story, Miss Circle
met Mr. Rectangle, got married, and had many children that looked like their parents and grandparents.
The second level started with an activity which identifi es the main objects of the
problem as underlined by the RME theory. According to the fi rst level of the van
Hiele model and the second characteristics of the RME theory, the students (a) identifi ed various geometrical shapes by examining objects in their classrooms, (b) drew
certain geometrical shapes (Fig. 1 -right), and (c) named the shape of a set of various
objects presented to them by the teacher.
The third level of the teaching procedure included activities using appropriate
social interaction to refi ne the models of the problem. Firstly, a child had to draw a
shape from a bag and to fi nd out the name of the shape without seeing it. Then, the
students split into groups and each group had to construct a dog or a man using a set
of shapes. The fi nal part of this level involved a computer-based group activity in
which the student had to recognize and choose the correct shape among other shapes
(Fig. 2 -left) as implied by the fi rst van Hiele level.
N. Zaranis63
In the fourth level of the teaching procedure, according to the second level of the
van Hiele model and the RME theory, we implemented a process of reinvention
with the development of the shapes in a higher cognitive level where the properties
of an object were presented in a software activity (Fig. 2 -right). Next, the children
were separated into groups and cooperated with one another to make a shape with
their bodies on the fl oor (Fig. 3 -left). Then, they divided into groups and each group
was assigned a specifi c shape. Each of these groups was instructed to make fake
cookies from plasticine in the form of the groups' assigned shape. At the end of this
activity, the students in each group shared their cookies with the other groups.
In the last level of the teaching process, as the second level of van Hiele theory
implied, the students played card games with the properties of shapes. The goal
of this card game is to focus on the connections and aspects of the properties of
circles and triangles as implied by the fi fth characteristic of the RME theory.
There were two kinds of card games: the white cards with shapes and their properties of sides and the yellow cards with shapes and their properties of angles. The
students are separated into groups and each student in a group starts with a number
of cards in their hand. Each student takes his/her turn throwing a card on the table.
Fig. 1 Students watched the story "The Family of Shapes" (left —fi rst level) and did a drawing
activity (right —second level)
Fig. 2 The student had to recognize shapes (left —third level) and students viewed the properties
of a triangle on the computer (right —fourth level)
Geometry Teaching Through ICT in Primary School64
The purpose of the game is to match cards with identical properties and to collect
those cards. At the end of the game the child who had the majority of cards was the
winner. Afterwards, there were computer activities where the children had to recognize the shapes from using only the properties of the shapes. The computer presents
a picture as a puzzle. The students then must drag and drop the corresponding shape,
based the geometrical property displayed on the screen, into the box (Fig. 3 -right).
In the software represented above, once an activity is selected, a problem is
announced verbally and directions are given to the user through a recorded message.
The feedback users get after following these directions is represented by two different screens, one positive and one negative. This feedback is accompanied with the
corresponding audio messages. In the fi rst case, the user receives a "well-done"
message and in the second case the user gets a "try it again" message. In both cases,
though, an effort was made to keep these messages to be as little emphatic as possible. This way, the children's' interest is focused more on the mathematical procedure of the application rather than their result or the competition.
Educational Measures
The present research was conducted in three phases. In the fi rst phase, the pretest
was given to the classes of the experimental and control groups during the beginning of December 2011 to isolate the effects of the treatment by looking for inherent
inequities in the geometry achievement potential of the two groups. The pretest was
referred to as First Class Primary Shape Test (FCPST) and it contained thirty tasks
in total. The fi rst twenty tasks of the FCPST were based on the fi rst level of the Van
Hiele model and the last ten were from the test that was used in the research by
Clements, Swaminathan, Zeitler-Hannibal, and Sarama (1999) based on the second
van Hiele level. Due to the young age of the students, the pretests were administrated in the class with explicit and detailed instructions of the teacher. These were
pencil-and-paper tasks in which the children were asked to select shapes including
Fig. 3 Students made a shape with their bodies on the fl oor (left —fourth level) and completed a
software activity (right —fi fth level)
N. Zaranis65
rectangles, squares, triangles, and circles on a page with various geometric fi gures
(Fig. 4). Each task had a weighted grade that was computed from the student's
answers. Particularly, for each correct answer the student was given one grade and
lost one grade for each incorrect. Scores were computed for each of the individual
geometrical tasks of the FCPST. Since the numbers of problems varied across tasks,
a mean proportion of correct responses for each of the thirty tasks were produced by
dividing the number of correct responses by the total number of problems on that
task (possible range of standardized scores, 0-1.00). Moreover, for the purposes of
the present study, we measured the score of circles and the score of the triangles
separately. The scale used to measure the unstandardized scores for circles is based
on a scale from 0 to 69. The scale used to measure the unstandardized scores for
triangles is based on a scale from 0 to 40.
Similarly, during the third and fi nal phase of the study, after the teaching intervention, the same test (FCPST) was given to all students in both the experimental
and control groups as a posttest at the beginning of March 2012 to measure their
improvement on circles and triangles separately.
Research Design
The present study was a quasi-experimental design with one experimental and one
control groups. Eight fi rst grade classes from Athens and two from Rethymno participated in this study. From the eight classes located in Athens, we randomly
assigned four classes to the control group and the remaining four classes were
Fig. 4 Student marks circles
Geometry Teaching Through ICT in Primary School66
assigned to the experimental group. We then randomly assigned one of the two
classes from Rethymno to the control group and the other class to the experimental
group. Therefore, fi ve classes were in the control group (n = 121) and the remaining
fi ve classes were in the experimental group (n = 113).
Results
A set of analyses was conducted to determine the effects of the mathematics intervention on fi rst grade students' geometry knowledge for circles and triangles. The
pretest and posttest were taken by 234 students. Analysis of the data was carried out
using the SPSS (ver. 19) statistical analysis computer program. The independent
variables were the group (experimental group and control group) and the shape (circles or triangles). The dependent variable was the students' FCPST posttest score.
Comparing the Diffi culty Between Understanding
Circles and Triangles
The fi rst analysis was a paired t -test among the students' FCPST pretest scores of
circles and triangles in order to examine whether the concept of triangles is more
diffi cult to understand than circles. There was a signifi cant difference in the students' FCPST pretest scores for circles (M = 0.94, SD = 0.04) and triangles (M = 0.83,
SD = 0.07); t (233) = 25.93, p <0.001.
The descriptive statistics for students' scores for circles and triangles are presented in Table 1 . Observing the standardized values, students scored higher for
circles and triangles after receiving the intervention than before receiving it.
Moreover, the score of the students in triangles was lower than those in circles after
the teaching intervention (Table 1).
Evaluate the Effectiveness of FCPSM for Circles
Before conducting the analysis of ANCOVA on the students' FCPST posttest scores
for circles to evaluate the effectiveness of the intervention, checks were performed
to confi rm that there were no violations of the assumptions of homogeneity of
Table 1 Descriptive statistics for students' standardized scores of experimental and control groups

variances and homogeneity of regression slopes (Pallant, 2001). The result of
Levene's test when pretest for circles was included in the model as a covariate was
not signifi cant, indicating that the group variances were equal, F (1, 232) = 0.476,
p = 0.491; hence, the assumption of homogeneity of variance was not been violated.
The value of the covariance by dependent variable interaction (group × score for
circles) was not signifi cant, F (1, 230) = 2.042, p = 0.154, η^2 = 0.009; therefore, the
assumption homogeneity of regression slopes was tenable. After adjusting for
FCPST scores for circles in the pretest (covariate), the following results were
obtained from the analysis of covariance (ANCOVA). A statistically signifi cant main
effect was found for type of intervention on the FCPST posttest scores for circles,
F (1, 231) = 46.513, p < 0.001, η^2 = 0.168 (Table 2); thus, the experimental group performed signifi cantly higher in the FCPST posttest for circles than the control group.
Evaluate the Effectiveness of FCPSM for Triangles
Then, the analysis of ANCOVA on the students' FCPST posttest scores for triangles
was performed to evaluate the effectiveness of the intervention. The result of Levene's
test when pretest for triangles was included in the model as a covariate was not signifi cant, indicating that the group variances were equal, F (1, 232) = 0.044, p = 0.834;
hence, the assumption of homogeneity of variance was not been violated.
The value of the covariance by dependent variable interaction (group × score for
triangles) was not signifi cant, F (1, 230) = 0.214, p = 0.644, η^2 = 0.001; therefore, the
assumption homogeneity of regression slopes was tenable. After adjusting for
FCPST scores for triangles in the pretest (covariate), the following results were
obtained from the analysis of covariance (ANCOVA). A statistically signifi cant
main effect was found for type of intervention on the FCPST posttest scores for
triangles, F (1, 231) = 69.715, p < 0.001, η^2

= 0.232 (Table 3); thus, the experimental
group performed signifi cantly higher in the FCPST posttest for triangles than the
control group.

Geometry Teaching Through ICT in Primary School68
Results of this study expand the research on the effects of appropriate software
embedded in a computerized environment as a tool for visualization and mathematical reasoning used alongside with specially designed activities (Bobis et al., 2005 ;
Dimakos & Zaranis, 2010 ; Dissanayake et al., 2007 ; Gersten et al., 2005 ; Howie &
Blignaut, 2009 ; Starkey, Klein, & Wakeley, 2004 ; Trouche & Drijvers, 2010 ; Wong
et al., 2007 , 2011 ; Zaranis, 2012). Also, the outcomes of the present study create a
new teaching model with computer and non-computer activities based on the theoretical framework that blends together Realistic Mathematics Education and the van
Hiele model of geometric thinking in primary school.
Discussion
The overall purpose of the study was to investigate the impact of instructional intervention using the First Class Primary Shape Model (specially designed mathematics
activities and software based on Realistic Mathematics Education and the van Hiele
model) for the purpose of teaching the basic geometrical concepts of circles and
triangles in regard to the geometry competence of the fi rst grade students of primary
school. In this research, we found that it is more diffi cult for fi rst grade students to
understand the concept of triangles than circles. These students carried a relatively
great amount of geometric knowledge from kindergarten and as a result, it is possible that the students understand circles and their properties better than triangles
because triangles are more complex shapes than circles (Bobis et al., 2005 ; Clements
& Sarama, 2004). Our fi ndings agree with similar researches (Satlow & Newcombe,
1998 ; Walcott et al., 2009 ; Wong et al., 2007 , 2011) which implied that circles are
simpler and triangles are most complex. As a result, the research question answered
positively.
Moreover, we found that the students that were taught circles with educational
intervention based on FCPSM had a signifi cant improvement compared to those
taught using the traditional teaching method according to the fi rst grade curriculum
(hypothesis 1). Our results overlap with the results of other analogous studies which
indicate the positive effects of a computer based-model of teaching geometry (Bobis
et al., 2005 ; Dissanayake et al., 2007 ; Wong et al., 2007 ; Zaranis, 2012). Therefore,
the fi rst hypothesis was confi rmed.
Also, our fi ndings suggest that the students were taught triangles with educational intervention based on FCPSM had a signifi cant improvement compared to
those taught using the traditional teaching method (hypothesis 2). Our outcomes
overlie the results of other similar studies which indicate the positive effects of a
computer based teaching model for geometric shapes (Dimakos & Zaranis, 2010 ;
Howie & Blignaut, 2009 ; Starkey et al., 2004 ; Trouche & Drijvers, 2010 ; Wong
et al., 2011). Thus, the second hypothesis was answered positively. In addition, as it
mentioned in the results section, students in both the experimental and the control
groups scored higher for shapes of circles or triangles after receiving the teaching
intervention than before the teaching process.
N. Zaranis69
Moreover, an important statistical outcome of the present study was that the
partial eta squared for triangles (η
2
= 0.232, Table 3) is higher than it was for circles
(η
2
= 0.168, Table 2). This outcomes supports that, our teaching intervention had a
somewhat greater impact in learning triangles than of learning circles for fi rst grade
students. Also, the present study demonstrates that our fi rst grade teaching process,
the non-computer based mathematics activities and the computer based mathematics activities, may support the learning of both diffi cult and simple mathematics in
the primary school level. Our fi ndings agree with other similar researches supporting the effective role of ICT in education and more specifi cally in mathematical
reasoning (Clements & Sarama, 2004 ; Dimakos and Zaranis 2010 ; Furner &
Marinas, 2007 ; Hardman, 2005 ; Howie & Blignaut, 2009 ; Keong et al., 2005 ; Vale
& Leder, 2004).
The above discussion should be referenced in light of some of the limitations of
this study. The fi rst limitation of the study is that the data collected was from the
participants residing the cities of Athens and Rethymno. The second limitation was
the generalizability of this study which was limited to participants attending public
schools. Therefore, the results from this research can be generalized only to similar
groups of students. The results may not adequately describe students from other
regions of Greece. However, as the study was of small scale and context specifi c,
any application of the fi ndings should be done with caution.
Furthermore, the undertaken computer assisted educational procedure revealed
an extended interest for the tasks involved from the part of the students. It is an
ongoing challenge for the refl ective teacher to decide how this technology can be
best utilized in education; especially in light of the current researches on the effects
of such an implementation. This study is one small piece in the puzzle of geometry
education in primary schools.

The use of ICT in kindergarten for teaching addition
based on realistic mathematics education
Nicholas Zaranis
© Springer Science+Business Media New York 2014
Abstract The purpose of this study is to investigate if information and communications technology (ICT) helps improve kindergarten students' basic mathematical
achievement regarding addition. Our research compares the level of mathematical
competence of the students taught using our ICT oriented learning method which
specifically takes advantage of 'Realistic Mathematics Education' (RME) for the
concept of addition, as opposed to traditional teaching methodology. The designed
software consisted of a story and several activities with and without the use of
computers for addition. It was designed following the background ofthe RME theory.
The study dealt with kindergarten students in Crete, who were divided into two groups
(experimental and control). The experimental group consisted of 165 students who
were taught addition with the support of computers. There were 170 students in the

control group which were not exposed to the computer oriented curriculum. Students in
both groups were pre-tested and post-tested for their mathematical achievement. The
results of the study indicated that teaching and learning through ICT is an interactive
process for students at the kindergarten level and has a positive effect for the learning of
addition using the background ofthe RME theory. Also, the most important result of
this study was that this teaching intervention appeared to be more effective for the
kindergarten students with medium-level mathematical abilities.

1 Introduction
Nowadays, it is widely accepted that information and communication technologies are
used in every steps of education (Druin and Fast 2002; Passey 2006; Zaranis 2011).
Technology acts as a catalyst in children, provides social interaction and moreover
provides additional opportunities for a rich learning environment that is consistent with
Educ InfTechnol
DOI 10.1007/s10639-014-9342-8
N. Zaranis (*)
Department ofPreschool Education, University ofCrete, Panepistimioupoli Gallou Rethymno,
Rethymno 74100, Greece
e-mail: nzaranis@edc.uoc.grmodern times (Plowman and Stephen 2003). Although concerns about developmental
convenience of technology have been announced, many studies have determined that
technology has had positive influences on children cognitive and sensual developments
(Chen and Chang 2006; Zaranis and Oikonomidis 2009).
A growing body of literature provides increasing evidence of the effectiveness of
using computer technologies to facilitate instruction and learning across a variety of
school subjects (Bayraktar 2002; Clements 2002; McKenney and Voogt 2009; Trundle
and Bell 2010). Particularly, studies have demonstrated that computers have supported
the development of the abilities in children's memory, problem-solving, literacy and
math (Dodge et al. 2003; Morrow et al. 2003; Ihmedieh 2010; Judge 2005; Clements
and Sarama 2003; Walcott et al. 2009). Indeed, ICT can play an essential role in
achieving the objectives of the kindergarten curriculum if supported by appropriate
software applications embedded in appropriate educational scenarios (Dwyer 2007; Lee
2009; Fisher et al. 2012).
2 ICT and mathematics
A child requires particular skills to start learning basic mathematical calculations in
kindergarten such as counting, recognizing number symbols, subitizing small quantities, discerning number patterns, and comparing numerical magnitudes and estimating
quantities (Bobis, et al. 2005; Desoete, et al. 2010; Gersten et al. 2005; Kroesbergen,
et al. 2007). Information communication technologies in the cognitive field ofmathematics help in developing proper mathematical skills and the cultivation of deeper
conceptual thinking in comparison to the traditional mathematical teaching method
(Dimakos and Zaranis 2010; Hardman 2005; Keong et al. 2005).
Various researches' results relate the appropriate use ofcomputers with the ability of
students to more efficiently understand the different mathematical notions (Howie and
Blignaut 2009; Trouche and Drijvers 2010). Also, a vast number of studies show a
positive interrelation between the use ofcomputers and the development ofmathematical thinking in school (Clements 2002; Vale and Leder 2004).
Although computers can be a valuable tool, there are disadvantages for the incorporation of them in a classroom. When computers and other technological tools used
continuously, students can develop a dependency on these tools. Just as students who
are never required to do math without a calculator lose their ability to solve math
problems by hand, students who use computers for almost every activity experience a
decrease in their ability to spell even write by hand. Students should practice these
simple skills without technological tools regularly to ensure that their skills do not
atrophy (Sáinz, and Eccles 2012).
Also, computers present an added challenge for teachers because educators have to
deal with students of different levels of computer literacy. Some students enter the
classroom fully versed in computer applications, while others come with no previous
experience. It is difficult for teachers to deal with this huge difference and ensure that
they provide to students who need help with that aid while require from capable
students to slow their academic progress and wait (Dina, and Ciornei 2013). While
computer games are just as, ifnot more, engaging than board or card games, they do
not afford the same degree ofplayer interaction. Many computer games are individual
Educ InfTechnolpursuits. When students complete these digital games and activities they miss out on
the interaction practice that they receive through the playing of traditional games
(Sampayo-Vargas et al. 2013).
Nonetheless, computer based activities should reflect the theoretical ideas behind
them (Clements and Sarama 2004; Dissanayake et al. 2007; Zaranis and Oikonomidis
2009). Following this principle, the software designed and the students' activities that
were developed and examined for the purposes of this study were inspired by the
framework ofRealistic Mathematics Education (RME).
RME, founded from the work of Hans Freudenthal (1973), places an emphasis on
making mathematics education a relatable and usable experience for students. This is
achieved by emphasizing the connections between the real world and the mathematical
world. By staying close to reality, educators are able to give mathematics a sense ofvalue
inwhich students can findreal life associations (Freudenthal 1973). Moreover, RME is an
active and constantly evolving theory of teaching and learning mathematics (Van den
Heuvel-Panhuizen 2001). Indicative of this, the learning and teaching trajectories with
intermediate attainment targets were first conducted for the subject of mathematical
calculation at the kindergarten level (Van den Heuvel-Panhuizen and Buys 2008).
In the whole trajectory of the RME teaching theory, five main characteristics of
understanding mathematical concepts are involved: (a) introducing a problem using a
realistic context; (b) identifying the main objects ofthe problem; (c) using appropriate
social interaction and teacher intervention to refine the models of the problem; (d)
encouraging the process ofreinvention with the development of the problem; and (e)
focusing on the connections and aspects ofmathematics in general (Van den HeuvelPanhuizen 2001). These should be the main focuses of the learning and teaching
procedure concerning addition in kindergarten.
Following the theoretical framework that blends together Realistic Mathematics
Education (RME) and the use of ICT in kindergarten, we designed a new model
referred to as the Kindergarten Addition Model (KAM) which consisted offive levels.
The Kindergarten Addition Model (KAM) was designed by the group ofkindergarten
teachers and developed in cooperation with the researcher in the Department of
Preschool Education ofthe University of Crete according to the kindergarten curriculum during the 2012. The main purpose of the model is to foster young students'
mathematical concepts and skills about addition and to engage them in self-regulated
learning, using computer and no computer activities. In this article the abbreviation
KAM is used for the Kindergarten Addition Model. Our study was based on the above
mentioned international literature; we set out to investigate the following research
questions:
1. Will the students who will be taught with educational intervention based on KAM
have a significant improvement on their general mathematical achievement in
comparison to those taught using the traditional teaching method according to
the kindergarten curriculum?
2. Will the students who will be taught with educational intervention based on KAM
have a significant improvement on addition in comparison to those taughtusing the
traditional teaching method according to the kindergarten curriculum?
3. What is the mathematical level of the students who had the highest benefit from
KAM according to their general mathematical achievement?
Educ InfTechnol4. Will the students who will be taught with educational intervention based on KAM
have a significant improvement on counting in comparison to those taught using
the traditional teaching method according to the kindergarten curriculum?
5. What is the mathematical level of the students who had the highest benefit from
KAM according to their mathematical achievement on counting?
The present study makes an important contribution to the literature; we examined
and compared the effects ofa new model which combines computer and non-computer
activities for teaching addition and counting.
3 Methodology
The present research was conducted in three phases. In the first and third phases, the
pre-test and post-test were given to the classes respectively. In the second phase, the
teaching intervention was performed.
3.1 Research design
The present study was a quasi-experimental design with one experimental and one
control groups. Twenty-fourkindergarten classes from Rethymno participated in this
study. From these classes, we randomly assigned twelve classes to the control group
(n=170) and the remaining twelve classes were assigned to the experimental group
(n=165). In the control group there was not computer available for students to use in
the classroom and students were taught mathematics as usual. The classes in the
experimental group had a computer for everyday use by children as part of the
educational process and they were taught mathematics with the help of computer.
Forthe uniformity ofthe survey, instructions were given to the teachers who taught in
the experimental or control groups. The teachers who participated in the study were
students from the University of Crete ofthe Department ofPreschool Education in
4th year oftheir studies and they did the teaching procedure during their final thesis
work.
3.2 Participants
The study was carried out during the 2012-13 school year in 24 public kindergartens
located in the city of Rethymno, Crete. It was an experimental research which compared the KAM teaching process to traditional teaching based on the kindergarten
curriculum. The sample included 335 kindergarteners consisting of 159 girls and 176
boys aged 5-6 years old. There were two groups in the study, one control (n= 170) and
one experimental (n=165). The experimental group has 85 boys (51.50 %) and 80 girls
(48.50 %). The control group has 91 boys (53.50 %) and 80 girls (46.50 %).
3.3 Instructional intervention
In the second phase, the control group taught with traditional teaching according to the
kindergarten curriculum. Group and individual activities were given to children every
Educ InfTechnolday. The experimental group covered the same material at roughly the same time
according to the KAM procedure.
3.3.1 Experimental group
In the experimental group the content ofthe 4 weeks syllabus ofthe KAM was divided
into five levels. It comprised of mathematical activities focusing on addition and
counting. The content of the 4 weeks syllabus of the KAM was divided into five
levels. It comprised ofmathematical activities focusing on addition and counting.
The first level ofthe teaching intervention was according to the first characteristic of
the teaching theory of RME which introduces a problem using a realistic context. In
this level a story called 'An adventure in the forest' was presented to the students using
a computer. It involved several characters from favorite fairy tales ofchildren like Little
Red Riding Hood, Hansel and Gretel, Snow White, the Seven Dwarfs and the Big Bad
Wolfand it included addition and counting problems. It was designed using Flash CS3
Professional Edition and presented with a computer in the classroom. In this story Little
Red Riding Hood and the Seven Dwarfs (Fig. 1-left) were friends and played games.
Later in the story, the Big Bad Wolfkidnapped some ofthe Seven Dwarfs because he
was hungry. In the end they became friends and everybody was happy. Then a child
repeated the story and the students painted some oftheir favorite characters ofthe story.
The second level started with an activity which identifies the main objects of the
problem as underlinedbythe RME theory. According to the second characteristics ofthe
RME theory, the students identifiedthe main objects ofthe additionby counting objects.
The teacher ofthe kindergarten gave three candies to George and two candies to Maria.
Then, she asked the children, "How many candies have George and Mary together?"
Another activity was a dice game and the children had to add the numbers by counting
(Fig. 1-right). Finally, a computer activity took place with problems ofaddition.
The third level ofthe teaching procedure included activities using appropriate social
interaction to refine the models of the problem. Firstly, the children played the super
market game. One student played the customer who wanted to buy something and the
other student acted as the employee. For instance, the kindergarten teacher said, "John
had five euro and wanted to buy two things." Next, the students had to construct the
problem ofthe using mathematical symbols e.g. numbers, the plus sign and the equal
sign (Fig. 2-left). The final part ofthis level involved a computer-based group activity
in which the student had to construct the mathematical problem (Fig. 2-right) as implied
by the third characteristic ofthe RME theory.
Fig. 1 Students watched the story 'An adventure in the forest' (left -first level) and use math symbols for
addition (right - second level)
Educ InfTechnolIn the fourth level of the teaching procedure, according to the RME theory, we
implemented a process ofreinvention with the development ofthe problem in a higher
cognitive level. In this level the objects were hidden. For instance, the kindergarten
teacher gave some chocolates to the children and hid them in their bags (Fig. 3-left).
Then the children had to construct the mathematical problem of the hidden objects.
Next, the children played a card game where each card had an addition problem which
was showed to the students only for 10 s. Finally, a software activity followed with
hidden objects (Fig. 3-right).
In the last level ofthe teaching process, the activities focused on the connections and
aspects of mathematics in general as implied by the fifth characteristic of the RME
theory. The students are separated into groups and played the game "the super market".
One student was the buyer and the other was the employee ofthe super market (Fig. 4-
left). The buyer wanted to buy two things. The students knew how much money had
the buyer and the cost ofthe first thing that he bought. The children had to find how
much money the second thing cost. Afterwards, there were computer activities where
the children had to find the missing number of an addition problem (Fig. 4-right).
In the software represented above, once an activity is selected, a problem is
announced verbally and directions are given to the user through a recorded message.
The feedback users get after following these directions is represented by two different
screens with a happy cartoon and another with a sad cartoon.
3.3.2 Control group
The control group covered the same material at the same time with similar activities as
the experimental class. The content ofthe teaching was 4 week syllabus according to
the kindergarten curriculum. It comprised of mathematical activities focusing on
addition and counting. Additional activities were given to the student ofcontrol group
Fig. 2 The student had to construct the mathematical problem (left and right - third level)
Fig. 3 Students played games with hidden objects (left and right -fourth level)
Educ InfTechnolin order to cover the time corresponded to the computer activities of experimental
group.
Activities was assigned and collected daily, there were quizzes given periodically, to
be carried out individually and in small groups. In the zoo activity, the teacher of the
kindergarten asked Maria to take two animals for the basket and George three. Then,
the teacher asks a child, "How many animals have George and Mary together?" (Fig. 5-
left). Another activity was the fisherman. The children had to fish tow fishes from the
"lake." Each fish had a price on it and the child had to find out how much money the
fishes cost (Fig. 5-right).
A common activity was a game with abacus and the child had to add the numbers by
counting (Fig. 6-left). Moreover, the activity with the "blocks of house" was very

attractive to the children (Fig. 6-right). The teacher said, "The Little Red Riding Hood lived on the fifth floor and the Snow White on the first. One day the Little Red Riding Hood visited Snow White. How many floors Little Red Riding Hood must went on in order to go her house?"
3.4 Educational measures
In the first phase, the pre-test was given to the classes ofthe experimental and control groups during the beginning ofDecember 2011 to isolate the effects ofthe treatment by looking for inherent inequities in the mathematical achievement potential of the two groups. The pre-test was the Test ofEarly Mathematics Ability third edition, TEMA-3 (Ginsburg and Baroogy 2003).
The TEMA-3 is a norm-referenced, reliable, and valid test of early mathematical ability that is appropriate for children ofages 3 years and 0 months through 8 years and
Fig. 4 Students played games with missing numbers without a computer (left) and with computer activities (right -fifth level)
Fig. 5 Students played the "Zoo activity" (left) and "The fisherman" (right) in exercising in addition
Educ InfTechnol11 months. The form ofTEMA-3 contains 72 items. The purposes ofTEMA-3 are to: a) identify the children who are significantly behind or ahead of their peers in the development ofmathematical thinking, b) identify specific strengths and weaknesses in mathematical thinking, d) suggest instructional practices appropriate for individual children, e) document children's progress in learning arithmetic and f) serve as a measure in research projects. Also, one of the purposes for developing the TEMA-3 was to provide researchers with a statistical test that was based on current research and theories about mathematical thinking. In particular, TEMA-3's availability would stimulate the study of mathematical thinking in young children (Song and Ginsburg 1987).
Due to the young age ofthe students, the pre-tests were administrated in the children individually. These were pencil-and-paper tasks in which the children were asked to select shapes including: reading and writing numbers, verbal counting, enumeration, cardinality rule, produce sets, choosing the greater and the lesser number, addition, subtraction, multiplication (Fig. 7).
Each task had a grade that was computed from the student's answers. Scores were computed for each of the individual mathematical tasks of the TEMA-3. Since the weight of problems varied across tasks, the total correct responses for each of the seventy two tasks were produced by adding the all correct responses of each problem on that task (possible range ofscores, 0-202). Moreover, for the purposes ofthe present study, we measured the total score, the score of the addition tasks and the score of counting tasks separately. The scale used to measure the scores for addition is based on a scale from 0 to 31. The scale used to measure the scores for counting is based on a scale from 0 to 19.
The THEMA-3 is not a timed test; therefore, no precise time limits are imposed on the children being tested. On average, children will be able to complete the relevant portion ofthe test in 45-60 min.
Fig. 6 The games "abacus" (left) and "The blocks ofhouse" (right)
Fig. 7 Student marks the larger number (left) and does addition (right)
Educ InfTechnolSimilarly, during the third and final phase ofthe study, after the teaching intervention, the same test (TEMA-3) was given to all students in both the experimental and control groups as a post-test at the beginning ofMarch 2012 to measure their improvement on general mathematical ability, addition and counting.
4 Results
A set ofanalyses was conducted to determine the effects ofthe mathematics intervention on kindergarten students' mathematical achievement fortheir general mathematical knowledge, addition and counting. The pre-test and post-test were taken by 335 students. Analysis of the data was carried out using the SPSS (ver. 19) statistical analysis computer program. The independent variable was the group (experimental group and control group). The dependent variable was the students' TEMA-3 post-test score.
4.1 Evaluate the effectiveness ofKAM for general mathematical achievement
The first analysis was a paired t-test among the students' TEMA-3 pre-test scores of mathematical achievement in order to examine whether the experimental and control group start from the same level. There was not a significant difference in the students' TEMA-3 pre-test scores for experimental (M=45.65, SD=20.51) and control groups (M=43.68, SD=23.76); t(328.56)=.814, p=.416.
Before conducting the analysis of ANCOVA on the students' TEMA-3 post-test scores for general mathematical achievement to evaluate the effectiveness of the intervention, checks were performed to confirm that there were no violations of the assumptions of homogeneity of variances (Pallant 2001). The result of Levene's test when pre-test for general mathematical achievement was included in the model as a covariate was not significant, indicating that the group variances were equal, F(1, 333)=.223, p=.637; hence the assumption of homogeneity of variance was not been violated.
After adjusting for TEMA-3 scores for general mathematical achievement in the pretest (covariate), the following results were obtained from the analysis of covariance (ANCOVA). A statistically significant main effect was found for type of intervention on the TEMA-3 post-test scores for general mathematical achievement, F(1, 332)= 18.104, p<.001, η2=.052 (Table 1); thus the experimental group performed significantly higher in the TEMA-3 post-test for general mathematical achievement than the control group.

Error 40995.912 332 121.641
Educ InfTechnol4.2 Evaluate the effectiveness ofKAM on addition
Then, an analysis was a paired t-test among the students' TEMA-3 pre-test scores of addition in order to examine whether the experimental and control group start from the same level. There was not a significant difference in the students' TEMA-3 pre-test scores ofaddition for experimental (M=5.15, SD=3.576) and control groups (M=4.79, SD=3.819); t(333)=.898, p=.370.
Also, the analysis of ANCOVA on the students' TEMA-3 post-test scores for addition was performed to evaluate the effectiveness ofthe intervention. The result of Levene's test when pre-test for addition was included in the model as a covariate was not significant, indicating that the group variances were equal, F(1, 333)=.672, p=.413; hence the assumption ofhomogeneity ofvariance was not been violated.
After adjusting for TEMA-3 scores for addition in the pre-test (covariate), the following results were obtained from the analysis of covariance (ANCOVA). A statistically significant main effect was found for type of intervention on the TEMA-3 post-test scores for addition, F(1, 332)=14.320,p<.001, η2=.041 (Table 2); thus the experimental group performed significantly higher in the TEMA-3 post-test for addition than the control group.
4.3 Evaluating the stratification of students according to their success in TEMA-3
Moreover, a stratification ofexperimental and control group according to their success in TEMA-3 was divided into three equal categories: less than 32 (33.33th percentile - low), 32 to 55 (33.33 th to 66.66th percentile - medium), and more than 55 (66.66th percentile - high). In the following Table 3 the students' performance is presented including both groups (i.e. the experimental and the control group) before teaching.
The Table 3 shows that 34.5 % ofthe students ofthe experimental group exhibited high grading, 37 % exhibited medium grading, whereas 28.5 % exhibited low grading. Likewise, 32.4 % of the control group exhibited high grading, 29.4 % medium and 38.2 % low. In other words, students' performance in the medium category of the experimental group appeared to be superior (i.e. 37.0 % compared with 29.4 % ofthe control group).
A two-way ANOVA was conducted that examined the effect ofclass (experimental versus control) and the students' level of mathematical achievement (low versus medium versus high) on their improvement of TEMA-3 on addition (post-test minus pre-test score). There was not a significant interaction between the effects ofclass and mathematical level on students' according to their success in TEMA-3, F(2, 329)=.955, p=.386, η
2
=.006. On the contrary, the effect of mathematical level was
Table 2 Comparison ofstudent scores on addition in post-test: ANCOVA analysis

Educ InfTechnolpre-test scores of counting for experimental (M=8.90, SD=3.889) and control groups (M=8.66, SD =4.680); t(325.317)=.520, p=.603.
Also, the analysis of ANCOVA on the students' TEMA-3 post-test scores for counting was performed to evaluate the effectiveness of the intervention. The result of Levene's test when pre-test for counting was included in the model as a covariate was not significant, indicating that the group variances were equal, F(1, 333)=1.511, p=.220; hence the assumption ofhomogeneity ofvariance was not been violated.
After adjusting for TEMA-3 scores for counting in the pre-test (covariate), the following results were obtained from the analysis of covariance (ANCOVA). A statistically significant main effect was found for type of intervention on the TEMA-3 post-test scores for counting, F(1, 332)=8.882, p=.003, η
2
=.026 (Table 5); thus the
experimental group performed significantly higher in the TEMA-3 post-test for counting than the control group.
4.5 Evaluating the stratification of students according to their success in counting
Moreover, a stratification ofexperimental and control group according to their success in the counting portion ofTEMA-3 was divided into three equal categories: less than 7 (33.33th percentile - low), 7 to 11 (33.33 th to 66.66th percentile - medium), and more
Fig. 8 Mathematical improvement on addition after the teaching intervention according to the levels of general mathematical achievement
Educ InfTechnolthan 11 (66.66th percentile - high). In the following Table 6 the students' performance is presented including both groups (i.e. the experimental and the control group) before teaching.
The Table 6 shows that 26.06 % ofthe students ofthe experimental group exhibited a high grade, 43.03 % exhibited a medium grade, whereas 30.91 % exhibited a low grade. Likewise, 29.41 % ofthe control group exhibited high grades, 34.12 % medium and 36.47 % low. In other words, students' performance in the medium-level category ofthe experimental group appeared to be superior (i.e. 43.03 % compared with 34.12 % ofthe control group).
A two-way ANOVA was conducted that examined the effect ofclass (experimental versus control) and the students' level ofmathematical achievement in counting (low versus medium versus high) on their improvement of TEMA-3 in addition (post-test minus pre-test score). There was not a significant interaction between the effects of class and mathematical level on students' in counting, F(2, 329)=2.203, p=.112, η
2
=.013. On the contrary, the effect of mathematical level in counting was
significant (F(2, 329)=4.990, p=.007, η
2
=.029), with the improvements of addition
in the low and high levels were lower (low- M=2.79, S.D. 3.827, high- M=2.04, S.D.= 2.586) than those in the medium level (M=2.33, S.D.=2.993) after the teaching intervention (Table 7, Fig. 9). Also, the effect of group was also significant (F(1, 329)=9.839,p=.002, η
2
=.029), with children in the experimental group scoring higher
(M=3.43, S.D.=3.074) than those in the control group (M=2.61, S.D.=3.683) after the teaching intervention.
The Bonferroni post hoc tests indicated that students' improvement on addition of the medium group differed significantly from students' improvement of the low (p=.005) group.

Educ InfTechnolResults of this study expand the research on the effects of appropriate software embedded in a computerized environment as a tool for mathematical reasoning used alongside with specially designed activities (Bobis, et al. 2005; Desoete, et al. 2010; Dimakos and Zaranis 2010; Dissanayake, et al. 2007; Gersten, et al. 2005; Kroesbergen, et al. 2007; Howie and Blignaut 2009; Starkey, et al. 2004; Trouche and Drijvers 2010; Zaranis 2012). Also, the outcomes ofthe present study create anew teaching model with computer and non-computer activities based on the theoretical framework that blends together Realistic Mathematics Education in the kindergarten level.
5 Discussion
The general purpose of the study was to investigate the impact of instructional intervention using the Kindergarten Addition Model (specially designed mathematics activities and software based on Realistic Mathematics Education) for the purpose of teaching the mathematical concept of addition in regards to the mathematical competence ofthe kindergarten students. In this research, we found that the students who were taught with educational intervention based on KAM had a significant improvement on their general mathematical achievement in comparison to those taught using the traditional teaching method according to the kindergarten curriculum. Our findings agree with similar researches (Judge 2005; Keong, et al. 2005; Walcott, et al. 2009; Zaranis 2011) which implied that ICT helps students to understand mathematical notions more effectively. As a result, the first research question answered positively. Moreover, we found that the students that taught with the educational intervention based on KAM had a significant improvement in addition in comparison to those taught using the traditional teaching method according to the kindergarten curriculum. Our results overlap with the results of other analogous studies which indicate the positive effects of a computer based-model of teaching math (Bobis, et al. 2005;
Table 7 Frequencies ofthe two groups in the pre-test ofcounting

Medium Experimental 3.36 3.208 165
Control 1.66 2.374 62
Total 2.33 2.993 58
High Experimental 2.46 3.587 50
Control 2.12 2.986 170
Total 2.04 2.586 113
Total Experimental 3.43 3.074 129
Control 2.61 3.683 93
Total 2.73 3.154 335
Educ InfTechnolDissanayake, et al. 2007; Kroesbergen, et al. 2007). Therefore, the second research question was confirmed.
Also, our findings suggest that students with the medium level of general mathematical achievement, who were taught addition with educational intervention based on KAM had a significant improvement, compared to those with high and low level of general mathematical knowledge students who were taught with the same method. Our outcomes overlie with the results of other similar studies which indicate the positive effects of a computer based teaching model for mathematical notions (Keong, et al. 2005; Zaranis 2011). Thus, the third research question was addressed.
In addition, as it mentioned in the results section, students that were taught with educational intervention based on KAM had a significant improvement on counting in comparison to those taught using the traditional teaching method according to the kindergarten curriculum. Our outcomes overlap with the results of other similar studies which indicate the positive effects ofa computer based teaching model for mathematical notions (Dimakos and Zaranis 2010; Howie and Blignaut 2009; Starkey, et al. 2004; Trouche and Drijvers 2010). As a result, the fourth research question answered positively
Also, our findings suggest that students with a medium-level ofmathematical achievement in counting, who were taught addition with educational interventionbased on KAM had a significant improvement, compared to those with high-levels and low-levels of mathematical achievement in counting who were taught using the traditional teaching
Fig. 9 Mathematicalimprovementonadditionaftertheteachinginterventionaccordingtothelevelsofcountingskills
Educ InfTechnolmethod. Our outcomes overlie with the results ofother similar studies which indicate the positive effects ofa computer based teaching model for mathematical notions (Plowman and Stephen 2003; Zaranis 2012). Thus, the fifth research question was addressed.
Moreover, the important outcome of the present study was that our model (KAM) helps the children in the medium-level of math achievement on addition to have the greater improvement on math understanding than those students in the low and high levels. Also, we faced the same results when we measured the students' level of understanding of counting. The medium level students had the greatest improvement on counting with the suggested model (KAM). We see that the students had the same behavior in counting and addition. That is because, as it is mentioned on the theoretical background session, counting is the first level of addition according the RME theory. Thus, the students who had as good background with counting were treated in the same manner with those who had a similar achievement on addition.
During the study observational notes were taken by the teachers who reported that children in experimental group were eager to have their turn in computer, and all ofthe children were generally attentive. The children in the computer group were able to use the computer with relative ease and exhibited mutual consulting, cooperation, and collaboration. Subjects did not explore the keyboard and few of the children in the experimental group consistently requested assistance as to whether their answer was correct. These children seemed unwilling to allow the computer to "tell them" iftheir answer was correct or incorrect.
Finally, we wantto emphasize thatthe enthusiasm ofthe children and theirwillingness to engage with computers during the research should serve as a reference for teachers of preschool education. Teachers are required to build up the excitement this and to give children a richpedagogical framework, which includes the computer as an integral part of the program so that education cannot be divorced from the real, everyday life.
The above discussion should be referenced in light ofsome ofthe limitations ofthis study. The first limitation of the study is that the data collected was from the participants residing the city of Rethymno, Crete. The second limitation was the generalizability of this study which was limited to participants attending public schools. Therefore, the results from this research can be generalized only to similar groups of students. The results may not adequately describe students from other regions of Greece. However, as the study was ofsmall scale and context specific, any application ofthe findings should be done with caution.
Furthermore, the undertaken computer assisted educational procedure, which is an ongoing challenge for the reflective teacher to decide how this technology, can be best utilized in kindergarten education. Especially in light ofthe current research which is simply one small piece in the puzzle of mathematical education in the kindergarten level.

New ICT tools allow children to take advantage of new learning platforms as well aiding them effectively in attaining new knowledge through activities related to their immediate interests and real life scenarios. Nowadays, computers and digital applications are a part of the daily life of children. In kindergarten education, properly designed digital educational activities can become a very powerful educational tool for efficient and effective learning. The utilization of interactive activities may contribute towards the growth of learning incentives as well as proper mental development in particular areas; such as mathematics and science. Mobile devices have new attractive features and provide considerable advantages in the teaching of mathematics in kindergarten education. Our study proposes the integration of mobile devices, running our own specially designed learning activity applications, in kindergarten classrooms. These applications are based on the three levels of Realistic Mathematics Education (RME) targeting fundamental mathematical concepts for the kindergarten level. We intend to gather information on effectiveness of the incorporation of these devices and applications as leaning tools for kindergarteners.
Keywords: Preschool Education; ICT; Mobile Learning; Digital Learning Activities; Realistic Mathematics

Introduction

The introduction of ICT (Information and Communication Technologies) in the field of Preschool Education has been a point of debate and controversy among researchers for an extended period of time. Due to the highly dynamic introduction of computers in the educational reality among the Western society and the influence of related research, computer aided learning is more realistic than it once was; thus gradually replacing any initial resistant reactions towards the use of ICT in a learning environment. A wide variety of ITC applications have become increasingly accepted as developmentally appropriate education resources for children of preschool and primary school age (Druin & Fast, 2002; Plowman & Stephen, 2003; Zaranis & Kalogiannakis, 2011a; Zaranis, 2012). Moreover, modern researchers have expanded the content of the term ICT to deal not only with the desktop computer but well as mobile technologies embedded in various devices (Plowman & Stephen, 2005; Cjeleaj, 2013) such as e-toys, digital cameras, smart games, electronic tables and smart mobile devices (Voithofer, 2005). Via the Internet, children are now able to surf and search for information, play games, watch videos and even make use of numerous online services such as making and receiving VoIP calls using Skype. There have even been reported cases of kindergarten children creating and maintaining their own blog and engaging in online social networking. Now digital media and interfacing with new technologies is a part of day-to-day life for children of all ages (Finitsis, 2012).

Computers not only isolate children but also act as a catalyst in their social interaction and provide children with additional opportunities for rich learning activities that are relevant to their growth characteristics regardless of age. International research studies (Yelland, 2002; Druin & Fast, 2002; Plowman & Stephen, 2003; Musawi, 2011; Zaranis, 2011; Zaranis, 2012) on the introduction of computers in preschool education show that computers in the classroom have positive results in regard to the learning of different subjects.

ICT can play an essential role in achieving the goals of the kindergarten curriculum in all areas and subjects (Plowman & Stephen, 2003; Chronopoulou & Riga, 2012) if the provided developmentally appropriate software applications (Haugland, 1999; Lee, 2009) are embedded in appropriate educational scenarios (Zaranis & Kalogiannakis, 2011b). In addition to the educational purpose, the use of computers in kindergarten is characterized mainly as a learning activity while the common child will see it as a game of sorts. Like many researchers, in formal and informal settings, we strongly endorse the need to focus our investigations on meaningful learning through playing. It is now clear that the use of this learning process is more than adequate in achieving given educational goals for children at the preschool and primary school levels (Plowman & Stephen, 2005; Zaranis, 2012).

In the classroom, ICT is treated as a learning tool (Zaranis & Kalogiannakis, 2011a). For the students, ICT is a means for achieving familiarity with new technologies as well as being a N. ZARANIS ET AL.
tool of investigation, communication and understanding across the full range of the curriculum.

In recent years, with the emergence of smart mobile devices, several researchers (Lam & Duan, 2012) have proposed the use of mobile devices for learning. There are multiple advantages with respect to the use of said devices in the learning process including stimulus, motivation, ease of use, availability, etc. (Vavoula & Karagiannidis, 2005). Such devices are becoming highly valuable tools in the educational process because of their attractive features (Klopfer, Squire, & Jenkins, 2002). Mobile devices are portable, more affordable, in relation to desktop computers, offer the opportunity for learning without local restrictions, use the possibilities offered by the wireless mobile technologies for easy access to information, promote the development of digital literacy, provide opportunities for independent learning, facilitate people with disabilities etc.

Shuler (2009) stated that applications on smart mobile devices have the potential to become the new means of providing educational content to students. As mobile technologies play an increasingly prominent role in the lives of children worldwide, national ministries and schools are experimenting with the use of these popular devices for a wide range of alternative methods of teaching and learning objectives. Smartphones and tablets are among of the six new emerging technologies that may have a major impact on teaching, learning, and research in primary education (Johnson, Smith, Willis, Levine, & Haywood, 2011).

Particularly in the subject matter of mathematics, Zaranis (2011) made a comparison between the learning outcomes of computer based teaching and mathematical thematic teaching; more specifically, targeting the teaching of "Realistic Mathematics" for children ages 4 to 6 years old in Greek Kindergarten. Compared to the traditional thematic teaching method, results showed that computer-assisted learning may significantly enhance the development of mathematical skills and the cultivation of a deeper perceptual ability for the pupils (Zaranis, 2011; Zaranis & Kalogiannakis, 2011b).

The main purpose of this study is to provide a better understanding of the characteristics and the effect of ICT, especially mobile learning, in the context of kindergarten education. We will try to achieve the above through a systematic literature review on the introduction and use of ICT and smart mobile devices in kindergarten education. In particular, we will study the use of educational applications in the form of digital activities for preschool education. This paper will also present the first phase of an instructional intervention that utilizes a series of educational applications designed according to the principles of Realistic Mathematical Education. Our research materializes in the form of digital activities performed on smart mobile devices. These activities consist of comparison, sorting, matching, structured counting, efficient counting and the general knowledge of numbers exercises.

The originality of this work lies in the fact that it is the first study carried out in the field of kindergarten education in Greece. It attempts to take advantage of the children's existing familiarity with the use of smart mobile devices (tablets) to provide a benefit to the learning process. In the context of this document, a detailed and systematic effort will be made towards achieving a theoretical justification for the implementation of reformed teaching proposals.

ICT and Children as "iLearners"

Researchers Christie and Johnson (2009) indicate that digital media has now permanently settled in the lives of young children. As pointed out by Lavidas, Komis, & Gialamas (2012), many times children surpass adults in their modern technological knowledge even before attending kindergarten. Hertzog and Klein (2005) define a distinct line between the current generation of children and their parents. They very aptly report that children do not need to adapt to the new technological society because they were born in it; unlike their parents who have acquired their technological knowledge as somewhat of a foreign language at an advanced age. Consequently, according to Prensky (2001), young children can be described as "digital natives" since they are growing up in the digital world. Most recently, Prensky (2010) refers to today's students as "iLearners" deriving from the fact that digital devices such as smartphones and tablet computers dominate the daily lives of children in Western societies from the age of 6 months.

The Lieberman, Bates and So (2009a) report that several studies have shown that digital media can introduce children to abstract concepts that were previously considered too advanced for their age. In her research, Yelland (2005) has shown that activities entailing the use of digital media, within the school environment, facilitate collaborative learning for young children and the development of logical thinking while reinforcing their ability to solve problems. Digital learning activities may encourage children to work together. They have been found to be more effective than traditional learning activities (Zaranis, 2011; Zaranis & Kalogiannakis, 2011a).

Young children have access to new technologies not just in the school environment but also out of school, at home (Plowman & Stephen, 2005; Somekh, 2007). For some children, the first educational experience with computers begins in the kindergarten age, between 4 to 6 years old. Existing studies have shown that children of this age can successfully handle computers with the appropriate instruction (Zaranis, 2011; Zaranis & Kalogiannakis, 2011a). In a study of the comparison between learning at home and in the kindergarten classroom, Plowman, Stephen and McPake (2010) found out that ICT is used to promote three main areas of learning. The extension of knowledge about the world (cognitive objects), the acquisition of functional skills (such as the operation of the mouse) as well as the development of the propensity for learning (by strengthening a range of emotional, social and cognitive functions of learning). Recent studies have identified a number of emerging digital devices, such as tablets, as being appropriate for the education and entertainment of children (Vereniki & Kervin, 2011).

Lieberman et al., (2009a) commented that young children age three to six years old play with a vast variety of digital learning activities, now available on desktop monitors and portable screens, spending a constantly increasing amount of time doing so.

Furthermore, Couse and Chen (2010) state the advantages offered by the use of mobile devices with touch screens compared to typical computer applications controlled by a mouse. The significant potential offered by tablets should also be noted, as they are not only useful and portable, but also more affordable compared to laptops (Leoni, 2010). The acquisition cost of applications is very competitive and often includes the ability of a user to download a "light," often free, or trial version of applications. Fuegen (2012) identifies tablets as compact laptops with optimized operating systems, devoid of a physical keyboard, however, provide interactive capabilities via built-in functionality and the use of third party applications (mobile
2 Copyright © 2013 SciRes. N. ZARANIS ET AL.
apps). Similarly, the term smartphone describes mobile phones which, besides the usability of voice data over cellular networks, have similar features and characteristics of tablets but with a smaller screen size.
Orlando (2012) commented that portable devices fit perfectly in the lifestyle of young children as they do not need to sit at a table or an office to use the device, they do not need to handle a mouse, while the interface offered with a single touch on the touchscreen is irresistible. Children now use the new technology at a younger age than ever before (Common Sense Media, 2011). A study including Australia, New Zealand, USA and Great Britain showed that most children ages two to five years are more able to interact with a tablet than to tie their shoes (Orlando, 2012). Moreover, the possession of smart mobile devices by children ages four to fourteen years old has doubled since 2005 (NPD Group, 2008).
According to a survey by the MDG Advertising Company (2012), preschoolers today make use of mobile devices more than ever in the past. The same survey indicated that more than half of all first time iPad and iPod device users are children under the age of five. However, not all researchers explicitly support the use of smart mobile devices by young children. Banister (2010) notes the lack of research on the use of tablets in education as they have only recently been introduced into the market. In addition, Marsh (2010) advocates the "dichotomy" that arises between the activities at hand and the technology supporting it. He claims that the emerging phenomenon of "digital activities" differs from that of the spontaneous children's play because the digital activity depends largely on, and is often limited by, the actual design of the software and hardware.
Learning via Mobile Devices
Sharples, Taylor and Vavoula, (2007) define mobile learning as any kind of learning that takes place in learning environments and areas which take into account the mobility of technology, the mobility of learners and the mobility of learning. Mobile learning through the use of tablets and smartphones presents new opportunities for strengthening the learning experiences in ways that simply other devices cannot achieve (Lam & Duan, 2012).
High-resolution screens allow tablet users to share static content and resources such as images and videos in an easy way. Most tablets have no phone features making them ideal tools for education since disruptive elements for the learners' attention such as incoming text messages or unwanted calls that are present in phones and smartphones alike, are absent. Tablets are able to offer the benefits of mobile applications in a broader context in all levels of education, not only as an affordable solution for one-to-one learning but also as a feature rich tool for work inside and outside the classroom.
Wakefield and Smith (2012) indicate that the technological analysts characterize the tablet as an ideal tool for all levels of education. After the introduction of tablets in the classroom of several schools in the United States, students report that they want to participate in learning activities due to the novelty of the medium, the visual characteristics and ease of use. In the classroom, tablets can be used to create text, audio or video notes. Students, independent of age, can store educational materials in a digital portfolio. Using a tablet, learning can be achieved through the active participation of students and the use of interactive activities and animations. Additionally, the attractive appearance of the working environment and the innovative touch interface are considered key learning facilitators for young children and students with learning disabilities. The characteristics of tablets including light weight, portability, touch screen, large icons, speakers, voice commands, zoom features and the cognitive simplicity are some of the key advantages that make them an affordable and more than efficient tool for the education of young children (Buchanan, 2010).
At least 1000 universities and colleges create and distribute free educational content in a format suitable for reproduction on smart mobile devices (MDG Advertising, 2012). According to McManis and Gunnewig (2012), this fact creates new requirements from the devices users as well as other opportunities for innovative services through these devices.
Several governments worldwide have given special attention to the development and implementation of mobile learning in order to improve teaching and learning effectiveness. Lam and Duan (2012) state that pioneers in this initiative are not only the governments of developed countries but also of developing countries that have begun to adopt policies and measures for the development of mobile learning. Characteristically, they indicate that the Royal Thai Government plans to provide tablets to 800,000 students of all educational levels by the next school year. As early as 2011, an initiative of the Indian government was to build the cheapest tablet in the world. It was sold to students at a subsidized price of 35 dollars, implementing the transition from the traditional to mobile learning in a faster and easier way. Simultaneously, the Turkish government announced that it plans to spend 8 billion dollars for the purchase of 15 million tablets, which will be distributed among school-age children throughout the country.
Finally, as reported by Kenny and McDaniel (2011), while overcoming past misconceptions that perceived the use of technology only as electronic gaming and play among students, many teachers and schools united are beginning to allow students to bring their own smart mobile devices into the classroom; especially since recent studies have shown that video games, including learning activities, have become an integral and essential part of the way in which young people learn.
Mobile Devices in Kindergarten Education
Egan and Hengst (2012) show that, even though educational software has been available almost 30 years now, the educational community of kindergarten education initially resisted the use of computers in the teaching of young children. Many educators, inspired by Piaget's theory of the developmental stages of children, considered that young children need only the physical activity and the ability to handle tangible objects in order to consequently achieve understanding of the various abstract concepts. However, since the mid-1990s, researchers found that virtual manipulations which are facilitated by computer software are similar to physical manipulations and therefore, the use of ICT could effectively support the learning process, particularly in mathematics, and the educational development of children as a whole (Yelland, 1998; Clements, 2000).
Nowadays, the use of ICT in the education of young children, as well as the development of educational software and relevant activities in preschool education, has already spread in many educational systems (Druin & Fast; 2002; Plowman & Stephen,
Copyright © 2013 SciRes. 3 N. ZARANIS ET AL.
2003; Zaranis, 2011; Zaranis, 2012). Research results point out the potential of ICT as a teaching tool (Segers & Verhoeven, 2005) and as a cognitive tool (Clements, 2000; Klein, Nir-Gal, & Darom, 2000). Such results seem to formulate a common agreement at the level of educational policy and school practices that promote the rational integration of ICT in early childhood education (NAYEC, 1996; Yelland, 2002; Plowman & Stephen, 2003; Bolduc & Lefebvre, 2012). Several studies indicate that computers are developmentally appropriate technological resources for pupils of preschool and primary school education and show how technology can be used to support and encourage the development and learning in these age groups (Musawi, 2011; Zaranis & Kalogiannakis, 2011a).
The integration of mobile devices into the preschool curricula aims at strengthening the interest of young learners and in enhancing their participation and cooperation with their classmates and teachers (Lindahl & Folkesson, 2012). According to Nix (2005) this type of learning attracts the interest of young students and it is considered both an enjoyable experience and an attractive learning environment. Rushton, Juola and Larkin (2009) point out the need for proper learning conditions and indicate that children learn more easily in positive and encouraging learning environments. These said learning environments allow the students to make their own decisions regarding which topic to study out of their own free will. Rushton (2008) states that the creation of a classroom environment that enhances student expression and selection opportunities provides a welcoming atmosphere towards helping children to learn at their own pace. Learning environments, which through various mediums provide differentiated teaching to young learners, allow children to be actively responsible for their learning, by simultaneously stimulating various areas of their brain thus resulting in better intellectual development (Rushton & Larkin, 2001).
The portability of tablets allows children and kindergarten teachers to make use of various locations in the classroom enabling the creativity and collaboration of small groups of students. Additionally, the sophisticated user interface of tablets allows both individual interaction and often, mutual interaction, depending on the application at hand, between two or more children (Wakefield & Smith, 2012).
Research findings (Abrams, 2009; Jenkins, 2009; Dickens & Churches, 2011 as cited in Peluso, 2012) correlate the effectiveness of learning through educational content delivery based on touch screen technology. A study by Chiong and Shuler (2010) in the United States involving iPod touch devices and audiovisual material properly configured for children ages three to seven years old showed that children drew remarkable gains in vocabulary and phonological awareness. Another recent survey by Bebell, Dorris and Muir (2012) on kindergarten students selected randomly to use tablets for the study of literacy, showed that infants who used tablets recorded remarkably strong performance in their phonological awareness and their ability to represent sounds with letters in relation to other children that did not.
Sandvik, Smørdal, and Østerud (2012) point out that as well as tablets are highly portable technology, learning can take place in a variety of everyday activities in the kindergarten, in a formal and informal context, inside and outside the classroom. As reported by McManis and Gunnewig, (2012), the new digital tools, such as smart mobile devices and their accompanying applications, can offer unique opportunities for kindergarten children to participate in useful and targeted activities; either individually or collectively with their peers and their kindergarten teachers.
Digital Activities and Children
The introduction of smart mobile devices in the daily life of children positively supports integration of digital applications in childhood education. There is a positive continuum between the everyday life of children and their school life. Moreover, it is important that the technological instruction offered by the school equips children with the necessary knowledge and skills for later life as well.
Digital learning activities on mobile platforms are very popular among students, especially at younger ages. Particularly, in the last few years, the accession bid of educational digital activities as teaching tools in the educational process has increased. The term electronic or digital activity refers to all categories of activities that are implemented through digital

technology. It concerns activities and games that run on large classic game consoles, specialized consoles, personal computers, smartphones and tablets (Chiong & Shuler, 2010). Researchers such as Klein et al., (2000), Lewin (2000), Segers and Verhoeven (2005), Comaskey, Savage and Abrami, (2009). Zaranis and Kalogiannakis (2011b) document the positive impact of digital applications in the educational development of preschool age children. Other studies show that electronic activities and games attract children and seem to stimulate them in a more constructive manner than the standards the conventional education has adopted so far (Klawe, 1999; Prensky, 2001; Zaranis & Kalogiannakis, 2011a).

Since the early 1990s, the trend has been that of edutainment. This refers to the blend of gaming and educating based on the logic of activities developed with clear educational orientation (Shaffer, Squire, Havelson, & Gee, 2005). The contribution of digital activities lies in the fact that they allow children to participate in worlds in which they learn to think, speak and act in new ways. Being rich in features, these virtual worlds constitute a very promising framework for learning, as children can play many different roles (Squire & Jenkins, 2003; Shaffer et al., 2005; Squire, 2006). Digital activities are considered to be particularly effective when they are designed to examine a specific problem or to teach a specific skill. For example, encouraging learning in the thematic areas of the curriculum such as mathematics, natural sciences and language where the specific objectives can be determined and when it is selectively developed within a context relevant to the learning activity and the specific target (Johnson et al., 2011).

For children aged three to five years old, educational digital activities often focus on readiness skills for the kindergarten, including reading (letter recognition, letter formation, correlation of sounds and letters, simple spelling), mathematics (recognition of numbers, formation of numbers, counting, grouping), thinking and reasoning skills, perceptual skills, daily life skills (hygiene), social skills, creativity and self-expression; as well as the understanding of concepts such as family relations, emotions, professions, etc. (Lieberman, Fisk, & Biely, 2009b). Lieberman et al., (2009b) distinguish the quality of digital learning activities in the following categories:

1. Well-designed activities—provide powerful interactive experiences which can enhance the learning of young children, fostering skills development, as well as their healthy development;

4 Copyright © 2013 SciRes. N. ZARANIS ET AL.

2. Poorly designed activities—simple sedentary activities that contribute little in children's learning, skills development or their healthy development while potentially associated with obesity and poor physical condition;
3. Very poorly designed activities—can potentially cause considerable damage to children either through strengthening the aggressive or antisocial behaviour, approbating ethnic or transgender stereotypes and promoting bad eating standards.

A finding of several studies in children three to six years old correlates the benefits of using digital activities in different sectors (Figure 1).

More specific benefits are identified in the following sectors:

1. Learning—Digital activities can provide considerable educational services to children. Comparative studies have suggested that well-designed educational activities provide potentially more motivation and result in encouraging learning compared to traditional teaching methods (Swing & Anderson, 2008);
2. Cognitive skills—Using digital activities, children learn cognitive skills through repetition, as relevant studies have found improvements in operating memory, spatial ability, visual attention, etc. (Thorell, Lindqvist, Bergman, Bohlin, & Klingberg, 2009);
3. Social interaction—In preschool education, young children often engage in cooperative social interaction when playing digital activities (Christie & Johnson, 2009).

If materials for play and learning (including computer activities) are designed to indulge the interests and abilities of children, as well as their instinct to learn, students are more likely to develop and strengthen their initiative, their attention, their industriousness and their love for learning (Kagan & Scott-Little, 2004; Sadowski, 2006).

However, as pointed out by Garrison and Christakis, (2005) not all digital activities are developmentally appropriate or meticulously designed to enhance the procedure according to which young children play and learn.

Realistic Mathematics

The foundations of children's mathematical thinking form in the early years of their life. They gradually acquire their first experiences with time and space then with basic mathematical processes (measurement, calculation, sorting and comparison) (Gadzichowski, 2012). Research findings prove the existence of logical principles for counting from the age of three (Geiman & Meck, 1983). Other researches indicate that numbers and numerical phenomena sparks the intense interest of children from an early age (Zaranis & Kalogiannakis, 2012). Mathematics in preschool education is approached as a foundation that will help children learn about the world around them and to adapt to this world (Tzekaki, 2007; Zaranis, 2012). Egan and Hengst

Figure 1.

Benefits of the use of digital activities by young children.

(2012) report that a large body of research shows that the time spent in the kindergarten is a crucial period for children to develop fundamental numeric skills. In their research on the development of mathematical concepts in kindergarten, Clements and Samara (2007) concluded that the numerical abilities of children, developing before they enter the first grade of primary school, are the best predictors of their subsequent mathematical progress; more than other skills. When monitoring 200 students from the kindergarten up to the third grade, Jordan, Kaplan, Ramineni and Locuniak, (2009) concluded that the conquest of mathematical concepts in the kindergarten is positively correlated with the achievement of high mathematical performance at the end of the third grade.

Consequently, the teaching of mathematical concepts in the kindergarten has a huge significance, as it assists children to acquire the necessary mental condition and the necessary cognitive foundation for the systematic learning of "real" mathematical concepts, later on, in primary school. The aim of kindergarten is not just to teach mathematics but to initiate children in ways of thinking that characterize the mathematical science while providing a parallel realization of their social dimension.

For many years, the central theme for scientific debate was the formulation of a comprehensive mathematical theory towards interpreting phenomena related to the teaching and learning of mathematics. Such a theory aimed to provide educators with the ability to help students understand mathematics as a subject and as a tool for solving everyday problems. Over the last few years and in the context of the above considerations, various reform proposals for the teaching of mathematics have been developed internationally, posing their focus on the problem solving procedure. One of these proposals is the Realistic Mathematical Education (RME) which was developed in the Netherlands and supports the view that the same phenomena through which the mathematical concepts acquire content, should be used as a basis for a teaching process that aims to impart these concepts (Freudenthal, 1983).

According to Freudenthal (1983), mathematics is a human activity and therefore it must constitute a human value, must be close to reality of fact, be close to children and have a relationship with society. The central idea of the Realistic Mathematical Education is when saying, "I know math" really means "I know how to do math" (Streefland, 1991). The student becomes able to easily handle the mathematical language, to solve and construct problems, but mainly, to recognize mathematical concepts within specific situations. The term "Realistic Mathematics" refers to mathematics, which relate to problems of the real world as well as to phenomena, which appear in our daily life (De Lange, 1996). This form of mathematical education is characterized as "realistic" because it relates to the real world, in addition, to that special emphasis given in situations in which the students can envisage with their imagination.

The digital learning media can contribute to the learning of mathematical concepts by young children. Many aspects of early informal learning of mathematical concepts, such as enumeration, arithmetic problem solving, and spatial syllogism along with general geometrical knowledge, are developed dramatically during the preschool age. Therefore, digital technologies and accompanying software that teach early learning of mathematical concepts have received considerable attention from the scientific community (Lieberman et al., 2009a). The use of mathematics-related computer programs in preschool

Copyright © 2013 SciRes. 5 N. ZARANIS ET AL.

children leisure activities enhanced the mathematical knowledge of those children (Starkey, Klein, & Wakeley, 2004). Jordan et al., (2009) report in a similar study, that young children were able to develop mathematical skills and relevant reasoning and thinking skills while using developmentally appropriate mathematical software.

Today, the use of mathematical technology in kindergarten education and the first primary grades is a standard. It is included as one of eight Standards for Mathematical Practice in the Common Core State Standards for Mathematics (Common Core State Standards Initiative, 2010). The principles that underpin the Realistic Mathematical Education constitute a framework in which technology could offer significant assistance in the teaching and learning of mathematics (Clements, 2000).

A Proposal for Teaching Realistic Mathematics through Mobile Devices

Currently, within the Faculty of Education, Department of Preschool Education, University of Crete, systematic research is being carried out in order to investigate whether there are compelling benefits to using tablet computers in preschool education in an attempt to implement teaching reform proposals, such as Realistic Mathematical Education and the Natural Sciences. This proposition is carried out by creating educational applications for the mobile device platform in the form of digital learning activities, using specialized software (App Inventor). These applications intend to help preschool children in learning mathematics by following the principles of RME, focusing primarily on the existence of rich thematic frameworks associated with a child's experiences. For this reason, digital applications are combined with group and individual activities without the use of a tablet including board games, dice, activities with given and hidden objects, etc. This form of digital application was chosen because studies (Nix, 2005; Vavoula, Pachler, & Kukulska-Hulme, 2009) have shown that digital educational activities are not only appealing to the students' interest but are also considered to be a pleasurable pastime while establishing a new and attractive learning environment. Today's students are more likely to enjoy a learning experience embedded with digital activities because these games are based on the primordial form of learning "play and learn" from which they derive their benefits as an educational tool (Squire, 2006). Specifically, we have developed sixteen different activities that cover four levels of mathematical intervention (ground or zero, first, second and third) based on the principles of RME for preschool education (Van Den Heuvel-Panhuizen, 2008; Zaranis, 2011, 2012). The purpose of the next step of the research is to extensively implement such applications and other educational activities in kindergarten classrooms in order to systematically evaluate their integrity and educational use compared to the traditional method of teaching.

According to Van Den Heuvel-Panhuizen (2008), the knowledge of formal mathematical concepts may differ considerably from child to child when entering into kindergarten. To elabo-

rate, some of these children are quite familiar with simple counting while other children are not. Likewise, the extents to which they are capable of distinguishing between the different meanings of numbers may vary. The understanding of resultative counting children have developed upon entering to kindergarten differs significantly too. The somewhat variable initial situation in which the children's different initial levels of mathematical knowledge upon beginning the kindergarten could be described as the ground level. In general, an elementary numerical sense develops before and during the preschool education, in four general levels (Figure 2).
In addition to the pre-existing ground level, the three general levels that are developed during kindergarten education are as follows:
1. First level—The level of context-bound counting and calculating simple addition and subtraction;
2. Second level—The level of object-bound counting and calculating simple addition and subtraction problems where the objects are displayed and then hidden;
3. Third level—The level of pure counting and calculating addition and subtraction with the use of a missing variable.
The first level consists of context-bound situations in which pupils are instructed to count up to ten, organize numbers in the proper order, and make reasonable estimations or comparisons of numbers through concepts of more than, less than or equal too. Basic addition and subtraction problems are introduced at this level.
The relevant object-bound counting and calculating of the second level, which occurs in problem situations, focus directly on the quantitative aspect. In contrast to the first level, questions asking that the students count and state the number of given objects, in a given scenario, are presented and understood in the second level. This applies, however, only if the questions asked are associated with specific objects involving natural numbers. The second level also consists of activities in which pupils able to choose an appropriate strategy for solving simple addition and subtraction problems in which the objects at hand are displayed for a brief period of time before they are hidden.
The following are several examples of level two questions:
How many pieces of candy are in the box? How many chairs are there? How many people are waiting in line? Which box has the most sweets? How many of the seven candles will remain lit if the wind blows out three?
Finally, the third level consists of pure counting and calculating, questions using real numbers, rather than objects, focusing on the aspect of a missing variable. For instance, "What will remain if you subtract three from seven?" By previously hiding objects after a brief period of time (second level), children were obliged to use their fingers or other representations for more the complex tasks as the visual objects were being removed from the equation. This way, the enumeration is no longer dependant on the objects themselves, and is instead put into perspective using physical or mental representations of these objects. These representations can occupy different levels of abstract problems including the use of real numbers in addi-
Figure 2.
Levels of realistic education in kindergarten education.

tion and subtraction problems with a missing variable.
As Van Den Heuvel-Panhuizen (2008) claims, this can occur by using a "birthday hat" but there are other possibilities, such as the kindergarten teacher asking the children to describe their age without using words. At the third level, children can represent the numbers one to ten using their fingers, as well as by using lines and dots. They are then able to use these skills for addition and subtraction activities. The use of numbers and the execution of the arithmetic operations used in the third level are not generally one of the targeted objectives of the kindergarten curriculum but there are usually children who are able to work at this level.
At the ground or zero level, students are instructed to use various portable applications. In one of the applications, for example, they have to place a certain number of chicks in their nest or to count the number of animals that appear on the screen (Figure 3). Variables are randomized numbers from one to ten for each round.
The other tasks at hand are to help a climber pass over mountains, counting each mountain on the way and to a help a monkey down a ladder, counting each rung as it descends (Figure 4).
At the first level the children are expected respond to questions such as, "How many of the apples in her basket can Helen buy with 5 euro if each fruit costs 1 euro?" Another example problem is, "Each child needs a ticket to enter the castle. How many children will not be able to enter?" (Figure 5).
At the second level the children are asked to solve problems such as, "Place as many eggs as you would like in the fridge," after the selection is made the eggs are concealed. "Helen came and took 1 egg from the fridge. How many eggs are left?" (Figure 6).
Finally, for the third level applications, pupils are told to answer more complex questions such as, "Johnny has 5 pieces of candy. His uncle came and gave him some more candy. Now Johnny has 8 pieces of candy. How many pieces of candy did his uncle give him?" Alternatively, in the case of subtraction, the children are told that a monkey has cut a number of bananas from the tree. Some of his animal friends suddenly appear and

Figure 6.
Example of a second level portable applications.
eat an unknown number of those bananas. The remaining bananas are displayed and the children are asked to find the number of bananas that were eaten (Figure 7).
Considering the categorization of Naismith et al., (2004), we can claim that from a pedagogical point of view, the mobile applications we created follow either the behavioral or the constructivist teaching method. Some applications follow the behaviorist perspective by providing fast and immediate feedback while utilizing reinforcing learning elements like the confirmation of the correctness of an answer. Others utilize the constructivist perspective as they provide open type learning experiences for the students. All applications provide feedback both in the case of error as well as the successful completion of an activity. This feedback is in both visual and audible form so that it is easily understandable by pupils. Simple feedback is provided through graphic characters (e.g. the appearance of a happy or sad face), while more complex feedback is provided by the narrator through an audio message (e.g. "Try again," or "Well done, you did it!").
The applications were created using the application development software App Inventor (AI) and were tested on the Android operating system. Android was preferred over the iOS operating system (Apple) mainly because of its flexibility for the creation of applications as well as the existence of a very large variety of available devices with various price ranges and features. AI was first announced as a small project of Google Labs at the end of 2010. In late 2011, it was moved to the center of mobile learning in MIT (Massachusetts Institute of Technology) for public use as open source software (http://appinventor.mit.edu/). AI is a new free online block based visual development environment for creating mobile applications of the Android operating system (Hsu et al., 2012).
The design process of the educational software had three main components:
1. The research and development of the original applications prior to their implementation in kindergarten;
2. The modification of the existing applications during the pilot test in order to respond more effectively to the needs of children and kindergarten educators;
Copyright © 2013 SciRes. 7 N. ZARANIS ET AL.

Figure 7.
Examples of third level portable applications.
3. The creation of new applications that meet the demands of preschool educators.
The produced software should have the following characteristics: 1) It should be user-friendly so that children can easily handle it without any special assistance from an adult; 2) It should not require any reading and writing knowledge for its use so that it is suitable for the preschool age; 3) It should combine animation and sound. At the preschool age, sound is essential, as speaking is the only way to give instructions to children.
In order to examine the children's knowledge in the comparison, classification, matching, structured counting, efficient counting, basic addition and subtraction and general knowledge of numbers, we will most likely use the Utrecht Early Mathematical Competence Test (for children aged 4.00 - 7.05). This criterion was designed by a team of scientists from the department of special education at the University of Utrecht in the Netherlands, in order to be used for the assessment of early mathematical competence in preschool age children (4.06 - 7.05) (Van de Rijt, Van Luit, & Pennings, 1999). In 2008, the weighting of this criterion in Greece led to the expansion of the age range for six months. We will use all of the worksheets from this test, because we assume that it is suitable for the purpose of our research.
Conclusion
As already mentioned, the purpose of this paper was to provide a better understanding of the characteristics and the effect of ICT and mobile learning in the context of preschool education. In addition, we will try to examine children's knowledge by comparing the learning outcomes of teaching using specially designed applications for smart mobile devices (tablets) and the thematic teaching in mathematics; specifically targeting "Realistic Mathematics", for children ages 4 to 6 years attending Greek kindergartens.
Although the research is still in a preliminary stage, initial results of the statistical analysis of pre tests (which were held in a small sample of kindergarten students in specific geographic regions of Greece) allow us to assume the following:
1. The tablet aided learning compared to the traditional teaching method produces better learning outcomes for the students;
2. The teaching of Realistic Mathematics with the use of educational software for tablets produces better learning outcomes in relation to teaching based on the Greek Cross Thematic Curriculum Framework (CTCF, 2003).
With great interest, we look forward to the learning outcomes that result from the teaching intervention using a large and properly weighted sample of kindergarten students. We intend to expand our research in kindergartens located in all geographical regions of Greece in order achieve a larger possible representative sample distribution.
Discussion
Quite often, the debate on the use of ICT in mathematical education is limited by and focused on the tool itself rather than on the activities and in the specific problem situation that the student is presented. In contrast, the activities and applications that we have created refer to real world problems and situations. The next stage of the research will be carried out in kindergarten education in order to systematically evaluate the integration of ICT and its educational benefits compared to the traditional method of teaching.
This study is preliminary in its nature, as our research serves to demonstrate a potentially greatly beneficial installation of

mobile learning in childhood education. With the execution of a systematic study, we believe that our findings will contribute to the acceptance that the positive effects derived from the use of mobile devices and ICT in kindergarten in general, do not exist only in the presence of a computer in the classroom, but also by the way in which the technology is used by teachers. The primary concern, therefore, is how to maximize the benefits of these new instruments in order to enhance, rather than hinder, children's ICT experiences for the benefit of learning.

Design And Understanding

Janet Ainley and Dave Pratt
Institute of Education, University of Warwick, UK

We explore ways in which access to technological tools can support new approaches to the design of pedagogical tasks and at the same time is providing us with new insights about the nature of mathematical understanding. We describe a novel approach that situates the challenge of designing pedagogic tasks in the same framework as that of locating mathematical understanding. An example of the use of this design approach is explored.

Introduction

In this paper we explore ways in which access to technological tools can support new approaches to the design of pedagogical tasks and at the same time is providing us with new insights about the nature of mathematical understanding. It is not new to argue that technology offers opportunities to re-think both the content and the implementation of the curriculum, not only allowing the same curriculum to be taught and learnt in new ways, but fundamentally challenging the current sequencing of some topics. However, we describe a novel approach that situates the challenge of designing pedagogic tasks in the same framework as that of locating mathematical understanding. Such a framework promises to point designers towards the search for purposeful tasks which are linked to aspects of mathematical understanding that are under-researched.

The Current Context

More than twenty years ago the Cockcroft Report into the learning and teaching of mathematics in the UK expressed the widely held view that 'Mathematics is only 'useful' to the extent to which it can be applied to a particular situation' (Cockcroft, 1982, para 249). Although this view is not unproblematic, the issue of 'applying' mathematics, or of making links between school mathematics and the 'real world', continues to concern mathematics educators, researchers and curriculum designers. At first glance, the need for mathematical learning to include an understanding of how mathematical ideas can be useful may seem obvious. However, even a brief look at the typical content of the school mathematics curriculum makes it clear that the view which is presented of the uses of mathematics in the real world can be highly contrived:

• Ravi bought a pack of 30 biscuits. He ate one fifth of them on Thursday. He ate one eighth of the remaining biscuits on Friday. How many biscuits did he have left?(DfEE 1999) 11

There has been a considerable amount of research in mathematics education into the difficulties which children have in applying mathematical knowledge, and particularly in combining mathematical and 'real-world' knowledge appropriately when tackling problems set in real-world contexts (see for example Boaler, 1993). Cooper and Dunne's (2000) detailed study of pupils answering such contextualised questions in tests has indicated that in order to engage appropriately with the mathematical focus of such questions, pupils have to understand complex but implicit rules about the extent to which they should attend to features of the realworld setting. This suggests that the apparent difficulties which pupils have in 'applying' mathematical ideas may in fact be a product of pedagogic approaches and assessment.

A different approach to linking school mathematics to the 'real world' is to design tasks that offer 'authenticity' by resembling out-of-school activities, such as setting up a classroom shop. However, the structuring resources provided by this situation will be very different from those offered when the child really goes shopping: the prices of items on sale may be simplified to an unrealistic extent, getting the correct change will not be of the same level of concern, and even with an element of roleplay, the social interactions of the classroom shop will not provide the structure and constraints experienced in a real shopping trip (Brenner, 1998). In the classroom shop the 'shopper' cannot make real choices about what to buy, or how much to spend, or indeed choose not to buy anything. In Walkerdine's (1988) words: " everything about the task is different from shopping … the goal of the task is to compute the answer rather than to make a purchase" (p. 146).

In contrast to these school-based approaches, we turn to situated cognition research which has studied mathematical practices in the real-world contexts of shopping and employment (for example, Lave and Wenger, 1991, Nunes et al, 1993), often referred to as street mathematics. From such studies we identify the purposeful nature of the activity as a key feature which may be transferred to the school context, rather than the superficial characteristics of the setting (Ainley, Pratt & Hansen, 2006). Lave and Wenger (1991) claim that in out-of-school contexts, "learners, as peripheral participants, can develop a view of what the whole enterprise is about". This overview of the purposes on the activity is generally absent in school mathematics. A significant difference between learning street mathematics, and learning school mathematics, is that the ideas that you learn in school do not enable you to use mathematics to get things done in the ways that adults do: indeed children rarely see adults using the sorts of mathematics that they learn in school. We argue therefore that an important challenge for pedagogic task design is to create tasks which are purposeful for learners within the classroom context, rather than attempting to make links to (supposedly) real-world settings. Whilst the use of technology is not essential

to such design, it has enormous potential to provide opportunities for learners to use mathematical ideas in powerful and meaningful ways.12
One source of ideas that has influenced our response to this challenge can be found in the Constructionist literature (Harel and Papert, 1991). Although the Constructionist ideals have evolved out of early work with the programming language Logo, we have found them illuminating in a more general sense. Many authors in this tradition have reported on the significance of allowing students control over their own decisionmaking as apparent when they are allowed to build a project through the use of Logo. In our interpretation, the key notion here is that the students are making decisions for themselves in ways more akin to engagement with street mathematics than is typically found in classrooms, where control is often strictly in the hands of the teacher. Tasks involving building and mending computer-based artefacts are specific examples of how control can be transferred from the teacher to the student.
Purpose and Utility
We conjecture that engaging purposefully in the use of mathematical ideas in a welldesigned task leads to learning which is different from that which might arise when practicing an associated technique or exploring why that technique works in more traditional classroom tasks. Based on our previous research, we have developed a framework for pedagogic task design which offers a new perspective on the issue of creating opportunities for pupils to learn about the ways in which mathematical ideas are useful, using the linked constructs of purpose and utility.
Purpose, as we use the term, refers to the perceptions of the pupil rather than to any uses of mathematics outside the classroom context. There is considerable evidence of the problematic nature of pedagogic materials which contextualise mathematics in supposedly real-world settings, but fail to provide purpose to which the learner can relate, either in terms of the overall task, or the ways in which mathematical ideas are used within it (see for example Ainley, 2000; Cooper and Dunne, 2000). The purpose of a task, as perceived by the learner, may be quite distinct from any objectives identified by the teacher, and does not depend on any apparent connection to a 'real world' context. The purpose of a task is not the 'target knowledge' within a didactical situation in Brousseau's (1997) sense. Indeed it may be completely unconnected with the target knowledge. However, the purpose creates the necessity for the learner to use the target knowledge in order to complete the task, whether this involves using existing knowledge in a particular way, or constructing new meanings through working on the task. Movement towards satisfactory completion of the task provides feedback about the learner's progress, rather than this being judged solely by the teacher (Ainley et al, 2006, Ainley and Pratt, 2005).
Within such purposeful tasks there is the possibility of creating opportunities to understand the utility of mathematical ideas. We define the utility of a mathematical idea as how, when and why that idea is useful. Traditional approaches to teaching mathematics in school address instrumental understanding of procedures, and relational understanding of mathematical concepts (Skemp, 1976), but generally fail to address the utility of these ideas. The pedagogic tradition, embodied in textbooks around the world, is to begin with procedures and relationships, and to address 13 utilities as the final stage in the pedagogic sequence (if at all). We conjecture that utility is not merely an application of a concept but a separable dimension of mathematical understanding, alongside the instrumental and relational components. The potential of technological tools to allow learners to use powerful ideas before they need to learn the detail of how to perform calculations greatly expands the possibility to introduce ideas of utility early in the pedagogic sequence.
In order to illustrate the place of utility in mathematical understanding, we shall reflect on approaches to teaching proportion. We choose this not only because it is a highly significant concept in the school curriculum but also as it was the focus of a recent research experiment.
An illustrative example based around the concept of proportion
Proportion lies at the heart of mathematical curricula and is commonly regarded as one of the most significant challenges for the child's cognitive development during the secondary phase of education. In fact the concept of proportion is, like all powerful ideas, a synthesis of many component notions and it is part of the design challenge to decide which of those notions to foreground when offering experiences to the learner.
In the UK curriculum for the early years of secondary schooling (DfES, 2001), children are expected to:
"Compare ratios by changing them to the form m : 1 or 1 : m.
For example: The ratios of Lycra to other materials in two stretch fabrics are 2 : 25 and 3 : 40. By changing each ratio to the form 1 : m, say which fabric has the greater proportion of Lycra." (p. 81)
Using an instrumental approach, a child might memorise a procedure for tackling problems of this kind in which the 2 is divided into the 25 to give 1 : 2
1
12 and
similarly 3 : 40 is transformed into 1 : 3
1
13 . A further routine might then be needed to
decide which of these ratios indicates a higher proportion of Lycra. Of course, there are many places where the child's memory could fail, leading to errors of one type or another.
Skemp (1976) has contrasted such an approach with one which is based on relational understanding. Then a child would have a range of strategies that could be used, which might include reducing the ratio to a unit as above but might also include recognising that other approaches are equally useful. For example, having reduced the first ratio to 1 : 2
1
12 , the problem can be solved by multiplying this by 3 to give 3
: 2
1
37 and making the comparison with 3 : 40. Indeed the child who has relational understanding might be able to use one method to confirm another.
Most teachers would recognise the superiority of relational understanding over instrumental understanding for most mathematical situations. Nevertheless many teachers and text books appear to adopt approaches which are likely to reinforce instrumental rather than relational understanding. We argue that a major reason for 14 this is that the kinds of pedagogic tasks which are regularly used, both in teaching resources and in assessment, are ones which can be completed using instrumental approaches, and provide little incentive to explore the concept relationally. Furthermore, the Lycra task, although set in a 'real world' context, fails to provide any purpose for making the comparison of the composition of the two fabrics, and thus offers no opportunity for pupils to appreciate the utility of ideas of ratio and proportion.
We now consider an alternative approach to the design of a pedagogic task for proportion. Our starting point is to consider contexts in which the utility of the mathematics becomes apparent, and to use such a context to design a task which has a purposeful outcome for pupils.
In a recent experiment, we gave the following task to 11-12 year olds:
Children in a primary school want to make a 'dolls' house classroom'. Use the piece of furniture you have been given to work out what size they should make some other objects for their classroom.
Each pair were given an item of dolls' house furniture, and also had available measuring tapes and a spreadsheet. The role of the spreadsheet here is highly significant: it provides the calculating power to allow pupils to work with real data, however 'messy' the results, and at the same times offers a visual space in which to record their explorations.
The Dolls' House Classroom task focused on scaling, a key idea in ratio and proportion. The outcome of the task was to be a set of instructions for another group of children to make items for the dolls' house classroom. The activity of comparing the item of dolls' furniture with its full-size equivalent in the classroom involved measuring and discussion, as the pupils decided on which were the most important measurements to use.
We report here on the activity of one pair of boys. Initially the boys tried to relate the task to their own experiences. One boy told the teacher about how his grandfather used to make dolls' furniture. The other talked about scaling in maps in response to the teacher's mentioning of the term scale factor. From an early stage, the boys questioned the nature of the task that they had been set. (Figures in brackets indicate time elapsed in minutes.)
[6:06] Is this real? Are a Year 6 class really going to do this?
The researcher admitted that this was not actually going to happen.
[6:35] Why can't they just buy the dolls' house?
What do we make of these questions? Are they challenges that suggest the boys are resisting the invitation of the teacher to engage with the problem? If so, it would be hard to explain the subsequent activity, which was marked by the boys' considerable intent and persistence. Rather, we believe that these questions indicate a process in which the boys were beginning to take ownership of the task, 15
When students take ownership of a task, the levels of engagement can be very high; it is our belief that the opportunity to make choices is influential in helping students to make a problem their own. Furthermore, a well-designed task will also enable students to follow up their own personal conjectures when they try to make sense of the task.
The boys used the spreadsheet confidently as a tool to support their exploration. Their spreadsheet shows several different attempts at ratio. In one set of cells, they divided the height of the real table by that of the dolls' table (68.5 / 4.3 = 15.93). But when it came to the width of the table, they divided the dolls' table by the real table (5.5 / 134.2 = 0.040983607). In another part of the spreadsheet, they divided the width of a real shelf by the width of a real table (75.5 / 134.2 = 0.562593). Each of these calculations has possible utility for their task but whether any particular approach has explanatory power depends on how exactly the boys wanted to use the result and what sense they could make of the feedback from the spreadsheet. The nature of the task allowed them to explore all three routes, and to compare them, rather than following a route defined prescriptively by the teacher.
Such explorations enabled the boys to construct meanings for the divisions being carried out on the spreadsheet. The spreadsheet both handled calculations which would have been beyond the boys' competence, and displayed a complete record of their work, allowing them to focus on whether the ratio was actually useful to them in their task. The purposeful nature of the task produced an emphasis on how the scale factor might be useful, admittedly in a situated narrative, rather than on technical aspects of calculating a scale factor.
We claim that these boys were connecting to what we recognise as the concept of proportion not through instrumental or relational understanding but by developing a sense of the utility of scaling for pursuing their problem. We use the term "their" advisedly. The construction of a utility for scaling was dependent upon them adopting the problem for themselves and this would only be achieved if they found the problem purposeful.
We see the design of tasks that are likely to be purposeful and yet at the same time are likely to yield utility-based understanding as key to resolving the teacher's predicament of how to promote deeper understanding. At the same time, we note how poor the Lycra problem was, despite its apparent reference to a real world scenario, as a vehicle for promoting such understanding.
Final comments
Within our framework, purpose and utility are closely connected. Indeed we see purpose as an element of designing for abstraction whilst we frame utility as an element of abstraction in context. Appreciation of the utility of mathematical ideas can best be developed within purposeful tasks. A focus on purpose in isolation may produce tasks which are rich and motivating, but which lack mathematical focus. However, if the tasks are designed appropriately, learners may use a particular mathematical idea in ways that allow them to understand how and why that idea is 16 useful, by applying it in that purposeful context. This parallels closely the way in which mathematical ideas are learnt in out-of-school settings.
It is generally acknowledged that pedagogic approaches that focus mainly, or exclusively, on instrumental learning of procedures will result in impoverished learning. However, even approaches that emphasise relational learning tend to give little attention to utilities. We suggest that this results in mathematical knowledge becoming isolated as weak connections are made to the pupil's existing knowledge of the contexts in which it may be usefully applied.
Pedagogic design based on the framework of purpose and utility inverts the pedagogic tradition of school mathematics by placing the emphasis primarily on the utilities of a new mathematical idea, and the use of technology greatly increases the scope for this. Thus the learner is able to construct meanings that are shaped by strong connections to the application of that idea: in Lave and Wenger's terms, to develop a view of what the whole enterprise is about.
This inversion is made possible by the power of technology to offer opportunities for using a mathematical idea before you learn about its procedures and relationships. Technology affords the possibility of pursuing purposeful tasks by working with mathematical tools, instantiated on the screen, whilst coming to appreciate the utility of those tools, in ways which lead to powerful mathematical learning.

Mathematics Investigations: Towards curriculum design and implementation
Mara Alagic, Wichita State University, USA
mara.alagic@wichita.edu
A teacher's perspective on the nature of mathematics, the potential of a technology, and the training that they receive determines their effectiveness in the integration of that technology. How to teach for transfer is yet another crucial piece of teacher knowledge for creating and sustaining technology-based learning environments. Sense-making, self-assessment, and reflection on what worked and what needs improving are teaching practices congruent with metacognitive approaches to learning. These practices have been shown to increase the degree to which students transfer their learning to new settings and events. The course Mathematics Investigations is designed to deal with current demands of digital technologies integration and inquiry-based approaches to teaching and learning mathematics. The course has five components (of unequal weight): Problem sets, Reflections, Self Evaluations, Readings and Final Presentation. As a final product, each student compiles a Digital Resource File that consists of five problem sets, a final presentation, and additional resources relevant to their future work. Students are guided and encouraged to develop their fluency in dynamic geometry, spreadsheets, selection and use of virtual manipulatives, and other Web resources. University-wide available courseware is used to support complementary online activities, group discussions, and the virtual classroom.
Each problem set focuses on one mathematical idea or concept and begins with an open-ended, real-life-related and challenging problem. The problem set consists of 5-7 additional problems scaffolding "down" the main concept. The final product demonstrates a gradual development of a selected concept through a sequence of word problems. Although students are encouraged to collaboratively discuss their work, each student works on a unique collection of problems and submits their work individually. Each problem set utilizes technology tools in an essential way. At the end of the problem set, a required metacognitive reflection reports about students' thinking during the process of problem set design. Two self-evaluations per semester each consist of (a) a self-report to inform the instructor how the student is progressing in the class; (b) dispositions (both for student and instructor), (c) grade records (spreadsheet kept by student), and (d) student's plans for future work related to the course.
Weekly discussions are carried out through the use of online courseware. The classroom learning network includes discussion groups, Reflective pods. Each pod consists of approximately four students. Students are asked to reflect on certain questions that are supporting ongoing classroom activities. On a rotating basis, one member of the group summarizes. Summaries are brought in for face-to-face class discussions. Instrumented techniques in tool – and object perspectives
Mette Andresen Danish University of Education, Denmark
mea@dpu.dk
The aim of this paper is to report from a study of the role of instrumented techniques in the students' learning process. The paper analyses an episode from a case study of students solving differential equations in a CAS environment. The analysis demonstrates how tasks can be designed with the aim to encourage the students to change between the perspective of tool on a mathematical conception and the perspective of object on the conception. Reasons are given in the paper for the assertion, that changing between these two perspectives supports the instrumental genesis as well as the conceptual development.
Instrumental genesis and instrumented techniques
The French theory of instrumental genesis is based on the idea that an artefact, for example a CAS calculator, does not in itself serve as a tool for the student. It becomes a tool, referred to as an instrument in this notion, only by the student's formation of (one or more) mental utilisation scheme(s). The term instrumental genesis denotes the process in which the artefact becomes an instrument. (Drijvers and Gravemeijer 2005 pp 165-169). The formation of utilisation schemes and the building up of instrumented action schemes proceed through activities in 'The twosided relationship between tool and learner as a process in which the tool in a manner of speaking shapes the thinking of the learner, but also is shaped by his thinking'. (ibid. p 190). The French framework is underlying the theory of instrumental genesis: according to Luc Trouche the scheme concept, encompassing utilisation schemes and instrumented action schemes, was introduced by G. Vergnaud as 'an invariant organization of activity for a given class of situations. It has an intention and a goal and constitutes a functional dynamic entity. In order to understand its function and dynamic, one has to take into account its components as a whole: goal and subgoals, anticipations, rules of action, of gathering information and exercising control, operational invariants and possibilities of inference within the situation. (Trouche 2005 p 149)
The formation of utilisation schemes and instrumental action schemes, thereby, is pivotal for the instrumental genesis. Since the utilisation schemes are mental, they are not directly accessible for study and analysis. The concept of instrumented techniques, taken as the external, visible and manifest part of the instrumented action scheme, therefore, is of special interest. An instrumented technique is 'a set of rules and methods in a technological environment that is used for solving a specific type of problem.' (Drijvers & Gravemeijer 2005 p 169). An instrumented technique includes conceptual elements as far as the technique reflects the schemes. This leads me to two crucial points: 20
A student's development of an instrumented action scheme can be studied by inquiry of the student's development and use of instrumented techniques related to the scheme.
Development of mathematical conceptions cannot be studied if use of technology is considered separate from the student's other activities.
The first point stresses the importance of empirical studies of students' work. The second point opposes my research to the standpoint, that teaching may be performed independently of what tools the students have at their disposal. This is in line with Jean-Baptiste Lagrange who stressed, that 'the traditional opposition of concepts and skills should be tempered by recognising a technical dimension in mathematical activity, which is not reducible to skills. A cause of misunderstanding is that, at certain moments, a technique can take the form of a skill.' (Lagrange 2005 pp 131-132).
Tool – and object perspectives.
During a recently concluded research project (Andresen 2006) on the teaching of differential equations in upper secondary school in laptop-classes, I have constructed and tested a conceptual tool, flexibility. This notion of flexibility encompasses the tool – and object perspectives subject to this paper. In the following, the definition of flexibility is reproduced without further explanations. For a discussion of details and examples, see (Andresen 2006). Definition: The flexibility of a mathematical conception constructed by a person is the designation of all the changes of perspective and all the changes between different representations the person can manage within this conception. The changes of perspective considered are divided in three groups:
a) Dualities of perspectives intrinsic to mathematics: 1. Local – global, 2. General – specific 3. Analytic- constructive
b) Dualities of perspectives linked to the construction of epistemic knowledge: 4. Process – object, 5. Situated – decontextualised
c) Dualities of perspectives linked to the construction of pragmatic knowledge: 6. Tool – object, 7. Model – reality, 8. Model of – model for
Three main representations are considered: graphic representation, analytic representation (or formal language), and natural language. A fourth, called technical representation (or computer language) is included as well, caused by the use of laptops. There is no symmetry between the four representations.
The conceptual tool flexibility serves to capture and conceptualise certain learning potentials experienced by teachers and students, for instance, when using the laptops in a modelling-context. One element of flexibility with special relevance for the theme of this paper is changes between a tool perspective on mathematical conceptions and an object perspective on the same conception. The notion of a tool perspective on a mathematical conception is opposed to a pure skill understanding of mathematical activity and the notion includes the technical dimension mentioned by 21 Lagrange. The duality composed by a tool perspective on a mathematical conception and an object perspective on the same conception appears to be appropriate in problem-solving settings, in the same way as Anna Sfard's process – object duality (Sfard 1991) is useful to frame aspects of learning mathematics. The term tool perspective here refers to the mathematical processes, carried out to serve a concrete purpose. This resembles the use of the term tool synonymously with instrument in contrast to artefact. This notion of tool perspective on a given mathematical conception is in accordance with Régine Douady's definition: 'We say that a concept is a tool when the interest is focused on its use for solving a problem. A tool is involved in a specific context, by somebody, at a given time. A given tool may be adapted to several problems; several tools may be adapted to a given problem.' (Douady 1991 p 115)
The distinction between the pair of process – and object perspective and the pair of tool – and object perspective can be illustrated by the following example: a tool perspective on the conception of derivative of a function could be the derivative seen and used as a means for finding out how the function changes over time. The corresponding object perspective could be the derivative, characterised or categorised by its merits and demerits when it was assessed in the context of solving a specific problem. In contrast, a process perspective of derivative could be focusing on the actual determination or calculation of the derivative in question. The corresponding object perspective could be the derivative, generally characterised or categorised by its qualities within in a structure of functions. Mathematical activities, then, are considered from a tool perspective when they are part of a (problem solving) technique, regardless of its being instrumented or not. The generation of the instrument, then, is in a crucial way linked to the change to object perspective: From the object perspective corresponding to a tool perspective, a unit is considered which may encompass intension, goal, conditions and prerequisites, restrictions, function and dynamics. Like in the case of process – object, the object perspective implies an encapsulation of the conception as a tool. So for the student, the development of an object perspective gradually leads to master the techniques in which the conception is embedded and to complete the formation of the connected instrumented schemes.
Change of perspective to support learning
Basic to the research, which lead to the construction of the conceptual tool flexibility was the idea that learning is supported by alternating diving into the process of solving a problem and taking a distant look upon the activities and efforts (Andresen 2006). Edith Ackermann presents this idea in (Ackermann 1990) as a mean to integrate, roughly speaking, Jean Piaget's and Seymour Papert's views on children's cognitive development. In her paper, Ackerman combines the Piaget'ian construction of invariables with Papert's situated learning in her dynamical approach to cognitive growth. Flexibility incorporates this basic idea in the form of the aforementioned changes within dualities of perspectives on given mathematical conceptions. One aim of the research project was to inquire how the teacher can provoke and support the 22 students' change of perspective in both directions within these dualities, and to interpret the role of such changes for the students' ongoing mathematical activities. In the actual case, a group of three students used several instrumented techniques during three episodes. The episodes were analysed and interpretations of the techniques' role in the students' learning process are presented.
Case
The case presented in this paper is part of the data from my Ph.D. project. These part of the project's data were produced from a small scale, qualitative inquiry which encompassed classroom observations in four classes, 50 lessons in all, field notes, students' written reports and teaching materials prepared for a sequence of teaching differential equations from a dynamical point of view using the software Derive. A group of three students were working with a differential equation model of the transformation of cholesterol in the human body. The students were in third year of an experimental class in upper secondary school, where all the students had their own laptops at their disposal from first year on. The CAS software Derive was installed on the laptops. This case is based on group's work during one lesson which was video recorded. The students' written report and the teaching materials were examined in relation to the analysis of the case.
The students were preparing a written report on a series of tasks, which concerned exploring a model for transformation of cholesterol, presented in the textbook. The tasks aimed to stimulate the students' learning about equilibrium point and general as well as specific solutions to differential equations. Further, the tasks concerned relations between general and specific solution and connections between analytic and graphic representation, both mediated by computer language. In the case, the group was in an early phase of their work, concentrating on this text from the teaching materials (Hjersing et.al. 2004):
... another handy form is:

$$\frac{dC}{dt} = !(8.2)$$

(Bubba changes his diet at t0 = 0, with C0 = 180 mg/dl, the new daily cholesterol intake is E = 250 mg/day.)
If we let t0 = 0 be the time where Bubba starts eating at the grill and if Bubba's level of cholesterol at that time is supposed to be C0 = 180 mg/dl, then Bubba's cholesterol level is expressed:

0.1(265)
(0) 180
dC
C
dt
C
= !
= (8.3)
Tasks 23
1. Find the equilibrium point for (8.2) and analyse the variation of the sign of the
right side.
Is the equilibrium point a sink or a source? Use the answers to sketch (in hand)
more solutions to this differential equation.
2. Find the general solution to the differential equation (8.2) (Show calculations)
3. Find the specific solution to the initial value problem (8.3)
4. If Bubba keeps this high cholesterol level diet for a very long time (one year or
more), at what level will he end? Explain how you reach the conclusion?
During the case, the students used several instrumented techniques: First, in episode
1, they used the Derive command RK
1
to obtain a graph of the solution to the
differential equation (8.2) with the initial conditions t0=0, C(t0)=180. In episode 2,
they used their compendium of formulas supplied by paper and pencil techniques to
find the general solution to the equation. The solution was typed into the computer
and the students used the Derive command VECTOR to get a family of graphs of
solution curves, as kind of an intermediate between general and specific solution. To
answer the next question, they substituted the initial values in the formula for the
general solution, calculated the constant d (determined by the initial values) and
substituted it into the expression. To answer question 4. in episode 3, the students
repeated graphing the same solution curve as they graphed in the first episode, but
this time based on the expression obtained from the preceding answer. Their answer
to question 4., then, was based on visual inspection of this later graph.
Episode 1
To answer question 1., the students sketched the graph and wrote:
' The function nears 265, so, 0.1 is the rate of growth and 265 is the point of
equilibrium.
The right-hand side is positive if his start C is below 265 and negative if it is above. The
equilibrium point is a sink, that is, a stable equilibrium.
The students made at least one guess before they reached this result: their first try in
the written report was a RK command, which was impossible to graph because the
capacity of the computer-memory was exceeded. So, their strategy implied a trial-and
error use of an instrumented technique that can be described as follows: 1) substitute
the left side from the differential equation into the RK command, 2) type in the
names of the independent and the dependent variables, 3) type in the initial values
and 4) try to find values for the x-increase and the number of tangent-segments,
which allows for: 5) graph the solution. Apparently, the students identified the
horizontal asymptote by inspection of the graph and then graphed the function y=265
to verify the result visually. Afterwards, the equilibrium point was identified with
this horizontal asymptote. So, since the graph with its asymptote was used to

1
stands for the 4.order Runge Kutta method of numerical solution 24
determine the equilibrium point, the graph with asymptote was in this case seen in a
tool perspective and it was obtained using the instrumented technique sketched
above.
The second part of the answer must be obtained from analysis of the differential
equation. Therefore, the graphic method used in the first part of the solution serves to
link graphic and analytic representations closely.
Episode 2
To answer question 2, the students wrote:
General solution:
The equation for cholesterol is of the type dy/dx=b-ay and may be solved as follows: (b
is a constant)
First, the students used paper and pencil and they looked in their compendium of
formulas to find the general solution. They tried to identify the type of equation.
The paper and pencil technique implied to 1) identify the type of equation, 2)
recognise it in the compendium, 3) identify and substitute the actual values of the
constants in the expression for the solution. The students typed the results into the
computer stepwise, as they were asked to show the calculations. Apparently, they
then wanted to graph the result, which is, obviously, impossible. The students used
the command VECTOR to graph a family of solution curves, which could be seen as
kind of an intermediate between general and specific solutions. The report reveals,
that they did not completely manage this instrumented technique at that stage of their
work so they must have made more than one trial: The command VECTOR(C = 265-
....) would not result in graphs as shown, as far as "C = 265..." is evaluated logically.
To succeed in graphing that family of curves it is necessary to delete the "C=".
Intermezzo
The students answered question 3 by 1) substituting the initial values in the formula
for the general solution, 2) calculating the constant d and 3) substituting it into the
expression. Though, the dialogue in the group revealed no clear signs of having
developed a general perspective of solution to the differential equation (Andresen
2004).
Episode 3
When starting to answer the last question in this task, question 4, it was clear from
the dialogue in the group that the students did not try to estimate the result, based on
the preceding answers. Apparently, the fact that the students found equilibrium for
the general solution earlier in the lesson did not 'ring a bell' when they were asked to
argue for their latest result.The students spent some time in the group discussing how
long time they had to take into account. Two of the three refused to consider the fact,
that they found an asymptote.
In the final report, the students wrote:25
"Based on the graph we conclude, that the equilibrium point does not change even if the
starting point is different. The general as well as this solution therefore near to the same
equilibrium point and whatever long he keeps the high level, the equilibrium point does
not change."
In the final version of the report, the students simply graphed the specific solution
from episode 1 once more. Since the window was changed it is obvious that they regraphed it. The written comment reveals that the students did not expect the
coincidence between the equilibria points for the general solution and the specific
one in question. This fact questions the students' adoption in advance of the general
perspective on solution to differential equation. In line with this the last statement, in
my interpretation, reveals unfamiliarity with the conceptions of asymptotic behaviour
and of equilibrium.
Conclusion
In the case, the students' work with the task concentrated on two mathematical
conceptions, represented by the example of one differential equation: 1) equilibrium
point for differential equations and 2) solutions to differential equations. The
equilibrium point was closely connected to asymptotic behaviour of the solution
curve. So, an instrumented technique of solving and graphing the solution curve,
encompassing the RK command and seeing the curve with its asymptote in a tool
perspective, was used by the students to build and strengthen their conception of
equilibrium point.
Determination of the general solution was carried out with a combined paper &
pencil- and computer-instrumented technique, where the last part concerned change
to graphic representation. Especially, the computer-instrumented part of the
determination served to link between a family of solution curves, on the one hand,
and the specific solution curve, examined earlier, on the other hand. The family of
solution curves served as pseudo-graphing the general solution.
The experiences of asymptotic behaviour and of coincidence between the asymptotes
of these solution curves, provoked by the task, supported the students' change of
perspective on the two conceptions in question: Realising that "whatever long he
keeps the high level, the equilibrium point does not change" is one step to adapt an
object perspective on equilibrium interpreted by horizontal asymptote. Likewise, the
family of graphs are visually convincing about the fact, that the general solution
should encompass the specific solution.
The case illustrates genesis of Derive-commands as an instrument in an ongoing
process. The first use of RK had the character of trial and error in episode 1 (omitted
from the data presented in this paper). The fact, that changes to graphic
representation were not carried out with full routine, is revealed in the report in the
case of VECTOR. But it was very clear, that especially the possibilities of graphing
shaped the students' thinking. So, the tool influenced: 1) Their strategy, which
implied to choose asymptote as the tool for finding the equilibrium, 2) Their thinking
of general solution by making it tangible by pseudo-graphing into a family of 26
solution curves and 3) Their idea of verifying the asymptotic behaviour by visual
inspection and comparison with the graph of y=265.
The idea of provoking changes between tool and object perspective can be realised,
for example by the asking of questions and tasks which involves ready-made
procedures as well as self-developed instrumented techniques for solving modelling
problems. The analysis of the case shows how the idea can facilitate proceeding of
students' work as part of their learning process.

Connecting Grade 4 students from diverse urban classrooms:
virtual collaboration to solve generalizing problems
Ruth Beatty and Joan Moss
Ontario Institute for Studies in Education of the University of Toronto, Canada
rbeatty@oise.utoronto.ca, jmoss@oise.utoronto.ca
We have been investigating the potential of a web-based collaborative workspace,
Knowledge Forum (Bereiter & Scardamalia, 2003), to support Grade 4 students in
generalizing with patterns as part of our research in early algebra. Our hypothesis
was that incorporating Knowledge Forum, with its underlying knowledge building
principles, might offer an authentic platform for developing students' mathematical
discourse. We present analyses of the Knowledge Forum database from a recent
study in which three diverse urban classrooms were linked electronically to
collaborate on solving a series of generalizing problems. Analyses of contributions to
the database revealed that the opportunity to work on a student-managed database
supported students in developing a community practice of offering evidence and
justification for their conjectures. The database also provided students with the time
and software capability to revisit and revise their notes and to develop a level of
discourse that elicited high-level mathematical problem solving.
Research context the mathematics of patterns and functions
Patterning activities have been heralded as an important foundation for the
development of mathematical functions. It has been proposed that patterning
activities can support students in understanding functional relationships and provide
a rich context for generalizing. In fact in recent years the inclusion of patterns can be
seen in elementary curriculum documents and text books in many countries.
However, substantial evidence from past research suggests that with current
instruction the "route from perceiving patterns to finding useful rules and algebraic
representations is complex and difficult" (Noss et al, 1997). Further, even when
students find rules, they do so with an eye to simplicity rather than accuracy, commit
to their first conjecture even in the face of invalidating data, and do not attempt to
support or justify their conjectures (e.g., Stacey, 1989; Mason, 1996; Lee, 1996).
The research that we have been conducting has focused on a study of new
approaches to support students in working with patterns. In line with suggestions of,
for example, Mason (1996) and Lee (1996), we have been working to broaden
students' conceptualization of patterns as a means of understanding the dependent
relations among quantities that underlie mathematical functions, and further, as a
means of developing students understanding of generalizing by seeing "the general
through the particular, and the particular in the general" (Mason, 1996).
An important part of our work with grade 4 students has been our investigation
of whether Knowledge Forum (Bereiter & Scardamalia, 2003), and its underlying
knowledge building principle of epistemic agency, can promote inquiry-based
mathematics learning. Knowledge Forum (KF) is a networked multimedia 28
community knowledge space created by community members. Our conjecture was
that incorporating KF would allow students access to multiple pattern "seeings"
(Mason, 1996) and that the discourse structure would provide an authentic context
for collaborative problem solving and extended discussions that would necessitate

the provision of evidence and justifications. Although the scope of this paper does not allow for a discussion of KF, we will briefly describe how KF works and outline the theoretical principle of epistemic agency, which we believed would contribute to our research goals.
Knowledge Forum: How Does It Work?
Knowledge Forum was developed as an online forum for discussion and knowledge building by learning theorists Bereiter & Scardamalia based on their early work in intentional learning (please see Bereiter & Scardamalia, 1989). When students work on KF they have the opportunity to contribute individual ideas or to build onto the ideas of others by writing and posting "notes". A note (Figure 1) contains a space for composing text, and metacognitive scaffolds designed to encourage students to engage in theory building while they write their notes (Scardamalia, 2002). These scaffolds include
my theory, I need to understand, new information,
a better theory, and putting our knowledge together.
Students can also use the graphics palate to create
illustrations, or scan drawings, function tables or
photographs. When notes are contributed to the
database, the notes are automatically labeled with
the author's user name (usually first and last initial)
and the note's title.
Students' notes are contributed to problem
spaces called "views'. Figure 2 presents a view of the Perimeter Problem, one of six generalizing problems used to create the six views in our database. The small squares represent student notes and the connecting lines represent discussions created as students read and respond to each other's
contributions. Some of these notes have
small circles that are referred to as "buildons", i.e., responses to notes posted by other students. A unique feature of KF
that distinguishes it from other CSCL
(computer supported collaborative learning)
environments is the physical layout of the
problem space as students contribute their
ideas. The database views are continuously
evolving interactive discourse spaces,
where each thread of conversation is documented, webs of interchanges graphically displayed, and collective understandings captured as they progress. 29
Epistemic Agency and Higher Order Mathematizing
While we believed that establishing a database to house discourse and promote collaboration would contribute to our research goals, the theoretical frame underpinning KF, particularly the emphasis on student agency and the centrality of student ideas, was a fundamental reason for incorporating KF in our study. Bereiter and Scardamalia (e.g., Bereiter, 2002; Scardamalia, 2002) use the term epistemic agency to characterize the responsibility that the group assumes for the ownership and improvement of ideas that are given a public life in KF. In this discourse structure, it is not the teacher who asks for clarification and revision of the ideas or conjectures that the students have contributed, but rather the students themselves who take on this responsibility with an eye towards moving the theorizing forward. We wondered if this responsibility would result in an increased engagement in the language of and disposition for mathematical discourse.
We developed three specific research questions to allow us to determine how the principle of epistemic agency was manifest in this study, and the extent to which it underpinned the progression of students' mathematical thinking.
Our research questions
1. Will students provide evidence and justifications for their conjectures, and will this disposition develop as students gain experience working through problems on KF?
2. Will students revise their ideas?
3. Given that the database is entirely student-managed, will students take on the responsibility of developing their mathematical understanding by moving thinking forward through working collaboratively?
Procedure
Students from three different Grade 4 classrooms (8-9 year olds) in two different schools (n=51) were linked electronically and invited to collaborate in solving six generalizing problems, for which students were asked to discern a functional relationship between two sets of data and express this as a "rule". There were three pairs of problems, which were matched for structural similarity and increasing difficulty. The first two problems (Linear Pair 1) both had an underlying functional rule of y=mx+b. The second two problems (Linear Pair 2) had an underlying function of y=mx-b. The final two problems (Quadratic Pair) were based on the quadratic function, x
2
-x/2, which posed an unfamiliar challenge to the students since they had previously worked only with linear functions. The KF database was available to students over an eight-week period, and on average each student had approximately 30 to 45 minutes per week to work on-line. The time that the students had to work on the database varied depending on the classroom and the availability of computers. No teacher or researcher posted notes on the database, so that it was clear to students that it was their responsibility to work together to find and "prove" the solutions to these problems. 30
The data for the present study come from the 247 notes that the students in the three classes posted in response to the six generalizing problems. Each note was read and coded by the researcher (first author) and one or more research assistants.
Evidence and Justifications
All notes were rated for the level of evidence and justification offered and were coded as Level 3 (high), Level 2 (medium), or Level 1 (low). Notes designated Level 1 were those in which only a conjecture was offered - My theory is that the rule is x4 -4. Notes coded as Level 2 offered a conjecture with some sort of explanation of problem solving strategy. I figured out the rule and it is the number times 4 (the four sides) minus 4(because you use one twice at each corner). Notes coded as Level 3 were those that offered a conjecture and evidence within the context of the particular problem, and included multiple representations, and/or a detailed account of a problem-solving strategy.
The note below (PP19) titled "I got it!" was offered by a student, JF, as an explanation for the Perimeter Problem (Steele & Johanning, 2004). In this problem students are asked to find a rule that will allow them to ascertain how many squares are in the perimeter of an nxn grid. This note is as an example of a note coded as Level 3 because it includes a proposed rule and contextualized explanations based on this student's particular way of perceiving the problem:
.
I got it! - JF
I got x+x+(x-2x2)and i tried it out for a lot of them and it worked:
5+5+(5-2x2)
5+5=3x2
5+5=6
10+6 = 16 so that means the rule is x+x+(x-2x2) and that's it! if you seperate the question into two you have 5+5 and +(5-2x2) so let's focus on 5+5 and that equals 10 and that means that we can do this
So now we can focus on this part: =(5-2x2) so 5-2=3 and the space left in the square is 6 and 3x2 is 6 so it's x+x+(x-2x2)
Our analyses revealed that there was an
even distribution of the three levels of
notes throughout the database, with 82
notes coded as Level 1, 81 notes coded as
Level 2, and 84 notes coded as Level 3.
However, when we looked at the level
note as a function of the three problem
pairs, we found that the proportion of
[illegible]
high-, medium-, or low-level notes was different for each of the problem pairs with the highest proportion of Level 3 notes posted for the third pair of problems (40%), and the lowest for the first pair (13%). Our analysis of the database revealed that the majority of students moved through the problems in chronological order starting with the first pair of linear problems and finishing with the quadratic problems. Thus, as students became more experienced at working in KF, they became more sophisticated and more mathematically oriented in their offering of evidence and justification. Table 1 shows the levels of notes as a function of Problem Pair.
The students established a community practice of routinely offering notes that included justifications for their answers using language, tables of values, symbols and/or images to justify their conjectures.
Revision of notes
An important feature of KF is that notes can be revisited and revised at any time. To answer our second research question we counted the number of times that students revised their own notes in each problem view. Each time a student added or modified an idea in their note, it was counted as a revision. There were 194 revisions, with a spread of 0-11 revisions per note. Although it might seem self-evident that revisions would lead to a higher level of note, we wondered about the nature of these revisions given that this was a student-managed database. We discovered that there was a relationship between number of revisions and level of note. The Level 3 notes went through an average of 3 revisions (M=3.1, min 0- max11), the Level 2 notes went through an average of 1 revision (M=1.4 min 0 max 5) and the Level 1 notes went through on average less than 1 revision (M=0.6, min 0 max 2). This indicated to us that when students revised their notes, they did so by improving upon and adding to their previous ideas, thus adding to the overall level of mathematical knowledge.
When we examined notes that had been revised by the author, we could see that the impetus to revise was either based on other students' responses to an offered conjecture, or based on the student's own dissatisfaction with their solution. To illustrate the former, we present the following discussion, which began when a student, SR, posted a note containing his strategy for solving the Perimeter Problem in the form of a table of values. In response to SR's note, two students posted notes (PP24 and PP25) requesting that SR provide a rule to explain his data. SR then posted a revised note in which he described his rule using diagrams, a table of values, and an explanation for his rule.
PP23 My thinking - SR
square grid shaded squares
3x3 8
4x4 12
5x5 16
6x6 20
PP24 rule? - SV 32
I need to understand what is your rule, evidence and how did you get your rule.
PP25 Finish please - BA, MD,
We do not think that is a rule , so can you explain the rule as well as you can show it. We also agree with you because your T-table is right. But your rule needs improving.
PP26r4 My thinking - SR
3x3
8
4x4 12
5x5 16
6x6 20
My theory is that the rule is that the rule is x4-4
Rule: Output equals Input x4-4Evidence: It is x4 in the rule because the number of sides a square has is 4. It is -4 because when you are multiplying 4 each corner you are repeating the number of squares one more.
SR was prompted by others to refine his ideas. In contrast some students recognized that their original conjectures contained only a partial solution, and used the time to think provided by working on an asynchronous database to continue to revisit and revise their initial ideas. The following note entitled "Relationships" was written by a student, NS, who posted a solution to the Perimeter Problem but recognized that her solution was not fully explained. As she commented in her note; "I think I still have to think a little more to explain my theory".
PP19 Relationships - NS
My theory is that the Output # is = to the input # times 4 - 4.
My evidence is that 3x4=12 and -4 is 8 which is the output. You need to multiply the input x 4[only one side] because without multiplying you wouldn't get 12. Then when you minus another # besides 4 the output wouldn't be 8. The same rule applies for all the other numbers.
Like: 100x4= 400-4=396 10x4=40-4=36 14x4=56-4=52
I think I still have to think a little more to explain my theory.
When we analyzed NS's contributions we could see that she revised this original note

a total of five times over the course of three weeks. In her final revision (PP19r5), posted three weeks after her original entry, she contributed an addition to her original idea that included a more conceptual orientation to the problem structure.
PP19r5 A better theory - NS 33
You need to x 4 because you need 4 sides to make a square. Like 3x3 means 3 is the length and the other 3 is the width so one length or width x 4 = to the whole perimeter.
This kind of revision and rethinking was typical of many of the efforts of other students as well.
Progressive Mathematical Discourse
In knowledge building communities members make progress not only in improving their personal knowledge, but also in developing collective knowledge through progressive discourse (Bereiter & Scardamalia, 2003). We found many instances of students making concerted efforts to move the understanding of the group forward. A numerical count revealed that 65% of notes were written in response to other students' notes, indicating that students were reading each other's contributions and building onto the ideas of others, rather than simply posting individual ideas. There were many instances of exchanges in which individuals extended the ideas of others. Also, there were strings of discussions that revealed commitment to the notion of moving the discussions forward to include broader issues of mathematical understanding. To conclude we present two discussions taken from two different problems, both of which involved students from all three classrooms.
The first is from the Perimeter Problem. This discussion began with a solution posted by a student, AW, (PP 38) which she titled 'Eureka!'. The solution strategy that she proposed involved calculating the total number of squares in the grid, calculating the total number of squares in the centre of the grid, and subtracting the centre blocks to find the number of squares in the perimeter.
PP38 Eureka! AW
for the 5x5 question you do 5x5=25 the square of 25 is 5 and you minus two from the square and square that then minus it from your original number and you have your answer!
First i drew the five by five grid and there was nine in the middle to take away - 3x3=9
so then i figured out a 6x6 square was 36 and i know that inside there would be a 4x4 square to take away so the difference between 6 and 4 is 2 - so it was 36-16=20
nxn=nsquared -(n-2)squared -
so minus (n-2)squared from nsquared
In response to AW's note, SI offered a note in which he proposed a different rule for the problem based on multiplying one side of the grid by 4 then subtracting out the overlapping corners .
PP40 Another rule - SI
I have another rule for you and it is the output x4-4.In the rule it is x4 because
there is 4 sides in a square. It is -4 because when you multiply 4 you are 34 repeating the
corners twice so you -4.
In her response to SI, (PP41), AW postulated that there may be more than one solution to the problem.
PP41 2 rules - AW
but there might be two rules because we got the same answer so i think there is more then 1 way to figure the problem out
Another student, GA, then questioned AW's rule not on the basis of whether it yields the correct answer, but rather on the basis of elegance. She titled her note "Both right?"
PP42 Both right? - GA
I agree with you and disagree with you because you've got the answer but in a complicated way. I disagree with you because there's an easier way than taking the square of 25, subtracting 2 from it and square that and then subtract that from your original answer. I got the rule times 4 - 4 because a square has 4 sides and you don't count the corners twice. I agree with you because for the first few questions you got it right.
At this point in the discussion AW became firm in her conjecture that there is more than one solution to the problem.
PP43 Two Ways - AW
Why can't there be two ways. There are different ways to do lots of different problems i think you can have two ways nxn=nsquared -(n-2)squared -
so minus (n-2)squared from nsquared works and x4-4 works
This last discussion comes from the Handshake Problem. This problem, which has been shown to be difficult for much older students (e.g. Cooper & Sakane, 1986), asked students to find the quadratic rule to determine how many handshakes there would be if everyone shook hands with everyone else in any size group. Initially many students came up with a recursive numeric pattern, as the note HP5 exemplifies. However, in contrast to findings of other research with older students, a number of notes were posted by students who realized the limitations of this recursive approach, and questioned one another as to how to find the explicit functional rule. As M and J state in their note (HP8), "the thing about math is to figure out the fastest and most accurate way to do things."
HP5 Follow the Next Output Number - TH
If there is 3 people there are 3 handshakes. If there is 4 people there are 6 handshakes. So I think that it is like 2+1=3 that is the next handshake output. So 3+3=6 that is the next handshake. My rule will be the input+output=next output.
35
Number of people Number of handshakes
2 1
3 3
4 6
5 10
HP8 M and J's Theory - MT
I was wondering could you do this rule for 149 378 people? Because the thing is in our theory you have to know the number of handshakes before the one you're doing...but the large numbers are so big it would take forever to figure it out! The thing about math is to figure out the fastest and most accurate way to do things.
HP9 I need to Understand - VT
I need to understand if there is another way to get the answer? I want to solve how many handshakes would 10 people do without making a Tchart.
HP10 Thinking - SR
My theory is that the rule is the number x the number - 1 divided by 2. I think that it is the number x the number - 1 because a person can shake with the number of people 1 less than the person because the person cannot shake with itself. It is divided by 2 because 2 people make a handshake.
Discussion
Throughout the database we found evidence of what Bereiter and Scardamalia have termed epistemic agency. Students revised their own notes, and encouraged others to revise and reconsider their initial theories. Epistemic agency was also seen in students' disposition for offering not just solutions for problems but offering evidence and justifications as well. Furthermore, our analyses revealed that the level of justifications increased as the students gained more experience on KF. By the third pair of problems students routinely offered evidence to support their theories and frequently contextualized their justifications within the structure of the problem. Finally, it was clear in this student-managed database that students worked collaboratively not just to find the solutions of the problems given, but that their discussions broadened to include such themes as the elegance of finding explicit functions from recursive numeric patterns, and the possibility of multiple rules for mathematical problems.
How our work addresses the themes of the ICMI Study 17
Although our work is aligned with the general questions of classroom connectivity in particular Theme 7, in addition our research has raised several interesting issues that relate to other themes of ICME Study 17. 36
Theme 2 - In assessing the notes posted in the database, we have come to understand that KF has the potential to capture significant moments of learning.
Theme 3 - Not only does KF allow teachers to step back and assess student thinking, whilst simultaneously allowing the progression of ideas to become the responsibility of the students, teachers in our study were also introduced to a new view of student learning in general and of mathematics in particular. Some questions that have arisen centre on how to support teachers as they implement a knowledge building pedagogy, and how to organize classrooms to optimize a knowledge building pedagogy.

Providing mathematics e-content
Emran Behrooz
Isfahan Mathematics House, and Sepahan Soroosh International IT Training Corporation (SITCO) IRAN
emran1349@yahoo.com
Mathematics learning seems to be hard and exhausting task for many learners. Mathematics educators and teachers always try to stimulate the public and specially students for studying mathematics.
Certainly ICT is an effective tool for providing an interesting atmosphere for mathematics learning. Using this tool, one can make some virtual spaces such as exact diagrams and figures, attractive animations, and most important, making games and parametric programs to provide mutual interactions between learners and teaching media, such that they can change the parameters and see the results in figures or in the processes of the programs and much easier understand the concepts.
Isfahan Mathematics House(IMH) was trying to organize content provider teams of these specialists and professionals as its member: Mathematics educator, Mathematicians, Scenarists, Graphic experts and Programmers and multimedia experts. The team was making up some mathematics contents, but it faced to a big problem. It was the lack of communication between these people since many of them don't understand others with different background. For example the art experts don't understand mathematics and vice versa.
As a solution we tried to train some "interpreters" who can understand or have more feeling of both sides, and finally some successful results raised. In this article we are trying to report these activities with many useful experiences for all interested in the process of providing mathematical e-content. 38
Designing Didactical Tools And Microworlds For Mathematics Educations
Peter Boon
Freudenthal Institute, Utrecht University, the Netherlands
p.boon@fi.uu.nl
This paper reports on the extensive design activities by the Freudenthal Institute over the last few years in the field of small didactical tools and microworlds (java applets). New technologies have led to new ideas on visualising and learning mathematics. The effort made in several development and implementation projects have resulted in a collection of robust and well-tested didactical tools. Many of these applets have found their way to the practice of mathematics education and many schools work with these new tools. More research is still needed though (and planned) to obtain a detailed image of the possibilities and constraints of these new tools and their role in longer learning trajectories.
Introduction
The objectives of the Freudenthal Institute are research and curriculum development for innovation and improvement of mathematics education. From the very start of the introduction of the computer in mathematics education the possibilities of this medium were seriously investigated, and software development has always been practised at the institute. About 8 years ago, new technologies and programming tools that facilitate faster computer graphics led to a glut of new ideas for visualising and new ways of learning mathematics and creative programmers and designers produced some quite exciting prototypes. Of course this was just the first stage in the development of robust, well-tested and researched didactical tools. In the next stage further development, field testing and refinement were performed in several research, development and implementation projects, in real educational settings and in close

co-operation with teachers. A considerable collection of applets have found their way to the practice of mathematics education and there is much appreciation for these new tools in schools. Yet more research is needed (and planned) to obtain a detailed image of the possibilities and constraints of these new tools, especially regarding their role in longer learning trajectories.
To give an insight in the design activities and the development process, some paradigmatic examples of applets are described. First a distinction is drawn between three different kind of applets. The borders between these three categories are not very rigid, but this classification helps to structure the underlying design choices.
• Applets that offers a 'virtual reality'. These applets are used for representing and simulating real-world objects and processes that form the basis of mathematical reasoning. 39
• Applets that facilitate the use of 'models'. These applets offer interactive models that can be helpful in building and understanding the more abstract mathematical objects and concepts.
• Applets that offer a mathematical microworld. In these applets mathematical objects like formulas, equations and graphs can be constructed and transformed.
For each category one or more examples are described and used to illustrate and discuss typical issues and problems in the design process.
Theoretical Framework
The theoretical foundation is mainly based upon the theory of Realistic Mathematics Education (RME). The main idea of RME is to create opportunities for students to come to regard the knowledge they acquire as their own knowledge. Therefore, contextual problems which students recognise as relevant and real, and which also evoke productive solution strategies, play an important role. In RME, the intended goals are built progressively upon the students' informal ideas and strategies (Freudenthal, 1991).
For RME to work, it is necessary to know how students model new situations. Students are confronted with problem situations for which they do not have the appropriate models at their disposal; i.e. models which describe possible structures or patterns in the situations. At this point, theories on symbolising - individual as well as social aspects - are useful (Gravemeijer et al., 2002).
Applets that offer a 'virtual reality'
In the RME theory, real-world situations and experiences form the starting point of mathematical activities. Educational designs should for that reason contain carefully chosen real-world situations that are suitable for being mathematised. Software that simulates these situations can be used to recall old experiences and extend these with new ones by purposefully provoked interactions.
3D-Geometry has shown to be a very fruitful subject for this approach. We developed a number of applets on this subject for students of all levels.
The term 'virtual reality' is possibly somewhat misleading. In common virtual reality software the aim is to create a 'world' that should be experienced to be as real as possible. In the applets the aim is to make a firm connection with real-world experiences, but also to make a step to more model-like representations, in which certain mathematical concepts can emerge. The design challenge lies in finding a balance between giving the user freedom in his constructions and explorations in the virtual environment and imposing constraints to guide the user to the intended experiences. For example, the block building environment (figure 1) gives the user freedom in making his own constructions, but the environment also enforces a cubic structure that draws the attention more easily to orthogonal co-ordinates as a means to model space. 40
A quite different example of this category is the applet Fruit Balance (figure 2). It offers a real pair of scales that can be used to compare the weights of three different pieces of fruit. The task is to find the weight of all of them, when one is given. It is a nice example of the RME approach. A meaningful problem is introduced, without offering ready-made mathematical tools like standard solving algorithms for a set of equations with multiple variables, but offering a tool to explore the problem situation. The often informal strategies that students put forward can become the start of a learning trajectory on solving equations, based on 'guided reinvention', one of the important aspects of RME. Of course the most important thing is the design of such a trajectory, in which the student's explorations, reasoning and solutions are shared, discussed and generalised to other problems. Otherwise the applet activity would be just a nice puzzle without a substantial role in the learning of mathematics.
Applets that facilitate the use of 'models'
Geometrical shapes and objects are not only used in the mathematical domain of geometry. Often they appear as model for representing more abstract mathematical concepts and processes. A nice example of such a model is the number line that can be used in arithmetic. Processes such as addition and subtraction can be modelled by making step or jumps on the number line. For a developer of it-tools is a challenge in making those models dynamic, and in developing interactions or games in which especially the dynamic processes can be made visible and controllable. The applet "Jump tool" offers such a dynamic and interactive version of the more static representations of the number line.
Figure 1
Figure 241
Another example of a geometrical way to model mathematical objects is the 'area model' for algebraic quadratic expressions. Variables are used in the width and height of rectangles, and quadratic expressions represent their areas. Several applets were designed using this model. 'Geometric Algebra 2d' is one of them (figure 3). In this applet, line
segments of both constant and variable length can be combined to compound line segments and rectangles. By constructing these rectangles, the resulting algebraic expressions for the area are produced. Other, equivalent expressions can be made by splitting and joining the rectangles. Some interactive game activities were designed, in which students have to make factorisations by combining a number of small rectangles to a single one (figure 4).
Although students liked to work with these applets, it appeared that their skills in manipulating the rectangles did not automatically enhance their abilities with and insight in algebraic manipulations. Explanations of these shortcomings can be found in the RME theory. Especially the part on emergent modelling is useful (Gravenmeyer, 1994). In the RME view it is important that formal mathematics can be developed as a tool for solving problems that are real for students. One should

join split
split
completely
join
samen
separate
Figure 3 42
start with investigating phenomena and problem situations that can be structured and solved by the mathematics that has to be learned. In working on these problems models can be used as mediating tools that bridge the gap between informal solving strategies and the formal mathematics. So a model is more than a (visual) representation of a piece of abstract mathematics. First, it has to be developed as a tool for structuring a real situation or problem. The strong relation between the rectangles in the applet and the algebra is obvious to experts, but for learners for whom algebra is still a unknown area, the world of rectangles can become isolated and not transferable. This is especially the case if there is no proper attention for the problems for which the model, and in the end the algebra, offers a generic tool. The sketched model development requires a carefully designed learning trajectory of which the applet activities are just a part.
Another applet, 'Algebra Arrows', is based on the well-known 'machine' model for functions and formulas, in which functions are represented as input-output machines. In this applet the designer has tried to facilitate the model development, as described above, more extensive. The applet offers students a tool to build their own models to structure and solve problems. It has several levels of application and is meant to facilitate a step by step development of the function and formula concept and to get acquainted with commonly used mathematical objects and representations (Boon, 2005).
Applets that offer a mathematical microworld
The third category contains applets that work on formal mathematical objects, like formulas, graphs equations etc. In this sense they are comparable with mathematical
Figure 5
Figure 4 43
tool like the graphic or symbolic calculator or CAS. The difference is that the applets are didactically designed and do not aim at merely carrying out the standard operations and algorithms. Most of them allow interactions and transformations on the objects that are not common in the standard mathematical tools. They often have a built-in task for students to perform. Some of the routine work is performed by (CAS) facilities of the applet, other parts, always carefully chosen, are left for the student to do, supported by proper feedback. In this way it is possible to focus on certain concepts and skills.
An example of an applet in this category is 'Solving equations with the coverup strategy' (figure 6). Using this applet students can solve a certain type of equation by selecting a part of the expression with the mouse and giving it a value. (Figure 6 shows a solving scenario.) The applet doesn't impose a blind algorithm. It lets the student interact with the expression and gives insight in its structure. With growing insight, it becomes possible to make larger and more efficient steps in the solving process.
In the design of these environments it is important to find a balance in directing the student to desirable skills and giving room to personal strategies and exploration. When the latter is missing the applet becomes just a training tool for ready-made algorithms. For understanding the features of this kinds of tools, it is important to reflect on the role of (solving) algorithms in mathematics education. In a mechanical approach of mathematics education, algorithms are seen as the starting point of a learning trajectory. The learning objective is a proper application of these given algorithms. In the RME approach algorithms themselves and the understanding of how they work are products of the learning trajectory as well. So it is important to work on problems that involve mathematical objects in a way that permits explorations and student's own alternative strategies. Of course there should be guidance and negotiation towards the known and most efficient strategies, but not by imposing them from the start. Another important requirement of the RME approach is that the elementary mathematical objects that are the 'building blocks' of the activities in the applets are 'real' for students, that is to say they already have a meaningful foundation, based on processes of a lower order. 44
Challenges and future development
In the different development and research projects carried out at the Freudenthal Institute, the applets discussed in this paper to have additional value in RMEdesigned learning trajectories. It was noticed too that a proper design of the whole learning trajectory is vital for exploiting the benefits of single applets. Our division in three different categories also defines more or less their possible places in such trajectories.
Especially learning trajectories with applets that help students in developing the founding models for 'inventing' the formal mathematical tools are interesting, but also difficult to design. One of the problems is that applets that support model development often tend to impose a ready-made model that is not flexible enough to evolve. For applet designers it is a challenge to exhaustively explore the dynamics of this new medium and apply them to overcome this problem. For development researchers the challenge lies in the design of convincing learning trajectories that integrate these new tools.
Applets are distributed over the world wide web, which makes them accessible quite easily. But the web offers other features as well, such as easy to use and placeindependent communication and registration facilities, that can also be used to enhance education as well. At the Freudenthal Institute an environment was developed that can be used by schools and individual students to store the results of their applet activities. It has been noticed that working with the applets could be fleeting because of the lack of persistence of the achieved results, the impossibility to reflect on them later and to share them with the teacher or other students. In a new planned research project on tool use, these new storage and registration features will be integrated with the applets and other activities in a new and innovative learning arrangement for mathematics.
Note
Figure 6 45
At www.fi.uu.nl/wisweb/icmi2006 a collage of some of the Freudenthal applets is shown. The entire collection can be found at www.wisweb.nl

This contribution deals with the work of the European Research Team TELMA (Technology Enhanced Learning in Mathematics) of the Kaleidoscope network towards understanding the role played by theoretical frames in design and research in that area, and building tools to improve communication between researchers from different cultures. We present two facets of TELMA work: a "cross-experimentation" project in which each TELMA team experimented with an Interactive Learning Environment (ILE) for mathematics designed by another team; and the design of a methodological tool for systematic exploration of the role played by theoretical

frames in the design and analysis of uses of ILEs. We focus on the methodological dimension of this work, showing how we employ the construct of didactical functionalities as a means of comparing and integrating the research conducted by the teams. We provide some preliminary results of the joint experiment and use of the methodological tool.
Introduction
This contribution originates from TELMA, a European Research Team (ERT) established as one of the activities of Kaleidoscope, a Network of Excellence (IST-507838) supported by the European Community (www.noe-kaleidoscope.org). The contribution reports on the work developed within TELMA for analysing the influence of different theoretical frameworks in the design and/or use of digital technologies for shaping mathematics teaching and learning activities and discusses some of its outcomes that we think of interest for this ICMI Study. It is especially related to theme 4 of the ICMI Study: "Design of learning environments and curricula". Indeed it addresses some of the research questions raised in this theme: "How can theoretical frameworks be helpful for understanding how design issues impact upon the teaching and learning of mathematics?", "What kind of mathematical activities might different technologies and different theoretical

backgrounds shape and how can learning experiences (including the tools, tasks and settings) be designed to take advantage of these affordances?", and, last but not least, "Which methodologies can be developed and applied to understand and compare different approaches, theoretical frameworks, and backgrounds?".
Background: Kaleidoscope and TELMA
Kaleidoscope's central aim is to address the lack of harmonised research in the field of Technology Enhanced Learning (TEL) in Europe by integrating various existing initiatives and research groups. The aim is to develop, on the one hand, a rich and coherent theoretical and practical research foundation, and, on the other hand, new tools and methodologies for an interdisciplinary approach to research on learning with digital technologies at a European level. The network is doing this by supporting a range of integrating actions, including European Research Teams (ERT) such as TELMA. ERT are integrating activities, which aim to network European excellence through specific research challenges. The key idea of creating an ERT is to stimulate the mutualisation of knowledge and know-how of a number of recognized research teams on the identified issues, and to favour the construction of shared scientific policy, building complementarities and common priorities.
TELMA is specifically focused on Technology Enhanced Learning in MAthematics. It involves six European teams with the aim of building a shared view of key research topics in the area of digital technologies and mathematics education, proposing related research activity, and developing common research methodologies. Each team has brought with it particular focuses and theoretical frameworks, adopted and developed over a period of time. Most of the teams have also contributed learning environments integrating digital technologies for use in mathematics learning, designed, developed and tested in accordance with their own theoretical perspectives
3
. We will refer to these as Interactive Learning Environments (ILEs).
The starting phase of TELMA was very challenging, requiring six teams with different backgrounds, work methodologies, and ILEs, to begin to share knowledge, developing a common language and common topics of interest. This demanding task was addressed by working on a number of topics considered important for mutual knowledge and comparison (including research areas and goals, theoretical frames, ILEs implemented or used, contexts, work methodologies). Each team had responsibility for one topic and, on the basis of materials sent by the other teams, produced a report analysing the different contributions and developing them into an integrated presentation (the result is available the TELMA web site (www.itd.cnr.it/telma).
This first effort, based on the descriptions provided by the teams and analysis of papers they had published, helped to identify some common sensitivities to, for example: the contextual, social and cultural dimensions of learning processes; the

role played by semiotic mediation; instrumental issues. It also made it evident that the diversity of the theoretical frames we employed
4
affected the ways we dealt with
these common sensitivities in the design or use of ILEs. But reading and exchanging descriptions and research papers left us unsatisfied as we felt that our understanding of the underlying processes and their possible effects on practice remained too superficial. For that reason, we decided to develop a strategy allowing us to gain more intimate insight into our respective research and design practices. This strategy consisted of a 'cross-experimentation' project and simultaneous development of a methodological tool for systematic exploration of the role played by theoretical frames in teaching and learning in mathematics using digital technologies.
In this contribution, we focus on this second phase of our collaborative work, introducing first the idea of "didactical functionality", which we used as a tool for approaching the relationships between theory and practice.
The notion of "didactical functionality" of a tool
The notion of didactical functionality of an ILE (see Cerulli, Pedemonte, Robotti, 2005) was developed as a way to link theoretical reflections to the real tasks that one has to face when designing or analysing effective uses of digital technologies in given contexts. It is structured around three inter-related components:
• a set of features / characteristics of the ILE;
• an educational goal;
• modalities of employing the ILE in a teaching/learning process related to the chosen educational goal.
These three dimensions are inter-related: although characteristics and features of the ILE itself can be identified through a priori inspection, these features only become functionally meaningful when understood in relation to the educational goal for which the ILE is being used and the modalities of its use. We would also point out that, when designing an ILE, designers necessarily have in mind some specific didactical functionalities, but these are not necessarily those which emerge when the tool is used, especially when it is used outside the control of its designers or in contexts different from those initially envisaged. In the second phase of TELMA work, this notion of didactical functionality thus took a central and unifying role:
• on the one hand, the cross-experimentation aimed to explore the didactical functionalities the different teams involved would associate with ILEs they had not designed, and how their particular educational contexts and the theoretical frames they used would influence their constructions;
• on the other hand, this notion was also used to structure the methodological tool for exploration of the role played by theoretical frames.

4
These were mainly: activity theory, socio constructivism, Vygotskian theories of semiotic mediation, social semiotics, theory of didactic situations (TDS), anthropological theory, Rabardel's theory of instrumentation, situated abstraction, AI theories. 49
In what follows we present these two facets of TELMA work, focusing on the methodological dimension.
The cross-experimentation
The idea of cross-experimentation is a new approach to collaboration, seeking to facilitate common understanding across teams with diverse practices and cultures and to progress towards integrated views.
Some important methodological choices:
There are three principal characteristics of this cross-experimentation:
• the design and implementation by each research team of a teaching experiment making use of an ILE developed by another team;
• the joint construction of a common set of guidelines expressing questions to be answered by each designing and experimenting team in order to frame the process of cross-team communication;
• the specific role given to PhD students and young researchers.
Each team was asked to select an ILE among those developed by the other teams. This decision was expected to induce deeper exchanges between the teams, and to make more visible the influence of theoretical frames through comparison of the vision of didactical functionalities developed by the designers of the ILEs and by the teams using these in the cross-experimentation.
The cross-experimentation involved a rich diversity of ILEs, educational contexts and theoretical frames, but important attention was paid to the control and productive exploitation of this diversity, especially through the joint construction of guidelines, developed through an on-line collaborative activity. On-line collaboration allowed the teams to communicate the results of their within-team discussions and resulted in an agreed joint set of guidelines (http://www.itd.cnr.it/telma/documents.php), negotiated between the teams to be as relevant as possible to their interests and theoretical frameworks, while remaining feasible in light of the constraints of time and empirical settings. These guidelines structure and support a priori and a posteriori reflective analysis of the crossexperimentation.
In order to allow as much comparability as possible between the research settings, it was also agreed to address common mathematical knowledge domains (fractions and algebra), with students between years 7 and 11 of schooling in experiments lasting approximately one month. Table 1 summarises the ILEs chosen, the teams who developed the ILEs and the teams conducting the experimentation.
An important role has been given to young researchers and PhD students. Starting from three draft sets of questions addressing the issues of contexts, representations and theoretical frames, they developed the guidelines through the Kaleidoscope Virtual Doctoral School platform, and have taken charge of the experimentation. This role is coherent with the general philosophy of TELMA and Kaleidoscope. It also has the benefit of allowing "fresh" eyes to look at the teams' 50 approaches, theoretical frameworks, and consolidated practice in order to make explicit those factors that often remain implicit in the choices made by more experienced researchers.

ILE Developer's team	Experimenting team(s)
Aplusix	MeTAH-Grenoble CNR-ITD, UNISI
E-Slate	ETL-NKUA UNILON
ARI-LAB 2	CNR-ITD MeTAH, DIDIREM, ETL-NKUA

Table 1: The tools employed by TELMA teams in the cross experiment
The selection of research questions, experimental settings and modes of use of the ILE, methods of data collection and analysis were all determined by each experimenting team after a period of familiarisation with the ILE itself, following the common guidelines developed through the on-line activity. Each team thus conducted an independent study of the use of an ILE. At the same time, however, the framework of common questions provided a methodological tool for comparing the theoretical basis of the individual studies, their methodologies and outcomes.
The current state of the project
The experimentations took place during the first term of this academic year. A priori analysis of the experiment, according to the guidelines, has been produced by each team. The a posteriori analysis, following the guidelines, is in progress. Comparison and discussion of similarities and differences between the reflective analysis carried out by the PhD students and young researchers and the analyses, expectations, and results obtained by the ILE designers is planned in the following months. However, preliminary comparison of each team's results has highlighted interesting issues and indicates directions for future investigation, as described in the following section.
Some preliminary results from the cross-experimentation
In order to point out and compare the preliminary results of the cross experiments a meeting was held. Each team reported on its own experiment focusing on the defined/employed didactical functionalities of the ILE used, trying to make explicit the relationship between such didactical functionalities and the team's theoretical assumptions. In order to structure this preliminary analysis each team was asked to complete a form before the meeting, focusing on the three dimensions of didactical functionalities. The form followed the principle of "necessary conditions" in the sense that not all the details of the experiments needed to be given, but only those that the team believed to be necessary conditions for the experiment to be successful according to the team's theoretical assumptions (http://www.itd.cnr.it/telma/documents.php).
Comparison of the forms completed by each team, and of the oral reports of the experiments, highlighted a set of issues that seem promising in terms of future investigations and in relation to the key question: How can the use a given ILE within a specific context be characterized by specific theoretical frameworks and by cultural and/or institutional constrains? 51
During the cross experiment some difficulties arose when teams attempted to use a given ILE in a context (both in the sense of school and of research context) different from that in which it had been developed. For example, the software Aplusix has been designed (by the French team MeTAH) to facilitate the teacher's work, and to offer him/her a good level of autonomy with respect to standard algebra curricular activities. The software allows students to build and transform algebraic expressions freely and to solve algebra exercises by producing their own steps as on paper; for each step the system gives an indication of correctness as feedback. Aplusix was designed to support the standard activity of algebraic manipulation, based on the solution of calculation tasks like expand, factorize, solve the equation, etc. However, the CNR-ITD team, adopting a socio-constructivist approach, faced the problem of planning open-ended tasks. According to this theoretical framework, open-ended tasks favour pupils' construction of meanings through exploratory activities. This was achieved by interpreting the feedback concerning the correctness of steps as feedback concerning the equivalence of expressions and/or statements. This change of perspective implied also that Aplusix was no longer used autonomously by students, but required the teacher to orchestrate the activity by asking the students to make their strategies explicit, to justify them and to discuss them with their classmates.
Adapting the way in which an ILE is used to a changed context, even if

possible, may also be complicated by the role played by different curricular constraints and school praxis. As an example, we consider ARI-LAB2 (developed in Italy by the ITD team). ARI-LAB2 is composed of several microworlds designed to support activities in arithmetic problem solving and in the introduction to algebra. One of these is the "fraction" microworld, which provides a graphical representation of fractions on the real line, allowing the user to build fractions by means of commands based on Thales theorem. Some teams encountered difficulties using this microworld in their school context due to the fact that Thales theorem is usually introduced in the curriculum later than fractions. The MeTAH team tried to use it as a "black box" but found this caused problems when pupils needed to make sense of feedback. Similarly, the DIDIREM team decided to switch to other microworlds of ARI-LAB2 because they judged it was not realistic to ask a teacher to change the mathematics organisation of the school year.
During the cross-experimentations another aspect has been highlighted related to the influence of theoretical frameworks on the use of ILEs. This is related to the role assigned to feedback by different teams. For example, the DIDIREM team, drawing on the theory of Didactic Situations, found the feedback provided by ARILAB2 too limited with respect to what is generally expected from a "milieu" offering an a-didactic potential for learning. On the contrary the ITD team, who had developed the ILE, drawing on a more general constructivist framework, considers the feedback sufficient because the teacher's role and feedback are considered as fundamental as those of the ILE. 52
These examples show how, in order to employ an ILE in a context different from that taken as reference by its designers, one has to face a set of problematic issues. To sum up, the highlighted issues include:
• educational goals
• typologies of tasks proposed to the students
• computer's feedback and autonomy of the ICT tool and/or of the pupils
• settings and role of teachers
These issues point to significant investigative directions to be addressed in the next year of the work of TELMA. In fact, in order to refine the comparison between the experiments, our preliminary analysis raises the need to refine the lenses through which the experiments are analysed and compared. Starting from the idea of didactical functionality, we need to address its three dimensions in more detail, and in order to do so, a first methodological tool has been developed in parallel with the preliminary analysis and will be refined and employed in the next year. Below we present the tool and indicate the kinds of analysis it can help to bring forward, showing how it was employed by one of the TELMA teams.
A methodological tool for systematic exploration of the role played by theoretical frames
Some preliminary remarks
In the design of this methodological tool, we were inspired by the work already developed in TELMA about theoretical frames, the common sensitivities and the evidence of differences in the ways these were dealt with, and also by the meta-study previously developed by DIDIREM researchers involved in TELMA (Lagrange & al., 2003). This led us to consider this methodological tool as a multidimensional tool structured around the notion of didactical functionality, and to associate to each component of the notion of didactical functionality a set of 'concerns', expressed in the most neutral way. Analysis using the tool will try to determine for each of these concerns whether and how it is addressed, and to elucidate the role played both explicitly and implicitly by theoretical frameworks. It is assumed that such a tool will help to establish productive links between different frames, and will support partial integrative views when these appear accessible and possibly productive, keeping in mind that a global integration is certainly out of reach, and even not desirable, the strength of any approach being attached also to the specific lens it chooses for approaching the complexity of the reality we study.
The methodological tool
a) Analysis and identification of specific ILE characteristics :
The analysis of an ILE using the definition of didactical functionalities generally involves two different dimensions, questioning on the one hand how the mathematical knowledge of the domain is implemented in the ILE, and on the other hand the forms of didactic interaction provided by the ILE. Both the implementation of the knowledge of the domain and the didactic interaction can be approached 53 through different perspectives, which are neither independent nor mutually exclusive. We have thus selected according to this dimension the following concerns:
- concerns regarding tool ergonomy
- concerns regarding the characteristics of the implementation of mathematical objects and of the relationships between these objects
- concerns regarding the possible actions on these objects
- concerns regarding semiotic representations
- concerns regarding the characteristics of the possible interaction between student and mathematical knowledge
- concerns regarding the characteristics of the possible interaction with other agents 5
- concerns regarding the support provided for the professional work of the teacher
- concerns regarding institutional and/or cultural distances
b) Educational goals and associated potential of the ILE
It is more the relationship between potentialities and goals rather than each of these considered separately which can contribute to illuminate the role played by theoretical frames in relation to this dimension, complementing what is offered by the information provided by the analysis of the ILE. It seems interesting to investigate the relative importance given in the definition of educative goals to considerations of an epistemological nature - referring to mathematics as a domain of knowledge or as a field of practice, considerations of a cognitive nature - focusing on the student in her relationship with mathematical knowledge, considerations focusing on the social dimension of learning processes, and finally institutional considerations. Thus the concerns we selected for this dimension are:
- Epistemological concerns focusing on specific mathematical content or practices
- Cognitive concerns focusing on specific cognitive processes or difficulties
- Social concerns focusing on the social construction of knowledge and on collaborative work
- Institutional concerns focusing on institutional expectations and on compatibility with the forms and contents valued by the educational institution
c) Modalities of use
The design of modalities of use and the a priori analysis of their implementation supposes a multiplicity of choices of diverse nature. It is reasonable to hypothesize that only a small part of these are under the control of theoretical frames, explicitly or even implicitly, many other being dictated consciously or unconsciously by the educational culture and the particular context within the realization takes place. The categories are:

5
Other agents can be other students, the teacher, tutors as well as virtual agents such as the companions implemented in some ILEs. 54
- Concerns regarding contextual characteristics
- Concerns regarding tasks proposed to students, including their temporal organisation and progression
- Concerns regarding the functions given to the tool including their possible evolution
- Concerns regarding instrumental issues and instrumental genesis
- Concerns regarding social organisation, especially the interactions between the different actors, their respective roles and responsibilities
- Concerns regarding interaction with paper and pencil work
- Concerns regarding institutional issues, especially the relationships with curricular expectations, values and norms, the distance from the usual environments
Using the methodological tool
The methodological tool has been used first in order to explore the role played by methodological frames in the preparation of one experiment: that carried out by DIDIREM. There is no space here for a detailed presentation of this analysis which is accessible on the TELMA website (Artigue, 2005). It shows that, in this experimentation involving two different microworlds offered by ARI-LAB2, nearly all the concerns mentioned above were addressed, but with evident differences in emphasis (four different levels of emphasis were distinguished). The analysis also shows how the three main theoretical frames used: instrumental approach, theory of didactic situations, anthropological approach (together with didactic knowledge about the mathematical domain at stake) influenced the choice of the selected microworlds and the design of the experiment. However, an interview with the young researchers of the team involved in the project also shows that many of their choices were not under the explicit control of these theoretical frames. Some of the choices can be explained a posteriori by referring to theoretical frames but had been used as naturalized and implicit conceptual tools. Others were dictated by institutional and cultural habits. We can hypothesize that, from one team to another one, differences in the implicit theoretical tools and cultural habits will be made visible by the exchanges organized around the cross-experimentation, offering us insights into the real influence of theory on research and design practices that the reading of papers hardly offers.
Conclusion
In this short text, we have tried to make clear the kind of contribution we can offer to this ICMI Study. This work tries to overcome the difficulties generated by the existing diversity of theoretical frames and the lack of communication between these, through a better understanding of the role played by theories, the development of methodological tools and cross-experiments. This is on-going work and, by the time of the Conference associated to this study, all the analysis being completed, we hope to be able to offer a sound contribution on these difficult but crucial issues. 55

Looking through zones at the teacher's role in technology-rich teaching and learning environments (TRTLE's)
Jill P Brown, University of Melbourne, Australia
jillb@unimelb.edu.au
The equilibrium of teachers and teaching is inevitably altered by the availability of electronic technologies. It is imperative to establish what it is that enables teachers to perceive, attend to, and exploit affordances of the technology salient to their teaching practice and likewise for students in their learning about function. This paper focuses on one teacher and his teaching where technology use is expected by curriculum authorities. The aim is to show how Valsiner's zones and Gibson's affordances have been used as a theoretical framework to document the teacher's role in integrating electronic technologies into his teaching. The students' subsequent use of technology to support their learning is also examined. Thematic matrices have been used to identify manifestations of affordances, affordance bearers used, and the conditions enabling perception or promoting enactment of particular manifestations of affordances. These conditions, the latter indicative of the Zone of Promoted Action, have been used to identify teacher's role as he canalises students' current and future thinking about concepts and methods taught. The teacher's approach also impacts on the Zone of Free Movement/Zone of Promoted Action complex of the future.
Introduction
A broad variety of electronic technologies has the potential to be used in mathematics classrooms today. The presence of these in the classroom can fundamentally change how we think mathematically and what becomes privileged mathematical activity. Classroom tasks can include those that are transformed by electronic technology use rather than technology being used to produce or check results but not necessarily contribute to the development of understanding, and concept and skill development. Whilst acknowledging that teaching and learning are inseparable, this paper focuses on the teacher and teaching by reporting a case study of a teacher and the Technology-Rich Teaching and Learning Environments (TRTLE's) within which he is a participant, these being environments where electronic technologies are readily available. Affordances and Valsiner's Zone Theory are being used "to analyse the role of the teacher in orchestrating technologyintegrated mathematics learning" (ICMI 17 Discussion Document, p. 7).
Affordances
A technology-rich teaching and learning environment affords new ways of engaging students in learning mathematics. Teachers and students equally have to learn to become attuned to the affordances of such environments. The construct, affordances, is used here following Gibson (1979) who made up the term to explain what is 57 perceived, and Scarantino (2003), whose more recent elaborations of the construct support its interpretation in an educational setting. Affordance to Gibson is a construct to help explain what motivates human behaviour (Reed, 1988). Brown, Stillman, and Herbert (2004) outline some of the different uses and meanings of the term and it potential usefulness as a framework to support analysis of TRTLE's. More specifically, affordances of a TRTLE are the offerings of the TRTLE for facilitating and impeding teaching and learning. They are potential relationships, involving interactive activity, between the teacher and/or students and the environment. In line with Gibson, the environment includes both animate and inanimate objects such as technology. To take advantage of opportunities arising, both teachers and students need to perceive affordances and act on them (Drijvers, 2003). This action may well be the rejection of a particular affordance in favour of another. This perception and subsequent enactment depends not only on "the technological tool, but [also] on the exploitation of these affordances embedded in the educational context and managed by the teacher" (Drijvers, 2003, p. 78).
Following Gibson and Scarantino, specific objects within the environment, the TRTLE, that enable an affordance to be enacted are affordance bearers. The manifestation of an affordance in a TRTLE in background circumstances [C]

involves an event [E] in which both the affordance bearer [AB] and the actor [A] are involved (e.g., a teacher [A] brings pictures of real world examples into the classroom for illustration of quadratic functions [E] on a laptop computer connected to a data projector [AB], given the relevant photographs were inserted into a PowerPoint presentation [C]). The affordance described here is communicate-ability a 'technological - communication affordance' (Kaput, 2004).

Situating the Research

The research reported here is situated within the Australian Research Council Linkage Project 2004-2006, Enhancing mathematics achievement and engagement by using technology to support real problem solving and lessons of high cognitive demand (the 'RITEMATHS' project). Within and across project classrooms the uptake and use of technology has been different. However, every teacher and student involved has the opportunity to use a selection of technology ranging from hand held graphing calculator, calculators including computer algebra systems, computers applications available on laptop or desktop computers to applets available on the internet. The broad aim of RITEMATHS is to discover the most effective ways to use technology to stimulate higher order thinking in mathematics classrooms, in the context of using real world problems. Within the project a design research methodology is being used, thus the teachers and researchers are partners working together toward this aim. This methodology values contributions of teachers equally with those of researchers, giving the practitioners a voice and further acknowledging that it is ultimately the teacher who orchestrates the learning of their students. The study reported here is part of a larger study (Brown, 2004; 2005a; 2005b) within RITEMATHS to establish what it is that enables teachers to perceive, attend to, and 58 exploit affordances of the technology salient to their teaching practice and likewise for students in their learning about function. This paper focuses on one teacher and the aim is to show how Valsiner's zones have been used to document his role in integrating electronic technologies into his teaching. The students' subsequent use of technology to support their learning is also examined. Particular emphasis is placed on determining what use students make of technology when given opportunities to choose the type of technology and the purpose they make of the technology selected.

Valsiner's Zone Theory

The theoretical underpinnings of this study also draw on zone theory from developmental psychology. Elsewhere, Valsiner's Zone Theory has been applied to the development of algebraic reasoning in primary settings (Blanton & Kaput, 2002), technology enriched teaching and learning environments (Galbraith & Goos, 2003), teacher education focusing on the learning of pre-service teachers (Blanton, Westbrook, & Carter, 2005; Evans, Galbraith, & Goos, 1993), and to preservice and beginning teachers using technology in mathematics classrooms (Goos, 2005). It is applied here to teaching and student actions in TRTLE's where the learning focus is mathematics in an attempt to elucidate the teacher's role.

Valsiner (1997) expanded on Vygotsky's Zone of Proximal Development (ZPD) and proposed two additional zones describing the structure of "the environment of the developing child" (p. 186) both between people in the environment and in terms of regulating an individual's "own thinking, feeling, and acting" (p. 188). "The zones are always temporary, constantly changing structures that organise the immediate construction of the future state out of a here-and-now setting" (p. 319). The Zone of Free Movement (ZFM) is described by Valsiner as dynamically "providing a structural framework for the child's cognitive activity and emotions … when internalized ZFMs regulate the relationships of the person with the environment" (p. 189). Valsiner (1984) links the affordance and Zone Theory frameworks.

Within the field of objects and affordances related to them in the environment of the child, the zone of free movement (ZFM) is defined for the child's activities. The ZFM structures the child's access to different areas of the environment, to different objects within these areas, and to different ways of acting upon these objects. (pp. 67-68)

In TRTLE's this includes affordances, allowable actions, and technology and other learning artefacts available to a student acting in the TRTLE at any given time. The ZFM "has a counterpart oriented toward the promotion of new skills" known as the Zone of Promoted Action (ZPA) (Valsiner, 1997, p. 192). Importantly, particularly in a secondary school setting, the ZPA is non-binding in nature. The ZPA describes "the set of activities, objects, or areas in the environment, in which the person's actions are promoted" (p. 192) by the teacher in the TRTLE as they attempt to guide their students' "actions in one, rather than another, direction" (p. 317). Valsiner argues that these two zone concepts should not be separated, rather they should be considered as a ZFM/ZPA complex working together "by which canalisation of 59 children's development is organized" (p. 195). Following Valsiner, the ZPD is "a narrowed down extension of Vygotsky's concept made subservient to the ZFM/ZPA complex" (Valsiner, 1997, p. 199). It "entails the set of possible next states of the developing system's relationship with the environment, given the current state of the ZFM/ZPA complex and the system" (p. 200). In the TRTLE the notion of ZPD helps capture those aspects of the student's learning that are in the process of being actualized.

Methodology

Capturing technology use as enacted by teachers and students is no simple task. Close scrutiny of TRTLE's where access to, and substantial use of, technology by both teachers and students is assumed, enables a comprehensive picture of what is occurring in such environments to be obtained. Increasing understanding of such situations subsequently supports others becoming more effective users of technologies in mathematics classrooms where the use of technology is expected by curriculum authorities. A qualitative approach provides such a picture. Technology is not only a focus of what is being studied, but also it is through the use of digital technologies for data collection, such as audio and video recordings of the TRTLE's, that a detailed picture of the environment is constructed and subsequently analysed. In addition, the use of a Key Recorder (available www.fi.uu.nl/wisweb/en/) enabling keystrokes of graphing calculators to be recorded and the subsequent reconstruction of actions taken and screens viewed adds to the richness of the collected data. An instrumental approach (Stake, 1995, p. 3) is being followed. The case presented here is part of a collective case study (p. 4). The larger study aims to construct a grounded theory establishing what conditions enable students and teachers to perceive and enact affordances offered by TRTLE's for the teaching and learning of functions. Evidence is presented here for one case detailing the role of the teacher in manifestations of affordances within the TRTLE, and the conditions that enabled or promoted their enactment. In this study the environment, that is, the TRTLE, includes electronic technologies and other objects, ways of acting with these objects by the teacher and students, and the teacher and students themselves.

The case being studied includes one teacher, James, a very experienced teacher of mathematics, and two of his classes, his Year 11 Mathematical Methods students (16-17 year olds) and his Year 10 Mathematics class (15-17 year olds). Students had access to both laptop computers and Texas Instruments graphing calculators (83/84 Plus) on a daily basis and this was the case in the previous year of their schooling. Use of electronic technologies is expected by the statutory authority overseeing the curriculum at both levels. Functions was one of the curriculum foci in both TRTLE's, but of a more introductory nature for the Year 10 class.

Within the larger study conducted by this researcher, data have been collected from teachers at all six project schools with more focused data collection from four of the schools, including eight teachers and nineteen TRTLE's over the first two years of the three year study. These data and subsequent analysis inform the analysis of the 60 two TRTLE's that are discussed here. Data collection included field notes, audio and video recordings, photographs, student scripts, graphing calculator key recordings, post-task student interviews, teacher interviews and reflections, and documentary materials from lesson observations.

For the Year 11 TRTLE, for example, observation included nineteen 50 minute lessons, two teacher designed task implementations (Quadratic Function Task [QF], Cubic Function Task [CF]), and a researcher designed task implementation, Platypus Task [PP]. The teacher designed tasks included students taking physical measurements involving hanging chains, curved sticks, and chromatography as shown in Figure 1. CF involved the use of only flexible sticks shaped into functions. Both tasks required students to relate coordinates of key features to particular forms of the given function type and make links between algebraic and graphical representations, refining the final unknown (dilation) parameter to identify the equation of the function being modelled. In the researcher designed task, students were presented with two sets of data representing a platypus population before and after an intervention project and asked to find a model to represent platypus numbers over time for both data sets. Students then considered questions such as, did the intervention improve the situation, what was the predicted population a decade later, and when would the population return to the initial value? The task required students to make use of functions once identified and promoted the use of a broader understanding of functions, including various manifestations of function calculateability, and function view-ability.

Figure 1. Data collection by students for Quadratic Functions Task

The intent of the diagrams in Figure 2 is to portray the differences between the ZFM/ZPA for the teacher and researcher designed tasks. Representing a zone whose boundary is fuzzy, partly indeterminate, and dynamic is clearly fraught with difficulties. The outer circle represents the ZFM, and given its later timing in the function unit, one would expect that the ZFM existing at the time of PP was greater than for the teacher designed tasks. The focus is however on the relationship between the two zones constituting the complex at the time of task implementation. Both teacher designed tasks involved repetition of the same sub-task, but for different general forms of the function. The ZPA for students when undertaking these two tasks was much smaller than their ZFM with students being told what actions they were to undertake. In the researcher designed task, the range of actions was greater and there was little repetition across sub-tasks. In addition, students had to decide what methods they should undertake to solve any sub-tasks. Hence, students had to select actions that they believed were appropriate from within their individual ZFMs. 61 The promotion by the task of student choices of actions resulted in the ZPA being significantly closer to their ZFM than was the case for the teacher designed tasks.

Analysis and Results

The identification of manifestations of affordances, affordance bearers, and the circumstances in which these occurred was facilitated by preliminary coding after the data were entered into a NUD*IST database (QSR, 1997). To identify conditions enabling and promoting enactment of affordances subsequent examination of both the coded data and re-analysis of the case record was undertaken. A thematic conceptual matrix (Miles & Huberman, 1994, p. 131) was developed to show manifestations of affordances, affordance bearers, and conditions enabling perception or promoting enactment of particular affordances of this TRTLE for student understanding of function. Table 1 shows one row of the matrix, one manifestation of the particular affordance: Function View-ability, that is, how particular views of a function can be observed. For illustrative purposes only the manifestation resulting from set viewing window to given values is reported. Other manifestations of this affordance included those resulting from using current window settings, editing viewing window to include key features or get a better/global view, editing viewing window to allow key feature to be clearly visible, using TABLE/TRACE to provide information regarding appropriate viewing window, and using context to select appropriate viewing domain, viewing range or an endpoint of either of these.

Table 1.

Manifestations of the affordance: Function View-ability (Affordances of TRTLE's allowing particular views of functions to be observed)

Manifestations of the Affordance	Affordance Bearers	Conditions Enabling Perception	Conditions Promoting Enactment
Setting Viewing Window to given values	S108 sets viewing window of graph of WINDOW	S108 adjusts his WINDOW Settings to those given. [Obs 16Mar05 36]	Lesson Element, Window Settings given
Slide 15: … WINDOW. Set Xmin = -2, Xmax = +2 and Ymin = -9 and Ymax = +9. Quadratic function test	(b) Sketch a graph [of a function given for T in terms of S] between Smin = 0 and Smax =360. ZFM ZPA ZFM ZPA 62	y = (x - 1)(x + 2)(x - 4) to -3 < x < 6, -12 < y < 12. [Obs 16Mar05 18]	GRAPH. [Obs 16Mar 44] [Quadratic function test]

The first column in the matrix includes summary phrases describing the

manifestation of the affordance and representative illustrative actions. The second column indicates the affordance bearers utilised in the enactment of the affordance, the WINDOW settings that allow direct manipulation of the viewing window. The final two columns describe the conditions existing either during or prior to the manifestation of the affordance being considered. The conditions are those either enabling perception (column 3) or promoting enactment (column 4) of a particular affordance. A condition enabling perception is a circumstance where a teacher or student action allows a particular affordance to be perceived. Conditions enabling perception include those where a learning experience is provided during which the student experiences a particular affordance, as is shown in Table 1 where students are expected to follow the instruction and experience the particular affordance thus facilitating future enactment. A condition promoting enactment is a circumstance where a teacher or student action promotes enactment of a particular affordance. In this case it is through the wording of the task that the teacher promotes the direct setting of the viewing domain of the graphing calculator.

To consider data at a more conceptual level, content analytical summary tables were constructed. Table 2 shows an example for the affordance function view-ability. The final column of Table 2 is indicative of the ZPA. The teacher's organisation of the students' ZPA canalises (Valsiner, 1997) the students' current and future thinking about the concepts and methods being taught.

For, example, James observed that determining settings for the graphing calculator allowing particular views of a function to be observed is no simple task, echoing earlier findings by Brown (2003) who found diverse initial actions and subsequent views as teachers began looking for a global view of a 'difficult' function. Many of the resulting views would be potentially problematic for students. James observed a similar difficulty with his students.

James: Interestingly, a lot of kids find the notion of setting a WINDOW to a particular graph [difficult], especially if you are doing real, in inverted commas, applications where you do some linear modelling and you might have so many books sold for so many dollars which ... is a problem that kids can relate to. And inevitably [you] see them with a graph with the four quadrants. And when you say to them, 'Now is it realistic to have a negative number of books?' 'No', or 'A negative amount of dollars?' and, 'No'. 'Well then, are those values realistic to have on your graph?' 'No'. 'Well, you would have more efficient use of your graph if you deleted those bits and use your WINDOWs'. 'But I don't know how to use WINDOWs, I don't understand'. [Interview 21Feb 05]

Table 2 6 3

Affordances of TRTLE's allowing particular views of functions to be observed

Manifestations of the Affordance	Conditions Enabling Perception	Conditions Promoting Enactment
Using current settings Serendipity Task - find graph of data/function		
Task - identify model of physical curve		
Setting viewing window to given values		
Lesson Element, Window Settings given		
Quadratic function test, sketch function over a specified domain		
Edit Viewing Window to include key feature, get a better/global view		
Lesson Element focused on setting of a 'good' window		
Functions task requiring exploration of graphs of families of functions		
Teacher Promotion - Can you Show me a bit more of your graph?		
Contextualised task requiring a suitable WINDOW		
Functions task requiring students to explore graphs of families of functions		
Editing viewing window to allow key features to be clearly visible		
Teacher scaffolding - understanding of the effect of c		
Lesson element, adjusting WINDOW Settings to view key features.		
Contextualised task requiring a suitable WINDOW		
Functions task requiring exploration of graphs of families of functions		
Using TABLE/TRACE to provide information regarding appropriate Viewing Window		
Did Not Observe Lesson element- find global view of a function		
Using context to select appropriate viewing domain, viewing range or an endpoint of one of these		
Did Not Observe Lesson element, context (biggest box) used to determine WINDOW Settings		
Contextualised task requiring a suitable WINDOW		
Functions task requiring students to explore graphs of families of functions		
Teacher belief in importance		

Thus he sees function view-ability as an essential affordance for his students to enact and actively enables its perception and promotes its various manifestations. On one occasion James was observed promoting use of context (finding the biggest box volume) to select an appropriate viewing domain.

James: When you do those cut-outs, of x, what is the biggest value of x that you can cut-out? If you have a look at your picture, what did you put for your diagram? If you started to make those corner cut-outs bigger, what would be the biggest cut-out that you could make?

Cam: Five.

James: Five. That is right. So for your WINDOW, you would set Xmin to be zero. And Xmax to [pause]?

Cam: So that, is that [wrong]?

James: No, you are right up to there.

Cam: So we didn't have to do that much?

James: But, beyond here [x = 5] it is not a realistic part of the problem. Because the biggest value of x you could ever cut out is 5. Okay?

Cam: Yeah.

James: So you would set your WINDOW to? [Obs30Mar05TB5 177-187]

Here James has deliberately organised the learning experience so that this particular manifestation of the affordance is promoted. Thus through the ZPA he hopes to canalise the students' future cognitive actions as they internalise the conditions he has orchestrated for their learning. In promoting use of the context to support the determination of a suitable viewing window for the function and the subsequent 64 successful problem solution, James is also hoping that in future situations his students will be able to independently perceive and enact this affordance where appropriate.

Concluding Remarks

Valsiner's zones together with Gibson's affordances have provided a suitable vehicle for elucidating the role of the teacher in technology-rich teaching and learning environments. The teacher makes use of the ZPA to promote particular student actions involving technology in an effort to give them experience of particular affordances of the TRTLE and to increase the future ZFM of the students.

A model for teaching mathematics via problem-solving supported by technology

Henry Buitrago Roa, Universidad Antonio Nariño, Bogotá D.C
hbuitrago@yahoo.com

A model for teaching mathematics is developed based on problem-solving and the use of technology in education. The research model stems from a ten year-old intensive Calculus project containing workshops designed over Computer Algebra Systems (CAS). Emphasis is placed on distance learning attributes such as creativity, critical thinking, autonomous learning, group work and the capacity to evaluate results, study errors, and contextualize the study area. The pedagogical model is centered on the student's talents for deep learning via the solution of problems with real applications that require understanding, creativity, the use of technological tools, and the development of an appropriate language for documentation, communication and socialization. Technological tools for education include systems that allow the visualization of concepts, simulation and experimentation, operation strength and self-evaluation environments.

Teaching centered around student learning

The model studies the elements of teaching based on the student's ability to learn under the premise that the student assumes responsibility for the learning process. Accordingly the student must be responsible and motivated to learn and furthermore be willing to perform group work, utilize technology and appreciate self-evaluating environments.

A dynamic distance learning environment is generated by first considering what pedagogical activities must be developed. This is the study of the student's

interaction with three learning instances, as shown in Figure 1 below.
Working alone: The student must be able to work alone and develop autonomously the necessary cognitive abilities to learn and apply the acquired knowledge to practical tasks and open problems.
For this aspect tools must be provided for effective self-evaluation and result verification. 67
Figure 1. Relational model
Interaction with the teacher: The student must learn to rely on the teacher's orientation and professional knowledge.
For this the teacher must guide the student in a personal fashion by evaluating the progress and providing the necessary indications, materials and support.
Collaborative work: The student must learn to appreciate groupwork as a strategy for the construction of knowledge and problem-solving. Interaction with other students provides another way to answer arising questions while interacting in a workplace environment.
For this collaborative tools must be developed as well as verification and self-evaluating environments.
The study of the relational model leads to the choice of appropriate learning theories and pedagogical strategies to support the teaching model. These are shown around the relational model in Figure 2 and figure 3.
Finally, the model must include stages of evaluation where the instructor may evaluate the implementation of the strategies and their effect on student learning to further vary the activities accordingly. 68
Figure 2. Pedagogical model
Figure 3. Stages of the strategy
Structural design of the laboratory workshop
Once the pedagogical components are established a laboratory workshop is designed. The model relies on certain talents from the interested student some of which are:
Discipline: Students must be able to maintain their own learning rhythm without the physical guidance of a teacher.
Responsibility: Students must acquire a sense of responsibility of being the principal element of the learning process. They must understand the objectives of the learning program and take them as their own. 69
Scheduling: the effective management of time is essential to reach the objectives of every course.
Curiosity, research and analysis: Students must learn to obtain and discern what is the pertinent information needed at any particular instance.
The relationship between the didactic model and the structure of the lab as a distance learning element is presented in Figure 4.
Figure 4. Learning components of the workshop.

Components of the workshop:
Problem-solving: The solution of theoretical and applied problems is the pedagogical basic tool of learning assumed throughout the work. Problems related to the area of knowledge and to predetermined standards are chosen. Emphasis is placed on both theoretical concepts and solution methods and techniques.
Individual work and hand calculations: Students must internalize the structure and the meaning of the problems by manipulating symbols with pencil and paper and performing the appropriate operations and calculations. Designing the strategy of the solution autonomously is very important. Afterward, the student will be allowed to verify results with technology.
Group work: Discussion is the basis of collaborative problem-solving. It allows for the presentation of different points of view and strategies of solution present in different levels of understanding. Above all it permits the creation of a language and of an abbreviated system of symbols the pertains to communication.
Research: Comprises various talents such as search techniques, information confrontation and discernment of core elements, translation skills and use of 70 technology, among others. For this probing activities are developed for the enhancement of knowledge and problem-solving.
Technological components with Maple:
The technological platform used was the symbolic mathematical software Maple V. Activities were presented in a standardized format. These activities will be explained further:
Guided exercises: A problem is presented to the student with all phases of solution explicitly designed in Maple. The student must actively perform the operations and learn the method, algorithms, arguments and styles as well as the Maple commands. The guided problems offer guided examples of methods of proof. The student learns to do and structure mathematics while solving itemized parts of a bigger complete solution of a complex problem. Real problems are presented and their solutions are explored step by step by using Maple commands. The student must analyze the arguments and answer both conceptual and operational questions at each step. Other problems are proposed to check the apprehension of procedure. The technological platform allows the student to perform and check difficult operations.
Interactive exercises: Problems presented where the student must provide the answer by reasoning, hand calculations or use of technology. These may include steps towards a solution or simply a specific answer to a problem. Feedback in provided for self-evaluation and knowledge enhancement. Feedback includes generally the complete solution to the problem sometimes with other examples. Feedback for errors may include partial solution to the problem and possibly examples and counterexamples.
The interactive problems allow the student to appreciate and solidify what has been learned by offering an opportunity of self-evaluation. The tools permit the construction of solutions whose validity can be checked without the presence of the teacher. The problem is called interactive because the student gets feedback even if the solution is wrong and hints are given towards the real solution or reasons are given for the mistakes. The problem can be solved any way and only solutions or steps of solutions are checked. This was done by programming over the software program Maple is built on. Programming allows for the prediction of errors of many types and the presentation of corresponding correct solutions to operational problems, procedure problems or conceptual problems.
Interactive solutions to problems: Explicit versions of the previous type of exercise where solutions are framed against arguments of solution.
Use of Internet: Mostly utilized in a bibliographical or communications context. For example, workshops can be downloaded and worked on collectively through chats or message boards.
Feedback and self-evaluation: Classical feedback provided by an instructor is itemized and studied via explicit indicators of the actual relationship between the objectives wanted through problem-solving and the activities presented in the 71 workshop. Some of the feedback is classical via examinations, papers or simple instructor observations. Yet the core idea is to provide the tools necessary for selfexamination.
Finally, the feedback and evaluations are studied so the material can be restructured and emphasis can be placed on what the student needs to reorganize and enhance knowledge. The teacher is an important player in this part of the process and must be able to guide new understanding and abilities to the effective crystallization of basic ideas and knowledge in the area.
The evaluation phase
Evaluation allows for consistency and quality of the learning process and provides the teacher with the appropriate feedback on the learning of each individual student. In Figure 5 evaluation processes and components are established which will allow to design and efficient pedagogical model for self-learning.
Standards are taken as the bases of the evaluation process. These are defined as follows:
Standards are clear and public criteria that provide knowledge of what students should learn and apply in solving problems of their environment and constitute a reference point of what should be known and applied in a particular area of knowledge and a specific level of proficiency. These may depend on social, cultural and political needs of a community. Especially created in order to change the emphasis on concepts in education, mathematical and geometrical standards are included in the laboratory workshop design.
Figure 5. Conceptual structures of evaluation 72
Indicators: Are characteristics or components of the standards that allow for the determination of the level of proficiency of the student in that particular task associated with the standard. The breakup of abilities allows for the evaluation of strength of knowledge and of weakness and errors. The classification of levels of abilities permits the evaluator to understand and measure the attainment of objectives in a specific fashion.
Rubric definition: A mathematical rubric is the specific talent or ability that must be attained by the student in order for learning or acquiring knowledge in an area of mathematics and a certain level of proficiency.
Rubric evaluations study certain aspects or indicators and assign well-determined levels in such a way that:
Two evaluators must reach the same results of evaluation, in this work this should include one evaluator being the student.
The aspects are well-defined and do not allow for the consideration of irrelevant factors.
The result must correctly and pertinently evaluate the status of the student with respect to the standards.
Evaluation: It is important to utilize both formative and summative evaluation. On the one hand, it is important to determine not only the tools that allow for the learning of a particular subject area but those that allow for the correct feedback. On the other hand, evaluation of the problem solving abilities and strategies must be included with that of the conceptual understanding and the operational proficiency in the production of a correct solution. The study of the abilities as a whole: the correct utilization of concepts learned, the abilities of creating problem solving strategies, and the abilities to assess the validity of a solution change the emphasis of a solution from that based on simple procedural and operational proficiency to one that allows the use of technology correctly in every day life. Diagnostic evaluation must be utilized for the correct planning of the activities of the course and can be applied at various stages. Well-chosen rubrics allow the ERRORS to be determined diagnostically also. Therefore every evaluation can be used as feedback for the present and future design of the course.
To conclude, the study focuses on learning via problem solving intending to use technology as a support for self-learning in providing self-evaluation tools such as: well-defined and easy to determine rubrics consisting of specific indicators of abilities tied to each problem and subject area and which are presented at an appropriate time and in a pertinent setting of a workshop; tools for communication, development of language, and research; operation, procedure and solution verification; and through these tools the personalized guidance of the teacher.

Evolving technologies integrated into undergraduate mathematics education
Chantal Buteauó and Eric Muller
7
Department of Mathematics, Brock University, CANADA
[cbuteau,emuller]@brocku.ca
This submission focuses on the design of learning environments and curricula and describes a twenty-five year evolution of integrating digital technology
8
in the
teaching and learning of mathematics at Brock University. It provides information on actual uses of technology in university level programs for students, majoring in mathematics, or taking mathematics for their major in another discipline, or aiming to be teachers. A brief history explains the ever increasing use of established mathematics and statistics computer systems in courses and programs until the Department had gained enough experience with technologies to institute a new core mathematics program MICA (Mathematics Integrating Computers and Applications). Student interest in the MICA program is demonstrated by a threefold increase in mathematics majors. The submission pays special attention to the role of the teacher. First, a new faculty member reflects on the teaching adjustments she made to teach in a department that has built an array of technologies into its courses. Second, it explains how technology, in a first year core mathematics course, helps to shift the mediator responsibilities from the teacher to the student. Of particular significance is the students' enthusiasm and willingness to work beyond all expectations on their main project in which they construct Learning Objects.
Introduction
There are many publications (for examples Kallaher (1), and Baglivo (2)) that describe the integration of established Computer Mathematical Systems (for example Maple) and Computer Data and Statistical Analysis Systems (for example SAS (4)) into mathematics and statistics education at the university level. Because of this wealth of publications and because the Department of Mathematics at Brock University had, by the mid 1990s, integrated such systems in the majority of its courses, we will focus our discussion on the Department's next evolution. We describe how the Department integrated communication technology (e.g. Internet)

and environment building technology (e.g. VB.NET (3)), into an innovative core mathematics program called MICA (Mathematics Integrating Computers and Applications). For us it is evident that this step was only possible because the majority of faculty had substantial teaching experience in courses that integrate

6
Chantal Buteau joined the department in 2004 as Assistant Professor. She was hired to be involved in the MICA courses and future mathematics teachers.
7
Eric Muller is Professor Emeritus and has spearheaded the integration of technology into mathematics programs at Brock University. He was one of the participants of the first ICMI Study on Technology.
8
In what follows the term digital will be understood whenever we mention technology. 75 technology in a significant way. The MICA courses provide working examples of mathematics learning environments that integrate technologies. Furthermore, within these courses, students learn how to construct technological environments to explore mathematics. Future teachers have an important place in these courses as they learn to develop technological learning environments that focus on the didactical development of mathematical concepts.
This submission is made by two practitioners who, in the words of the Discussion document, 'can make solid practical and scientific contributions to ICMI Study 17'. The reader will find; in Section 1 a brief 25 year history of the integration of technologies in mathematics programs at Brock; in Section 2, a discussion of one role that evolving technologies can play in mathematics education; in Section 3, a summary of important aspects of the MICA courses; in Section 4, a description of some didactical considerations that were introduced in MICA specifically for future mathematics teachers, and; in Section 5, a reflection by Buteau on the challenges and adjustments that were required in her teaching in order for her students to achieve the learning expectations of MICA.
Section 1: A brief history of the evolving integration of technologies
In 1985, at the time of the first ICMI Study, the Department of Mathematics was making innovative use of technology in some of its courses. In large enrolment service courses, some faculty (3) were generating individualized sets of problems for each student and Muller (4) was assessing an experimental Calculus course with over 100 students who worked with Maple in a laboratory setting. In this presentation we reflect on the Department's subsequent sustained development of the use of evolving technologies in its undergraduate mathematics programs. Although one can point to certain years when major changes were implemented, the reality is that evolution and innovation in university mathematics education is a slow process. One reason for this is that few mathematics doctoral programs require teamwork or provide opportunities for reflection on the teaching and learning of mathematics. Yet these experiences are necessary for faculty in a department to work as a team and for its faculty to critically redesign a mathematics program. There is much evidence that technological innovations that are instituted in a course by a single faculty member rarely survive when the course is taken over by another colleague. Therefore, for changes to permeate beyond a set of courses, a consensus needs to be built with the majority of faculty in a mathematics department. The changes that occurred at Brock required many hours of discussions between colleagues and demanded that they approach the subject with open minds. In retrospect, a major argument for the use of technology and for a complete review of the mathematics programs was generated from faculty experiences in Maple laboratories. There they observed student activity and involvement. In general they found that students in laboratories were much more engaged than in the traditional tutorials and that they were also asking more significant mathematical questions.
By 1995 a majority of students in all mathematics programs were using technology in a significant way. In general students were working with Computer 76 Mathematical Systems or Statistical Analysis Systems. By this time, faculty who were keeping up with the evolution of technologies, especially in the areas of communication and computer environment building, were convinced that learner experiences in mathematics could be further enriched and that these experiences could be structured so as to lead students towards more independence in learning. Over the next five years an innovative core program in mathematics was developed and approved. The philosophy and aims of this program, MICA are described in the Brock Teaching journal (5). Student interest in the MICA program is demonstrated by an increase in mathematics majors from 52 in the first year of the program, 2001, to 140 in 2005. In the following sections we explore how the faculty worked to meet MICA guiding principles, including 1) encouraging student creativity and intellectual independence, and 2) developing mathematical concepts hand in hand with computers and applications.
Section 2: Evolving roles of technology in mathematics education at Brock
In this discussion we describe the evolution of the use of technologies in Brock's mathematics programs. In order to facilitate our points of view we shall use the following definitions :
• Digital information – data, algorithms, responses, etc. that are available through technologies;
• Knowledge – the acquaintance of information obtained through experience or instruction;
• Understanding – the power or ability to acquire and interpret knowledge.
A principal aim of integrating technologies into mathematics programs at Brock is to teach students how to transform information into understanding. Initially the teaching and learning process matched the one that the Department used before the birth of digital information, namely
Figure 1
This model also works well with mathematical technologies such as Maple, Mathematica, Minitab, SAS, etc... These are more than repositories of information, they are intelligent
9
, in the sense they are capable of generating new information. A challenge for undergraduate mathematics education continues to be that such systems can, for the knowledgeable user, provide solutions to most well structured problems that arise in the first three years of a traditional university mathematics program. The integration of these technologies into the Brock mathematics programs changes the

9
In this text we use the term 'intelligent' to distinguish from technologies that are passive, i.e., strictly provide data.

first box in Figure 1 and adds digital information to traditional forms of information (texts, lecture notes, etc.). This addition provides many ways in which to enrich the base of student knowledge, for example: faculty can spend more time on the development of mathematical concepts because they and the students can rely on the technology to provide technical information; alternative representations are often easily generated; students can work on problems and applications that are not bound by traditional course information, and; learners can explore conceptually advanced mathematical concepts which are normally deferred until all the analytical skills have been addressed. In summary, by the mid 1990s, information technologies were well established in a majority of mathematics Brock courses.
By that time some faculty became aware of the great potential of communication environment building technologies. Their vision was that a program would be developed to integrate these and to motivate its students to take on, more and more, the responsibility of mediator in their own mathematics learning (second and fourth box in Figure 1). Ralph (7) summarizes the situation as follows: "The central challenge of any mathematics program is to create an environment in which students become internally directed and personally invested in moving themselves along the long road to mastery. The problem with traditional undergraduate mathematics programs in this regard is that if students try to take the initiative in creating and investigating problems and applications of their own devising, they quickly come up against difficulties that they cannot handle with purely analytical tools. For this reason, traditional programs must be very tightly choreographed around the problems that can be solved by hand and over the years this approach can become "canned" and regimented. Technology can offset the rigidity of a traditional mathematics program by providing students with access to an endless supply of problems and applications that can be investigated both computationally and analytically." Therefore the aim of the proposed MICA program was to change the model in Figure 1 to the following:
Figure 2
In many ways this parallels the development that one would hope for in a mathematics program that has a core of modelling courses. However students in the MICA program build on a knowledge base that is more extensive as the information they have access to includes both passive and intelligent digital sources.
How does one educate a student to become her own mediator and how is this done as early as possible in their university mathematics experience? At Brock students take, in their first semester, a course in Calculus and one in Linear Algebra. Both of these courses include extensive experiences with Maple and with Journey

Through Calculus (8). A brief discussion on the first MICA course that students take in the second semester and upper year MICA courses will highlight the approach that the Department has taken to encourage creativity and intellectual independence as the students develop mediator skills.
Section 3: MICA courses – directions and the integration of technologies
In the first part of the MICA I course, students are exposed to a rich context for conjectures: prime numbers and Collatz conjecture. During lectures
10
, students work in small groups of 3 or 4 and raise original questions and conjectures about the topics. These are written on the board and a discussion on their testability follows. For their first assignment, each student designs a program (vb.NET) in which they explore a conjecture of their own. In the second part of the course, students are introduced to modular arithmetic leading to the theory behind RSA encryption. The speed of the theoretical presentation is determined by the students as they lead the way by making observations and conjectures from explorations, computations and theorems. Of course the lecturer guides students but importantly he/she reacts to class questions/ observations/ conjectures that are constantly encouraged and raised. Students then implement the complete algorithm of RSA encryption. The last topic in the course is discrete and continuous dynamical systems. Each student designs a program that outputs numerical values and graphs the cobweb diagrams of the logistic function. This topic concludes with an exploration, in the lab, of the system stability which students simultaneously test and visualize the theory with their own program.
A major part of MICA I is the original final project that encompasses a computer program and a written report. Each student selects a mathematical topic in which they are particularly interested and intrigued. Mathematics students focus on a mathematical investigation. Future teachers design a learning program about an elementary or high school mathematical concept. Students from another core discipline investigate a mathematical application to their own discipline. In this project students essentially construct and implement a Learning Object -- an instructional component that focuses on one or two mathematical concepts and that is designed for another person. These objects are interactive, engaging, easy to use, and are designed to mediate the user from information to understanding. In the MICA program Learning Objects may include exploration of a mathematical conjecture or of a mathematical application. The main goal in MICA I course is to bring students to experience becoming the mediator through the design of original Learning Objects.
The first experimental project on Learning Objects at Brock was undertaken in the summer of 2002. It involved a team composed of mathematics professors, practicing mathematics teachers, future teachers, and mathematics and computer

10
Presently the course runs with two hours of lectures and two hours of labs per week. The experience of the Department is that this type of course works best with a maximum enrolment of 35 students in each section. 79
science students. Examples of finished products can be viewed on the departmental website (9). Other examples of Learning Objects developed by students in the MICA courses are also available (10).
It is our experience that the construction of a Learning Object not only builds on the designer's mathematical and didactical knowledge but it reveals these understandings in a visual and interactive way.
In the MICA II full year course the focus is on mathematical modelling of diverse types including, for example, discrete dynamical systems, stochastic models, Markov chains, empirical models, and queuing models. These topics, covered in the MICA way, are all implemented (mainly in VB.NET and Maple) by students and are concluded with simulation and conjectures. For example, students design (VB.NET) a Learning Object to explore the distribution histograms and graphs of random variables. This is done before the students see the Central Limit Theorem in their Statistics course. Therefore students are guided through different computations, and are asked to develop conjectures based on their observations. Not all students are able to conjecture the theorem on their own, but after a full class discussion about plausible conjectures they are able to identify examples of the theorem in their results. When students finally see the theorem in their statistics class, it is no longer a theorem outside them, but indeed, it is somehow internalised since they personalized it within the design and use of their Learning Object. MICA II students work on two main original projects for which they personally decide on a topic. Their projects are

significantly more sophisticated than in MICA I, since they have a better mastery of the technology and importantly, they have become more confident in their role of mediator.
The MICA III full year course is focussed on partial differential equation modelling including for example heat flow and wave propagation. Guided assignments and projects (mainly in Maple and C++) each include an original part in which students have to fully use their role of mediator. For example, students were assigned to extend and improve some MAPLETs that animate solutions of particular PDEs. Two students presented their remarkable MAPLET extension at the Maple Summer Workshop in Summer 2004. With mastery of technology and with their ability to mediate their own learning, undergraduate students can contribute to the development of new mathematics.
Section 4: Technologies and the education of future mathematics teachers
Teacher Education in Ontario follows a consecutive model. This means that individuals interested in teaching must first graduate with a university degree and then apply to a Faculty of Education for a one-year program. After completing this additional year they receive a teaching certificate. For future elementary and middle school teachers and for future mathematics teachers at the secondary level, the consecutive model clearly places important responsibilities on departments of mathematics. How can these future teachers be best educated in mathematics to meet their specific and desired goals? Unfortunately many universities do little more than to pay lip service to this population of students. Within the Brock community, Muller 80 has been proactive in negotiations across different Faculties in order to develop and establish concurrent education programs. In these programs, students follow integrated studies between a Faculty that offers a teachable subject
11
and the Faculty
of Education. For those students who enter university with a desire to become teachers, concurrent programs provide opportunities to reflect on didactical issues starting from their first undergraduate year.
The Mathematics Department at Brock has taken its responsibilities for future teacher education very seriously and has developed programs or courses for all levels of school teaching. Appropriate technologies such as Geometer's SketchPad and other Ministry of Education school licensed programs are used in appropriate courses. Concurrent education students who aim to specialize in mathematics and to be certified for teaching at the middle and high school levels, take a majority of the MICA courses which play a fundamental role for them. They provide a unique opportunity for these future teachers to reflect on their own development as a mediator. Furthermore in their MICA projects they construct Learning Objects which have strong didactical components.
Section 5: Reflections by a new faculty, Chantal Buteau
I am currently in my second year as faculty in the Department and I'm coming from a rather traditional mathematics education. I knew that I was joining a department that makes extensive use of technologies in its courses. Therefore I had mixed feelings, anxiety, insecurity and excitement. In service courses (Calculus and Statistics for large classes) my main concern was and is to focus on concepts rather than on computational techniques that can easily be handled using technology. I admit that it is a constant battle for me. When I was taught these concepts there was equal emphasis on concepts and computation abilities. Diverse and rich discussions with colleagues help me to find a good balance. Also, my class preparations keep changing as I rethink what should be first discovered by students in a guided assignment using technology rather than directly presented to them. My conception of assignments and exams also had to be changed. As a new lecturer, it has been a genuine and enriching challenge not to copy the teaching model I had experienced. In the MICA I course I faced teaching an innovative course in which the how to present the theory was more important than the what. On top of this, the how was supported by a programming environment. Fortunately, during my PhD, I had experienced some experimental mathematical investigations supported by technology. This was my beacon together with uncountably many discussions with my colleague Bill Ralph who has been teaching this course since the MICA program was first launched. It did take me some time to understand my role in the course. How can I best assist the students to become the mediator of their own mathematical development? What mediation should or should not be provided at any particular time? I had to adjust to the fact that a class can sometimes take a direction different
11
Teachable subjects are specified by the Ministry of Education as being appropriate major disciplines for future teachers 81
from what I had planed. This is not a secure position for a fairly new lecturer, as I had to build on class interactivity and not reject it. I challenge students to explore mathematics on a personal level. Students challenge my traditional education of mathematics teaching.
The astonishing pride of MICA I students for their final projects confirmed that the department is for me a great environment for learning how to teach mathematics in the XXI century.
Conclusions
Technologies are evolving so rapidly that there are many avenues that mathematics departments can take to integrate them into their mathematics programs. This submission describes one route that the Department at Brock has taken to structure technological environments to help students engage in abstract mathematics. We have found that the approaches, activities, and experiences in the MICA courses are able to harness the students' motivations thereby empowering them to become their own mediators in the development of their mathematical knowledge and understanding.

Varying pedagogical media: How interaction with spreadsheets might mediate learning trajectories
Nigel Calder
University of Waikato, New Zealand
NCALDER@waikato.ac.nz
This paper is concerned with the use of spreadsheets within mathematical investigational tasks. Considering the learning of both children and pre-service teaching students, it examines how mathematical phenomena can be seen as a function of the pedagogical media through which they are encountered. In particular, it shows how pedagogical apparatus influence patterns of social interaction, and how this interaction shapes the mathematical ideas being encountered. Notions of conjecture are considered, and the trajectories learners negotiate as they settle on subgoals, reflect on output, and further develop their emerging theory. The particular faculty of the spreadsheet setting is examined with regard to the facilitation of mathematical thinking. Employing an interpretive perspective, a key focus is on how alternative pedagogical media and associated discursive networks influence the way that students form and test informal conjectures.
Introduction
The pace of development in digital technologies is rapid, with an understandable lag between innovation and well documented classroom-based, educational research. There is benefit from examining more easily accessed software over extended periods, through a multitude of perspectives, so as to inform educational communities in different ways. It allows, for instance, the potential to move beyond the influence of a particular software package on a particular mathematical content area, to more generic pedagogical issues. Compared to some digital tools, spreadsheet software is relatively accessible and could therefore be considered to offer a more equitable digital environment, in both local and global situations. The study described was part of an ongoing research programme exploring how spreadsheets might function as pedagogical media, as compared with pencil and paper methods. In being used as a tool for investigation, how might spreadsheets colour the learning experience and, in particular, how might this influence learner's perceptions and understandings of mathematical phenomena? One aspect of this programme, to be pursued here, was to identify the ways in which participants approached mathematical investigations, from how they negotiated the requirements of the tasks, to how they produced their conjectures and generalisations. The paper then is positioned in the theme of learning and assessment, and has as its most prevalent approaches the contribution to learning mathematics and theoretical frameworks.
Literature Review 83
Greater emphasis on inquiry methods, activates interplay between the task of the individual learner, and the way in which that is understood as an engagement within a more social frame. While the introduction of a social frame is inevitable, this will vary according to how the activity is constructed and the perceived environment within which this takes place. The mathematical activity is inseparable from the pedagogical device as it were, derived as it is from a particular understanding of social organisation, and hence the mathematical ideas developed will inevitably be a function of this device (Brown, 1996). A hermeneutic, phenomenological perspective is concerned with interpretation where the subject views the world by means of a variety of cultural forms through which understandings are filtered. In this context, particular pedagogical media can be seen as cultural forms and different forms model different ways of knowing (Povey, 1997). Ricoeur's (1983) notion of the hermeneutic circle emphasises the interplay between understanding and the narrative framework within which this understanding is expressed discursively, and which helps to fix it. While these 'fixes' are temporary, they underpin the understanding that follows and the way this comes to be expressed. The internalisation is manifest in what they say and what they do. This enables the contention that examining the participants' social interaction and output, will give insight into the ways they internalize mathematical understandings. This can be reconciled with other theoretical perspectives (Mariotti, 2002) that position language, being cultural artifacts, as semiotic mediators.
The prevalence of digital media generally has begun to challenge the map of mathematical ideas encountered in schools. Access to many key elements of school mathematics has been altered, as different technologies offer new ways in which certain constructs are created and understood. Studies involving the dynamic geometry software, Cabri-geometre, (Laborde, 1999, Mariotti, 2002) assert that conceptualization of mathematical phenomena, will be different when engaged through the particular software lens. Meanwhile spreadsheets have been found to offer an accessible medium for young children tackling numerical methods. Researchers have highlighted their suitability for an investigative approach as students learn to pose problems and to create explanations of their own (Ploger, Klinger and Rooney, 1997), and simultaneously link symbolic and visual forms (Baker and Beisel, 2001). Other characteristics, including their interactive nature (Beare, 1993), and the capacity to give immediate feedback (Calder, 2004) appear to give the learner the opportunity to develop as a risk taker; to make conjectures, and immediately test them in an informal, non-threatening, environment. This permits the learner opportunity to reshape their conceptual understanding in a fresh manner. The capacity to provide instantaneous feedback also allows for conjectures to be immediately tested and perhaps refuted. Lin (2005) claims that refuting is an effective learning strategy for generating conjectures. Mathematical conjectures often have speculative beginnings and as Dreyfus (1999) implies, have elements of logical 84 guesswork. Other researchers often consider them as generalised statements, containing essences distilled from a number of specific examples (Bergqvist, 2005). In their embryonic form they emerge as opinions, mathematical statements, generalisations, or positions. These can then be challenged or confirmed with explanation, leading to mathematical thinking. Suggesting counter-examples, or exposition of how two mathematical explanations are similar, indicate a more robust form of examination of the conjecture (Manouchehri, 2004). The learner's perturbance, when gaining immediate access to counter-intuitive outcomes to inputted data, and the subsequent influence of that tension on the investigative process, also influence the investigative trajectory

Approach
The paper considers two settings where investigation takes place in a spreadsheet environment. The first situation located groups of three, first year, primary, preservice students in a typical classroom setting while groups, from the same class, worked in an ICT laboratory, doing the same investigation using spreadsheets. Their discussions were recorded and transcribed, each group was interviewed after they had completed their investigation, and their written recordings were collected. This data, together with informal observation and discussions, formed the initial basis for the research. Five weeks after the first data was gathered, a similar approach for data collection was used, with the students using the same medium, but a different investigation. The second situation involved ten-year-old students, attending five primary schools, drawn from a wide range of socio-economic areas. There were four students from each school, eleven boys and nine girls, of mixed ethnicity. The data was produced in the same way as the first situation. The transcripts from both were then systematically analysed for patterns in the dialogue, within and between the settings.
Results and Analysis

Two aspects were considered in the formation and testing of conjectures. Firstly, the data is examined for differences the pedagogical media may have evoked, with particular regard to the pre-service teaching students. An episode with the ten-yearold learners is then analysed with regard to the notion of subgoals
Comparison of two pedagogical media
The dialogue in each situation demonstrated a contrast in the initial approach to engaging in the mathematics. In the classroom situation it began with a group member initiating the negotiation of the meaning and requirements of the task with a single discrete numerical example. For example, group one.
Kari: Lets try each number one at a time. One times 101 is 101. 85
Group two likewise used this to begin the process of solving, but also to help determine the nature of the task; what it was asking them. For example:
Sarah: So if we had twenty three times a hundred you would have twenty three hundred...Lets say we do twenty three times a hundred and one, we would get twenty three hundred plus twenty three ones
As they made further sense of what the problem was about, they began to predict, verify and reflect in a discrete numerical manner.
Rachel: We went through one at a time and solved them. We solved them on paper and we solved them with a calculator.
In contrast, those groups working in the spreadsheet setting used the spreadsheet to get a broad picture; they utilised the formulae and copy down functions to create a numerical table that could then be examined for any pattern. They used more algebraic language, while the pencil and paper groups had more numerical reference.
For example:
Kylie: I haven't predicted. I was just going to put in A1 times 101 and drag it down.
Josie: So we're investigating the pattern of 1 to 16 times 101
This appears a more direct path to the patterning approach, and these groups quickly recognised a pattern, and explored further based on visual aspects. It also introduced a difference in terms of the technical language utilised. "Drag it down" is functioning language rather than mathematical, but the inference is clearly that there is a pattern, which might possibly lead to a generalisation; and that the spreadsheet by nature will enable users to quickly access that pattern. Most significantly, the social interactions appear to shape the analysis of the patterns in distinct ways. Given that the path to, and manifestation of, the patterns differs, the dialogue indicates a different approach once the patterns are viewed. Those using the spreadsheet used a more visual approach. They were observing and discussing visual aspects eg the situation of digits or zeros. For example:
Jo: With two digits you just double the number. You take the zero out.
Those using pencil and paper were more concerned with the operation aspects that generated the patterns. For example:
Sarah: Basically, if you times your number by a hundred, and then by one, you would add them together, and get your answer.
To generalise a pattern in terms of the sequence of digits is significantly different to generalising in terms of an operation. In this aspect, the different settings have certainly filtered the dialogue and approach to forming conjectures, and by inference the understanding.
The influence on sub-goals
The characteristic of spreadsheets to produce immediate responses to inputted data permitted new sub-goals to be promptly set, assisting the emergence of a theory. The data produced relates to an investigation involving exploring terminating and 86 recurring rational numbers, when one is divided by the counting numbers. In the first case they negotiated to gain some initial familiarisation of the task.
Sara: One divided by one is one - it should be lower than one.
They entered 1 to 5 in column A and =A1/1 in column B to get:
1 1
2 2 etc
This posed an immediate tension with their initial thoughts. After exploring various formulae and associated output, they settled on a way to easily produce a table of values to explore. The spreadsheet environment shaped the sense making of the task and the resetting of their sub-goal. Critically, it had enabled them to immediately generalise, produce output, then explore this visually. They generated further output:
1 1
2 0.5
3 0.333333..
4 0.25
5 0.2;
6 0.166666..etc.
Sara: So that's the pattern. When the number doubles, it's terminating. Like 1, 2, 4, 8 gives 1, 0.5, 0.25, 0.125.
Jay: So the answer is terminating and in half lots. Lets try =0.125/2; gives 0.0625- which is there. (Finds it on the generated output from)
The structured, visual nature of the spreadsheet prompted the children to pose a new conjecture, reset their sub-goal and then allowed them to easily investigate the idea of doubling the numbers. The table gave them some other information however.
Jay: 1 divided by 5 goes 0.2, which is terminating too. (Long pause)
After further exploring, they reshaped their conjecture, incorporating their earlier idea.
Sara: If you take these numbers out they double and the answer halves.
Jay: That makes sense though, if you're doubling one, the other must be half. Like 125 0.008; 250 0.004
Sarah: What's next. Let's check 500
Jay: Let's just go on forever!
They generated a huge list of output; down to over 4260.
Jay: 500 0.002; 1000 0.001. When you add zero to the number you get a zero after the point
Although this particular group didn't fully explore the relation of the base numbers to the multiples of ten, they have made sense of, explored, and generalised aspects of the investigation. The pedagogical medium through which they engaged in the task has influenced the contextualization and approaches they have taken. When asked: 87 "When you saw the problem, how did you think you would start?" the children's responses corroborated this perspective.
Sara: Re-read to get into the math's thinking, then straight to a spreadsheet formula.
Greg: I type what I think and try it
As well, the spreadsheet groups progressed more quickly into exploring larger numbers and decimals. This appears to indicate a greater propensity for exploration and risk taking, engendered by the spreadsheet environment. It seems the spreadsheets have not only provided a unique lens to view the investigation, but have drawn a distinctive investigative response.
Fran: Using a spreadsheet made it more likely to have a go at something new because it does many things for you. You have unlimited room. You can delete, wipe stuff out.
Chris: Columns make it easier- they separated the numbers and stopped you getting muddled. It keeps it in order, helps with ordering and patterns.
Conclusions
This study demonstrated that the different pedagogical media provided a distinct lens to contextualise the mathematical ideas, frame the formation of informal mathematical conjecture, and condition the negotiation of the mathematical understanding. As Brown (1996) argued, the mathematical understanding is a function of the social frame within which it is immersed, and the social frame evolves uniquely in each environment. The data supported the supposition that the availability of the spreadsheet led the students to familiarise themselves with, then frame the problem through a visual, tabular lens. It is clear also that it evoked an immediate response of generalisation, either explicitly through deriving formulas to model the situation, or implicitly by looking to fill down, or develop simple iterative procedures. Tension, arising from differences between expected and actual output, and opportunities, arising from possibilities emerging from these distinctive processes, led to the setting and resetting of subgoals. These, in turn, further shaped the understanding of the investigative situation, and the interpretation of mathematical conjectures.
The spreadsheet approach, perhaps due to the actual technical structure of the medium, led more directly to an algebraic process, with the language interactions containing both algebraic and technical terminology. It seemed, in fact, that the spreadsheet setting, by its very nature, evoked a more algebraic response. The participants in these groups were straight away looking to generalise a formula that they could enter and fill down. Their language reflected this, but the interactions also contained more language of generalisation, and it took them generally less interactions to develop an informal conjecture. Those working in the classroom setting used a discrete numerical example to engage in the problem; to make sense of its requirements as well as initiating the process of solving. They tended to try, 88 confirm with discussion and then move more gradually into the generalisation stage. Their conjectures were slower to emerge not only due to variation in computational time, but also due to the approach the spreadsheet evoked. The way they thought about the problem was different. Their initial dialogue seemed more cautious, and contained comments requiring a degree of affirmation amongst group members before moving into developing their conjecture. As a consequence the descriptions of the process undertaken and the mathematical thinking were more fulsome. This may be evidence of more fulsome understanding too.
The children also identified speed of response, the structured format, ease of editing and reviewing responses to generalisation, and the interactive nature as being conducive to the investigative process. While this particular medium has unfastened unique avenues of exploration, it has as a consequence fashioned the investigation in a way that for some learners may have constrained their understanding. The approaches and outcomes, as reflected in the dialogue, are different. If the dialogue between learners filtered the mathematical thinking and formation of conjectures in different ways, according to pedagogical media, then perhaps complementary approaches would give opportunity to enhance mathematical understanding. As well, how gestures might mediate the learning, and how the findings of this ongoing study might resonate with those investigating other software, for example Cabri-geometry, are key aspects to also consider.

An emergent field of enquiry:
the introduction in the classroom of E-Exercise Bases
Claire Cazes, Fabrice Vandebrouck
Equipe Didirem, Université Paris 7, France
cazes@ccr.jussieu.fr, fabrice.vandebrouck@univ-evry.fr
Investigating on E-Exercise Bases (EEBs) is a necessity. This presentation successively focuses on teachers, students and mathematics. The anthropological approach and the methodological individualism frame account for some regularities and disparities in teachers' and students' attitudes towards these tools and specify the kind of mathematical work accomplished. The results presented here are based upon observations in various French high schools and universities.
The purpose here is to enquire about the use of E-Exercises Bases (EEBs) in teaching and learning mathematics. It is especially related to theme 2 of the ICMI Study "learning and assessing mathematics with and through digital technologies". Indeed, some aspects of "how students learn mathematics with -these- digital technologies and the implications of the integration of -these- technological tools into mathematics teaching for assessment practices" are investigated. According to the discussion document of the ICMI Study, several approaches are given. After exposing the nature of EEBs and why we should inquire about their use, the three usual poles (teacher, student and mathematics) are successively analysed in an EEB environment. This study is supported by emblematic examples taken from quite an important number of observations in ordinary classes in France.
The nature of EEBs
EEBs mainly consist of classified exercises and propose in addition to these an associated environment which can include advice, solutions, corrections, explanations, tools for the resolution of the exercises, score and even sometimes corresponding courses etc. They differ from microworlds or computer algebra systems (CAS) which are open environments in which generally no specific tasks are predefined.
As an example, let us look at a particular EEB : Wims (http://wims.auto.u-psud.fr). This software is a collaborative one, available in six languages and initially developped by French Profesor Xiao Gang. All examples given hereafter will stem

from this EEB. Wims is a library of on-line interactive mathematics resources which includes exercises for all levels: from primary to tertiary education. Teachers can choose some of these exercises and build their own on-line worksheets for their students. Students can do the same exercise several times in order to improve their marks. In such case, the structure of the exercise will remain the same, but its numerical values will differ. 91
Faced with the variety of EEBs, some tools were designed to describe and to evaluate them, under various aspects. In a recent paper, Tricot (2003) uses three key concepts that are linked: usefulness, usability and acceptability. To show this variety, here are some variable characteristics of an EEB. Each time, we classify Wims in this variety.
• The EEB may be « opened » or « closed » to the teacher. Wims is opened because teachers may choose the exercises and the parameters linked and design the exercise sheet wanted. To create exercises, some computer knowledge is required.
• Expected answers differ from one EEB to another. For Wims, answers are numerical values, MCQs or short mathematical expressions but not sentences.
• Feedbacks are another EEB characteristic. Wims's feedbacks are: "right" or "wrong" with the right answer given and a mark. In several exercises feedback can be more interesting as we will see later. Wims does not provide any proof.
• Help or advice is also variable. Wims suggests some generic tools such as formal calculators and graphic tools but no specific helps adapted to any particular exercise.
Why investigate exercises set on line?
An inventory of didactic research in the area of ICT tools has shown the importance given by researchers to microworlds and CAS (Lagrange & al, 2000). On the contrary, research works especially devoted to questions raised by the use of EEBs are scarce. However, the number of EEBs is growing every day and EEBs themselves evolve very quickly. Moreover, it is not relevant to apply the results obtained with other ICT tools to EEBs. A lot of studies with microworlds and CAS consist in the building and the study of didactic situations where the "milieu" produces contradictions, difficulties and disequilibria (Brousseau, 1997); whereas, in EEB situations, the "milieu" is often friendly. Therefore, the economy of the mathematical work is altered.
The institutional encouragement to integrate the digital technologies into the curricula and educational practices is another reason to investigate EEB's use. For instance, in France, the network connection of educational establishments has allowed the introduction of new pedagogical tools called "Espaces Numériques de Travail" (global digital learning environments). Each student has access to a set of personal and general resources through the network. Some of these pedagogical resources can be EEBs. Another example of French institution commitment is a regional project focusing on the use of EEBs at high school level. Some specific results presented further stem from this project.
This trend is general. In their survey regarding the use of technology in mathematics courses in England, Ruthven and Henessy (2002) also observe that working with EEBs is often mentioned by teachers as a help to organise sessions where the students can work at their own pace. 92
The questions are: how to work with an EEB in a classroom? How do teachers manage the computer sessions? How do students work with this tool? And (part 4) what kind of mathematics are they doing?
How do actors (teachers and students) cope with the use of an EEB?
The use of an EEB brings modifications in the classroom. After having specified the observed sessions and the framework, we report in this part on teachers' and students' adaptations to these modifications.
Observed sessions
We observe ordinary classes and we are not concerned with the building and the analysis of didactical engineerings. All observed sequences in high school or university are training exercises and most are organized in the common following way. Before the sequence, the teacher builds a digital exercise sheet or designs a path in the EEB. During the sequence, students work, alone or in pair, in computer and paper/pencil environments. According to the EEB and the exercise, they may or may not put some advices into practice or ask the teacher. They enter their answer on the computer. The EEB then provides a mark, a comment, the correct answer or all the details of the proof. During the sequence, the teacher helps students individually. Most of the time, the program is long so that no student can finish it during the sequence. The end of the sequence is the end of the time granted: the teacher either says "you have to finish at home" or "we shall finish next time" or even nothing concerning the completion of the exercise sheet.
Framework
In part 2, we saw, that the institution must be recognised as essential in the process of ICT integration. However, students can have different paces during the observed sessions, and can also follow different paths among exercises. It is thus necessary to choose a framework to articulate these two aspects: institutional pressure vs individual approach. This is why we first turn our attention to the anthropological approach developed by Chevallard (1999). This approach with its institutional basis gives a proper place to institutional issues. To articulate this frame with the actors' individuality the analysis of EEB integration is supported by methodological individualism. The later is a philosophical method aimed at explaining and understanding broad society-wide developments as the aggregation of decisions by individuals. In sociology, Jon Elster among others follows this lead: "to explain social institutions and social change is to show how they arise as the result of the actions and interaction of individuals. This view, often referred to as methodological individualism, is in my view trivially true." (Elster, 1989). According to Bernoux (2000), the viability of a modification in a community is the result of collective rules and of the individual meanings linked to them. Notice that these individual meanings are not easy to identify.
The teacher's role 93
Analysis discussed here stem from observations at high school level. As mentioned previously all the observed sequences are training exercises in which teachers help students individually. However, there are some differences from one class to another and from one teacher to another. In our view point, the chosen framework can help to understand both regularities and diversities.
For teachers, rules come from the institution which encourages the use of ICT tools and allows the teachers some flexibility. For example, teachers involved in the regional project can, from a panel, choose their preferred EEB and the Region will finance the EEB which is not free. Another important rule exists even if it is not directly linked to ICT tools: the mathematics syllabus for high school requires teachers to manage specific sessions with pupils in difficulty. Observations show that teachers often use EEB to manage such sessions. EEBs allow them to respect the working pace of each student and to help them individually if necessary. So, it is a way to satisfy this double injunction which comes from the institution: to use ICT tools and to support individually students. It may be a way for teachers to make sense of the integration of ICT tools. Therefore EEBs are easier to integrate into their practice than other kind of ICT tools. This idea can be linked with Cuban's results (2001): « the point is that teachers change all the time. It is this kind of change that needs to be specified. Champions of technology wanted fundamental change in the classroom practice. The teachers that we interviewed and observed engaged mostly in incremental change." However, to keep this teacher's individual meaning, it is necessary for the institution to guarantee a good technical material and to maintain the student's individual help injunction.
Among these regularities, some disparities exist. First of all, teachers do not choose the same EEB. Interviews show that their expectations are also different. They do not choose the same didactical organisation. For instance, they may organize EEB sessions with weak students or with strong ones to have more time to work face to face with weak ones. They may also design different paths in the EEB according to the students. A difficulty observed and expressed by students and teachers, is to keep written tracks of the work done and, more generally, to articulate paper support with support screen. Teachers also have different choices about this point. For instance, some of them ask students to use a specific notebook for EEB sessions, others insist on the same notebook and a third group- frequently teachers recently involved with EEB- will have no notebook for EEB sessions.
The student's role
In this part, the discussion is based on observations at tertiary level. The chosen framework allows to discuss both observed regularities and diversities.
As in any classical exercises' session, the rule for students is to solve the exercise sheet and to ask for help if needed. However, students seem to work really hard during the observed sessions, may be more than in classical exercises sessions. Our explanation is that the rule is not exactly the same. Students know that if they do nothing, nothing will happen. In particular, there is no common solving moment they 94 can wait for. Actually, students have more responsibilities. They may choose their own path among the exercises: decide to use or not helps or to have a glance at solutions, decide what to keep on their written notes etc. Hence there is an obligation to act and a multiple choice of actions. We think that these two points help students to give personal meaning to these sessions. So the hypothesis to explore here is: working with an EEB introduces some liberty which enhances students' activity by adding more meaning to their work. Notice that these new responsibilities require them to produce more difficult cognitive efforts.
However, if all students seem more active in EEB sessions, the type of activity is different. We, sometimes, observe strategies such as scoring (students always solve the same kind of exercises to have a good mark) or random answering (especially in MCQ). Log files when available also show that, on the contrary some students work a very long time at home on the EEB. These different attitudes could also be linked with another rule: to pass the exam. In some interviews, some students said "working with an EEB is funny but we will never have such exercises at the exam". So a consequence from the dialectic between rules and individual meaning is: the more EEB sessions are linked to the exam, the stronger the students' efforts are. Thus to ensure a successful integration the first challenge for the teacher should be to build didactic organisations linking together classical sessions, EEB sessions and exams.
We have seen that EEB sessions can increase students' activity. Now let us inquire about what kind of activities.
Mathematical activities developed by an EEB use
Personal and institutional practices can be explained in terms of praxeologies in Chevallard's approach. They are described by three main components: the type of tasks, the techniques used to solve these tasks and the technologico-theoretical components that is to say the discourses and the mathematical basis which are used in order to both explain and justify the techniques. The advance of knowledge requires the routinisation of some techniques and in a more general idea, a work on the techniques. In this part we would like to stress out that EEBs can make this process easier. Moreover, we notice that EEBs enable to highlight some specific techniques.
The importance of the mathematical work dedicated to the technique
As previously mentioned, all observed sessions with EEBs are training exercises and students work on already learned techniques. The process of routinisation may require a critical quantity of exercices and EEB sessions is one way for students to reach their own necessary quantity. For instance, EEB sessions may allow to learn technical solving methods step by step. In the following example, students must choose the successive adequate operations and the computer executes them, giving the new equation after each step. At the end the computer assesses both the result and the number of steps to obtain it. 95
Fig. 1
This exercise is interesting because it allows to train oneself in one specific part of the technique: the choice of the operations. The computer takes in charge the calculation. Some of these exercises could not be suggested to students without EEB and would otherwise be sent back implicitly to a possible personal work.
Mathematical techniques highlighted
Due to the MCQ form of some exercises, student may use techniques such as testing or eliminating. For instance, here is a Wims exercise to work in algebraic and geometric frames. According to Douady (1986), this kind of tasks is known to be useful in the learning process because it creates a link between algebraic frame and graphic frame.
Fig. 2
It is necessary to discuss all these techniques: they are mathematical' ones and not classical' ones. Because they ask students to have a control over their result, it can be very interesting to train them into this type of reasoning.
Of course, it is also possible to search such exercises in a paper and pencil environment but, with EEB, it seems easier to generate as many exercises as 96 necessary for each student. Sometimes, EEBs also offer tasks which are impossible to work with in a traditional environment as in the following Wims' example.
Students must find an algebraic expression whose curve is the closest to the given one (here a lower red line). The student's answer is the formula g(x)=(x/2)+1. EEB's feedback is the representative line corresponding to this answer. The student may then realise that his/her answer is wrong and try to adjust it with a better one. The answer is wrong however it is not far off and the student may find the right answer on his/her own, making links between algebraic and geometric modifications. One can examine this exercise, in terms of didactical situation theory (Brousseau, 1997). In this example, the milieu is antagonistic and the student may acquire knowledge thanks to the feed-backs.
Fig. 3
Conclusion
EEBs are specific ICT tools consisting of classified exercises with an associated environment. The contribution wants to explain that specific research on EEBs' use is necessary for three reasons. More and more EEBs exist. Due to institutional injunctions in particular, their use will increase. Previous studies are frequently irrelevant as they differ from other ICT tools, for instance they provide mostly an allied "milieu". Based upon different EEBs' use observations in French context, this contribution focuses successively on teachers' and students' attitudes and on mathematics embedded in EEBs sessions. The anthropologistic approach and the methodological individualism frame allow us to focus on the actor's attitude.
Regarding teachers, EEBs appear as a way to organise individual support. This organisation may differ from one teacher to the next or even from one class to another. That is the result of the dialectic action of norms coming from the institution, and personal meaning coming from teachers. Students' norms, passing the exam and solving the exercises, and their individual meaning linked to the EEB session imply some regularities and singularities in their attitude. At last, EEBs seem particularly 97

adapted to work on techniques. Some techniques like testing, eliminating, solving step by step, or solving by trials and errors are highlighted by EEBs' use.
The continuation of the study will benefit from the work of TELMA, analysing the influence of different theoretical frameworks in the design and/or the use of digital technologies. TELMA is a European Research Team (ERT) established as one of the activities of Kaleidoscope, a Network of Excellence (IST-507838) supported by the European Community (www.noe-kaleidoscope.org).

Role of Digital Technologies in supporting Mathematics Teaching and Learning: rethinking the terrain in terms of schemas as epistemological structures

Mohan Chinnappan
University of Wollongong, Australia
mohan@uow.edu.au

In this discussion I wish to tackle the issue of how digital technologies (DTs) shape teaching and learning of mathematics. Teachers and students of mathematics use DTs in a multitude of ways to enhance mathematical understandings but there is limited information about the directions and nature of shifts in the conceptual ground gained by the learners and its relationship to pedagogical strategies adopted by teachers. The issue will be examined within the framework of schemas as epistemological structures. Working on the view that schemas provide visual representations of what is learnt, I propose to analyse a series of activities by students and teachers that involve the active use of a variety of DTs. The impact of DTs on students' and teachers' prior knowledge, and the extension of that knowledge will be a principal consideration.

Introduction

The nature of mathematics and mathematics learning continues to be a dominant theme in current debates about reforms in mathematics teaching and curriculum. In so doing, the mathematics education community at large is focusing on issues concerning how individuals come to understand mathematics and how teachers can better scaffold deep learning. Against this background, the perceived and actual role of digital technologies in mathematical pedagogies of practitioners has received particular attention.

In this discussion paper my aim is to a) characterize the development of mathematical knowledge by drawing on schemas as epistemological structures and b) examine the potential and actual role of digital technologies (DTs) in supporting the growth and transfer of such structures for learners and teachers of mathematics. The above aims are expected to address three themes that are the focus of the 17 th
ICMI
Study: Roles of different digital technologies, Contributions to learning mathematics and Role of the teacher.

Theoretical framework

Learning mathematics can be seen as the continuous process involving the assimilation and accommodation of new understandings into existing understandings. This Piagetian notion as it relates to mathematical learning is consistent with the view that mathematics constitutes a corpus of knowledge constructed and used by members of a community. This knowledge and the accepted conventions may appear to be static or 'given' at a particular point in time. However, these conventions and 99 facts about mathematics are subject to change as the community evolves, and other models are developed to make sense of the environment. Thus, there is a need to consider frameworks about learning and teaching that would provide windows into how DTs mediate thinking and construction of new forms of meanings.

Proponents of Activity Theory argue that DTs can be seen as cultural tools as that mediate thinking and thereby create new forms or levels of understanding. How can we characterize the trajectories of understandings that learners follow? While the notion of trajectories of understandings seems to impose boundaries to the path of understanding, we need some way to characterize changes in learner's attempt to make sense of the mathematical knowledge and its utility. The construct of schemas provides a solid base from which to examine this issue.

Schemas and mathematical knowledge development

One group of cognitive psychologists adopt the network perspective in making judgments about mathematical knowledge development (Anderson, 1977; Marshall, 1995; Sweller, 1989). According to this view conceptual growth and mathematical understanding can be interpreted in terms of conceptual nodes and relations between nodes. As students' experiences with a concept or a set of concepts increase, they come to form organised meaningful wholes called schemas. Schemas can be visualised as knowledge structures or networks having one or more core concepts that are connected to other concepts by relational statements. The relations that are found between concepts that form a schema could denote a number of features including information about (a) similarities and dissimilarities between those concepts, (b) procedures for using the concepts for solving problems and (c) affective factors about those concepts. Chinnappan (1998), for example, provided data that showed that schemas in the domain of geometry could be organised around axioms or theorems about Euclidean geometry.

According to Anderson (2000), two variables determine the quality of a schema: the spread of the network and the strength of the links between the various components of information located within the network. A qualitatively superior schema can be characterised as having a large number of ideas that are built around one or more core concepts. Further, the links between the various components in the network are robust, a feature which contributes to the accessing and use of the schema in problem-solving and other situations. A high quality schema can also benefit students by helping them assimilate new mathematical ideas because such a schema has many conceptual points to link with. As a theoretical construct schemas provide a useful way to interpret the growth of advanced mathematical knowledge by identifying pedagogically important relations.

Role of schemas in problem representation

It is assumed that performance in mathematical tasks is to a large measure dependent on accessing and using prior knowledge that is organised in the form of schemas. A major advantage of having knowledge stored in clusters or chunks is that they facilitate retrieval of the required knowledge from the long-term memory into the 100 working memory during information processing. In problem-solving contexts schemas play an influential role during the construction of a representation for the problem. Cognitive psychologists argue that the solution of mathematical problems can be greatly enhanced if students are taught to construct useful representations of problems (Frederikson, 1984, Kaput, 1987).

Building a problem representation can be a deliberate process in which students attempt to establish meaningful links between bits of information in the problem statement and knowledge embedded in their schemas that can be related to the problem. Students' repertoires of problem-related schemas could include, but not are restricted to, (a) knowledge of procedures and strategies associated with tackling a group of problems that are similar to the problem in question, (b) mathematical concepts and (c) knowledge about previous experiences with similar problems. Hence, building a representation of the problem involves, among other things, making decisions about what to select from the above range of schemas. This point was made by Hayes and Simon (1977) who have suggested that "the representation of the problem must include the initial conditions of the problem, its goal, and the operators for reaching the goal from the initial state' (p.21).

The construction of representations is a cyclic event where students continue to refine one representation or change to a different one until the correct match is found between schemas that have been accessed and the goal. The goal could be unknown value that has to be determined or a mathematical result that has to be proved via a chain of reasoning.

The above model suggests that instructional methods that would help students decompose problems into sub-problems would benefit them in three ways. Firstly, students might be expected to access previously acquired schemas from their memory by examining what is given in the problem. Secondly, the accessed schemas could be deployed in solution of sub-problems. Thirdly, students could relate the subproblems in ways that would help them reach the problem goal. The net effect of teaching for problem representation is that students are encouraged to access and use a greater proportion of their previously learnt knowledge.

In order for students to develop a sophisticated schema, say, about functions, they need to increase the number and quality of connections between the definition of functions, families of functions and use of functions among others. As the schema expands one might expect information about related concepts such as derivatives and optimisation become more easily incorporated. In other words, an existing schema that has the relevant prerequisite knowledge supports students' understanding of derivatives and optimisation. In this way schemas can be argued to provide a measure of the depth of understanding students develop about mathematical ideas. More critically, schemas provide a useful tool for the analysis of conceptual links between university and secondary mathematics.

Teaching based on schema analysis101

Once we have some information about the gaps and weaknesses in the students' schemas, we are in a better position to devise strategies to help students develop appropriate schemas or modify existing schemas by drawing on a range of digital technological tools. Let's us assume that students are experiencing difficulty in grasping the concept of functions. We could adopt the following three strategies in order to develop schemas and facilitate the transition to more advanced schemas involving a system of three or more linear functions.

Firstly, tutorial-type classes can be effective in 'reteaching' the target ideas such as systems of equations, variables, solution of equations and geometric interpretation of solution of two equations. The nature of the target ideas will naturally depend on the prerequisite knowledge that lecturers consider as necessary for the next level course.

Secondly, students could be encouraged to work in groups on a series of activities that are developed in response to improving the above schema. For instance, we could provide a practical problem that requires the generation and solution of a system of two linear equations. Student could attempt to solve this as a group, after which they could brain storm the problem and their solution in terms of the three concepts above. This activity has the potential to facilitate the construction of new links that were non-existent in the schema of the students in the first instance. Teachers could act as critical friends during this exercise.

The teacher's own understanding of the focus concept (functions) and his knowledge about how the DTs can be used effectively to aid students' thinking about the concept are key to the successful orchestration of the lesson and the above instructional strategies.

Digital technologies and mathematical problem representation

Teachers can use DTs such as computer softwares in multiple ways during the course of problem solving. Firstly, softwares could be used as an evaluative tool to check the quality of students' prior knowledge schemas. A useful strategy here would be to ask students to compare and contrast concepts and procedures that are found in the solutions produced by computers with that of their own. For instance, we could ask students to find the limit of a rational function,f(x) with and without the use of computers. Students' own solution attempts would reveal attributes of their schema in this area. Students could then be required to find the limit of the same function with the aid of computer programs. These programs have in-built facilities that help them visualise the function as well generate a table of values that demonstrate the link between values of x and the limit off(x). That is, softwares provide relatively easy and rapid access to multiple representations of the problem and associated concepts. Palmiter (1991) advocated this technique of using technology to help students build and refine schemas that are rich in conceptual information about calculus.

The comparison of students' answers and that produced by the computer softwares could thus be used as an important learning and diagnostic activity. The 102 more enriched interpretation of the problem provided by the computer solution has significant pedagogical value in that it would help students not only understand the limitations of their schema, but more importantly, demonstrate in a dynamic manner the relationship between the x , f(x) and the limit of f(x). We can go a step further by asking students to justify their solutions and computer-generated solution to peers, and explain any apparent contradictions. This activity would further enlarge their schema for the concept of limit.

Teacher and student knowledge schemas

The learning environment is one in which teachers and students engage in ways that would help teachers share his or her understandings with the students. This engagement can be mediated by the use of DTs with the aim of getting students to build the range of connections that are present in the teacher's schema As an illustration, some students tend to develop a limited understanding of the concept of fractions particularly as these relate to making sense of real-life applications. Teachers are expected to have a wider network of fraction schemas including the

prevalence of fractions in the interpretation of gradient and/slope of an inclined plane. Students could be encouraged to access this feature of fractions by examining contexts where the idea of gradient comes into play. Students could search these contexts on the Web, and teachers could ask them to engage in discussions, say about part-whole relations. The ensuing discussions could aid in the Aid in the discovery of new ways of thinking about fractions and contribute to improved connectedness, the construction of robust schemas. Here is a case of how DTs mediate thinking and active involvement of the learners. The ways tools mediate thinking and knowledge construction has been a central issue for mathematics educators (Gutierrez, Laborde, Noss & Rakov, 1999).
Teacher knowledge and student knowledge involving DTs
Engaging teachers
In a study of use of graphic calculators, Chinnappan and Thomas (2003, 2004) showed that an experienced teacher used digital tools to model the more abstract and complex areas of algebraic understanding. In a related study, beginning teachers engaged in online discussions to discuss the intricacies of teaching multiplications to young children (Chinnappan, 2003). These discussions were conducted via WebCT and other resources available on the Internet.
Engaging students
Chinnappan's (2001) work with young children's understanding and use of fraction concepts during problem solving also demonstrated the pedagogical value of softwares in supporting learners to reflect on their prior understandings. In this study, a software based on JavaBars mediated children's cognitive actions. Ekanayake, Brown and Chinnappan (2003) investigated the conceptual terrain of secondary students as they attempted to solve a series of geometry proof-type problems. The researchers developed a software to guide students to better access their prior knowledge of theorems as well reflect on the areas they need to work in order to 103 make progress with their problem-solving efforts. The need to develop softwares that would scaffold schema development was also supported in another study by Chinnappan, Lawson, Gardner, (1998).
Conclusion
How DTs support deep learning and teaching of mathematics is an important issue for the 17
th
ICMI study. My analysis here suggests that we need to examine the way we can map the learning trajectories of individual students, and what teachers do in using DTs to scaffold learning in the process. Schemas as epistemological structures, it would seem, provide a powerful alternative model to analyse the issue.

Integrating Graphic Calculator into the Singapore Junior College Mathematics Curriculum: Teacher Change
Chow Ming Kong, Tampines Junior College, Singapore
chow_ming_kong@moe.edu.sg
In Singapore, the revised junior college mathematics curriculum implemented in 2006 has specifically identified the graphic calculator as an important tool in the teaching and learning of advanced level mathematics topics (MOE, 2004). The study described here, which is part of my PhD thesis, investigates teacher change, in a time of transition from a classroom without graphic calculator use, to teaching in a classroom where graphic calculator has the potential to be an integral part of students' learning of mathematics. This study carried out in 2006 specifically seeks to describe how the concerns of teachers, the teaching strategies of teachers and the roles of teachers change when they integrate graphic calculator into the junior college mathematics curriculum. The study also aims to identify important features among teachers who are successful in integrating graphic calculator into the curriculum. This study is anticipated to complete by end 2006. The contributions from this study will be discussed in anticipation to theme B on teachers and teaching.
Introduction
The graphic calculator is a powerful handheld device that is becoming increasingly affordable and accessible to students and teachers in the classroom. The capabilities of the graphic calculator include drawing of graphs and the execution of numerical, matrix and statistical calculations. There is a large amount of research supporting the use of calculators in teaching and learning of mathematics (Dunham & Dick, 1994; Heid, 1997; Husna, Munawir & Suraiya, 2005; Penglase & Arnold, 1996). The graphic calculator reduces the drudgery of applying arithmetic and algebraic procedures when these procedures are not the focus of the lesson. Students are free to spend more time on problem solving. The graphic calculator also makes it possible for students to visualize data in more than one way. With graphing calculators, students can switch between graphical and numerical representation of data (Waits & Demana, 2000).
The graphic calculator has brought about changes in the curriculum, the assessment mode and the way teachers teach mathematics in various parts of the world. In Singapore, with the revised mathematics curriculum in 2006, graphic calculator will form an integral part of the teaching and learning process in schools. The use of graphic calculators will be expected for all three Advanced Level 106 mathematics papers (H1, H2 and H3
12
) offered at junior colleges (MOE, 2004). This
provides a rare opportunity to investigate teacher change in a time of transition.
Rationale and Purpose of the Study
Since the 1980's, many countries have realized the potential of graphic calculators and have integrated or have made recommendations for its integration into the mathematics curriculum. The availability of graphic calculators has resulted in the teaching of mathematics to be reexamined at both the secondary and collegiate levels (Dunham & Dick, 1994). The National Council of Teachers of Mathematics (NCTM) has long advocated the use of calculators at all levels of mathematics instruction, and graphic calculators are no exception (NCTM, 1989, 2000). In 1989, in the Curriculum and Evaluation Standards for School Mathematics, the National Council for Teachers of Mathematics (NCTM) made the following recommendations: "Scientific calculators with graphing capabilities will be available to all students at all times" (p.124). NCTM's most recent standards document, Principles and Standards for School Mathematics (2000), placed greater emphasis on the implementation of technology in the teaching and learning of mathematics by making technology one of its main principles. This principle states: 'Technology is essential in teaching and learning mathematics; it influences the mathematics that is taught and enhances students' learning' (NCTM, 2000, p. 24).
At present, there is much research being done on graphic calculator usage (Kor, 2004; Noraini, 2005). The majority of research on graphic calculators seems to fall into two categories; namely, student performance, and attitudes and beliefs. Most research studies on graphic calculators involve the investigation of the teaching of a certain mathematics topics using graphic calculator and report on its impact on student performance and understanding of concepts (Burrill, 2002). Authors of various reports have concluded that benefits in student achievement can be derived from appropriate graphic calculator use (Heid, 1997; Husna, Munawir & Suraiya, 2005). The other category of research investigates how teacher attitude, belief and conception of mathematics affect the use of graphic calculator in the classroom (Jost, 1992; Simmt, 1997; Tharp, Fitzsimmons & Ayers, 1997). So far, there is no study done to investigate how the concerns of teachers change as they integrate graphic calculator into mathematics curriculum at secondary or tertiary school levels. The revised mathematics curriculum in 2006 provides a rare opportunity for me to investigate teacher change.
There is limited research on teaching strategies employed by teachers when they integrate graphic calculator into mathematics curriculum (Barton, 1995; Fox, 1997). The relationship between teachers' knowledge and pedagogical strategies and their use of graphic calculator is largely unexamined (Doerr & Zangor, 2000).

12
H1 level: Half of H2 in breadth but similar to H2 in depth; H2 level: Equivalent to current 'A' level subjects; and H3 level: Allows for a greater range of learning and research options. Must offer subject at H2 level. 107
However, a recent study was conducted by Ball and Stacey (2005) to describe the teaching strategies that teachers can use to produce students who are judicious users of technology. The four teaching strategies mentioned are (a) to promote careful decision making and technology use, (b) to integrate technology into curriculum, (c) to tactically restrict the use of technology for a limited time, and (d) to promote habits of using algebraic insight for overview and monitoring. This study aims to describe and analyze how the teaching strategies of teachers change when they integrate graphic calculators into junior college mathematics curriculum.
There are a few studies which investigate the role of teachers teaching with graphic calculator in the classroom (Barton, 1995; Doerr & Zangor, 2000; Farrell, 1996; Simmt, 1997). Doerr and Zangor (2000) conducted a qualitative classroombased research study on role, knowledge and beliefs of a precalculus teacher. Five patterns and modes of graphic calculator tool use were identified, supported by rich field notes. The results of the study suggested that nature of the mathematical task and the role, knowledge and belief of the teacher influenced the emergence of rich usage of the graphic calculator. The descriptions of various modes of graphic calculator use seem to illuminate certain roles of teachers like being an explainer and interpreter of results. Thus, this study aims to investigate how such roles of teachers change when they integrate graphic calculator into mathematics curriculum in junior colleges.
There is limited research on the factors that impact the integration of graphic calculator into the mathematics curriculum (Arvanis, 2003; Bynum, 2002). Arvanis (2003) investigated the extent Illinois high school Algebra I teachers used graphic calculators and what factors impacted this use. Algebra I teachers reported that the factors that most influenced their use were personal beliefs, 'offers something different to do', workshops and other teachers. The factors that limited their use of graphic calculators were emphasis on basics, cost, availability, not enough time, lack of training, and lack of materials. This study aims to further investigate factors that impact the successful integration of graphic calculator into the junior college mathematics curriculum.
Research questions
The purpose of this study is to pursue answers to the following research questions:
1. How do the concerns of teachers change when they integrate graphic calculator into the junior college mathematics curriculum?
2. How do teaching strategies of teachers change when they integrate graphic calculator into the junior college mathematics curriculum?
3. How do the roles of teachers change when they integrate graphic calculator into the junior college mathematics curriculum?
4. What features seem common among teachers who are successful in integrating graphic calculator into the junior college mathematics curriculum? 108
Significance of the study
This study aims to contribute findings and knowledge of change in teacher concerns, teaching strategies and teacher roles when they integrate graphic calculator in the junior college mathematics curriculum. From this research, the changes in

teaching strategies and changes in roles of teachers identified will serve to inform the wider community of mathematics educators resulting in improved pedagogy and practice in the mathematics classrooms. Knowledge of teaching strategies and teacher roles can also be used as a base for meaningful pre-service and in-service programmes. Another significant contribution will be the development of a framework which describes factors identified from findings in the Singapore context that results in the successful integration of graphic calculator into junior college mathematics curriculum. The success factors identified will serve to inform policy makers what factors demand greater attention at various stages of implementation of new technology in mathematics curriculum.
Research Methodology
The methodology used is case-study approach. Following Merriam's (1997) suggestions for case study research, data will be collected by means of classroom observations, interviews and document analysis.
Subjects
A formal letter will be drafted and sent to principals of junior colleges to request for mathematics teachers who would like to participate in this study. The mathematics teachers have to teach the revised syllabus mathematics (H1, H2) in 2006. A total of 9 subjects from 3 junior colleges agreed to participate in the study.
Instrumentation
Every subject in this study will be visited by me once a school term for three terms. Every school term consists of 10 weeks of study. The duration of study is from January 2006 to September 2006. During each visit, the sequence of events will be lesson observation, administering Teacher Concern on Graphic Calculator Use (TCGCU) questionnaire and interview. Data collection will involve the following aspects: lesson observations, teacher self-reflection of other lessons, a Teacher Concern on Graphic Calculator Use (TCGCU) questionnaire and interviews.
A significant part of the data collection is by means of classroom lesson observations. Only lessons that involve teachers using graphic calculators as part of their instructional strategy will be observed. Every lesson observation will be audiotaped. Detailed field notes about how each lesson is conducted will also be made. The times at which activities change and the times at which significant classroom events occur will be noted in the lesson observation checklist. After checking the audiotape, a comprehensive set of observations about the lesson will be made, describing up to 20 characteristics of the lesson. Characteristics that are monitored include lesson preparation, lesson proper, teaching strategies, classroom management and technical issues. The teacher interactions with individual students and the whole 109 class will be recorded. The teachers' use and students' use of graphic calculator will also be recorded. Thus the teaching strategies and roles of teachers are carefully monitored through examination of the types of instructional activities planned, their questioning techniques and how teachers explain concepts.
Based on three sources, a Teacher Concern on Graphic Calculator Use (TCGCU) questionnaire will be constructed: concerns of teachers found in the pilot study, concerns identified from relevant literature research and concerns found in Stages of Concern Questionnaire by Hall and Hord (2001). Care will be taken to attempt to fit concerns into seven different stages proposed by Hall and Hord. The seven stages are: Awareness, Informational, Personal, Management, Consequence, Collaboration and Refocusing. In each stage, the items which are statements of concern typical of that stage are obtained by adapting items from Stages of Concern questionnaire and writing as appropriate some new items to suit the local context. The Teacher Concern on Graphic Calculator Use (TCGCU) questionnaire will have a total of 35 statements of concern.
A preliminary version of the interview protocol has been developed based on review of selected literature (Simonsen & Dick, 1997). This interview protocol will be piloted by three mathematics teachers who have experience in teaching mathematics with graphic calculators and appropriate changes will be made. The final format of the interview protocol will be derived after additional input from two authorities in mathematics education research. The interview protocol contains primarily open-ended questions grouped into four areas comprising: (a) teacher concerns, (b) teaching strategies, (c) teacher roles, (d) success factors. Specifically, teachers in the interview will be asked twelve questions. Some of the questions are adopted from Simonsen and Dick (1997). For example, under teaching strategies, the teacher will be interviewed on how the presence of graphic calculator has helped them teach the mathematics topic differently to illuminate students' learning of mathematics. The teachers will also be interviewed if there are any specific functions in the graphic calculator that deliberately made them enthusiastic about their teaching.
Conclusion
This study carried out in 2006 specifically seeks to describe how the concerns of teachers, the teaching strategies of teachers and the roles of teachers change when they integrate graphic calculator into the junior college mathematics curriculum. The data collection is anticipated to complete by end 2006. The findings from this study will be discussed in anticipation to theme B on teachers and teaching. Being offered an opportunity to participate in the discussion will definitely be beneficial and enriching to me as a new researcher and as a PhD student.

Graphs 'N Glyphs as a Means to Teach Animation and Graphics to Motivate Proficiency in Mathematics by Middle Grades Urban Students
Jere Confrey, Alan Maloney, Lewis Ford, and Kenny Nguyen
Washington University in St. Louis
The Graphs 'N Glyphs mathematics education initiative aims to provide a model for filling the need of under-resourced urban students to become proficient both in the mathematics necessary to successfully pursue high school and advanced mathematics, and in electronic technologies required for robust economic and employment prospects. Grounded in learning progressions and modeling approaches to multiplicative reasoning, the multi-representational software provides a microworld-type environment in which students learn the mathematics underlying 2-D and 3-D animation and computer graphics, in order to produce their own increasingly realistic and complex computer animations. Ultimately the project aims for students to build explicit mathematical proficiency with rational numbers, ratio, proportion, fractions and decimals, as well as periodic functions and early trigonometric reasoning, in a motivating context of a computer animation and graphic design. Level one of the project focuses on object construction on the coordinate plane; congruence, similarity, reflection and scaling through tessellations; ratio as the foundation of both translation and scaling; and, finally, designing original animations.
Introduction
Students are typically told that they must study mathematics in order to keep open their options to pursue quantitatively-oriented careers in math, science, technology, or engineering. For most of them, this is a very distant and abstract motivation, especially for students whose familial network does not include members who currently engage in such work. Indeed, it is estimated that only 10% of students in the United States complete the prerequisites necessary to take Calculus (Roschelle et al., 2000), which provides evidence that these long-term motivational statements are not very successful in convincing students to persist. Yet, these same students live in a world permeated by the use of technology—the Internet, satellite communications, cell phones, and the management of virtually all the systems within which they live (economic, transportation, demographics, medicine, etc.). In the 2003 U.S. census it was estimated that approximately 55% percent of people in the U.S. have cell phones (U.S. Census Bureau, 2004, 2005) and ever-increasing access to related digital technologies, video, cameras, etc. In order to secure even a middle-class income, students must be competent in the use of these new technologies (Murnane & Levy, 1998). We refer to this as a key technology-knowledge gap, especially ironic in that those countries with the most access to the products of these revolutions are often demonstrating the least progress in developing the underlying necessary student proficiencies. 113
We are currently developing an exciting new software environment that addresses this gap while teaching basic transitional mathematical ideas to students in grades 5-8. The research is specifically targeted to encourage and engage the participation of urban students, many of whom live in poverty and whose access to adequate preparation for advanced mathematical study is severely limited. The environment, called "Graphs 'N Glyphs" (Confrey & Maloney, 2006), is designed to introduce students to how computer animations are produced and to permit them to create, edit, share, and publish their own animations. Thus, through this software and project, we invite them to participate in a compelling animation microworld while making the underlying mathematical and computational elements visible and comprehensible. In doing so, we aim to teach students the fundamental mathematical ideas of integers and rational numbers operations, similarity and scaling, graphing and tables, basic geometric concepts, transformations, and ratio reasoning. Other targets include angles, elementary trigonometry, percents, and decimals. The context of animation provides opportunities to strengthen and connect students' numerical and geometric knowledge, and to build on the foundations that can be established in early childhood, as synthesized recently by (Clements, 2004). The software environment, when fully developed, will also teach students about optics and acoustics, permitting them to explore further ideas in geometry, trigonometry and periodic functions, and the science that underlies onscreen modeling that produces realistic objects and animations.

While our presentation for this work is limited to level one (simple 2-D animations), we developed a short movie to excite students about Graphs 'N Glyphs, with our collaborators at Virtual Ed, Inc. The movie introduces students to Fritz the Robot who, initially, is consigned to the 2-D world (http://www.virtualed.biz/wu/applet_1_framework.html). As the movie progresses, Fritz is brought into the 3-D world and students are confronted with the question "How do animators use math and science to make a robot such as Fritz look and act real?" We use this question throughout our work with students to try to get them to understand why mathematics is needed to make objects look realistic. In short, we are trying to make them understand that mathematizing the (3-D) world is how animators model the real world on a (2-D) television screen or computer monitor.

Theoretical Approach

Our software design draws on four major thematic approaches from mathematics learning theories: a) modeling, b) project-based instruction, c) learning progressions, and d) microworlds. The work extends these four theoretical themes by linking the software directly to professional use software for animation and graphics, i.e. a tools and professions-based approach. In this way, the work draws upon the study of communities of practice (Lave & Wenger, 2002) and on how their practices can be useful in drawing students into the pursuit of quantitatively linked careers (Hall, 1999). 114

The theme of modeling through the development and revision of inscriptions (graphics, tables, transformation records) that permit one to render graphical and acoustic animations on the computer is the underlying philosophy behind the work (Latour, 1990). We use the definition of modeling by Confrey & Maloney (in press), and build on the work of Lehrer and Schauble (2000, in press), in which one conceives of a student learning via a continuum of models from physical microcosms to hypothetical-deductive.

Our intervention consists of a combination of elements on and off the computer; we emphasize the importance of building in different levels of abstraction in the software (Lehrer et al., 2002).

The activities and their individual tasks form a learning progression akin to learning trajectories described by Simon (1995), (Gravemeijer et al., 2004), and Clements & Sarama (2004), and conceptual corridors as described by Confrey (in press).

These elements are drawn together with the development of the concept of microworlds defined first by Papert (1980) and extended by Weir (1987) and then Hoyles (Hoyles et al., 1991). In Graphs 'N Glyphs, we draw upon the changed definition of Microworld, from "teaching computers to solve problems" to "designing learning environments for the appropriation of knowledge and, as a consequence of this change in focus, the transitional object takes on a central role" (Hoyles, 1993, p. 2). In our microworld, students explore the potentially rich environment of animation and use it as a means for mathematical inquiry. By working through the activities and tasks, they begin to explore their own definitions of mathematizing environments, distance, scaling, and so on.

Software Design

The software interface comprises four primary windows and a graphical display for the animations. Students build objects in a graphing window that consists of a local and global plane, use a table for displaying the point values in relation to the local and global planes, a transformational record by which the animations are enacted, and an object palette for saving and reproducing objects and their characteristics. The windows are linked dynamically and can be adjusted to support predictions, data gathering, and feedback. Feedback consists not only of interface and usability hints but also allows students to assess their progress on the various activities and tasks in the curriculum. Students who feel they have not mastered certain concepts can choose to keep the detailed feedback available even as they move on to more advanced topics.

The software is collaboratively designed by a team of mathematics educators and game and graphics designers. The design team has sought to build software that acts as a genuine transition to the use of professional animation and graphics tools such as Photoshop, Freehand, Flash, and 3-D Studio Max. At the same time, the mathematics educators sought to ensure that the (usually invisible) mathematics that underlies animation and graphics packages would become visible to the student. 115 Mastery of this mathematics accompanies and is required for creation of the animations. Pedagogically, the designers also sought to implement conceptual corridors in the way tasks are sequenced. Practice is required, and assessments are continuously and periodically gathered. The design, finally, depends for its final form on implementation in classrooms where student interactions are encouraged and teacher guidance and monitoring are assumed.

Research

Research on the use of the software is underway through the use of clinical interviews. These interviews consist of working with urban students in St. Louis through a series of tasks, many of which themselves develop the basic skills necessary for working with the software. The interviews will heavily inform eventual evolution of the software from its current state as a developmental alpha to a beta version that we will use during the spring and summer of 2006 on groups of students. Results of these interviews will be incorporated into our conference presentation.

Conceptual Trajectories Embedded in Task Design and Articulation

We outline the conceptual trajectory embedded in the first level of our materials and describe how we have developed and sequenced the tasks to incorporate increasing resources for building animations and to complete subtasks along the way. Each subtask must be related to both the goal of proficiency in mathematics, as evidenced by performance on embedded and external assessments, and in the use of the software as a tool for potential transition to professional graphics and animation software.

The overall trajectory of level one of the project can be described in five phase as follows:

I. Introduction to the Cartesian plane and to building objects on the plane

II. Introduction to Congruence, Similarity, Reflection and Scaling through Tessellations

III. Translations along a diagonal line as a manifestation of ratio

IV. Mazes: Ratio in translations and scaling

V. Designing original animations

Example 1: Introduction to Cartesian plane and constructing objects (phase I). In the first set of activities using Graphs 'N Glyphs, students learn about graphing on the 2-D plane (introducing metrizability of the Cartesian Plane and reinforcing wholenumber addition and subtraction), a simple dot-to-dot model for reproducing and modifying basic shapes, and "Taxicab Geometry", a non-Euclidean geometry closely related to Euclidean geometry (differing by one axiom and arguably developmentally accessible earlier as a better model for human-created cities) (Krause, 1975). Activities to reinforce operating, locating, and graphing on a coordinate plane (and screen animation space) include a Battleship-type game and predicting geometric shapes from point coordinates. Integer addition and subtraction are reinforced through navigation, using both magnitude and direction, to destinations on 116 a one-dimensional map (a street). These integer operations are extended to two dimensions via Taxicab Geometry, which combines horizontal and vertical movements to get from point to point, rather than diagonal definition in Euclidean geometry). Thus integers (and, shortly thereafter, rational numbers) are interpreted graphically. The graphical representation sets up the use of rational numbers in multiplicative operations, including ratio and similarity.

Students then combine these skills in creating their own objects using a dot-todot representation. Not only will they need to master coordinate graphing (in order to place their dots) but they are asked to make an existing drawing "more realistic" with additional points.

Example 2: Congruence, Similarity, Reflection, and Scaling through Tessellations (phase II). Fundamental to this part of the level one learning progression is the understanding of the multiplicative (ratio) relationships underlying the concepts of similarity (Lehrer et al., 2002) and scaling (Confrey & Scarano, 1994). Students identify and develop their concept of what constitutes a similar figure in 2-D space, and are introduced to ratios as mathematical tools to preserve the similarity of figures. Students are challenged to construct and use congruent copies of screen objects to build tessellations, and then to scale those objects to build different tessellations. Students distinguish between additive incrementing and multiplicative change of objects' side lengths, and to recognize the role of ratio multiplication in preserving similarity. The scaling of figures by means of whole-number ratios, followed by composition of ratios to generalize the utility or the concept and improve their proficiency with and understanding of ratio is supported by the software as students build tessellations with larger versions of the initial objects, and experiment with decimal values for the scaling factor. This conceptual development then supports more sophisticated use of the animation tools in the next activity.

Example 3: Mazes (phases III and IV). Graphs 'N Glyphs maze activities complement the development of the ratio concept in scaling by employing it in translations as well. Students are provided (and later design) characters that must traverse a maze—moving their character (object) across the screen, through or around obstacles, and finishing at a goal with particular spatial or action requirements. The activities comprise increasingly complex animation tasks. To avoid or pass through obstacles, students must scale their characters, which reinforces and expands the scaling proficiencies established in the Tessellations activity. Moving their characters across the screen, however, promotes a different recognition and use of ratio, though still within the context of animation. The initial mazes can be negotiated solely with vertical and horizontal translations. Subsequent mazes, and the goals of the tasks, however, provide a need for diagonal movements. Some mazes can be traversed with a combination of horizontal and vertical translations, but this is time-consuming. Other mazes include channels or paths that are themselves diagonal. Students construct schemes to utilize ratios to combine the vertical and horizontal components of slope (Confrey & Scarano, 1995), and then use 117 similarity to recognize the ratio relationship implicit in a long straight diagonal and accomplish a long diagonal translation in a single step. Students' fluency and flexibility of ratio use is promoted, in part, through the students challenging each other with mazes they construct themselves.

At the end of these three activities, the students will possess the necessary mathematical and software skills to create animations using Graphs 'N Glyphs (phase V). Thus, the final project, worked on intermittently throughout the project, will be to create an original animation and share it with other students, teachers, and parents. Students will be given a project description that includes criteria on which their projects will be assessed. In addition, they will take pre- and post- assessments on their knowledge and understanding of the relevant mathematical concepts. Finally, they will be asked a set of questions, tailored to their animation, to explain the interrelationships among the three representational spaces, and will be assessed on their ability to apply mathematical concepts to explain the representations.

Conclusions

Computational environments represent a powerful link between the use of the mathematics and the deeper understanding of how the use of (ubiquitous) animation and computer graphics work. Traditionally, we speak to students about the utility of studying mathematics without providing them compelling illustrations. Microworlds like those created in Logo (Papert, 1980) provided interesting ways to link the graphical display from the turtle to concepts of programming and geometry, and in doing so, strengthened students' understanding of all three ideas. In this way, it did provide a form of a career trajectory, as a means to transition to other computer languages.

The vast changes in graphics capabilities, driven by both game environments and simulations capabilities (flight simulations, military applications, engineering environments) have largely failed to influence the teaching of mathematics at the elementary and middle grades. Some exceptions include gaming environments like Sim City (Bos, 2001; Squire, 2005) and, to a smaller effect, Civilization (Squire, 2006).

As an extension of these efforts, our research team has chosen to concentrate on providing students access to intermediate or transition tools for animation to draw students into the question of how images on computers are made lively, realistic, or 3-dimensional on discrete, pixel based, two-dimensional video screens. In pursuing this question, we have created two kinds of multi-representational symbolic inscription tools, (1) tabular displays of objects and the effects of the transformations on ordered coordinate pairs, and (2) a transformational record which creates the sequence of animation actions.

Through this research, we will assess how successful the conceptual trajectories are in building the students' mathematical understanding, in assessing the sophistication and comprehensiveness of the student-created animations and their use of various resources and tools, and the relationship between the two, as well as the 118 ways in which students' sense of themselves as potential students of math, science and technology changes, over the course of the participation in the interviews and subsequent workshops.

Developing Dynamic Sketches for Teaching Mathematics in Basic Schools

Valentina Dagiene, Vilnius University, Lithuania
Egle Jasutiene, Institute of Mathematics and Informatics, Lithuania
dagiene@ktl.mii.lt

Reflecting on the actions and activities that are enabled by a new technology can catalyze a reconceptualization of the content and methods of teaching mathematics. Software might provide tools that enhance students' actions and imagination. The five years long research has been developed on two phases. The first phase was to analyze problematic dimensions of teaching mathematics in schools using computerbased technologies and searching the most suitable software for the National curriculum of mathematics. The next step was to investigate (also to localize) the Geometer's Sketchpad and to built the various sets of dynamic sketches for teaching and learning mathematics in basic schools. More than 800 dynamic sketches have been developed within 9 th and 10 th grades (years 16 and 17) mathematics curriculum. Two CDs and descriptions have been prepared and published. The paper explores the main questions of developing dynamic sketches for mathematics curriculum of basic school in Lithuania.

Introduction

Together with the rapid increase in the number of computers in schools a similar increase in the number of software products of the new technology has come. Mathematics is one of the main subjects in schools which require a lot of students' efforts. Using technology while teaching mathematics is not only necessary but rather inescapable (Balacheff, 1996; Hoyles & Jones, 1998; Posmastier, 2003). Regarding the Strategies of Information Technologies Implementation of Education in Lithuania a wide attention is paid to educational software's implementation to curricula of various subjects: schools are supplied with such software and prepared methodical materials on it, besides different kind of workshops to teachers to introduce them the software are being held. That is one of the most important means to direct the computerization of schools towards the positive direction of upbringing improvement.

Mathematical literacy in school is continuously gaining the stronger emphasis – that is one of the aims suggested by the politicians of the European Union. All pupils have to perceive the basic elements of mathematics. That's why they need a fair motivation. In this case the implementation of information technologies is one of such inviting solutions. "Computers have much more to offer than drill and practice; in fact, they can be used in conjunction with all parts of the constructive learning process, when embedded in classroom culture where there is communication and cooperation. There are several ways in which computers can be used; for example in 121 practicing of skill in a way that incorporated understanding or in simulations that enhance concept building" (Becker, 1996).

Dynamic sketches created by computer provide the possibility of a deeper acquaintance with mathematical definitions, theorems, and properties. Often geometry is presented in static form in which the true and deeper meaning of a theorem does not get the true exposure it should. Thus the sketches developed by using computer-based technology help to look deeper to theorems of mathematics of secondary education (Jackiw, 1988). D. Tall in his paper stresses that students using paper and pencil drawings of graph saw them as geometric shapes rather than a process of inputting x and outputting y (Tall, 1996). The field of dynamic experimentation has been opened to new objects, the conics, where one can manipulate hyperbolas, ellipses, parabolas or their equations.

The main properties of software that supports teaching of mathematics

When implementing IT in Lithuanian schools the computer applications that could be helpful for the implementation of the purposes, aims and didactical attitudes that are introduced in National Curricula and Educational Standards, and at the same time simple to use and handy for introducing of the wider scope of mathematical topics were searched.

With reference to these criteria in 2001 the educational software "Geometer's Sketchpad 3.11" [www.keypress.com/sketchpad/] was bought to all Lithuanian schools; it was localized, and in 2004 the localization was cardinally updated presenting the Lithuanian version of "Geometer's Sketchpad 4" (Jackiw, 2006). This educational software helps to implement the purposes, aims and didactical attitudes that are introduced in National Curricula and Educational Standards.

According to Jackiw (2006) Geometer's Sketchpad 4 is "a software system for creating, exploring and analyzing a wide range of mathematics. You can construct interactive mathematical models ranging from basic investigations on shape and number to advanced, animated illustrations of complex systems." It allows an organized set of primitive actions to be turned into complex one using macroconstructions. The drawing produced at the surface of the screen can be manipulated by grapping and dropping around any point having sufficient degrees of freedom (Jasutiene et al, 2005). Therefore teaching pupils to draw sketches helps to develop their creativity, algorithm thinking, carefulness, accuracy, and mathematical skills. The sketches created by pupils or teachers may be used for demonstration or research purposes. Dynamism of sketches created by the software may replace multiplex actions of drawing geometrical shapes on paper or on the desk. 122

Modeling and using dynamic sketches

Drawing of sketches

The experience of other countries indicates that sketches are often used to solve particular task, for example, to demonstrate Pythagorean theorem, the Golden Rectangle Revisited, and so on (Key Curriculum Press). There is, however, a group of sketches created to study particular mathematical or even physical topics.

In order to construct a meaningful sketch you need: 1) to choose a topic which visualization can be supported by "The Geometer's Sketchpad" possibilities, 2) to model the sketch, and 3) to construct the sketch. The Geometer's Sketchpad is convenient to introduce approx. 50% of math topics introduced in secondary schools, i.e. plane geometry, plane analysis, basics of geometrical functions and their charts, basics of mathematical analysis, trigonometry, part of stereometry (part since the software does not support 3D system), differential equations' directional fields, number line and basic arithmetic operations, as well as vectorial algebra and complex numbers.

After the proper topic of mathematics is chosen it is needed to analyze for which purpose the sketch will be created, i.e. which definition, property, or theorem must be demonstrated by the sketch. Special regard has to be paid in order to avoid the situations when the created sketch could serve as an obstacle of learning process or could bring confusion to pupils' minds.

The modeling of sketch should begin after these considerations are taken into account. The modeling of sketch is quite difficult stage and requires different skills and knowledge: 1) knowledge on mathematics theory, 2) skills of methodology of mathematics teaching, 3) deep sophistication on software, and 4) ability of information structuring. Possibilities of the Geometer's Sketchpad allow creating sketches that universally approach geometrical objects and their relations. For example, functions may be analyzed regarding two different aspects: changing functions' coefficients as parameters, selecting concrete and definite values or using the scroll bar for changing coefficients and observing function's chart as well as changing function's chart (dragging one of the chart's points) at the same time observing how the coefficients of function are changing.

Therefore when modeling the sketch on paper the common picture of mathematics is needed to be seen and the context of the future sketch has to be anticipated. After getting acquaintance with the software, the creation of dynamic image of the modeled sketch becomes not so complicated. However, programmer, who is intended to create the sketch, besides the understanding of the software, has to obtain deep knowledge of algebra, geometry and methodology of teaching mathematics as well as skills on algorithm approach.

Principle of the Geometer's Sketchpad is rather simple: we have an empty sheet of paper, ruler, pencil, calculator, and several drawing commands, thus we have to create. Very often quite complex dynamic images have to be created by using the merest means. In such case quite a few steps have to be performed. For example, to 123 create a decision model of inequality the algorithm of approx. 200 has to be implemented. The Geometer's Sketchpad does not limit the possible number of algorithm steps. It rather depends on the computer facilities as well as person's invention.

When creating a sketch the ordinary means that are not included in the software often may be necessary, e.g. the scroll bar for changing coefficients or angles' marking arc. Such means may be created by user and then implemented in various sketches. However, when looking at the final sketch all drawing steps remain invisible. In most cases just desired result, i.e. the complete image, is displayed. Thus, to create a sketch there is a need of time, knowledge of the theory and teaching of mathematics as well as familiarity with software possibilities.

Set of dynamic sketches for mathematical lessons

In 2003 the research on software implementation in Lithuanian comprehensive schools has been performed and it has revealed that just 27% of schools are actually using the Geometer's Sketchpad during lessons (Ministry of Education, 2003). It is not an easy task to the teachers themselves to develop sketches. The main reasons of this are the following: lack of time to properly prepare (teachers have many lessons), fear of technology and insufficient computer skills. Therefore the decision was made to help teachers to create sketches that are needed according to the National mathematics curriculum and to provide instructions on implementing those sketches in their lessons.

Senior grades (16-17 year) were selected as target group of the research since: 1) the curricula of these grades embrace the most part of mathematics' topics that can be visualized by dynamic sketches, 2) in these grades the major part of new definitions, properties, and proofs (although most of them do not need to be demonstrated, their sense is still obscure to students; students remain not persuaded in their correctness) are introduced, 3) in these grades the summarized course, which has influence to further studies, is provided.

Regarding these criteria the curricula of mathematics in 9-10 grades was analyzed and the topics that can be directly visualized by the Geometer's Sketchpad were selected. For 9 th grade the following topics were chosen and sets of sketches were developed (the number of sketches are presented in brackets): linear function (146), quadratic function (90), systems of linear equations (21), similarity of triangles (78), solution of quadratic equations (19), and circle and circular disk (116). Similar actions were applied to 10 th grade curricula – after analysis the following topics and sketches were selected: graph of a function (95), set of equations and inequalities

(Z3), quadratic inequalities (39), trigonometry functions of acute angles (83), and exploration of triangles (74).
Although the Geometer's Sketchpad possibilities depend on invention of user, there was no visualization provided for combinatorics, probabilities, solid geometry, and percentage. Visualization of these topics using the Geometer's Sketchpad is too 124 complicated and in some cases even impossible or inadequate in order to introduce certain topics in understandable way for students.
All sketches were developed implementing solid methodology: 1) a short description, containing the information on what to do with the sketch and where attention should be paid, was provided together with sketch, 2) sketches were dynamic, i.e. it's possible to drag objects, change parameters and therefore the possibility to go back to the initial state always remains, 3) there is a help provided to user and upon the demand the answers can be given as well.
All sketches are provided in CDs with descriptions, that help to use the sketches, theoretical material of a textbook, and recommendations on how to solve certain tasks regarding mathematics' textbook in efficient way.
Two types of dynamic sketches have been developed: 1) visualizing theory and 2) visualizing problems. The dynamic sketches that visualize problems have several properties: 1) one dynamic sketch embrace whole group of problems and 2) in many cases they widen the problems' conditions. The dynamism of Geometer's Sketchpad's sketches provides an opportunity to visualize a whole group of problems by using one sketch. Solution of quadratic equation may serve as an example. By solving a parametric quadratic equation the whole set of such equations may be solved.
By creating sketches the complete image of mathematics had to be demonstrated and therefore sketches of problems provide more information than it is required regarding the condition. For example, a student is asked to calculate length and width of the rectangle when the area and the perimeter of the shape are provided; in this case the dynamic sketch provides the graphs of functions related to rectangle's perimeter and area as well. This is the way how the simple problem of solid geometry becomes related with function and the relation between different mathematical topics appears.
Thus, The Geometer's Sketchpad helps to look at mathematics as an entirety rather than jumble of separated topics. However, when developing sketches their creators were avoiding to "overweight" them and were trying to organize material in such way that it wouldn't bother the main idea of a problem.
In 2003-2005 more than 800 dynamic sketches were developed: compact disks "Mathematics 9 with Geometer's Sketchpad" and "Mathematics 10 with Geometer's Sketchpad" (Jasutiene et al, 2003; 2005).
Teaching by using dynamic sketches: an example
There is an example of dynamic sketch that illustrates the 10
th
grade topic "system
of equations when one equation is non-linear". According to the National mathematics curriculum [4] a student should: 1) approximately calculate the solution of system of linear equations containing two variables, 2) solve ordinary equation 125 systems where one equation is linear and another quadratic (either in graphic way or in alteration way).
For this topic three dynamic sketches have been developed: 1) graphical solution of the system of two linear equations, 2) graphical solution of the system of two equations where one equation is linear one and another's graph is a circle, and 3) graphical solution of the system of two equations those graphs are circles. The first sketch analyses how the changes of the coefficients a, b, and c, result the graph of the equation ax+by=c and provides the graphical interpretation of system of two linear equations.
By changing the coefficients of linear equations students examine the whole group of linear equations' systems and may find the answer to the following sketch's problem question: how many solutions the system of two linear equations may have? This is the way to remind students the graphical method of solving the system of two linear equations, that was introduced them in the 9
th
grade.
The second sketch is intended to analyze: 1) how the change of the coefficients result the graph of equation ax+by=c, 2) how the change of the values d, e, and f result the graph of equation (x-d)
2
+(y-e)
2
=f
2
, and 3) the graphical interpretation of the solutions of the equation system

+ =
" + " =
(x - d) (y e)- f
a x b y c,
2 2 2
(Fig. 1).
Fig 1. The graphical solution of sets of equations: a) system of two linear equations, b) system of linear and circle equations, c) system of two circle equations
Such dynamic sketch is not complicated to develop - approx. 30 steps is enough, since The Geometer's Sketchpad possibilities provide an opportunity to develop graphs of functions directly (Jackiw, 2006). The short description on what should be changed or moved and what to notice is provided together with the sketch.
The sketch illustrates the whole group of systems of equations where one equation is linear one and another's graph is circle. When changing the values of equations' coefficients-parameters, the obtained systems and the interpretation of their graphical solution may be observed. That is the most important feature of such sketch [8, 9]. 126
To provide the entire picture of the topic the third dynamic sketch is developed; it illustrates: 1) how the change of values of the coefficients a, b, and c result the equation graph (x-a)
2
+(y-b)
2
=c
2
, and 2) the graphical interpretation of the solutions of equation system

+ =
+ =
(x - d) (y e)- f
(x a)- (y - b) c ,
2 2 2
2 2 2
. In fact, when examining the given
examples in the sketch the whole trick is to answer the question how many solutions such system can have.
Developed dynamic sketches help to reveal the whole picture of mathematical topic and the sketch of extended course may incorporate itself in the common context of the given topic. Dynamic sketches are easy to control since all of them have a similar structure; by examining the first sketch it's already possible to guess what the second and the third one will be about. Usage of these dynamic sketches helps to examine the systems of equations and it brings valid convenience as well, i.e. teacher doesn't have each time to draw new examples of graphs of systems of equation on the desk.
Conclusions
ICT enhance teaching mathematics and motivate students for investigation. The first step is to provide schools with the software proper to teach mathematics. The further step of particular importance is to prepare action plan that would embrace teacher training, information dissemination, development of methodological and educational aids, guidance for assessment, etc.
In Lithuania The Geometer's Sketchpad country license was purchased in 2001 and right after that teacher training and information dissemination were initiated, however that was not enough. Just small part of teachers began to use the software during their lessons. The main explanation of this was lack of time to prepare for the lessons.
Regarding this the decision to reconsider the mathematics curriculum for basic school and relate it with scripts developed by using the Geometer's Sketchpad (dynamic sketches and proofs) was made.
For 9
th
and 10
th
grades (16-17 years) more than 800 dynamic sketches and scripts according to the mathematics curriculum were prepared. Two CDs and descriptions of them have been developed.
The model and examples described in the paper emphasize educational aids for basic school curriculum. The developmental model should be modified to other levels and grades. However, the basic procedures would be quite similar. 127

A pedagogy-embedded Computer Algebra System as
an instigator to learn more Mathematics
13
Thierry Dana-Picard and Ivy Kidron
Department of Applied Mathematics
Jerusalem College of Technology- Israel
Email: dana@jct.ac.il - ivy@jct.ac.il
The constraints of a Computer Algebra System are generally classified as internal constraints, command constraints and organization constraints. In fact, a fourth kind of constraints exists, namely motivating constraints. These constraints consist in features or commands of the CAS whose understanding demands sometimes from the user to acquire more mathematical knowledge than what has been taught in a standard course. Theorems can appear which necessitate learning beyond the syllabus framework. Such 'new' theorems appear generally in two situations, namely when using a pedagogy-embedded feature of the CAS (either a posteriori help, or a priori hints), or when using certain commands and trying to analyze the results. We describe a research frame in the first year Foundation Courses in Mathematics, in our Engineering College. With this research, we wish to understand more deeply the instrumentation processes at work with the students and to check motivations for a change in the institution's culture.
Levels of intervention of a Computer Algebra System.
As an assistant to mathematical learning, a Computer Algebra System (a CAS) offers three levels of help:
a technical tool performing technical tasks;
a tool whose performances help to develop more conceptual understanding;
a technological help to bypass a lack of conceptual knowledge, where such knowledge is out of reach, at least in "the next future".
The first level is the blackbox level and has no great pedagogical value. Maybe it allows the teacher to save time for reflexion and theoretical understanding, but a perverse effect is the loss of manual computation skills, as noted by (Herget et al.,

2000). Integration techniques, techniques for solving equations, either linear or nonlinear, are abilities which could disappear. The following claim has been heard in a professional meeting: "nowadays, there are computers who make the computations;

13
This research was supported by the Israel Science Foundation (grant No. 1340/05). 129
thus there is no need anymore to teach integration techniques". We disagree with this
claim, and wish to show that, on the contrary, Computer Packages enable to learn and
to understand more Mathematics than expected.
We can distinguish a level 1 , where the student uses the CAS for verifying results.
There are at least two kinds of verifications:
Verify either a numerical result or a "closed" algebraic expression. The mathematical
correctness of the verification is not always evident. For example, two different CAS
or even two different commands of the same CAS, or a CAS and hand-work, can
provide different algebraic expressions, both valid. As inert expressions, they are
different, but when defining functions, which are dynamical objects, different
expressions can define the same function. The verification issue has been addressed
by Lagrange (1999) and Pierce (2001).
Perform the passage from n to n+1 in a recurrence, after the CAS enabled to
conjecture a formula (see (Garry 2003) page 139).
Steiner and Dana-Picard (2004) commented aspects of level 2. Low-level commands
are important for cognitive processes attempting to afford a good conceptual insight.
A CAS command is called a low-level command if it performs a single operation,
while a macro is a command programmed to perform a sequence of low-level
commands. Low-level commands act as the atoms of every computerized process for
solving a problem.
Because of syllabus limitations and of time limitations, level 3 is less commonly
considered. It appears close to the frontier of the syllabus, either for exercises aimed
to broadening knowledge beyond this frontier, or for problem solving when the
necessary theorems have not been taught and will not been taught "in the next
future". Technical use of the CAS fills the gap; see (Dana-Picard 2005b).
A fourth level exists: a CAS is a device whose performances may incite the user to
acquire more mathematical knowledge. The reason can be one of the two following:
Multiple commands are available for seemingly the same purpose. For the user to
make an intelligent decision which command to use, he/she must have a good
knowledge of the Mathematics implemented in the algorithms.
There exist situations where a unique algorithm is available, either because of the
theoretical state-of-the-art or because of the decisions of the developers. This limits
the diversity offered by the CAS; this issue is studied by Artigue (2002), page 265. In
such a case, the theorem transformed either into an algorithm or into a command is
not always a standard theorem taught in a standard course; see the example with
Derive in section II. 130
In every case, the implemented Mathematics has to be understood. In order to afford
a real understanding of the process, the user has to learn new Mathematics. We called
this occurrence a motivating constraint of the software (Dana-Picard 2006).
Generally, the word constraint evokes a limitation, an impossibility to go beyond a
certain borderline. For a software package, this can be a limitation on the size of
numbers, on the number of successive parentheses, etc. Among the most documented
internal constraints are the finiteness of the screen for graphical applications, and the
fact that the real numbers are always approximated by rational numbers. Following
Balacheff (1994), Guin and Trouche (1999) distinguish three types of constraints of
the artifact, called respectively internal constraints (linked to hardware), command
constraints (linked to the existence and syntax of the commands), and organization
constraints (linked to the interface artifact-user).
The constraint that we meet here is of a totally different nature: instead of limiting
the user within the borders of a certain topic, the CAS demands from the user to go
further, to learn a new theorem, a new technique. It is a motivating constraint, which
leads to a broadening of the student's mathematical landscape. After its apparition,
the mathematical knowledge is not supposed to be only shown anymore, the student
is incited to learn the new theorem, and then becomes able to manipulate this
knowledge, either with or without the help of the technology.
Pedagogy-embedded CAS.
Until recent times, the CAS did not give hints in order to find a pathway towards the
solution of the given problem. This is not true anymore: pedagogical features have
been implemented into Computer Algebra Systems. We call such systems pedagogy
embedded CAS.
Derive 6 has a step-by-step feature, well developed for Calculus commands. Every
step corresponds to one low-level command, as it implements one single theorem
such as an integration formula. There exist surprising situations, e.g. the following
formula is a central item:
f x dx ( ) f x f a b x dx
b
a
b
a
= ( ) + (+ !)
2
1
(*) ( )
As an example, look at the following integral:
+ !
=
a
p p
p
x a x
x dx
I
0
( )
, where p is a nonnegative real parameter. For p=0,1,2, the computation is straightforward, but for
larger integer values and for non integer values of the parameter, the work is nonilluminating. For given a, and for p=1/3, other CAS, where this formula seem not to
be implemented, cannot generally compute the integral in a reasonable amount of 131
time. Knowing the formula (*) enables to compute the integral with paper and pencil,
within a few steps, and last but not least, for the general parameter:
! + ! !
!
+
+ !
=
+ !
=
a
p p
p
p p
p
a
p p
p
dx
a x a a x
a x
x a x
x
x a x
x dx
I
0
0
( ) (( ))
( )
2 ( )
1
( )
-
2
1
2
1
-
0
a
dx
a
= " =
Formula (*) is not trivial; it is commented, and examples are given, in (Dana-Picard
2005b). An experienced lecturer, working in another institution, told to one of the
authors: "I would not dare to ask my students to know such a theorem". We think that
this implementation is a good opportunity to teach the theorem and some of its
applications. As A. Rich says: "The transformation rules Derive displays are those it
uses to simplify an expression. They may or may not be the same as those currently
taught to students. However, if teachers see an advantage to an unfamiliar rule used
by Derive, they may want to ask their students to verify the validity of the rule and
then the students will have an additional tool in their arsenal" (Böhm et al., 2005,
page 36).
This parametric integral has been proposed to an average student, named Ori, during
the preparation to an oral examination. At first glance, as he thought that the
parameter is a non negative integer, he proposed to decompose the integrand into a
sum of partial fractions. The tutor showed him the Derive's step-by-step-solution.
Tutor: Do you recognize a known formula?
Ori shows Formula (*), then says: No, actually we have not been taught this.
Tutor: Can you apply the formula?
Ori: Yes. (works for a while); oh, I never saw this, you must teach this!
During another session, Ori is proposed the integral
+ !
=
4
0
4
dx
x x
x
! . He says: this
is the same case I saw last time; let us apply the formula.
Finally, at the end of the same tutorial session, he "receives" the following integral:
+
=
2/
0
cos sin
cos
#
dx
x x
x
K .
Ori: It's not a power, but it must work the same way, as it's the same structure.
Tutor: And what about
+
=
2/
0
cos sin
cos
#
dx
x x
x
L
p p
p
?
Ori: Surely the same thing.
He makes the work and claims: Oh yes! You must teach this in classroom!" 132
Maybe that without the step-by-step, the user would not have discovered the formula.
Therefore, we consider this feature as part of the software's motivating constraints.
Maple is pedagogy embedded (via the Student package); here the conception is
different from Derive's step-by-step philosophy, and the learning process induced by
them develops otherwise. We present here an example in a different context.
Consider the following initial value problem:

=
! =
y)0(1
xy ×
dx
dy
. Working with paper and
pencil, a student is generally taught to use an integrating factor.
When using Maple's assistant for Ordinary Differential Equations, the student can
choose the method: Lie methods, Classification methods, etc., but the usage of an
integrating factor is not available for this exercise. A noticeable fact is that the
pressing a button is accompanied by the (optional) translation of the command in
Maple's language. The option "Laplace Transforms" leads to a much more
complicated form. Therefore the student is incited to learn what these methods are,
how they work and which benefit he/she can afford from their usage instead of what
has been taught in regular class.
Tools shape the learning environment (Trouche 2004b), and the last influences the
mathematical contents. The two embeddings of pedagogical features that we saw
above, and the learning processes spanned by them are different. Note that each kind
of software follows general algorithms, starting from pattern recognition, and whose
sequential steps are based on the implementation of general theorems. The human
brain works less sequentially, therefore intuition can lead to other pathways towards
the solution of the exercise. With the integral of section II, we presented earlier an
example of such a situation. This does not mean that technology has not been
programmed properly: a proper usage of technology does not require from the
technology to mimic human actions.
Let us compare briefly the two ways. On the one hand, Derive's step-by-step feature
gives an indication on how the software works; if the student did not know how to
solve the exercise, he/she has now an opportunity to understand by some kind of
"post-mortem" analysis. Maybe an unknown theorem appears, as in our example, and
the student can wish not only to discover it and to use it afterwards, but to try to have
a more profound insight in its proof and its mathematical meaning. On the other
hand, Maple's assistant lets some freedom of choice to the student, by offering
different options before the computation is performed. This is still more evident
when using the tutor for computing integrals. In this case, all the rules are presented
as "buttons"; after a button has been pressed, an immediate indication is given 133
whether the rule can be applied or not. If not, the student is invited to choose another
rule, and so on.
Finally, we wish to note that even without a specific pedagogical feature, a CAS can
be an instigator to further mathematical learning. This is the case in (Kidron 2003)
for the conceptual understanding of the limit notion in the derivative, and deep
learning of the theory is motivated by the usage of Mathematica.
Instrumentation.
At the beginning, we saw Derive's step-by-step as providing the student with "a
posteriori assistance", in order to understand what he/she would have been required
to do. Actually, the usage of the step-by-step feature of the software can be
considered as an "a priori" usage, in one of the following fashions:
The user can discover a way of solving the problem either different from his/her way;
Suppose that the student did not find how to solve the problem; he/she can ask for
the first step (pressing the appropriate button) and the CAS opens a pathway. At
every step, the student can abandon the step-by-step session. This is based on general
theorems that the student does not automatically know.
When such a situation occurs in classroom, the teacher can build various activities,
enriching by a large amount the mathematical knowledge and culture of the learners.
If at the beginning, the student influenced the software's behavior in order to obtain
the needed result, in the second scenario the software forces the educator to teach and
the student to learn a new topic, a new theorem.
We have here elements of an instrumentation process (Chevallard 1992, Lagrange
2000, Artigue 2003 page 250, Trouche 2004a): "Les potentialités et les affordances
d'un artefact (en occurrence le CAS) favorisent le développement de nouveaux
schèmes (ou font évoluer les schèmes antérieurs) de résolution d'un type de tâches
(ici le calcul d'une intégrale définie)" (Trouche 2005; private e-mail). More briefly:
"Instrumentation is precisely this part of the process where the artifact prints its mark
on the subject" (Trouche 2004b, page 290).
Of course, this process is not reduced to the acquisition and internalization of one
single theorem; the present examples are only one occurrence of the mechanisms
involved.
Contribution to the institution's culture.
We use the word "institution" in the sense of (Artigue 2002). Each institution has to
decide whether to introduce the usage of a CAS in Mathematics courses or not to do
so; not to deal with this issue is also a kind of decision. For example, the institution
named JCT decided to teach MatLab and to use it in every engineering cursus. 134
Both authors act as coordinators of first year Foundation Courses in Mathematics, i.e.
courses in which all Engineering students at JCT are involved. In a small subset of
classes, which can also be viewed as an institution, the authors adopted other
packages; for example, a course in Ordinary Differential Equations has been given
last year together with practice sessions based on the usage of a CAS. The
"institution culture" has already changed in certain classes, and is susceptible to
change the institution's culture in a larger scale (e.g., all the first year Foundation
Courses in Mathematics at JCT):
"Tools are not passive, they are active elements of the culture into which they are
inserted."(Noss and Hoyles 1996), page 58).

Teachers & Teaching:
Technology and Teacher Education — Some Thoughts
Mili Das, Institute of Education for Women, Hastings House, Kolkata,India
milidas@vsnl.net
Today as in earlier times, there is much rhetoric about the revolutionary impact on
students' learning that will result from brining a new technology into the classroom.
In the past, it was the motion picture, or the radio — the usual teaching aids and
instructional television. None of these fulfilled expectations. Now, it is the computer
that is believed to herald a new era of more effective learning. With respect to the
mathematics classroom, computers are claimed to have the potential to change
pedagogical approaches radically and to improve students' learning. Traditional
classroom teaching methods related to mathematics have been associated with direct
teaching, black-board demonstration, use of textbooks or work-books, drill and
practice activity, homework and so on — a positivistic, behaviourist model. Teachers
who generally teach mathematics this way will most likely use technology similarly.
But this traditional classroom and teaching techniques are creating an environment
that tend to undermine higher order learning skills, such as creativity, independent
thought, inquiry and innovation. It is fundamental to our homogeneous medium for
learning that we allow others to tell us what to learn, how to learn and even why we
are learning. These mean pupils are being deprived of the scientific approach of
teaching — learning systems being the generation of this technological era. Basic
differences in the new evolving paradigm will be put the learner in charge. To create
such an environment, it is necessary to introduce new technologies like computers,
websites on the Internet and DVDs in classroom teaching. So, the objective of this
paper is to discuss how the would-be teachers and teachers can be oriented with the
use of new technology. What kind of programme should be arranged for the trainees
in teacher education courses; to familiarise them with the uses and importance of
these technologies? The importance of a mathematics laboratory will also be
discussed in this context.
Mathematics has always occupied an important position in the school curriculum.
Mathematical skills and applications form an indispensable tool in our daily life. In
the present era of technology, mathematics plays a very important role. There is
hardly any discipline that does not owe anything — directly or indirectly — to
mathematics.
However, mathematics is still characterised as a 'dull' and difficult subject,
primarily due to its hierarchical concepts, deductive approach in proofs and abstract
nature of content. A phobia about mathematics has been created in the minds of 137
children; a fear that mathematics is 'difficult to learn'. As a result, students seem not
to express enough interest in the subject and thus become weak.
Its abstract nature and hierarchical concepts are not the only reasons
contributing to distaste for mathematics. Traditional methods of teaching the subject
in schools are also responsible for this. Every year, at the time of the practiceteaching period, I supervise 45 to 50 mathematics lessons from standards VI-VIII,
executed by my trainee students, visiting different schools in Kolkata. My
observation is that the traditional 'chalk & talk' method cannot be a solution to the
inherently abstract nature of mathematics. On the other hand, if trainees use various
types of teaching aids, students respond better than usual to the typical mathematics
lesson. These aids, including the use of concrete objects and visual presentation, have
a hugely positive impact on teaching and learning mathematics. This approach, and
similar ones, will motivate students towards learning mathematics. However, to
interact with the present-technology based educational system, we need something
more — aware, and able teachers. But more on that later. School students should be
provided with a dynamic system of teaching — a learning facility to achieve the goal
of mathematics.
So, our first objective is to find out how the new/digital technology can be
blended with the 'chalk & talk approach' in schools. To bring in computers, CDROMs, DVDs and the Internet into classroom teaching, we have to first familiarise
our teachers with the uses and importance of these.
Secondly, we have to remove the 'fear' of handling computers or any other
computer-related technology. All these are possible through short-term
courses/training/re-training programmes on the use of technology and its implications
in the teaching-learning process, for teacher-trainees and freshers who plan to take up
teaching as a profession.
An alternative approach is the inclusion of some technology-based concepts
and their uses in the curriculum of the Teacher Education Course. With this view, the
Technology Based Teaching Strategy (technology based instruction, CD-ROM,
websites, DVD) has been introduced in the Teacher Education course of Calcutta
University from the year 2004. But no provision has been allotted to develop
practical experience. Only theoretical concepts would not inspire teachers to adapt a
technology-based instructional approach in the classroom.
The proposed Programme:
In teacher education colleges, there should be provision for a mathematics
laboratory with the following equipment:
a) Tables, Charts on different topics of Arithmetic, Algebra, Geometry,
Trigonometry, Mensuration, Calculus and Coordinate Geometry.

b) Models of different mathematical shapes. 138
c) Experiments to verify different results/formulae in different branches of mathematics.
d) Computer, CD-ROMs, an Internet facility, Data-Projector to prepare lessons (courseware).
e). Books and Journals
f). Portraits of Mathematicians
Not just the facilities; the adequate practice of these tools is important.
In this laboratory, trainees should also be provided with the practical experiences. Like other scientific subjects, laboratory experience in mathematics is important in providing direct access to teaching accessories, so that these can be used confidently by trainees to make the teaching lesson effective and also enhance their own concepts.
The type of programme that can be adopted in the teacher education course to acquaint mathematics teachers with the use of digital technology, and to train them to enhance their concepts using the mathematics laboratory to prepare courseware, is elaborated below.
Details of the program:
1. Trainees (trainee-teachers and would-be-teachers) have to prepare 5 or 6 simulated lessons in his/her total training period.
2. Concept & Purpose :
The dictionary meaning of the word simulation is 'pretence' or 'imitation'. A simulated lesson is a micro-lesson that is taken up for teaching in a make-believe classroom situation. The primary purpose is to enable a teacher to practice teaching with the focus on a single teaching skill, as well as to develop the skill of operating the computer as a teaching tool.
At this stage, trainees will take the help of charts/models and can perform experiments to develop a clear concept to prepare the simulated lesson. The prepared simulated lesson has to be presented on the computer to his/her peergroup.
3. The characteristics of a simulated lesson are as follows:
a) The roles of student, teacher and observers are to be played by the trainees (by rotation). 139
b) The lessons have to be short, aiming to maximise the use of a particular teaching skill
c) The ultimate aim is to make the teacher aware of the behaviour he/she displays in the class, of its purpose, and relevance to teaching learning.
d) Suggested skills for practice:
•Skill of Introducing a lesson
•Skill of Questioning.
•Skill of Explaining.
•Skill of Reinforcement.
•Skill of Closure.
•Skill of using the black-board where necessary
4. Preparation of courseware:
In the mathematics laboratory, trainees will be provided with the following experiences:
a) The teacher educator will explain the concept of a simulated lesson and will explain the components of each skill before preparing the lesson.
b) Before preparing a lesson, trainees will select a topic and will try to get more ideas using related charts or model or performing hands-on experiments. If necessary can collect information from the books and journals .
c) Trainees will then prepare the courseware as per the guideline of simulated lesson and then offer a presentation.
d) Working strategies:
•Trainees in the mathematics group are to be divided into small batches of 8 to 10 members each as per the strength of the class. This will be called a practice cycle.
•In a practice cycle, all the trainees will play the role of teacher one by one and two others will be the observers and the rests will be students by rotation.
•Subject teacher (teacher educator) may check the lesson before commencement of the practice.
5. Suggested distribution of time:
a) Concepts developed from charts, models or hands on experiment: 15-20 minutes (common for all).
b) Preparation time for courseware: 30 minutes (common to all).
c) Teaching time: 7-8 minutes.
d) Feedback by observers: 4-5 minutes. Teacher supervising the practice may comment on the skill after one complete cycle.
e) Feedback will be provided by observers in a given format. Observations will also be explained. 140
6. Evaluation:
a) Trainees will maintain a notebook that will be presented at the final examination and duly signed by the Supervisor (teacher educator). The notebook will comprise the following:
•Name of the skill, and its brief description.
•Teaching mode used.
•The courseware/simulated lesson

T: Discuss the change and ask for observations.
Since students know the area of triangle formula, and have seen the change in the area of the triangles with the change of height, they are convinced that 142 if height and base of a triangle are fixed, the area will remain unaltered, no matter what the triangle looks like.

Relation
between the
heights of the
triangles lies
within the same
parallel lines
3. Linking
past
knowledge
and
experience
T: What can you say about the pair of parallel lines given in the figures for each type of triangle in fig-1?
S: The heights of the triangles remain the same as they lie in the same pair of parallel lines.

4.
Specifying

the main
points
T: We have already seen that:
i) Triangles having same bases
and same heights will be equal
in area.
ii) Triangles in the same pair of
parallel lines have same height.
From these two properties it is
inferred that "triangles on the
same base and within the same
pair of parallel lines have same
area".
Now we will learn the formal
proof of the theorem.
5. Using
appropriate
devices
Charts, computer & CD 143
In this way, trainees will practise six skills of teaching. They will benefit in multiple ways through this programme:
• Teacher-trainees will be able to use technology comfortably in the classroom.
• Teacher-trainees will be able to integrate technology as a complementary tool for teachers in the classroom. This is a balanced approach.
• The variety of experience provided to students through this dynamic approach will go a long way in removing the abstractness of mathematics as a subject.
• This will also motivate students towards learning mathematics and provide a meaningful experience towards holistic learning.
Note: The author regrets that examples of other teaching skills couldn't be elaborated upon due to shortage of space. This will be provided at the time of a formal presentation.

Towards guided reinvention in a multimedia learning environment for prospective teachers
Jaap den Hertog
Freidenthal Institute, Utrecht, the Netherlands
j.denhertog@fi.uu.nl
This paper discusses the role of a multimedia learning environment, MILE, for the learning processes of prospective teachers. MILE is a Multimedia Interactive Learning Environment for prospective primary school teachers, with content for primary mathematics teachers' education programs. We summarize an investigation on student-teachers' use of language and how they give meaning to mathematics and didactics. Our analysis shows: (1) the evolving and shifting nature of meanings and processes of signification; (2) the important role of experiences from the past, but in particular from their work as trainees at primary schools; (3) the use of mathematical language and the consequences for a didactical way of thinking; (4) how student-teachers' observations lead to hypotheses and local theories. In our conclusions, we related our findings to the construction of a teacher education course that allows student-teachers to use MILE to develop mathematic and didactical insights on materializing. Teacher educators need help to capitalize on crucial moments in the interaction amongst student teachers. The study showed that the teacher educator needed resources to recognize those moments and to optimize class discussions.
Introduction
MILE is a Multimedia Interactive Learning Environment for prospective primary school teachers, with content for primary mathematics teachers' education programs (Dolk, Den Hertog & Gravemeijer, 2002). It is computer based and provides a database of real classroom teaching open for didactical investigations, allowing student teachers to investigate many aspects of mathematics education in primary schools. Besides the video database, the environment consists of communication tools for learners, a search engine--allowing users to search for classroom footage in a video database, and accompanying students' and teachers' materials--, a student teacher's journal, and thematic suggestions for investigations. These investigations offer student teachers opportunities to develop conjectures about teachers' practical knowledge and teaching behavior and about the effect of the teacher's behavior. The environment allows them also to analyze students' learning over time, and to investigate parts of the process through which students develop mathematical understanding.
We want prospective teachers to learn more about the RME. Mostly, these practitioners had learned some mathematical principles in secondary school. They are used doing mathematics without learning what it is to be a mathematician. 145 Mathematical reasoning and heuristic approaches are no daily practice for them. Moreover, they mainly learn about mathematics education through experience in the full practice of primary school, first in an internship, later on as teachers. That means that the biggest part of their competences in mathematics education is acquired by teaching primary students.
Initially, the expectations were that it would be possible for prospective teachers to learn in an investigative way within the MILE-environment. Quickly, it proved that these student teachers had no proper attitude and the teacher educators had not the abilities at one's disposal to coach them in a proper way. That is the reason that mostly, one uses this environment only with forms of directed guidance and learning questions at hand. This tension between ideal and reality necessitate research.
The Study
Theoretical framework
In the following we describe parts of the theoretical framework, taking a particular look at the Sociomathematical and -pedagogical norms (Stephan 2003). Paul Cobb emphasized that learning mathematics is a matter of a process of cognitive construction and of acculturation. Prospective teachers undergo all kinds of influences during their training: on the one hand the culture of teacher education, on the other the primary school where they server their traineeship, and added to that their social group. Their system of values is therefore determined in several different areas. We look also to the Mathematical and pedagogical conceptions. Many teachers, Cobb (1987) and Gravemeijer (1989) said, tend not to distinguish between Vorstellung and Darstellung. In their view, it would be better for teachers to think from an 'actor's point of view', in which the students' reality is put in a central position. Teachers themselves also attribute meanings, and these by no means have to correspond with those students give.
We are also using a semiotic perspective (Van Driel 1995, Bakker 2004, pp. 187-198). In Charles Sanders Peirce's way of thinking, every sign points to a concept. Then there is also the form the sign assumes (since a sign does not have to be a material), that which he called the representamen. This can occur in any number of forms: words, images, sounds, odors, flavors, acts or objects. But such things have no intrinsic meaning and become signs only when we invest them with meaning. "Nothing is a sign unless it is interpreted as a sign', declares Peirce. And then there is the meaning the sign evokes: the interpretant. How does the idea arise that a specific meaning belongs to a sign? At first similarities and experiences will stimulate that. In Peirce's words that lends a kind of iconicity. On the second level the term indexicality is used. This experience is emphatic, because it is based on the experience of the actual proximity of two phenomena. The third level of experience leads to symbolization. All kinds of conventions and agreements play a part in symbolic meanings, such as the scale in the drawing of the tiled square.
Aim of the study 146
This research study, of which this report is a part, is an ongoing one. It is an explorative research and we want to know more about:
the evolving and shifting nature of meanings and processes of signification;
the important role of experiences from the past, but in particular from their work as trainees at primary schools;
the use of mathematical language and the consequences for a didactical way of thinking;
how student-teachers' observations lead to hypotheses and local theories.
Participants and data sources
This pilot case study involved four students in their third year of education. They have finished most of PABO's standard program, and now only have to do their practical, in-service, training. Their participation in this study was voluntary. All these students are interested in mathematics education. The group consisted of one man and three women, all of them 21 years old.
The observations were partly participating, we interviewed also. In accordance with the hypothetical learning trajectory of Martin Simon (1995) the activities were developed in advance and we made hypotheses about the learning processes if the student teachers. During the research we audiotaped and we made reports.
Task Design
The study took place over four meetings which had a cyclical character, allowing for in between evaluation of the data and preparation of the next cycle. The cycles could be typified as follows:
Orientation on materialization. The students became aware of the formal and informal knowledge they possessed on the topic.
2. Observing some situations from practice and giving meaning from the materialization approach.
3. Putting more detail on the observations and their interpretation.
4. Evaluating newly gained knowledge.
It had been agreed in advance with the participants that they would spend twenty hours on the study: four two-hour meetings, an hour and a half of preparation and an hour and a half for processing the results. In preparation for a meeting they were given information about materializing with some questions as guidance. They afterwards made an evaluative report as well. Every meeting consisted of a number of parts: an initial activity, a discussion of the article and the preparations, followed either by work in MILE, working on the computer in pairs or using the video projector with the whole group. Every activity ended with a moment of evaluation and reflection, during which we analyzed our findings and observations.
Analysis of student activity
When we asked the student-teachers to make multiplication problems and support their 'thinking' with materials we saw that they took an observer's point of view.
When the question arose "Why do you use mathematical materials in daily practice? 147 One of the participants gave as her opinion that it is done to make education more fun and because it helps to explain. Another participant wonders whether materials would still be necessary in grade 6. You should not use a material, such as the arithmetic rack, if children can do without. In the end, together the students reach a kind of "definition" of material:
You can touch it.
It is 3D
Visualizing is what matters: the students can see what they are doing.
When the participants afterwards observed in MILE in pairs we saw that their view of the situation was fairly global, and afterwards their main interest is in understanding the greater picture. Questions such as 'Have the students worked with tiled squares before?' and 'What materials are normally used in grade 2?' emerge. Based on their observations, they made an hypothesis: 'Every time the students learn something new, they fall back on materials. The materials visualize what you are doing, and you will visualize the materials later on'.
In the evaluation the students explain they find observing in MILE a difficult part. Roelien thinks she chose the wrong fragment: 'This is about organization'. The other students explain to her that the teacher makes remarks about the way of thinking to solve the problems. Together, we conclude that teaching a mathematics lesson does unavoidably lead to things being interlaced. The students say they have so little insight into the order of the lessons, that they did not have time to reflect on the aspect of materializing in the video-clips.
It seems that if these four prospective teachers put the iconic interpretations of the material first. As yet, they have little experience and little theoretical knowledge, which means they are not inclined to making indexical and symbolic interpretations. Yet they are open for a more conceptual way of thinking. They have learned in the past about strategies and about the use of contextual situations and they are using that kind of knowledge all the time. They barely shift to an interpretant that is a part of the network of mathematical and didactical knowledge.
The students tended to keep talking from an observer's point of view and their interpretants mostly suited their earlier experiences. Which reflections lead to thinking of the mental processes going on in the children's heads? In this meeting we established how curious these students were about 'good' mathematics teaching. To find it, they mainly zoom in on the 'what' and the 'how' of the activities, rather than the 'why.' Especially with MILE, it is noticeable that they want to know how the lesson is set up, though we had hoped for a deeper analysis, which was not yet possible. That raises the question of how we can get students to really research something. What indicators are needed? How do we deepen their insight into existing theories about the use of material?
Personal experiences 148
In the various conversations the four participants gave direct (and sometimes implicit) information about their needs, values and thoughts. Mostly, they centralize their own experiences, both those from their primary school past and from their traineeship. We missed in such situations a careful reflection and an attitude to learn from this kind of experiences. The four prospective teachers showed that emotions govern their way of thinking. Maybe, their learning style is reproductive (we didn't test that). In that case, they want examples of good practice, ready-made solutions for practical situations.
Dutch teacher training colleges develop more and more programs with studentcentered approaches. Learning from and by experience is an important approach. We see the influence of the ideas of Donald Schön (1987) who emphasized that practitioners require forms of action learning. Reflections on and conversations with the situation are important constituents of learning to master complex situations in the future. How can we encourage prospective teachers to construct new knowledge? In our opinion there are two possible entrances. We want to discuss with them the

mathematical language in relation to the thinking processes. Second, we try to let them formulate hypotheses and local theories.
Mathematical language
The importance of language in the development of mathematical thinking has recently been acknowledged by many authors (Van Oers, 2002). The precise relation between language and mathematics however is not a straightforward one. The adoption of mathematical language does not automatically amount to genuine mathematical thinking. Van Oers (2002) observed that the development of children's mathematical activity can stay on the line of symbol development for given meanings, or the line of meaning development. By treating terms in a mathematical way, reflecting and structuring their meanings, these gradually evolve into personalized mathematical meanings.
Prospective teachers thinking about their own language in relation to the language of the young students can be helpful to give a change to an actor's point of view. Then the teachers realize that their language - especially in mathematics - differs from the way in which students are talking about mathematical topics. So, to observe real life educational situations - and there are a lot of them in the MILE-environment - can be very helpful in understanding that different meanings of the same concept exist. It will be helpful to explain the dialogues between teacher and students and to hypothesize on mental processes and concepts.
By discussing a MILE-situation where a teacher who is instructing a grade 2 class, encourages the children to think of tiled squares the question arose: what exactly did the teacher say, and what did she mean by it? In the evaluation of the observation it emerges how difficult it is to describe that precisely. The student teachers think they know what the teacher said, but when we listen again, it turns out to be slightly different. One question that emerges is whether the teacher said to make problems for the tiled square or of it. This led to a discussion about aspects of mathematical 149 language and how children interpret it. What formulation is needed to make children grasp the intention? There are two options, 5x7 and 7x5. If you want children to explore these, how should you say it? Bas concludes: 'If you say "make problems 'of' it," the children will do 7x5 and 5x7. If you say "make problems 'for' it," they will just make a whole list of problems.'
The next possible question is: 'What are the thinking processes of the children in these specific cases?' A way in which we stimulate prospective teachers to take an actor's point of view with a more language based orientation is to let them describe a primary student's inner dialogue based on a situation from MILE. This assignment's purpose is to make the students put themselves in the child's place and realize everything that is involved in a mathematical situation.
Hypothesis and local theories
Students can create their own educational narratives based on the situations in MILE. Such narratives are more than stories about the situation. Mason claimed that description is a cornerstone of all research. 'Any description is based on making distinctions and drawing attention to relationships, through the process of stressing some features and consequently ignoring or down-playing others.' Mason formulated the following as being problematic in writing: 'If what we perceive is what we are prepared to perceive, and what we are prepared to perceive is what we have perceived in the past, how then do we ever come to perceive anything new?' This is a question about constructing knowledge. Within communications among educators these considerations will contribute to the development and sharing of educational knowledge (Gudmundsdottir, 1995; Mason, 2002). Constantly we challenge the student-teachers to develop local and global theories. On the one hand, they have to limit their investigation and the justification of their understanding to the multimedia cases; on the other, they have to extend their understanding into their future profession in the form of hypotheses. During their investigations they had to switch continually between these two perspectives. Here we give an example.
In the evaluation of a discussion where a teacher, instructing a grade 2 class, encourages the children to think of tiled squares the four prospective teachers started asking all kinds of questions, such as: 'why is a tiled square used for multiplication problems?' and: 'what is needed first when children are learning to multiply: "pencils in trays or tiled squares?" Apparently their schooling did not include an overview of the learning trajectory. One of the guys finally comes up with a 'theory,' in which notions of materializing, context and the use of models pass in review. She relates how young children start with counting, but quickly move on to ways of counting. Gradually they start to see the possibility of using groups. This kind of shortening leads to jump counting. Then shortening reaches the point where applying 'times' becomes more and more obvious. You mainly use the tiled square to show on the one hand the jump character, and on the other to also show that 7x5 and 5x7 give the same result. One of the other participants summarized this in his report:
What is the purpose of the problem?150
We discuss the problem and what its purpose is. At what point in the learning trajectory for tables and area/content will this form of mathematics be on offer. Roelien's theory: Counting for kindergartners -> ways of counting (2, 4, 6, 8, 10 of 3, 6, 9) -> groups -> 'times' problems -> squares -> area -> content.
Of course, posing questions, developing local theories, etc. are no miracles. But when there is a good environment with experienced teacher-educators, a shifting interpretant is within reach. For us the program of the teacher education is more successful if the prospective teacher is used to discuss his own opinion. We can learn a lot of Descartes' methodic emphasis on doubt, rather than on certainty. We observed that prospective teachers are directed to teacher thinking most of the time. But does that yield enough profit? We hope that prospective teachers will see that their didactizing is more successful if they know more about the mental processes in the heads of their young students.
Concluding Remarks
In this study we focused on the evolving and shifting nature of meaning and processes of signification. We saw that the four prospective teachers tended to put the iconic interpretations of the material first. It was also clear that our small group gave their personal experiences as first points of reference: from their school career, but in particular from their working as trainees. In the Dutch situation the programs of the teacher educations are more and more student-centered. We want the student teachers to do forms of action learning, but when their own experiences are too dominant, there are no good conditions for growth.
We proposed two methods for an effective approach: to discuss the use of mathematical language and see the consequences for a didactical way of thinking and to let them make observations in the MILE-environment and lead them to hypotheses and local theories. In that process we try to bring the student teachers to an actor's point of view instead of their usual observers' point of view. Of course, we discussed a very small part of the math education, for example, we did not talk about the way in which the student-teachers use theoretical knowledge. We reflected upon potentials to prepare prospective teachers for their role in creating opportunities for students to reinvent mathematics. The final goal is that they build up knowledge of their understanding of students' developmental possibilities, so that they can make plans for instruction and interact with students in the classroom.
Guided reinvention is a leading characteristic behind the development of a curriculum for primary school mathematics. To guide student-teachers into their reinvention of didactical theories, teacher-educators need to have deep insights into student-teacher's thinking, feelings, beliefs, theories, assumptions, etc. This study forms the groundwork for this latter knowledge.

In this paper we present and discuss an activity realized with K-8 level students using robots to learn functions in the mathematics classroom. Research presented in this paper is framed by project DROIDE which is a three years project. We are now in the first one. The aims of DROIDE are:
• to create problems in Mathematics Education/Informatics areas to be solved through robots;
• to implement problem solving using robotics in three kinds of classrooms: mathematics classes at K-9 and K-12 levels; Informatics in K-12 levels; Artificial Intelligence, Didactics of Mathematics and Didactics of Computer Science/Informatics subjects at high level;
• to analyze students activity during problem solving using robots in this different kinds of classes.
In spite of we are just beginning the research, first data collected show them as promising and we can already point out some implications for mathematics teaching and learning when robots are used as mediators between students and Mathematics.
Introduction
In late years it become widely acceptable that learning is not a merely individual activity, isolated from social, cultural and contextual factors (Lave, 1988; Collins, Brown & Newman, 1989; Cobb, 1994; Confrey, 1995, in Núñez, Edwards and Matos, 1998). Learning occurs in social contexts that influence (and are influenced by) kinds of knowledge and practices that are build (Lave and Wenger, 1991; Wenger, 1998 e Wenger, McDermott e Snyder, 2002).
Thus, we can not neglect the real world where actual students live - a world more and more informatized and consequently more mathematized. What is important to learn in our days is not the same at the time when students' parents were children.
The evolution of technical capacity of computing equipment and network communication possibilities brought new work dimensions and possibilities. But the great majority of classrooms does not reflect this turn that carried new pedagogical challenges (see Fernandes, 2004).
In Portugal, a lot of research, focusing in the use of information and communication technologies, has been driven, either in teachers' education programmes or with

14
Centro de Investigação em Educação da FCUL.153
pupils of K-5 to K-12 levels. This research has concerned mainly with the use of a certain kind of software (e.g. GSP, Cabri-Géomètre, Modellus, etc.) and calculators (graphic or not) in the classroom.
Informatics teaching is a recent curricular area in Portugal. Thus, there is few research concerning with that problematic.
Either in Mathematics Education or in Informatics teaching and learning area there are still questions that deserve our attention, namely, the use of robots to teach and learn mathematics and informatics.
The Project and its Aims
DROIDE
15
: "Robots as mediators between students and Mathematics and Informatics" is a three years project and we are now on the first year.
We place three kinds of aims for the project:
• to create problems in Mathematics Education/Informatics areas to be solved through robots;
• to implement problem solving using robotics in three kinds of classrooms: mathematics classes at K-9 and K-12 levels; Informatics in K-12 levels; Artificial Intelligence, Didactics of Mathematics and Didactics of Computer Science/Informatics subjects at high level;
• to analyze students activity during problem solving using robots in this different kinds of classes.

Thus, we established the following research problem: to describe, analyse and understand how students learn mathematics/informatics having robots as mediators between them and mathematics/informatics.
Within a perspective of interpretative nature – in which empirical work constitutes a guide to the search – we posed a set of questions that we would like to answer with this search:
(a) How do students appropriate certain mathematical concepts using robots?
(b) How do they use robots to learn how to develop algorithms?
(c) What is the role of robots in mathematics/informatics learning?
(d) In which way do robots facilitate mathematics/informatics learning?
(e) How can robots help in developing mathematical and informatics knowledge?
(f) What is the role of robots in developing students' mathematical competency?
(g) How does creating mathematical/informatics problems to be solved through robots influence upon teachers and future teachers' methodologies of work in the classroom?

15
The authors of this paper would like to acknowledge the collaboration of the other two colleagues of the project: Elci Alcione dos Santos and Luís Gaspar. We also acknowledge the support from Mathematics and Engineering Department (DME) and from Local Department of Ministry of Education (SRE).154
(h) How does the use of robots in teachers' education programmes develop competencies in teaching Mathematics and Informatics?
This paper relates an activity realized with K-8 students using robots Lego® Mindstorms™ Robotic Invention System™ in a mathematics class to teach functions
16
.
Theoretical Background
The research took into account Situated Learning Theories (Lave & Wenger, 1991, Wenger, 1998, Wenger et al, 2002). The notion of community of practice, such as it is used on theoretical perspectives of Jean Lave and Etienne Wenger, which consider learning as a situated phenomenon, are used to reflect upon emergent learning within students mathematical and computer science/informatics practices.
According to Wenger et al (2002) practice
17
is constituted by a set of "work plans,
ideas, information, styles, stories and documents that are shared by community members" (p.29). Practice is the specific knowledge that the community develops, shares and maintains. Practice tends to evolve as a collective product integrated in participants work and organizing knowledge in ways that make it useful for themselves insofar as it reflects their perspectives (Matos, 2005).
Wenger (2002) proposes three dimensions of the relation by which practice is the source of coherence of a community: mutual engagement, joint enterprise and shared repertoire.
Mutual engagement: a sense of "doing things together". Sharing ideas and artefacts with a common commitment to the interactions between members of the community.
Joint enterprise: having some object as an agreed common goal, defined by the participants in the very process of pursuing it, not just a stated agenda but something that creates among participants relations of mutual accountability; that become an integral part of the practice (Matos, Mor, Noss and Santos, 2005).
Shared repertoire: agreed resources for negotiating the meanings. This includes artefacts, styles, tools, stories, actions, discourses, events, concepts.
Methodology
Methodology adopted is organized in three stages according to the aims of the project: 1
st
- problems creation; 2
nd
- classroom implementation and data collection;
3
rd
- data analyses.

16 These robots are used at classrooms because students can interact with mechanical parts and see results immediately. This allows students to employ certain theoretical concepts and to understand how they work in reality. It is important to point out that it is not necessary to have prior knowledge in robotics neither in computer programming.
17 The term practice is sometimes used as an antonym for theory, ideas, ideals, or talk. In Situated Learning theories that is not the idea. In Wenger's sense of practice, the term does not reflect a dichotomy between the practical and the theoretical, ideals and reality, or talking and doing. The paper extension does not allow the development of the idea of practice. For discussion of practice related with mathematics education see Fernandes (2004).155
First stage – analyses of School Mathematics and Informatics curriculum by researchers, to choose didactical units where robotics can be used. Creation of problems/tasks (to be solved in Mathematics and Informatics classes).
Second stage – Problems/tasks implementation in Mathematics and Informatics classes.
Data collection – Data are being collected recording, on video, the activity of students observed.
Third stage – analyses of students activity at the time when they work (in mathematics/informatics) with robots. Methodology used has an interpretative nature.
Data analysis is supported by Situated Learning Theories. The unit of analysis considered was "(...) the activity of persons-acting in setting" (Lave, 1988, p.177).
Using Robots to Learn Functions: One Problem Proposed
In this part we will present a brief description of the context, of general plan of work for the unit of functions, of problem that were solved, and of mathematical activity and mathematics involved on the problem.
Context
Basic School of Caniçal, created in 1996, is situated at the East extreme of Madeira Island, at Caniçal village, whose population is about 5500 residents. Fishing is traditionally the economic base of the village. Building construction is an alternative as well as seasonal emigration whose implications in familiar structure is visible seeing that, grand parents and close parents are who care with young people. That fact is reflected on school performance of students.
In mathematics class students worked in small groups. The work involved, in a first phase, robots construction and programming to solve simple tasks using Windows® visual environment programming that come with robots kits. Subsequently, students used robots to recognise and apply coordinates system in robots programming, understand function concept, represent one function (direct proportionality) using and analytic expression and, to relate intuitively straight line slope with the proportionality constant, in functions such as x ↦ kx .
General plan of work for functions unit
First mathematical unit to be worked was functions. For that didactical unit we prepared four sets of problems. With Problem 1 we pretend that students recognize examples and counterexamples of functions in correspondences presented in such different ways and identify functions as examples of correspondences of daily situations. With Problem 2 we aim that pupils deal with other kinds of graphs, behind straight lines and recognize then as functions as well, if it is the case. With Problem 3 we pretend students to learn direct proportionality, as a function. Direct proportionality definition as a function emerges of the mathematical activity of students using robots. Finally, Problem 4 is about topics related with affin function, such as y-intersect, slope and the relation between the graphic of that kind of 156 functions with the graphic of the function of direct proportionality 'associated' to the first.
The robot travel
Now we present part of a problem that has been solved by students:
1. We asked Pedro and João to imagine and draw a graphic that represents a robot travel from a certain start. They presented the following graphics:
Fig. 1
1.1. Now you have to study the graphics presented by Pedro and João. Describe the robot travel relatively to its distance to the starting point.
1.2. Try to programme the robot in such a way that it realizes the proposed travels. Test it, and, if it is possible, confirm the results. Write the program(s) that you have done.
1.3. Did the robot realize both proposed travels? Present the difficulties that you found in programming the robot to such travels.
1.4. What is the necessary condition in order that one graphic represents the 'possible travel'?
Description of students practice
Students solved the problems in small groups, collaborating in problem solving, arising hypothesis and discussing their viability. Below we present a transcription
18
of
part of a class where students were solving question 1.1.

18
In this transcription (due limitations of space) we mainly present students exhibiting the result of the discussion they had on the group to the teacher. We choose to cut the episode in this way because we can 'see' on the transcription students building, intuitively, the concept of function.
Start 157
In Rui's group the solution of question 1.1. emerged only of the analyses of the graphics. The same happens with Ricardo's group, maybe because these two groups were very close on physical space, and listened the discussions among elements of the groups and between those and the teacher. In other groups to programme Pedro's travel was important to understand the graphic; to understand that the graphic is not translating the route of the robot but the relation between time and distance in the travel done by the robot. The work with the first graphic allowed students to understand the second graphic and consequently, to capture intuitively the concept of function.
Rui: Teacher…Teacher… This graphic is not good! [Pointing to the second graphic]
Teacher: It's not good? Why?
Rui: It's not good because in this way the robot is walking backwards. And the robot has always to go ahead.
Teacher: I do not understand what you mean [trying that Rui made explicit what he was thinking]
Rui: I don't know …
Rui looked to the graphic again and goes back to the discussion with the other group elements.
Rui: Teacher… we already know. Could you, please, come here?
Teacher: Yes?
Rui: This line is not what the robot route. It's the distance.
Teacher: Distance?
Rui: The distance from the starting point. And here is time. And we can not do that.
Teacher: What can't you do?
Rui: The robot can't do this route.
Meanwhile, Ricardo [a student of another group that was close to Rui's group and very attentive to the discussion] answered:
Ricardo: Can't be because the robot cannot walk backwards in time.
Teacher: What will happen if the robot walks backwards in time?
Rui and Ricardo [almost at the same time]: I don't know.
Teacher: Observe and study the graphics.
A few minutes later…
Rui: I already know! I already know! The robot had to be at to places at the same time , isn't it teacher? 158
When every group had solved the problem, teacher discussed with all the group mathematical ideas involved in the problem trying that, they together, make a synthesis of the main mathematical concepts.
In all this process of solving the questions a shared repertoire emerged. The vocabulary they used to approach problems and questions is a mix of vocabulary of two distinct domains (mathematics and robots). They are analysing a graphic but they talk about what a robot can and cannot do. Using the robots and its programming as a taken-asshared resource allow students to negotiate meaning among them (in the group) and between the group and the teacher and give meaning to students mathematical activity.
To have a join enterprise (that can be to solve the question, to please the teacher, to understand the meaning of mathematical concepts involved or only to play with the robots) is very important to motivate students to engage in the activity and is an integral part of students practice.
The co-definition of mutual engagement is visible through:
- a growing sense of responsibility in solving the questions posed by the teacher and in understanding what they are doing together and what is the meaning of what they are doing;
- not giving up until they found the problem solution;
- a pleasure in going deeper into their ideas and in building a solution to the problem and meaning to their answers.
In these three dimensions of the practice we talk about meaning. In fact Wenger (1998) argues that the social production of meaning is the relevant level of analyses

for talking about practice.
But when meaning is discussed in the sphere of mathematics education usually it concentrates on the meaning of (mathematical) concepts. Questions such as the following become important: What sort of meaning can be associated with certain mathematical concepts? What is the meaning of particular concepts to students? What sort of meaning can be associated with this concept from a mathematical point of view? What is the meaning of this concept from the perspective of the teacher? What is the shared meaning of this concept? (Skovsmose, 2005) 159
Findings
To analyse students practice in mathematical classes is fundamental as element that helps to understand learning. It is important that students' engagement in school mathematics activity is not only to accomplish a curricular programme but that they have a genuine interest by the domains they work and the use of robots have a relevant role as a mediator element in all this process.
In spite of we are now in an initial phase of data analyses we can already foresee some findings that show themselves as promising.
• Students felt comfortable both when building robots and using programming environment.
• Using robots in mathematics class promotes an increment either in discussion between students and between students and teacher and in collaboration on the resolution of proposed problems.
• Students recognize impossibility of executing a task without assuming it as an inability of them. This fact was evident, for instance, at the time when they are solving the previous described problem.
• Function concept was apprehended in a significative way. The definition of function emerged as a final conclusion of students work and not as a starting point.

Gender, equity, teachers, students and technology use
in secondary mathematics classrooms
Helen J. Forgasz, Shirly Griffith, & Hazel Tan
Monash University, Australia
Helen.Forgasz@education.monash.edu.au
In recent years we have been researching a range of issues associated with the use of digital technologies - computers, graphics calculators, and CAS calculators - in secondary mathematics classrooms. Gender and other equity considerations were a focus in some of the work; teachers' and students' beliefs about and attitudes towards the technologies were also central. In all of the studies, comparisons were made. The views of male and female students and teachers have been examined, students' and teachers' views compared, the perspectives of teachers in different countries contrasted, teachers' views on computers and calculators distinguished; and the examination results of male and female students using different digital technologies explored. In this proposal, synopses of various dimensions of a selection of the studies are presented. Taken together the studies reveal that gender differences favouring males with respect to technology use are evident, that teachers are generally supportive of the use of digital technologies for mathematics learning, and that curricular and school factors are associated with the classroom use of technologies and beliefs about their efficacy in fostering student learning.
Introduction
In Victoria, Australia, technology use across the curriculum has been strongly advocated and financially supported by government for some years. In the curriculum document for grades P
19
-10, the Curriculum and Standards Framework II
[CSFII] (Victorian Curriculum and Assessment Authority [VCAA], 2002), the "full use of the flexibility and value for teaching and learning programs provided by the increased application of information and communications technology (ICT)"
(VCAA, 2002a) is strongly advocated. In the Mathematics section of the CSFII, the use of a range of digital technologies for mathematics learning is strongly supported and, by implication, assumed:
Recent developments in the availability of calculators, graphics calculators and computer software have led to a major re-evaluation of school mathematics curricula in terms of content and strategies for teaching and learning mathematics. The Mathematics KLA supports these developments, by placing clear emphasis upon the sensible use of technology in concept development, as well as in technologyassisted approaches to problem-solving, modelling and investigative activities... At all times, the choice of the appropriate technology and the extent to which it is

19
P is the grade level prior to grade 1 161
employed should be guided by the degree to which these tools assist students to learn and do mathematics. [VCAA, 2002b]
Grades 11 and 12 in Victoria are considered the post-compulsory levels of schooling and involve a two-year program, the Victorian Certificate of Education [VCE]. Grade 12 VCE results are used for selection into tertiary institutions. At the grade 12 level, three mathematics subjects are offered and one of the outcomes stipulated for VCE Mathematics is "the effective and appropriate use of technology to produce results which support learning mathematics and its application in different contexts" (VCAA, 2005, p.7). In one of the three VCE mathematics subjects, Mathematical Methods, graphics calculators have been mandated for several years. In 2003-2005, a small number of students were involved in an pilot program, Mathematical Methods [CAS], in which CAS were used in place of the graphics calculator. In 2006, the two parallel versions of Mathematical Methods will be open to all students; at the same time, the assessment program will alter in that one of the two examinations for the subject will be calculator-free. By 2008, all students in Victoria taking Mathematical Methods will be using CAS calculators.
The studies discussed in this proposal were all conducted in Victoria. Each involved students and/or mathematics teachers from the secondary grades, 7-12. One study was focussed on the use of computers, one on computers and graphics calculators, one on graphics calculators only, and one on CAS calculators. One of the studies also involved mathematics teachers from Singapore. Each study involved comparisons being made. Students' and teachers' views were examined for gender differences as were students' mathematics achievements, teachers' and students' beliefs were compared, comparisons were made between the views of teachers from Singapore and Victoria, and teachers' views on computers and calculators were contrasted.
A synopsis of each study, with selected major findings, is presented below.
Study 1. A three-year study of computer use in Victorian grade 7-10 mathematics classes.
The overall aims of the three year study into computer use in Victorian grade 7-10 classrooms included: (i) determining perceived effects of using computers on students' mathematics learning outcomes, (ii) identifying factors that may contribute to inequities in learning outcomes (equity factors included: gender, socio-economic background, language background, Aboriginality, and geographic location) and (iii) monitoring how computers are being used for mathematics learning. The research design for the three years involved:
Year 1: surveys of mathematics students in grades 7-10 (N=2140: F=1015, M=1112, ?=13) and their teachers (N=96: F=52, M=44); survey of grade 11 students (N=519: F=237, M=281, ?=1) reflecting on previous use of computers for mathematics learning - 29 co-educational schools were involved.
Year 2: in-depth studies of 7 grade 10 mathematics classrooms at three schools - surveys, observations, interviews. 162
Year 3- repeat of Year 1 surveys in same schools - only 24 schools participated - grades 7-10 students (N=1613: F=810, M=794, ?=9), their teachers (N=75; F=41, M=34); and grade 11 students (N=376: F=166, M=210).
The findings from this study have been widely reported (e.g., Forgasz, in press a, in press b, 2005, 2004a, 2004b, 2003, 2002a, 2002b, 2002c). A brief summary of some of the main findings is presented below:
• Computer ownership by mathematics teachers was high (>80%), teachers considered themselves well-skilled with computers, and most had used computers in their mathematics teaching (≥ 70%); <10% had not and were not planning to do so. Computers were more widely used in single content areas than fully integrated across the mathematics curriculum. Teachers wanted more professional development to extend skills, increase confidence levels, and become more familiar with software applications.
• The most widely used mathematic-specific software applications were Geometer's sketchpad (22% of teachers) and Graphmatica (22%); the most frequently used generic software applications were spreadsheets (62%), wordprocessors (49%), and Internet browsers (32%). CD-ROMs accompanying textbooks were also widely used (26%).
• Teachers were generally supportive and confident about using computers in their classrooms. They identified greater access to hardware, more technical support, the availability of high quality software, and on-going professional development as the significant issues to be addressed if they are to use computers more in their mathematics teaching.
• Teachers (≤ 60%) were not fully convinced that computers aided students' mathematical understandings; males, however, were more positive about the effects than females. Students were even less convinced of this than their teachers (≤ 30%); again, males were more positive than females.
• Students attending schools in lower SES locations, government schools, and at lower grade levels, were more convinced than their respective counterparts that computers assisted their mathematical understandings.
• Compared to their respective counterparts, students from non-English speaking backgrounds, males, and those with high self-ratings of mathematics achievement, had higher computer ownership and held more positive attitudes towards computers for mathematics learning.
• Some teachers believed there were differences in the ways boys and girls work with computers. Compared to boys, girls were generally considered less confident, less competent, and less interested in using computers.
• Data from grade 11 students indicated that computers served as stronger motivators for males' than for females' enjoyment of mathematics, and in persisting with mathematics at higher levels of schooling and beyond. 163
Study 2. A comparative study of Victorian and Singaporean teachers' perceptions of computer and graphics calculator use.
The aim of this study, conducted in 2005, was to investigate and compare the use of and perceptions towards computers and graphic calculators among mathematics teachers at senior secondary levels in two settings: grades 11 and 12 in Victoria and junior college years 1 and 2 in Singapore - the two final years of schooling leading to tertiary entrance (Tan & Forgasz, n.d.; Tan, 2005).
Since 2002, only a small group of mathematically inclined students taking the subject Further Mathematics at the senior secondary levels in Singapore have been allowed to use graphics calculators in their examinations; the majority studied the subject Mathematics and graphics calculator were not permitted in the examinations. Graphics calculators will be introduced more widely into the revised mathematics curriculum at the senior secondary level in 2006.
A survey questionnaire was administered to 35 (19M, 16F) mathematics teachers from 14 independent (non-government, non-Catholic) schools in Victoria, and 33 (16M, 16F, 1?) teachers from five junior colleges in Singapore. It was found that graphics calculators were extensively used by the Victorian teachers, and that high proportions of the Singaporean and Victorian teachers had not or had hardly ever used computers with their mathematics classes. Interestingly, Victorian teachers' self-ratings of their graphics calculator skills (beginner, average, or advanced) were much higher than the Singaporean teachers'; only one Victorian indicated being a beginner and 18 claimed to be advanced, while 19 Singaporean teachers identified as beginners and only two to having advanced skills. The difference in perceived competency resonated with other findings that showed that a higher proportion of Victorian than Singaporean teachers had personal access to graphics calculators and had used them for a longer time. The Victorian teachers were found to be more strongly in support of graphics calculator use over computers, while the Singaporean teachers were more supportive of computer use over graphics calculators.
The teachers in both settings identified factors that affected their decisions to use the technologies. The data suggested that mandating technology tool use in an assessment program, as was the case in Victoria, plays an important part in explaining the extent of their use by teachers, and may also account for the Victorian teachers' preference for graphics calculators over computers.
Study 3: Perceptions of the impact of graphics calculators among teachers from Victorian Catholic schools
The aim of this study was to investigate teachers' perceptions of the impact of graphics calculators on their teaching practice, on student learning, and on the mathematics curriculum in grades 10-12 in Victorian Catholic secondary schools (Griffith, 2005).
A survey was conducted with 47 (25M, 22F) senior secondary mathematics teachers from 16 Catholic schools (6 girls-only, 6 boys-only, and 4 co-educational schools). It was found that the teachers had used graphics calculators with all of the grade 10-12 164
classes they taught, and that all students owned their own graphics calculators. The

teachers indicated that students in grades 10-12 were using the graphics calculators for in-class activities, problem-solving tasks, computational tasks, during investigations, and to do tests and School Assessed Coursework [SAC] tasks. In general, students were not using graphics calculators to write programs, play games, or to do puzzles or quizzes.
Some differences were noted in the views of male and female teachers on issues associated with graphics calculators use. While all believed that using graphics calculators had enhanced their mathematics teaching and changed how they taught, the female teachers felt more strongly than the male teachers that their students were able to solve non-routine problems on the graphics calculator that would otherwise be inaccessible using algebraic techniques, and that students were able to engage with challenging problems; they believed less strongly that students accepted answers given by the calculator and rarely checked for reasonableness. The females also believed more strongly than the males that the introduction of technology-free examinations (2006 change to the VCE mathematics assessment program) was a positive development.
In summary, the teachers generally believed that graphics calculators have had a positive impact on their teaching and on students' learning outcomes, and that the curriculum has been enriched. Female teachers tended to hold these views more strongly than their male counterparts.
Study 4. CAS calculators: Gendered patterns of achievement in a high stakes examination pilot program, and teachers' expectations of their
imminent mandated use in such courses.
The focus of this two-part study was on the introduction of CAS calculators for use in the high stakes grade 12 VCE mathematics examinations (Forgasz & Griffith, n.d.). For some years, it has been mandatory for students to use graphics calculators in some VCE mathematics examinations. Since 2002, a pilot study has been conducted involving small groups of grade 12 students using CAS calculators instead of graphics calculators in one of the three VCE mathematics courses on offer, Mathematical Methods (the subject most widely required as a pre-requisite for tertiary study). From 2006-2008 the CAS calculator will be optional, that is, there will be two parallel Mathematical Methods courses available for all students to study – one in which graphics calculators must be used, the other mandating CAS calculators. From 2008, only CAS calculators will be allowed.
Part 1 of this study involved an exploration of male and female students' results in Mathematical Methods over three years, 2002-2004. Comparisons were made between the achievements of the students in the CAS pilot study and those of the vast majority of students who used graphics calculators. Male and female results at the top two achievement levels awarded (A+ and A) in each of the three assessment tasks (one school-based, two external examinations) comprising the VCE Mathematical Methods subject for the year 2004 are shown in Table 1. 165
Table 1. Mathematical Methods and Mathematical Methods (CAS) results at top three achievement levels, by gender, 2004
Mathematical Methods Mathematical Methods (CAS)
Male Female M:F
2
Male Female M:F
N %
1
N % N % N %
Grade Task 1 (school-assessed)
A+ 1747 18 1261 15 1.20 42 17 20 13 1.31
A 2003 21 1939 24 0.88 57 23 28 19 1.21
Examination 1
A+ 1102 12 793 10 1.20 35 14 16 11 1.27
A 1306 14 1030 13 1.08 40 17 19 13 1.31
Examination 2
A+ 1013 11 593 7 1.57 33 14 12 8 1.75
A 1074 11 874 11 1.00 34 14 20 14 1.00
1
Within gender cohort percentages.
2
Male to female ratio (M:F) = Male % : Female %
3
Shaded ratios – when M:F>1 ie. greater % males than females
4
Bolded M:F ratio – higher M:F ratio for the two subjects
The data in Table 1 reveal that when within gender cohort percentages were considered, higher proportions of males than females were awarded the A+ grade for all three tasks in Mathematical Methods (CAS) than in Mathematical Methods with graphics calculators) for all three tasks; this was also true for 2 of the 3 tasks at the A level of achievement (Task 1 & Examination 1). Overall, the there was a wider gender gap favouring males in performance at the highest achievement levels for Mathematical Methods (CAS) than for Mathematical Methods with graphics calculators. Similar patterns were observed for the 2002 and 2003 results.
In Part 2 of the study, 38 teachers' views of the likely impact of the wider use of CAS calculators from 2006 and beyond were examined. None of these teachers was involved in the Mathematical Methods (CAS) pilot study. In one section of a survey questionnaire, teachers were asked to respond to the open-ended question, "From 2006 onwards students will be able to use CAS (Computer Algebra Systems) calculators in VCE Mathematics examinations. Please describe in your own words the impact you think CAS calculators will have on: your teaching, student learning, and curriculum". Separate spaces were provided for teachers to answer about teaching, student learning, and the curriculum.
In general, the teachers tended to respond positively about the introduction of CAS calculators in each of the three categories that they were asked to comment on: teaching (positive: 68%, negative: 32%), student learning (positive: 65%, negative: 166 35%) and curriculum (positive: 70%, negative: 30%). None mentioned any potentially differential impacts on male and females students.
General conclusions from the four studies
Overall, the results of the four studies indicated support among Victorian teachers for the use of digital technologies in the secondary mathematics classroom. The teachers considered themselves fairly well-skilled in using the technologies, but called for more professional development to enhance their skills and confidence. Not all teachers were convinced of the effectiveness of computers on students' mathematical understanding; students were even less convinced than their teachers. Yet, the teachers use the technologies fairly regularly, and have found that their teaching, students' learning, and the curriculum, have been affected – particularly in using handheld technologies. With respect to gender, the findings seem to support Hoyles' (1998) contention that more emphasis on computer use might negatively impact on girls. Other equity factors (e.g., socio-economic, language background, and geographic location) appeared to influence access to and attitudes towards computers. There were indications that males may be advantaged over females in using the sophisticated CAS calculators in high stakes examinations. Based on the comparisons between Singaporean and Victorian teachers, another important finding was that curricular expectations and requirements seem to influence teachers' beliefs about and use of particular digital technologies.

Development and Introduction of the New Content of Mathematics in Secondary Schools in Latvia
Ilze France and Evija Slokenberga
Ministry of Education and Science and Latvia University of Agriculture, Latvia
ilze.france@lanet.lv, evijamezi@e-apollo.lv
This paper examines the possibilities for and principles of developing and implementing a new math curriculum into the Latvian secondary education. To get a better understanding of the Latvian situation, we are offering a brief insight into the existing educational system. The existing standard and sample curricula for teaching math have become outdated and work is being done on developing a new standard and curriculum. The real life situation in Latvia with regard to the serviceability and availability of computers and the pupil's access to computers for learning math has been identified. The conclusion is that pupils use computers mainly in classes of computer studies, but very in little in math classes. Some research which directly deals with this particular problem is presented. When designing the new curriculum, our attention is focused on how to use the computer in teaching math while preventing its use as a means in itself.
Our approach is underpinned by objectives, tasks and philosophy of teaching math that would result in engaging the modern day technologies. In Latvia a new extensive project has started - "Curricula development and further education in science, mathematics and technology related subjects". A brief overview of the project performance with project objectives and developed products is presented. Some of the potential problems are considered that need be avoided in order to ensure the projects sustainability. The project is unique to Latvia and one of its central objectives is (through the standard, curricula and teacher support material) to demonstrate to teachers what, how and why to teach math in secondary school with the help of the computer. The project's implementation will allow us to introduce a unified concept for the teaching of science and math at the national level.
The tasks of education are to prepare a pupil for life and for further education. In order to accomplish that, the main focus should be placed on three activities: imparting knowledge, evaluating and making it practical (including creativity). Learning mathematics is essential for all three activities mentioned above.
Education System in Latvia
The Law of Education in the Republic of Latvia determines following levels of education:
- Preschool education 169
- Primary education

- Secondary education
- Higher education
For all the residents of Latvia primary education is mandatory, but secondary education and higher education are optional. The Cabinet of Ministers approves the standard of education, which determines the mandatory content of primary and secondary education. The curriculum standards are parts of the education standard. The Center for Curriculum Development and Examination for each subject develops a sample program, which serves as a guide to teacher. Each school and each teacher has rights to develop the corresponding study program for their school.
In the former Soviet Union the teaching of mathematics was centralized in the whole country, including Latvia. After the fall of the Soviet Union, as Latvia was developing as an independent nation country, the first curriculum standards were developed (in 1992). In 1998 work was begun to development new curriculum. In the process of the development of the new content of subjects, the results of various international studies were used, for example, international program of pupil's assessment in OECD countries [1]. Now we have new subject curriculum standards developed in primary education. The implementation /introduction began in the school year 2004/2005, and it is planned to completely finish this process in three years. Up to now the teaching of mathematics in Latvia has had more academic approach, and not offering the student practical tasks and not showing the connection of mathematics to real life. Now the new content of secondary education is being developed. In the summer of 2005 a new and important project, "The development of curriculum and further education in the natural sciences, mathematics and technologies in secondary education," was started, which is financed with the support of the European Social Fund.
Accessibility and the use of digital technologies in Latvia
Now in Latvian schools the computer is widely used in teaching computer studies, but only a little in other subjects, including mathematics.
In October / November 2001, at the request of the Ministry of Education and Science of the Republic of Latvia, the Center of Research of the Market and Public Opinion conducted the research "The attitude of 5
th
-12
th
grade pupils towards information
technologies and its use in schools, existing access to computers and the Internet". The research showed, that more than 90% of the pupils have access to computers [2], 60% of the pupils have access to the Internet. Almost all the pupils (95,6%) have acknowledged, that it is necessary to increase the number of computer classes in school.
In 1997 a project "Latvian Education Information Systems" (LIIS) was begun [3]. That ensured the introduction of information and communication technologies in 170 schools. In each school one computer classroom was set up and in 60% of the schools was provided direct access to the Internet. 70% of the teachers of Latvia have been trained in regular courses. In regions and in the larger cities regional computer centers are established, in which more knowledgeable teachers are training their colleagues. As a part of this LIIS project, training materials in various school subjects have been developed (volume - 100 000 pages) and can be found in the Internet, as well as a lot of learning programs and games. Unfortunately one should admit, that the majority of the materials related to mathematics, not always can be used daily by the pupil. The target group for those materials are the pupils, who have deeper interest in mathematics, in preparation for educational Olympics and for teachers. There is a lack of interactive materials, which are developed for the interesting independent studies in mathematics.
Presently computer is practically not being used in the learning process of mathematics in Latvia. As a part of the project "Curriculum Development and further education of teachers in the subjects of natural sciences, mathematics and technologies" the survey was conducted, in which 692 10
th
graders from 12 pilot
schools participated.
Asked about "The use of the computer in mathematics classes", 73% of participants responded, that opportunity to use computer in mathematics has not been offered.
Computer usage in mathematics class
There is no choice
Liked very much
Liked very much
Did not like
Not offered
Among those pupils, to whom such option to study mathematics using a computer was given, 14 % liked it and 10 % liked it very much. Only 3% of pupils did not enjoy learning mathematics with a help of computer.
Currently, one of the most widely accessible applications of the computer in mathematics would be to work with different information sources, for example, the Internet. Responding to the question about "Gaining information from different sources", 42% of students responded, that this form of work was not offered. 171

The development of the content of mathematics for the secondary school, using the computer as one of the means of teaching
Currently in Latvia work is being done in the project of developing new subject standards in secondary education and corresponding subject sample program. In developing new curriculum for mathematics, two main approaches in teaching are being observed, which are shown in the chart [4]:
What is mathematics? The main question in a
mathematics course?
Technology based
approach
Mathematics is the
means for serving
other branches of
science and practice
How?
Research based
approach
Mathematics is also
intellectual and
cultural value in itself
Why?
In the technological approach it is considered that the student has to be given an idea about as many issues as possible at the operational level without fundamental explanations. Much attention is given to motivation: Why are we introducing one or another mathematical tool, what practical problems one can solve using that, or what can be described, etc. It is typical for this approach to use mathematical algorithms. In the content there are many rules which tell what to do in one or another situation. However, once the pupil goes beyond the stated rules, he/she becomes quite helpless. When carrying out the curricula and training methodology reform, it is
important to avoid being carried away by one approach over the other. Realising the 172 possibilities afforded by the computer, its use in mathematics classes should cater for a balance between both approaches in teaching mathematics.
In the framework of the project "Teaching contents development and further education in mathematics and technology related subjects", extensive work has been started on creating a new math teaching standard, program sample and teacher support material. This is work that has no precedence in Latvia and as a result of that we expect to obtain a completely new insight into the teaching of math in the secondary school. The project has enlisted the help of math teachers, university lecturers, members of the publishing community which altogether form a professional team for the implementation of the project. The materials produced by the project are to be approbated and implemented on a common national basis.
The methodological teacher support material in math includes: samples of classes, samples of various level problems, research assignments, test work, samples of IT use and possibilities, interactive course for pupils. The objective of our work is to provide ready for work tools: fully fledged electronic teaching aids, work sheets for PC work, and references in subject teaching curriculum on how to use the computer in teaching math.
Visualization is a key element in the teaching process. A feature which we plan to introduce into the training process is the dynamic math application GEONEXT [5] which offers a new approach to teaching and learning math. We chose this software because it is widely available, free of charge and has a translated Latvian version. Thus we are hoping to foster a proactive research based approach that would facilitate formation of math oriented thinking in pupils.
There is a plan to also include in the curriculum Internet addresses relevant to each topic. Into the specific training content we plan to include assignments and research projects that require information processing with the help of spreadsheets.
One of our project's most essential products for pupils is the interactive training material which meets the standard and curriculum requirements. It is comprised of the theoretical material, problems with solutions, practice problems with solutions, and self-testing. Although similar teaching material is available on the Internet, it unfortunately does not address the specific circumstances in Latvia and is not available in the native language of the pupils. It is important that the interactive material is developed for each secondary school topic. The pupil, when working with the interactive teaching material, may proceed at his or her own chosen pace and determine what to study at a specific point in time.
The implementation stage performed by the teacher at schools is integral to the development of all the material (class samples, samples of different level problems, research projects, tests, samples of IT use and possibilities, interactive course for pupils). Therefore it is necessary to prepare the teacher for working with the material. To avoid risks associated with insufficient teacher training, the project framework provides for a 72 hour training course. The plan is that all secondary school teachers 173 in Latvia will undergo this course. This further education course for teachers will also include training into the use of computers in teaching math.
Due awareness of the potential problems relating to the implementation of the project is also important for ensuring the project's sustainability.
These are some of the risks we have identified:
• insufficient teacher training for conducting classes in computer room and for using PC for demonstration purposes;
• underfunding for updating PC resources - the service life of computers in schools might be 5 years;
• deviation away from a balanced split between the use of technology and research oriented approach to teaching math, resulting, for example, in pointless use of computers in math classes.
Although we are now only into the six month of the project we have accomplished quite a lot. Material for form 10 is developed and approbated in 12 pilot schools. Returns form pupils and teacher evaluations on the developed material is being compiled and used in further evolution of the material. Already by September 2006, new research data will be collected, which we would be pleased to present during the December conference together with the developed material.
In our move to modernizing the teaching content we are now facing an enormous challenge and would appreciate very much the opportunity to take part in this conference, thus learning more about other countries' experience and achievements in this area.

Learning communities with a focus on ICT for inquiry in
mathematics – affordances and constraints in development of
classroom practice
Anne Berit Fuglestad,
Agder University College, Kristiansand, Norway
anne.b.fuglestad@hia.no
In this paper I will report from research on use of ICT tools to promote students' learning of mathematics. The work is largely situated in a learning community with teachers and didacticians working together on planning for an inquiry approach to learning mathematics. A sketch of theoretical framework is presented with emphasis on seeing ICT as a personal technology, developing into an instrument for the learner and with considerations of affordance and constraints to analyse the activities. I will present and analyse cases of teachers and students' work on mathematics in the classrooms using ICT tools. I will focus on how the teachers plan for and support the students' learning in the classroom. In particular I will focus on how mathematical concepts and relations are represented in the work.
Background
There has been long time effort to integrate use of Information and Communications Technology (ICT) in Norwegian schools to support teaching of different subjects. Computer studies, (EDB), IT, ICT and recently "digital competence" has been an issue in several curriculum guidelines since 1987, emphasising use of computers or calculators for teaching and problem solving in mathematics. The new curriculum plan, which is in effect from august 2006, states "digital competence" as one of five fundamental competencies in every subject in the

curriculum (2005b).
However, in spite of the efforts, little has been achieved concerning integrating ICT in particular subjects, in mathematics particularly, in a way that affect the subject content and ways of teaching (Erstad, 2004). A lot is claimed to have been achieved in general concerning use of ICT in schools, but my impression from contact with teachers informally and from reports, is that the work mainly is concerned with general organisation, use of Learning Management Systems, internet to search for information, text processing and so on. Little has been implemented when it comes to utilising the potential of ICT in teaching and learning mathematical subject content except for schools involved in ICT projects or with particularly enthusiastic teachers. Recent reports support this. An evaluation of the implementation of the current plan reveals little use, and hardly anything was reported from the classes observed during the evaluation (Alseth, Breiteig, & Brekke, 2003). A recently published report (Ola Erstad, Vibeke Kløvstad, Tove Kristiansen, 175 & Morten Søby, 2005) reveals that the use of ICT-tools
20
in schools has decreased
since the previous report in 2003. Thus the development of ICT use in mathematics generally in Norway is a rather slow process.
Similar experience is also documented in other countries (Hennesey, Ruthven, & Brindley, 2005). Teachers have problems to find out how to implement ICT and there is considerable resistance and constraints, for example from caution on some uses, requirements in the syllabus and assessment system, and by teachers largely using ICT to support existing practice rather than transforming into new approaches to mathematics.
On many occasions when I have met teachers at conferences, courses or at school visits I understand from the conversation and they also expressed directly that they do not really know how to utilise ICT tools in mathematics teaching. They often express interest but also claim they have not sufficient insight in the ICT tools and how to use them for mathematics. Quite often teachers ask for good examples of tasks or teaching plans in order to understand how technology can help. This can also be caused by lack of knowledge and limited experience with ICT and suitable software.
Intentions in the curriculum
Digital competence in the new curriculum plan is one of five fundamental competencies in all subjects together with ability to express oneself orally and in written, read and calculate (UFD, 2005). The notion digital competence in mathematics is further elaborated to involve use of computers and calculators for games, investigations, visualisation and publishing. On higher levels in schools it deals with using digital tools for problem solving, simulations and modelling and in addition searching for information, analyse, and present data and be critical to sources and results. Furthermore it is important to be able to judge and utilise digital tools and know their limitations. The aim described here is similar in the current plan which has been in use since 1997.
In addition to the general aims described above, more details are given in different sections in the plan; like use of a spreadsheet with simple models for calculations, presentation of statistics in tables and diagrams, experiment with geometry, and use digital tools for work on functions.
Research question
A main focus in this paper is to research how the teachers can provide a learning environment for students' work with ICT tools in the mathematics

20
ICT- tools is here used in the wide sense, computer software and calculators, without specifying characteristics. 176
classroom and how teachers can support students' work to learn mathematics using ICT.
1. How are the mathematical concepts and relations visible in the students' work on computers?
2. What affordances and constraints do the students'experience with the ICT support for a mathematical task or problem?
The relation between the students' work on computers and the way the teacher provide support is a part of the questions. The teachers work is done in the context of a project working on developmental research. Development of learning environment, task design and study of the implementation is a central issues in the research, and our experiences can illuminate questions about how teachers can be supported when implementing ICT tools and what we can learn from their experiences in classes (ICMI-17, 2005). Some of the questions concerning design of learning environment can also be illuminated.
Theoretical background
Introducing ICT in mathematics classrooms aiming to influence teaching and learning have implications for the way tasks and lessons are designed. The aim is, with support from ICT tools and teachers planning for learning, the student will learn mathematics and gain deep and flexible understanding of the subject and how it can be represented with the use of digital technology.
The aim according to the curriculum, is that the students should be able to judge and decide when and which digital tools to choose for a specific task. To achieve this goal the students have to know ICT tools in a personal way, not just know the technical features, but know and appreciate what kind of mathematical representations and models can be build and make connections to the actual tasks or problems they are going to solve. This requires a deeper knowledge and sense of what opportunities the tools can provide, in Gibsons' terms (1977; Greeno, 1994), what affordances and constraints the ICT tools provide in a specific mathematical situation.
Implementing ICT tools as a part of the learning environment have implications for the way teachers and students' work. The teaching and learning environment have to be considered in relations to how computers can be regarded, as an amplifier or a reorgansator (Dörfler, 1993). Amplifier implies doing the same as before, more efficient but without changing the basic structure, methods and approaches. In this way we will not be utilising the potential of the tools. Dörfler, and also others, claim that introduction of computer tools implies reorganising. Similar arguments are expressed by Goos, Galbraith, Renshaw, & Geiger (2005): " The amplification effect may be observed when technology simply supplements the range 177 of tools already available in the mathematics classroom, for example by speeding tedious calculations or verifying results obtained already. By contrast re-organising occurs when learners' interaction with technology as a new semiotic system, qualitatively transforms their thinking, ….. ". I think of this as a personal process whereby students develop their understanding of the tools and the mathematics involved.
This personal transforming of the students' thinking with the tools, seems to me to have ideas in common with more recent ideas from the French didacticians concerning turning the artefact, ICT tools, into a mathematical instrument (Guin, Ruthven, & Trouche, 2005). The students build their own personal instruments from the artefact through his (her) activity with it. This is a two way process, named instrumental genesis, whereby the students interact with the artefact forming their own schemes in order to work on specific tasks (Trouche, 2005). The resulting instruments consist of a combination of the artefact and the students' corresponding schemes. This process is influences and supported by the way the teacher provide for students' learning, named the teachers orchestration for the learning.
ICT tools represent both affordances and possibilities for the user and constraints for the work with tools (John & Sutherland, 2005). The affordances and constraints are not just connected to the tools, but can also be due to the classroom organisation, curriculum issues or other factors influencing the teaching. Constraints are not just negative obstacles, but can also support and frame the development of the working situation (Kennewell, 2001). A task that is too open can be difficult for the students to solve. In this sense constraints rather complement the affordances than the being opposite. According to Kennewell (2001) "the role of the teacher is to orchestrate affordances and constraints in the setting in order to maintain a gap between existing abilities and those needed to achieve the task outcome, a learning gap which is appropriate to the development." The study of affordances and constraints can provide a framework for analysing the effects of ICT in combination with other factors influencing the teaching and learning (Watson, 2006; Kennewell, 2001).
I am aware that the presentation of the theoretical considerations here is short, and perhaps unclear. My intention for the suggested paper is to develop this further, and with these concepts providing a framework for the study.
Recent and on-going projects
In a development and research project named the "ICT competence project" the aim was to develop the students' competence to use ICT tools such that they would be able to judge hat ICT tools are appropriate to use for a specific task and choose for themselves, not just rely on the teacher to tell what tools to use. The projects followed seven classes from grade 8 to 10 in schools with six teachers taking part and concluding in 2004. 178
Project meetings with teachers and project leaders were arranged every term for discussion of teaching ideas, experiences and further plans. The first two years had a main focus on development, but in the last year data were collected for research in the form of observations, collection of students' work on computer files and paper, questionnaire and interviews with a selection of students and teachers. In a working period in the final part of the project the students' work were observed, and afterwards they were given a questionnaire about their experiences in the work, what tools they chose to use and why (Fuglestad, 2005b; Fuglestad, 2005a).
In an on-going project ICT and mathematics learning (ICTML), the aim is to build a learning community, involving schools, teachers and a group of didacticians at the university college. The project collaborates closely and has a common conceptual model with the project Learning Communities in Mathematics (LCM)
21
.
A central aim in the projects is to develop inquiry communities in mathematics (Jaworski, 2004). Some schools take part in both projects. The ICTML project has a focus on use of ICT-tools, in particular computer software, and how these can be utilised as support for mathematics teaching and learning and students' inquiry into mathematics.
Teachers and didacticians collaborate in workshops at regular intervals on developing competence with ICT tools and discussing ideas for teaching in schools and experiences. Furthermore didacticians take part in meetings at the school discussing and development of tasks or draft of lesson plans using ICT.
All kinds of activities in the project are audio or video recorded and material like students' work in written and on computer files are collected. This gives rich opportunity to study the development in the different parts of the projects.
Data for analysis
The focus of this paper is to analyse some representative cases of teachers' implementation of ICT tools to support mathematics learning and how the students' work on the mathematical content in the tasks or problems provided.
I will present cases of students' work on mathematical tasks in order to highlight different ways of setting the tasks and orchestrating for students' learning environment.
In the final part of the ICT competence project the students had a working period where they could choose what tasks and tools to work with, either ICT tools or others. I observed a group of students working on a task that they found rather difficult. I partly acted as a helping teacher, but gave only limited help. The task was to find the smallest surface area of a rectangular box with length the double of the width, and volume 500. I observed their work, which was started in one lesson and taken up again a few days later. The students chose to work on a spreadsheet and set

21
Both projects are funded by the Research Council of Norway, http://www.forskningsradet.no 179
up formulae for the surface and volume, but did not use a formula for the connection between length and width of the box. There were a lot of arguments and frustrations, they needed a lot of time but after some hints they succeeded.
In a school taking part in the ICTML project one of the teachers made a draft, a collection of small tasks, on different sheets in Excel. On the first sheet, the students were asked to fill in two numbers, which are numerator and denominator of a fraction. Then as a result some equal valued (similar) fractions emerged for the students to observe and reflect on. The students were asked to write about their observations and comment on what they found. On the next sheet the students moved on to a similar more challenging task. The teacher had planned for increasing openness and difficulty of the tasks as the students moved on to the following sheets in the file.
At a meeting with the other teachers and didacticians the task was presented and discussed. New elements in the task were discussed and the participants learned from the others about ways of implementing and improving parts of the spreadsheet tasks. So both didactical and technical issues were discussed. A few days later the tasks was used in a class and observed. The task was discussed in a new project meeting. In discussing the experiences and the task several changes was made and new ideas for tasks developed.
The planned paper will present and analyse these and other cases in order to illuminate the research questions and hopefully reveal some critical elements in the teachers' planning and the students' work on mathematics using computers.
Conclusion
The proposed paper will focus on students and teachers' work in the class with use of a computer with suitable software. The cases that will be presented will highlight critical points in the teachers' orchestration for students' learning and development of the ICT tools into an instrument for learning and solving mathematical problems.
The analysis is ongoing and more will be completed during the spring term 2006. Since the work is not finished I will not provide any conclusions.
The main contribution from the proposed paper will be on the two themes Teachers and teaching, and Design of learning environments.

More than Tools: Mathematically Enabled Technologies as Partner and Collaborator

Vince Geiger, Australian Catholic University, Australia
v.geiger@mcauley.acu.edu.au

This paper theorises an extension to a framework that describes students' use of technology when engaged in mathematical activity and discussion. The framework describes students' interaction with technology through a series of metaphors: technology as master; technology as servant; technology as partner; and technology as extension of self. These metaphors allow illustration of potential relationships between students' intentions, technological engagement and actions. The framework is conceptualized from within a socio-cultural perspective of learning/teaching mathematics and extends the Vygotskian principle of Zone of Proximal Development (ZPD) by elevating computer and graphing calculator technologies beyond that of simple cultural tools to that of quasi-partner or mentor. The framework was developed through an ethnographic case study of a single class of students over a two year period. It describes different types of interaction between technology and students as they are challenged by new ideas and concepts or as they explore nonroutine, contextualized mathematical problems. A component of the framework is used to analyse two episodes of student/student and student/technology interaction while working on a specific mathematical task. Implications are discussed for the use of the extension of this framework as a means for the promotion of more sophisticated uses of technology in mathematics classrooms.

Through their inclusion as mandatory elements in Australian state syllabuses and assessment regimes, policy makers have authenticated the arguments of researchers (e.g., Morony & Stephens, 2000) in favour of the inclusion of mathematically enabled technologies and applications (META) because of their potential to transform learning and teaching in Australian mathematics classrooms. Similar change is evident outside of Australia in response to the influence of bodies concerned with curriculum reform in mathematics (e.g. NCTM, 2000).
Considerable research effort has been directed towards understanding how META can be used to enhance students' learning in mathematics (Dunham & Dick, 1994; Weber, 1998; Barton, 2000) and, in particular, how these technologies can act as catalysts for more active engagement in learning and, consequently, greater conceptual understanding (Barton, 2000). Other proponents (e.g. Asp, Dowsey, & Stacey, 1993; Templer, Klug, & Gould, 1998) have argued that these technologies can allow students the freedom to explore new ideas and concepts.
This paper outlines a framework that describes students' action and interaction with technology from a socio-cultural perspective and identifies META as an element, 183 within this framework, that plays a role beyond that of a simple tool. In doing so, this paper addresses the theme of Learning and Assessing Mathematics With and Through Digital Technologies. This theme will be approached through the perspectives of Theoretical Frameworks and Contribution to Learning Mathematics.

Theoretical Framework

Sociocultural perspectives on learning emphasise the socially and culturally situated nature of mathematical activity, and view learning as a collective process of enculturation into the practices of mathematical communities. A central claim of sociocultural theory is that human action is mediated by cultural tools, and is fundamentally transformed in the process (Wertsch, 1985). The rapid development of computer and graphical calculator technology provides numerous examples of how such tools transform mathematical tasks and their cognitive requirements. From a sociocultural perspective, technology can be regarded as a cultural tool - sign systems or material artefacts - that not only amplify, but also reorganise, cognitive processes through their integration into the social and discursive practices of a knowledge community (Resnick, Pontecorvo and Säljö, 1997). Amplification takes place when a tool provides a more efficient procedure or pathway for engagement in a task, for example, the use of a calculator or spreadsheet to deal with a series of tedious numeric calculations. Cognitive reorganisation, on the other hand, occurs when the use of technological tools mediates a qualitative change in an individual's way of thinking about a mathematical idea or concept, or their approach to a problem solving task. This type of transformation is evident when students are encouraged to develop the capacity to take a multiple representational approach to solving nonroutine problems. The freedom to assign equal privilege to different problem solving approaches provides opportunity to break free of the straightjacket of traditional algebraic reasoning and represents a completely different way of thinking about how to initially engage with a problem solving task and then how to progress after this engagement.
While the approach taken here is essentially Vygotskian, Galbraith, Goos, Renshaw and Geiger (2001) have argued previously that the widely known definition of Vygotsky's Zone of Proximal Development (as the distance between what a child can achieve alone and what can be achieved with the assistance of a more advanced partner or mentor) can be extended to conceptualisation of the ZPD in egalitarian partnerships and by the way the ZPD concept creates a challenge of participating in a classroom constituted as a community of practice. The first extension suggests that peer groups of equal expertise can promote new learning via contributions from individuals with incomplete, though relatively equal, expertise that sum to something greater than their individual parts, and so through interaction collectively progress knowledge and understanding. This is different from the purely Vygotskian view in which productive learning arrangements require that at least one individual in a group possesses greater expertise in an area of learning endeavour. The second extension argues that through the establishment of a small number of repeated participation 184 frameworks such as teacher-led lessons, peer tutoring, and individual and shared problem solving, students are challenged to move beyond their established competencies and adopt the language patterns, modes of inquiry, and values of the discipline. Such a classroom environment, representative of an active community of learners, is augmented by the availability of technology as a means to amplify and reorganise ways of communicating within the community; for example, by allowing students to contribute to collective discussions either as private individuals (via a computer screen) or publicly (via a display available to all participants). An important observation of this study was that students who were less prone to contribute to more conventional classroom discussion did so readily through electronic media.
This paper will argue that while technology plays a role as a cultural tool, as outlined above, it can, in the minds of students, assume a more active and interactive role in the process of cognitive reorganisation - that of an almost peer with expertise that can be drawn upon in the same way as other members of a learning community.

A Framework for Analysing Students' use of Technology

There are a number of studies that have sought to develop taxonomies of student behaviour in relation to the use of technology while learning mathematics. Doerr and Zangor (2000), for example, in a case study of pre-calculus classrooms identified five modes of graphics calculator use: computational tool, transformational tool, data collection and analysis tool, visualisation tool, and checking tool. Alternatively, Guin and Trouche (1999) developed profiles of behaviour in relation to students' use of graphing calculator technologies. The modalities outlined in the profiles were characterised by random, mechanical, rational, resourceful, or theoretical behaviours in terms of their ability to interpret and coordinate calculator results.
It is from the perspective of learning as a sociocultural experience, however, that Galbraith, Goos, Renshaw and Geiger (2001) have developed four metaphors for the way in which technology can mediate learning. These metaphors, technology as master, technology as servant, technology as partner, and technology as extension of self, describe the varying degrees of sophistication with which students and teachers work with technology. While these metaphors are hierarchical in the sense of the increasing level of complexity of technology usage teachers and students may attain, it does not represent a developmental progression where once an individual has shown they can work at a higher level they will do so on all tasks. Rather, the demonstration of more sophisticated usage indicates the expansion of a technological repertoire where an individual has a wider range of modes of operation available to engage with a specific task. This means, for example, that a very capable individual may well use technology as a servant if the task at hand is mundane and there is no reason to invoke higher levels of operation.
A description of these metaphors is outlined in below:
Technology as Master. The student is subservient to the technology - a relationship induced by technological or mathematical dependence. If the complexity of usage is high, student activity will be confined to those limited operations over which they 185 have competence. If mathematical understanding is absent, the student is reduced to blind consumption of whatever output is generated, irrespective of its accuracy or worth.
Technology as Servant. Here technology is used as a reliable timesaving replacement for mental, or pen and paper computations. The tasks of the mathematics classroom remain essentially the same - but now they are facilitated by a fast mechanical aid. The user 'instructs' the technology as an obedient but 'dumb' assistant in which s/he has confidence.
Technology as Partner. Here rapport has developed between the user and the technology, which is used creatively to increase the power that students have over their learning. Students often appear to interact directly with the technology (e.g. graphical calculator), treating it almost as a human partner that responds to their commands - for example, with error messages that demand investigation. The calculator acts as a surrogate partner as students verbalise their thinking in the process of locating and correcting such errors. Calculator or computer output also provides a stimulus for peer discussion as students cluster together to compare their screens, often holding up graphical calculators side by side or passing them back and forth to neighbours to emphasise a point or compare their working.
Technology as an Extension of Self. This is the highest level of functioning, where users incorporate technological expertise as an integral part of their mathematical repertoire. The partnership between student and technology merges to a single identity, so that rather than existing as a third party technology is used to support mathematical argumentation as naturally as intellectual resources. Students working together may initiate and incorporate a variety of technological resources in the pursuit of the solution to a mathematical problem.

The Study

The research reported here describes one aspect of a three year longitudinal study although the data analysed in this paper are sourced from a single mathematics classroom over a two year period (Years 11 and 12, the final two years of secondary schooling; students are aged 16-17 years.). The author was also the teacher of this class. The students were studying a challenging mathematics subject designed for students intending to pursue serious study of mathematics at a tertiary level. The intended culture of this classroom is one consistent with the sociocultural perspective of learning and teaching (see Goos, Galbraith, & Renshaw, 1999) including the acceptance of emergent uses of technology. This means a variety of interactions that involve mutuality are encouraged, including: student/student interaction; student/teacher interaction; subgroup and whole class investigation and discussion of specific tasks or of a variety of projects simultaneously. Interactions between participants and artefacts such as texts and more importantly electronic technologies also characterise the way students explore and investigate new mathematical ideas and concepts.

Data Sources 186

On average a lesson was videotaped every one to two weeks, or more frequently if a technology intensive approach to a topic was planned. Audiotaped interviews with individuals and groups of students were conducted at regular intervals to examine factors such as the extent to which technology was contributing to the students' understanding of mathematics, and how technology was changing the teacher's role

in the classroom. At the beginning of the course and at the end of each year students completed a questionnaire on their attitudes towards technology, its role in learning mathematics, and its perceived impact on the life of the classroom. A final class interview/discussion reviewing the two-year program was videotaped. This paper presents two vignettes, drawn from observation and transcript data, to illustrate the role technology can play as a Partner in the generation and repair of new knowledge and understanding.
Vignette 1
Students (Year 12) were asked to develop programs for their calculators that found the angle between two three dimensional vectors as an application of the scalar product of vectors and as a means of validating results found from pen and paper techniques. The teacher provided only minimal instruction in basic programming techniques, and expected individual students to consult peers, who had varying degrees of knowledge, for assistance. Volunteers then demonstrated their programs via the calculator viewscreen, and examined the wide variation in command lines that peers had produced. This public inspection of student work also revealed programming errors that were subsequently corrected by other members of the class. For example, the class disputed the answer obtained by executing the program shown in the first part of Figure 1.
Fig. 1. Correcting errors in a student program
His actions guided by fellow students, the presenter scrolled down through the program and replaced the plus sign in the denominator with a multiplication sign (Figure 1, second screen). The amended program again produced an incorrect answer, and yet another correction (Figure 1, third screen) – suggested by students, not the teacher – was required before the correct output was obtained.
Vignette 2
In this episode we observed how one student consistently rejected the teacher's invitations to discuss his thinking with peers, participate in whole class discussions, and generally take some responsibility for advancing his mathematical understanding. This situation began to change when the student participated in the activity described in Vignette 1. The student presented the program which included the initial screen illustrated in Figure 2 and then the second and third last screens (Figure 2, second and third screens). 187
Fig. 2. Presentation of the Dodge program
The choice of option 1, in response to the question posed in screen 3, resulted in the display of the answer to the calculation the program was designed to deliver (screen 4). The choice of option 2 resulted in no answer being provided (screen 5) in the manner of a taunt.
Now while the student had used the task to demonstrate dissent in relation to his current experience of mathematics, his clever use of the very method of discourse the teacher has been encouraging the student to use persuaded the teacher not to issue a reprimand of any type. The student responded, over subsequent lessons, by increased involvement in classroom presentation whenever technology was used to mediate discussion. This included the presentation of improved, and increasingly sophisticated, versions of his initial program. This was followed by an animated program he had created that depicted the adventures of mathematical objects (various irrational numbers) as human-like characters – Dodge: The Movie. The enthusiastic and admiring response to his "movie" (and the sequel – Dodge II: The Revenge of Dodge) was significant in drawing this student into the kind of mathematical discussion he had previously resisted, and he became a willing participant in subsequent discussions both technology-focused and otherwise.
Discussion
Technology is often viewed as a neutral tool useful for the illustration of mathematical ideas and concepts but with little potential for mediating interaction. Doerr and Zangor (2000), for example, found that the use of the graphics calculator as a private device led to the breakdown of small group interactions. The two vignettes above demonstrate the potential of technology, including associated presentation tools, for drawing in students who are initially reluctant to engage in, or in some cases resist, the social and cultural norms of a community of learners. In the first vignette, technology supported the interaction of peers of roughly equal expertise in repairing a faulty calculator program. The technology not only provided the medium in which the students worked but it also stood alone to make public a particular student's work; holding it up for scrutiny and providing the opportunity for supportive critique. In this case, technology has assumed the role of almost equal partner in the interaction. It has offered to the group a skill or expertise that they lacked to get the job done. Once injected into the interaction it allowed the group to progress the development of an individual who had encountered difficulty in progressing by himself. The significant contribution technology has made in this 188 episode is more than that of a simple tool; it is an instance where the boundaries between tools and human learners is blurred.
The second vignette features a student who uses the method of discourse he had previously resisted to register dissent in relation to the way mathematics classes were conducted in this course. Having received positive reinforcement from his peers (and no negative feedback from the teacher) he is slowly drawn into the ways of interacting with his learning community that he has previously shunned; initially when technology was involved and then, eventually, at other times. Technology, again, has acted as more than a simple tool. Firstly, it acted as a partner that assisted him to express the personal frustration that lay in a conflict between his view of how to learn and do mathematics and the social and cultural norms for doing the same in this particular classroom. Technology had acted as a partner in crime in this instance. Secondly, however, technology has almost acted as a supportive go-between that has encouraged him to move from the fringes of his learning community into the mainstream.
Implications for Learning and Teaching
The conceptualization of technology as a quasi-peer offers the following insights into the process of integrating META into mathematics classroom.
Technology can be regarded as more than a passive cultural tool to be appropriated by teachers and students to enhance mathematics learning and teaching. Rather, META can make contributions to social and cultural activity beyond that of merely mediating interaction. The vignettes presented above highlight instances where technology has played a far more important role that that of a simple presentation tool that assists in mediating discussion and interaction. In these instances, technology has almost taken on its own persona and has offered contributions to these learning episodes that students, by themselves, would not have been able to replicate. This is emphasized, particularly in the second vignette, where a student is empowered by a technological partner to voice a controversial view via a method of expression sanctioned by the learning community from which he had excluded himself. Further, he was then led by the same technological partner back into a human community from which he had previously dissociated himself.
The notion that META can be regarded as quasi-peer within a community of practice extends Vygotsky's notion of a ZPD to include technology as contributing member to a group of learners rather than merely a cultural tool. This implies that META should be afforded even greater attention in terms of its pedagogical power than has been previously assigned and so has implications for both teacher pre-service instruction and for in-service professional development.

Understanding technology integration in secondary mathematics:
Theorising the role of the teacher
Merrilyn Goos, University of Queensland, Australia
m.goos@uq.edu.au
Previous research on computers and graphics calculators in mathematics education has examined effects on curriculum content and students' mathematical achievement and attitudes while less attention has been given to the relationship between technology use and issues of pedagogy, in particular the impact on teachers' professional learning in specific classroom and school environments. This observation is critical in the current context of educational policy making, where it is assumed – often incorrectly – that supplying schools with hardware and software will increase teachers' use of technology and encourage more innovative teaching approaches. This paper reports on a research program that aimed to develop better understanding of how and under what conditions Australian secondary school mathematics teachers learn to effectively integrate technology into their practice. The research adapted Valsiner's concepts of the Zone of Proximal Development, Zone of Free Movement and Zone of Promoted Action to devise a theoretical framework for analysing relationships between factors influencing teachers' use of technology in mathematics classrooms. This paper illustrates how the framework may be used by analysing case studies of a novice teacher and an experienced teacher in different school settings.
Mathematics, science and technology education in Australia are currently experiencing major impetus for innovation and reform. The Australian Government's policy statements on educational innovation and teacher quality (Commonwealth of Australia 2003) emphasise that Australia's future lies in its potential as a knowledgebased society built on the intellectual capabilities and creativity of its people. Teachers and students are expected to become partners in a learning society underpinned by science and mathematics and successful schools are portrayed as those drawing on the resources of technology to facilitate learning. Throughout Australia there are moves to encourage – and in some cases mandate – the integration of digital technologies into school education through curriculum initiatives, funding for infrastructure, and the development of professional standards for teachers. In the current context of educational policy making it seems to be assumed that supplying schools with hardware and software will increase teachers' use of technology and encourage more innovative teaching approaches that produce improved learning outcomes for students. Yet internationally there is research evidence that that improving teachers' access to educational technologies has not, in general, led to increased use or to movement towards more learner-centred teaching practices (Cuban, Kirkpatrick & Peck, 2001; Wallace, 2004). 191
Windschitl & Sahl (2002) have identified two factors that appear to be crucial to the ways in which teachers might embrace, ignore, or resist technology. First, teachers' use of technology is mediated by their beliefs about learners, about what counts as good teaching in their institutional culture, and about the role of technology in learning. Second, school structures – especially those related to the organisation of time and resources – often make it difficult for teachers to adopt technology-related innovations. Clearly, there is a need to interrogate assumptions about relationships between access to technology and its use by teachers. This paper does so by offering a framework for theorising interactions between pedagogical knowledge and beliefs, school structures and other institutional constraints, and professional learning opportunities, together with analyses of examples of teacher learning and development drawn from a series of sociocutturally oriented research studies carried out in Australian schools. The paper addresses the ICMI Study 17 theme of Teachers and teaching by considering the role of the teacher viewed through the lens of this theoretical framework.
Theoretical Framework
Early research in this area examined the effects of technology use on students' mathematical achievements and attitudes and their understanding of mathematical concepts, often using quasi-experimental designs that compared technology and nontechnology users (Penglase & Arnold, 1996). However these studies did not distinguish between the use of technology and the context of that use, and little attention was given to issues of pedagogy and the nature of teachers' professional learning within and beyond the school environment (Windschitl & Sahl, 2002). To address some of these issues my colleagues and I have carried out studies informed by sociocultural theories of learning involving teachers and students in Australian secondary school mathematics classrooms (e.g., Galbraith & Goos, 2003; Goos,

2005). Sociocultural theories view learning as the product of interactions with other people and with material and representational tools offered by the learning environment. Because it acknowledges the complex, dynamic and contextualized nature of learning in social situations, this perspective can offer rich insights into conditions affecting innovative use of technology in school mathematics.
In this research program Valsiner's (1997) zone theory, originally designed as an explanatory structure in the field of child development, was adapted to apply to interactions between teachers, students, technology, and the teaching-learning environment. This framework extends Vygotsky's concept of the Zone of Proximal Development (ZPD) - often defined as the gap between a learner's present capabilities and the higher level of performance that could be achieved with appropriate assistance - to incorporate the social setting and the goals and actions of participants. Valsiner describes two additional zones: the Zone of Free Movement (ZFM) and Zone of Promoted Action (ZPA). The ZFM structures an individual's access to different areas of the environment, the availability of different objects within an accessible area, and the ways the individual is permitted or enabled to act 192 with accessible objects in accessible areas. The ZPA represents the efforts of a more experienced or knowledgeable person to promote the development of new skills. For learning to be possible the ZPA must be consistent with the individual's potential (ZPD) and must promote actions that are feasible within a given ZFM. When we consider teachers' professional learning, the ZFM can be interpreted as constraints within the school environment, such as students (their behaviour, motivation, perceived abilities), access to resources and teaching materials, and curriculum and assessment requirements, while the ZPA represents opportunities to learn from preservice teacher education, colleagues in the school setting, and professional development.
Previous research on technology use by mathematics teachers has identified a range of factors influencing uptake and implementation. These include: skill and previous experience in using technology; time and opportunities to learn (pre-service education, professional development); access to hardware and software; availability of appropriate teaching materials; technical support; institutional culture; knowledge of how to integrate technology into mathematics teaching; and beliefs about mathematics and how it is learned (Fine & Fleener, 1994; Manoucherhri, 1999; Simonsen & Dick, 1997; Walen, Williams & Garner, 2003). In terms of the theoretical framework outlined above, these different types of knowledge and experience represent elements of a teacher's ZPD, ZFM and ZPA, as shown in Table 1. However, in simply listing these factors, previous research has not necessarily considered possible relationships between the teacher's setting, actions, and beliefs, and how these might change over time or across school contexts. Zone theory provides a framework for analysing these dynamic relationships.

Background to the Research Program
The research program referred to above has used Valsiner's (1997) zone theory to investigate relationships between factors influencing how novice and experienced teachers use technology in the mathematics classroom. Examples from two separate studies are analysed later in the paper. A brief outline of the research design and methods for each study is provided below. 193
The first study, conducted in 2001, aimed to analyse processes through which mathematics teachers learned to use technology as an educational resource (Galbraith & Goos, 2003). Participants were a group of ten experienced teachers who volunteered for a training program, conducted intensively over a single week-end, that prepared them to deliver professional development workshops on the use of graphics calculators. These sessions engaged participants as learners in technologyrich activities that could be used in secondary school classrooms, and in discussion of associated teaching and learning issues. We followed the progress of three teachers who subsequently delivered professional development workshops at conferences or in their own schools, and interviewed them on how their views about technology had been affected by the training program.
The second study followed successive cohorts of pre-service teachers into their first years of teaching from 2000-2004. Its main aims were to identify factors that influence how beginning teachers graduating from a technology rich pre-service course integrate computers and graphics calculators into their mathematics teaching practice (Goos, 2005). One element of the research design involved individual case studies that captured developmental snapshots of experience during the final practice teaching session and towards the end of the first year of full-time teaching. Participants were visited in their schools for lesson observations, collection of teaching materials and audio taped interviews.
Case Study of a Novice Teacher Learning to Integrate Technology
Sandra was one of the pre-service participants in the second study selected for individual case study. Her practicum placement was in a large school in the State capital city. At this time the mathematics syllabuses merely encouraged teachers to use computers and graphics calculators, although new syllabuses to be introduced the following year would make technology use mandatory. The school was well equipped with computer laboratories and had recently purchased its first class set of graphics calculators. However, none of the teachers had yet found time to learn how to use the calculators. Sandra was very familiar with computer applications such as Excel and regularly searched the internet for teaching ideas and resources. She used both these technology resources in her mathematics teaching during her practice teaching sessions, although she had not observed other teachers in the school use any kind of technology with their classes. Before starting the pre-service course Sandra had no experience with graphics calculators but she was now keen to explore the possibilities this technology might offer for developing students' understanding of mathematical concepts.
Sandra was teaching linear programming, a topic that deals with the kind of optimisation problems commonly encountered in engineering and economics. As graphical methods are usually used to solve linear programming problems in secondary school treatments of this topic, Sandra decided this presented an ideal opportunity for students to use the graphics calculators instead of drawing graphs by hand. She adapted an activity from the internet that asked students to work out the 194 optimal quantities to be produced of two different kinds of pasta, using three different varieties of cheeses, so as to ensure maximum profit for the manufacturer. Because the students had never used graphics calculators before, she also devised a worksheet with keystroke instructions and encouraged students to work and help each other in groups.
Unexpectedly, Sandra encountered strong resistance from the students, which seemed to stem from their previous experiences of mathematics lessons. Other mathematics teachers in the school tended to take a very transmissive approach and focused on covering the content in preparation for pen and paper tests, so the students were not interested in learning how to use technology if this would be disallowed in assessment situations. According to Sandra, the students' attitudes could be summed up as: "Just give me enough to pass ... I don't want to know how to do group work, I don't want to know how to use technology".
In theoretical terms, the Zone of Promoted Action offered by the teachers in the school was not a good match with the ZPD defined by Sandra's pedagogical beliefs and her knowledge and skills in using technology to teach mathematics. Neither did her supervising teacher's ZPA provide a pedagogical model consistent with the technology emphasis of the pre-service course. Some elements of Sandra's Zone of Free Movement, such as her easy access to calculators that no other teacher knew how to use, presented favourable opportunities to use technology. However, most other aspects of her ZFM - students' attitudes and lack of motivation, curriculum and assessment requirements that excluded technology - represented constraints. Yet Sandra was not discouraged by this experience and remained committed to enacting her pedagogical beliefs about using technology.
After graduation Sandra moved from the city to a smaller rural school that was much better resourced with respect to graphics calculators but lacking in experienced teachers who knew how to use them effectively. All Grade 11 and 12 mathematics students had continuous personal access to graphics calculators via a hiring scheme operated by the school, and there were two additional class sets available for teachers to use with other classes - although Sandra was the only teacher to use these with younger students. She was also beginning to use temperature probes and motion detectors which could be used in conjunction with graphics calculators to collect and analyse data from experiments.
Compared with her practicum experience, Sandra's first year of teaching offered a more expansive Zone of Free Movement: motivated and cooperative students, good access to technology resources, and new syllabuses that mandated use of computers and graphics calculators in Grades 11 and 12. Yet there was no Zone of Promoted Action within her school environment, and geographical isolation, compounded by a very slow internet connection, made it difficult for her to access professional development and teaching materials (an external ZPA). While she was still able to draw on the knowledge gained during her university program (the pre-service ZPA), Sandra recognised her need to gain new ideas via collaboration with other more 195 experienced teachers beyond the school in order to further develop her identity as a teacher for whom technology was an important pedagogical resource.
Case Study of an Experienced Teacher Learning to Integrate Technology
Teachers who completed their pre-service education before computers and graphics calculators were introduced into school classrooms rely on formal or informal professional development to learn how to use technology. By comparison with Sandra, Lisa was a very experienced teacher but a relative novice in the use of technology when she participated in the research study associated with the graphics calculator training program described earlier. When reflecting on her initial professional development experiences in this field, she commented that she "got lost in the first ten seconds, and was really turned off so didn't touch them again for a while". After several more workshops she felt confident enough to use graphics calculators in her teaching, "but not confidently and not proficiently. Not really realising how much they improved the thinking, more just as a tool to do graphs and things".
The training program proved to be a turning point for Lisa as it emphasised the impact of technology in developing students' understanding of mathematical concepts and in facilitating classroom discussion, something that had been missing from her previous professional learning experiences:
It was out of that week-end that I really understood the impact that [graphics calculators] had on the pedagogy. Up to then I saw it as a tool to draw graphs and analyse statistics. But at that workshop, just one little thing from that workshop, how we were working in groups, and they explained to us how kids start trying to help. So when we were doing that we were grabbing somebody else's calculator and sharing our data, so it made the group work thing a whole lot better. And I really valued the part where we, as groups, we went out and used the overhead projector and we presented our information back to the group. So I just, I really started to see different ways of using it that I hadn't thought of before. So it really enhanced group work, it really showed me that you could do a lot more hands on stuff, the practical activity with the motion detectors. That graphics calculators are good for inspiring all those other good things in teaching, like the hands on, the group work, and really starting to think when we were fitting functions to the data. Really having to think and understand what the intercept and the gradient mean. We weren't just doing, we were really understanding at a higher level. I found that really powerful. Because I had thought that all they do is save you that boring part of maths.
Environmental constraints and affordances (ZFM) seemed to play little part in Lisa's learning, possibly because as Head of her school's Mathematics Department she had considerable autonomy in obtaining desired resources and in managing curriculum and assessment programs. Instead, the re-construction of her identity as a teacher can be understood in terms of the changing relationship between her goals and interests 196 (ZPD) and the ZPAs offered by the professional development and training she experienced. She described previous workshops she had attended as "off-putting", because the emphasis was on procedural aspects of operating the calculators and the mathematics presented was too difficult for participants to engage meaningfully with the technology. She contrasted this with the approach taken in the week-end workshops offered as part of this research project:
I didn't really feel super confident until I went to the workshop. And I think it was then, understanding the bigger concepts, rather than just pushing buttons. Because at the pushing buttons level you never really understand how they operate. And after that I was just so inspired. It was just that whole valuing and that sharing and learning from each other, and just to realise that other people are out there. So that was really the turning point for me to say that this is really exciting stuff.
Lisa seemed to find a professional development ZPA that matched her need to focus on pedagogical, rather than procedural, aspects of using technology, and acknowledged the potential for experienced teachers to learn from each other.
Discussion
This paper has analysed relationships between mathematics teachers' access to technology resources and the ways in which they incorporate these resources into their pedagogical practices. Evidence from research studies carried out in Australian classrooms suggests that simple notions of "access" and "use" are inadequate for understanding the roles that technology plays in mathematics teaching and learning. The case studies of Sandra and Lisa showed that teachers interpret access to technology in relation to what they believe is beneficial for students and feasible in

the light of their own expertise and institutional context.
Teachers' learning can be conceptualised in terms of relationships between Valsiner's (1997) Zones of Proximal Development, Free Movement and Promoted Action, and this provides a useful way of analysing the extent to which teachers adopt innovative practices involving technology. The ZFM can be interpreted as teachers' institutional context, the ZPA represents their experiences in learning about teaching with technology, and the ZPD is influenced by their knowledge of how to integrate technology into their teaching and their pedagogical beliefs. The case study of Lisa illuminated issues facing experienced teachers who are unfamiliar with new technologies such as graphics calculators. While her ZFM presented few constraints, she had to search for professional development (ZPA) that would extend, rather than only accommodate, her existing ideas about teaching with technology (her ZPD). On the other hand, novice teachers like Sandra who are knowledgeable and enthusiastic about using technology may encounter obstacles in their professional environment (ZFM) that hinder implementation of preferred teaching approaches. Thus the theoretical approach outlined in this paper provides a way of interpreting teachers' actions in mathematics classrooms and may generate informed discussion about 197 conditions that support or inhibit teachers' learning and adoption of new technologies.

The Unrealized Potential of the Internet
Mary W. Gray
American University, Washington, USA
mgray@american.edu
The role of the Internet in teaching and research has been given too little attention in mathematics education, particularly in developing countries and underserved segments of the population of developed countries. Those with inadequate Internet connectivity lack access to the research of others and experience difficulty in achieving recognition for their own work. Exchange of ideas in their formative stage as well as the distribution of completed writing is essential for full participation in the research community. Similarly, use of the Internet to share experience and innovation in teaching and to train teachers in-service and pre-service is a costeffective means of instituting widespread improvements, particularly with respect to increasing access for groups such as girls, adult learners, rural or disadvantaged populations, and the learning disabled. For the learners themselves, the ability to acquire information via the Internet can transform their educational experience. Although there is concern about the hegemony of developed nations in the Internet environment, the solution is inclusiveness, not isolation, as well as sharing within domestic culture. Although investment will be required, new technology and focus on community-based access will reduce the costs of providing adequate communications infrastructure.
In spite of the focus on the use of technology in mathematics education, there has been insufficient attention to the importance of the role of the Internet in teaching and research, particularly with respect to access, equity, and socio-cultural issues. In developing countries with limited resources, to the extent that Internet connections exist, they are generally confined to entrepreneurial enterprises, from local Internet cafes to outposts of multinational corporations.
22
Although the Internet first arose in a largely academic context, for the most part it is only in highly developed countries that university faculty and students, much less teachers and students in primary and secondary schools, have extensive access.
Computers are not as rare in developing countries as one might think and even the Internet has experienced rapid superficial growth, far surpassing already Bill Gates' 1997 prediction of 500 million users by 2007. However, educational use of the Internet is very limited outside of developed countries.

22
This observation is based in part on the author's extensive experience in the Middle East, including pre- and post-invasion Iraq, and to a lesser extent in Asia and Africa. 199
Extensive surveys have been conducted of the dispersion of the Internet in developing countries, including a number using a six part paradigm: pervasiveness, geographic dispersion, connectivity infrastructure, organizational infrastructure, sectoral absorption, and sophistication of use (Wolcott et al, 2000). Going beyond such simple metrics as numbers of hosts, the researchers measured dispersion of points of presence or toll-free access, domestic and international backbone width, collaborative arrangements and public exchanges, usage rather that just access, and whether the usage is conventional or innovative. By all measures, developing countries have a long way to go. Although they have not focused in much depth on the education sector, the general finding has been that while most universities have some Internet access, a single terminal may serve as many as a thousand students, and while secondary schools may have computers, they seldom have Internet access. As for primary schools, use of computers either for educational or administrative purposes is rare in most developing countries. However, business use, including commercial cybercafes, has expanded greatly, showing the potential for broader application of the technology.
This presents an obvious equity issue as between countries, but also means that there are inequities within the countries themselves--it is the urban, prosperous who acquire the information and skills available via the Internet. We discuss the existing situation and propose remedies.
Research
The obvious disadvantage to those having limited access to the Internet is that they experience difficulty in keeping up with the research of others and in making known their own contributions. Universities and research institutes in developing countries have few print journals available in mathematics or mathematics education (or any other field); whereas a typical US medical school library may subscribe to around 5000 journals, the best university medical school library in many developing countries may have no more than 20, if indeed it has any at all. Textbooks providing up-to-date information are in similarly short supply. There are programs, supplemented by pleas for assistance from particular institutions, providing such journals, but they are not only inadequate, but misguided. Internal and outside resources currently committed to these projects should be redirected to securing online access through JSTOR and other services and databases. The reasons to prefer online access--in addition to the fact that the cost in the long run is likely to be less--include the fact that the electronic journals can be made simultaneously available to many users, storage is not a problem, and searching for particular topics is much easier. Moreover, increasingly journals are published directly online. 200
Not only do those with inadequate Internet connectivity lack access to the research of others, but also they may have difficulty making their own work known. Exchange of ideas in their formative stage as well as the distribution of completed writing is essential to full participation in the research community. In addition, notices of conferences and other opportunities for collaboration come to most researchers via the Internet. Increasing amounts of information about scientific and technological developments are now available only on the Internet. Use of the Internet can improve resource mobilization and make it possible to carry on collaborative research among distant sites.
Teaching
The usefulness of computers in teaching has been well recognized, but too little emphasis has been placed on their enhanced value if there is Internet connectivity. The amount of educational material in all fields readily available free on the Web is huge and ever growing. True, discretion is required in deciding what is worthwhile and what is not, but that there is selectivity needed is not a reason for choosing not to avail oneself of the riches waiting to be discovered.
There is justifiable fear about the hegemony of American and European culture on the Internet and complaints about the necessity of knowing English to acquire much of the information found there. However, one should consider the benefits of having a language that also enables communication among developing as well as highly developed countries throughout the world in order to share knowledge and experiences. Moreover, the Internet can be used to preserve and nurture one's own language and culture through domestic exchanges online.
The benefits of using Internet resources in teaching are extensive and varied. There are voluminous lists of web sites providing, just as an example, up to date maps and statistics to which schools would otherwise be unlikely to have access. No longer must students hunt for stories and pictures of women or minority mathematicians nor must teachers seek in inadequate libraries for the story of the development of the concept of zero. Hieroglyphics, Mayan glyphs, Babylonian cuneiform--they are all there. The history of mathematics--and not just from a European perspective can be vividly incorporated into the teaching of mathematic via this application of technology. The audience can be widened to provide more equity in learning, but also in subject matter learned.
Interesting and relevant applications of mathematics and statistics, tutorial help, and innovative and effective teaching techniques can be found on the Web. In many developing countries resources are not available for in-service training of widely dispersed teachers. Topics such as dealing with learning disabilities are often 201 neglected in pre-service training as well. The ability of teachers to share their own ideas with colleagues in their own culture is another important benefit of Internet access.
Equity
The digital divide can be within a country as well as between countries, but this need not be. The Internet properly used has great potential for reducing this divide, for bringing the information age--and with it mathematics education--to rural areas, to girls and women, and to other underserved populations.
Distance learning applications of the Internet have great potential, especially to reach rural areas and to maximize use of scarce teaching resources. The development of adequate material can be capital intensive, but sharing from country to country as well as within a country can help. Convincing those in charge of the return on initial investment is key to establishing distance learning in terms of both hardware and teaching material.
It should also be understood that "distance" learning need not be over long distances. Particularly for part-time learners who must continue in full-time employment, the ability to get specialized training at convenient urban locations can be crucial to economic and social development.
Girls by no means have equal access to education in many developing countries. For example, in sub-Sahara Africa only six of ten girls attend primary school (compared to eight of ten boys) with the situation becoming even more disparate beyond primary school (LaFraniere, 2005). Long distances, lack of sanitary facilities, and sexual harassment problems can be overcome through distance learning. Setting up Internet access points, particularly in rural areas, can transform girls' prospects for education; the locations can also be used for adult reading and quantitative literacy programs, especially for women with small children. Such local access centers could also be used for teacher training.
But it is not only in developing countries that inequities need to be addressed and where investment in Internet access for the schools could be instrumental in doing so. Although public primary school students in some areas in developed countries may be designing their own web sites, there are others who have no access at all to the benefits of the Internet.
What is needed? 202
Distance learning has great potential, especially to reach rural areas and to maximize use of scarce teaching resources. The development of adequate material can be capital intensive, but sharing from country to country as well as within a country can help. Convincing those in charge of education that the return on initial investment can be massive is key to establishing distance learning support of both

hardware and teaching materials.
The correlation between the number of Internet hosts and the UNDP Human Development Index is high, which suggests that substantial investment will be needed to increase Internet access to the point where it can play an important role in teaching and research. Rather than focusing on individual access, the goal should be more socially beneficial community-based access.
Studies have shown that the major handicap in the broad use of the Internet is deficient telecommunications infrastructure. However, the answer is to leapfrog over, for example, the lack of landline connections. In India a nationwide cellular network was installed without an inch of copper wire, which might later be cut or stolen in any case, at a cost less than one-third of a landline installation. More generally, while there are always problems in the introduction of innovative technology, that the population in developing countries is relatively young is a big advantage.
Instructive is the burgeoning of Internet usage in China (in spite of the restrictive government policies that hamper the openness that should be part of Internet use). Chinese universities decided some years ago to make Internet connectivity a priority, with economic reforms providing the capital for the investment needed; the primary and secondary sectors have not, however, seen similar progress. Universities in developed countries have also made Internet access an important goal, although, at least in the United States, the access is uneven, depending on the institutions' resources. Essential to the Chinese experience was a prior decision to invest in telecommunications infrastructure and human resources.
In discussing Internet-inspired development, Shirin Madon (2000) asserts:
"The establishment of a strategic infrastructure is considered critical for developing countries where the marginal impact of improved network communications can be very high, leading to improved economic productivity, governance, education and quality of life, particularly in rural areas."
However, skepticism regarding the potential of technology includes a fear of increasing dependency on international resources in the form of financing or technical skill. Thus an important component of technological development must be 203
the training of the domestic workforce. In fact the Internet itself can play an important role in this preparation. For example, the Village Internet Programme of the Grameem Bank (Madon, 2000) helped to create technology-related jobs for rural poor and Cuba's school networking project (Press, 1998) stressed grassroots participation of schools in rural areas. In the field of mathematics education, even in developed countries, rural areas or depressed urban areas may have difficulty securing access to qualified teachers and material. Educational authorities must be encouraged to see investment in informational communication as a way to help relieve inequities. Too often education budgets are a source of cuts when savings need to be made in national budgets.
Governments need to understand their role in creating and disseminating knowledge. Because of the worry of the dominance of developed countries in the Internet environment, there is likely to be resistance to the notion of substantial investment. Therefore, "do it yourself" is an important concept for the development of information technology. To limit external dependency, human resource development for network users means concentration on training in data handling, software, monitoring, and management, not just technical matters.
Often nations are willing to commit funds for technology for commercial development purposes, but it makes no sense to invest in information superhighways while cutting down on the prerequisite, solid and adequate education for all. They must be ready to exploit the potential of the Internet for this purpose.

Learning mathematics in class with online resources
Ghislaine Gueudet
CREAD and IUFM de Bretagne, France
ghislaine.gueudet@bretagne.iufm.fr
Internet resources proposing mathematics exercises with an associated environment are frequently used in class, in many countries and for all levels. I address here the question of the theoretical approaches that can be used to describe and understand the way students work and learn mathematics with these resources. I study in particular the possibilities offered by the instrumental approach, complemented by the notion of didactical contract. The resources considered are complex. In order to study their use by students, is thus necessary to consider two activity levels: the resolution of one exercise, where students use the elements of the exercise's environment (feed-back, hint etc.) and the level of a whole session, where students develop working patterns. I describe on examples extracted from various teaching designs how the instrumental approach, and the notion of didactical contract, can help on each level to interpret the students' behavior with the resource. It permits to establish links between the behaviors and the mathematical knowledge involved, and to make a first step towards the consequences on the learning processes.
Introduction
The use of Internet resources in the teaching of mathematics is now widespread in many countries. The resources I consider here propose mathematics exercises with a given environment that can comprise for each exercise tools like a calculator; suggestions, or different kinds of advice; that can send a feed-back, or attribute a mark to the student (see Cazes Bal. (2005) for a grid describing the possible features). I term it an e-exercises resource in what follows. These resources can serve for distance learning, or be inserted in some collaborative learning settings. But they are also frequently used in class with a teacher, at least in France. These classroom uses raise many questions: why do teachers use such resources, that can seem poorer than, for example, microworlds? Which are the consequences of this use on the teaching and learning processes? Like Hoyles and Noss (2003) mention it, these questions have been little studied yet. In fact most of the works that consider internet resources in mathematics are very recent. Engelbrecht and Harding (2005) propose a very precise taxonomy of mathematics web sites, and discuss associated pedagogical issues. Their study is mainly directed towards the design of online courses and of settings using such courses. Bookman and Malone (2003) make precise observations about the way college students learn in an interactive environment (the connected curriculum project). They build a research agenda with three categories of questions: about the technology itself, about the role of the teacher, about the students behavior. But they do not discuss the possible associated theoretical frameworks. 206
In this paper I study the way students work and learn with e-exercises. That subject belongs to the second theme of the ICMI study : "Learning and assessing mathematics with and through digital technologies". I discuss more precisely the question of the theoretical approaches that can help to understand how the use of these resources can favor or on the opposite hinder learning. The instrumental approach is now currently used to study the consequences of the integration in mathematics classrooms of computer algebra systems. Can it also apply to Internet resources? Which phenomena can it illuminate, which other theories can complement it? I try here to contribute to answer to these questions, by analyzing examples stemming from various teaching designs and research projects.
In part two, I present the main principals of the Instrumental approach, and start discussing its potential applications to the use of e-exercises. I also briefly recall the notion of didactical contract, that I use to complement the instrumental approach. In part three, I present on some examples how the instrumental approach can be used to analyze the behavior of a student solving an exercise on the computer. Part four is dedicated to the subject of students paths and working patterns with an Internet resource.
Theoretical frames and e-exercises
Many theoretical frames permit to study mathematical learning in computerized environments. We retain here the instrumental approach, which is grounded in cognitive ergonomy. Rabardel (1995) stresses the difference between an artifact, which is just a given object, and an instrument. The instrument is a psychological construct; constituted of an artifact and of a psychological component defined through the notion of scheme. A scheme is considered here as an invariant organization of behavior for a given class of situations (Vergnaud, 1996). It has several components: goals, rules of action, of information and control, and operative invariants. These operative invariants are implicit knowledge, termed by Vergnaud theorems-in-action: propositions believed to be true by the subject.
Rabardel terms "utilization scheme" of an artifact a scheme organizing the activity with an artifact to realize a given task. He distinguishes between "usage schemes" corresponding to the management of the artifact, and "instrumented action schemes", directed towards the realization of the task. These schemes result from personal construction but also from appropriation of socially pre-existing schemes.
The instrument built by the subject comprises the artifact, and the schemes organizing the activity of the subject. The building process of the instrument is called "the instrumental genesis". Using an artifact influences the students' activity, and the activity influences the way the instrument is built. A detailed presentation of the instrumental approach can be found for example in Artigue (2002) and Trouche (2004). It has been mainly used to understand the impact on the learning processes of the introduction of computer algebra systems, especially through the identification of the schemes constructed by the students (see for example Lagrange 1999). It also 207
helps to understand unexpected uses of a given artifact: the subject constructs unexpected schemes, thus an unexpected instrument.
How can the instrumental approach be used to illuminate how students work and learn in a setting comprising such an e-exercises resource?
The possibilities offered by an e-exercises resource: access to exercises chosen according to their title or to their mathematical theme, help, feed-back etc. are easily understood by the students. For that reason, I will not refer here to "usage schemes", but only to "instrumented action schemes". The first step towards the description of such schemes is the identification of the possible tasks. An e-exercises resource can certainly be considered as an artifact. If it becomes an instrument, which kind of actions can be realized with that instrument? A computer algebra system, for example, can help to solve a mathematical problem. An e-exercises resource comprises tools that can help to solve a problem; but it also proposes problems, which makes a big difference.
Thus I consider here that it is necessary to distinguish between two levels of activity with an e-exercises resource. The first level is the level of one given exercise. The second level is the level of a whole classroom session. For both levels, several kinds of tasks can intervene, according to the scenario in use retained by the teacher, and more generally to the didactical contract (Brousseau & Warfield, 1999). The didactical contract has explicit, but also implicit rules, determining the roles of the teacher, of the student, and here also of the computer. For example, the e-exercises resource can send to the student a feed-back "right" or "wrong", a responsibility which is usually in the teacher's domain.
For the first level, the exercise's level, the task can be to find a numerical answer and type it in the "answer zone" of the computer. But it can also be to write the complete solution on a paper, if the teacher asks for it. Or on the opposite, the student can consider that the task is to obtain a feed-back "right" from the computer, and not to find a proper solution: this can be a consequence of the modification of the didactical

contract induced by the e-exercises resource. According to the characteristics of the resource, several artifacts can be available for these tasks. A calculator; but also the feed-back of the computer, or the advice associated with that exercise. The way these artifacts become instruments naturally depend on the task retained by the student. For the second level, the task can be to solve a given set of exercises. Things start to be really different from the exercise's level when the scenario in use retained by the teacher permits a freedom of paths within a certain range of exercises. In that case students can develop different working patterns, and thus assign themselves different tasks: tackling the maximum number of available exercises, or solving in detail only a few exercises for example. The artifact here is the effective resource made accessible by the teacher, thus it is not always the same for all the students in the same computer lab. These working patterns can certainly be interpreted as schemes. However, the description of these schemes involves rules of the didactical contract. Thus the contract appears as the main explicative tool for that level. 208
These first remarks are further discussed and illustrated by examples in the two following sections.
Instrumented action schemes for the exercise's level
When a student is solving an exercise, proposed by a given e-exercises resource, the artifact is the associated environment. Is it possible to identify instrumented action schemes constructed for that artifact? I try to answer this question on the following examples, stemming from observations realized in class at various levels.
The first example is the case of Alice. Alice is a sixth grade student. She works on an e-exercises resource proposing proportionality word problems. All the expected answers are numerical. The resource allows two attempts, with a feed-back "right" or "wrong" after the first try before attributing a mark. I observed Alice during four one hour sessions. She developed a very stable strategy; I describe it for the following exercise:
A car uses 20 liters of gas for 400 km. How much does it require for 100 km?
Alice knows that computations must be done, that these computations are likely to be division or multiplication, and that the expected result is a whole number. Thus she uses the calculator to make some tries, 100 times 20 for example. However, she controls the size of the result, and only proposes it if it sounds reasonable. Her first proposition is thus 4, obtained by computing 400/100 on the calculator. She naturally gets a feed-back "wrong". Then she goes on computing. Finally, she makes 100/20 on the calculator, finds 5, and proposes that answer. She gets a feed-back "Right".
Alice constructed here an unexpected scheme, relying on a mathematical theorem-inaction: "The answer to a proportionality problem whose text comprises only whole numbers is a whole number obtained by multiplying or dividing the given numbers".
Alice also controls the size of the numerical answer. The artifact helped that scheme to develop, because the calculator made it easier to try the possible computations; and that scheme governed the way the artifact was used, the feed-back was used here to test an answer that sounded acceptable. The pre- and post- test administrated indicate no improvement in her ability to solve such missing value problems. In her case, the unexpected scheme clearly hindered learning.
The use of the feed-back to develop attempts and errors strategies is frequent. These strategies are often grounded on mathematical knowledge; they are in fact schemes associated to the feed-back artifact. Let us give a second example. In an advanced linear algebra course where graduate students work on an e-exercises resource, the following exercise was proposed:
"Let E be a 35-dimensional vector space, and f an endomorphism of E, such that dim(Im(f0f))=13. Determine the minimum value of dim(Kerf)."
The students made several attempts; each time, the resource gives a feed-back with the right answer, and proposes to restart the exercise with new numerical values. 209
After a few tries, all the students were able to guess the general formula (and none of them was able to prove it):
Min (dim(Kerf)) = Integer part (1/2(dim E - dimIm(f0f) + 1)).
The mere feed-back would not lead to the formula with only a few tries. The complete constructed scheme associates the attempts, the observation of the right answer sent by the feed-back, and the following theorem-in-action: "To deduce the dimension of a kernel from the rank of an endomorphism, it is necessary to subtract it somehow from the dimension of the whole space".
That behavior was expected by the teacher, who proposed afterwards in a usual tutorial session a class discussion about the exercise, the formula and its proof. The exercise was finally solved during this session, and writing the complete solution was given as homework. The teacher wanted the students to face a puzzling situation, which motivated them to look for the complex proof.
Can all invariant behaviors of the students solving an e-exercise be explained by schemes? In fact, the central point is more: do all the descriptions in terms of schemes tell us something about mathematical knowledge? It is clear when a mathematical theorem-in-action is involved. But the operative invariant of the schemes are not always mathematical.
Let us consider the general case of the suggestions: different kinds of texts designed to help the students in their solving processes. They can be explanations, methods, hints etc. They are part of the artifact, they are a specific kind of tools that can be termed "cognitive tools" (Rogalski & Samurçay 1993) because they comprise knowledge. In a teaching design about sequences for university first year students using an e-exercises resource, I observed that some students always opened the "suggestions" window just after reading the text of the exercise, and before any personal attempt. It was a very stable, naturally unexpected, behavior. It is expected to make a personal attempt, and have a look at the suggestions if necessary only after a significant personal research. That unexpected behavior can be considered as a scheme; but the description of this scheme leads to an interpretation in terms of didactical contract. These students break the implicit rules of the contract by opening too quickly the "suggestions" window. They leave a part of their mathematical work to the computer.
In the next section further interpretations in terms of didactic contract are developed.
The session's level: working patterns
The possibility for students to work at their own pace, or to follow different paths, is often mentioned as a positive aspect of e-exercises. But do all kinds of paths favor learning? One can easily figure that a student choosing to work during a whole one hour session on the same simple exercise is not likely to learn much. I observed on many occasions that regularities appear in the paths chosen by the students; for that reason I use the term "working patterns". These working patterns naturally depend on 210
the features of the resource and of the associated scenario. For example, some resources send after a given number of exercises a feed-back comprising an advice about the next exercise to try; others even impose the next exercise. Anyway, at least when it is possible, students develop different working patterns.
I present here briefly an example issued from a research with sixth grade students working on proportionality problems with an e-exercises resource. This resource proposed sets of five exercises, identified by a title (the titles' list is displayed on the first screen). It attributed a mark over five for such an exercises set. When the mark is 3 over 5 or less, the resource suggests to restart the exercises set. If students restart, they are proposed the same five exercises with new numerical values. I observed several working patterns of the students working with this resource. The most frequent were: "Making one time each exercise" for students who solve one exercise, and then tackle the following one, independently of their success or failure; and "Following the computer's suggestions": for students who always restart when the resource suggests it. These working patterns remain stable. They can be interpreted in terms of schemes; but the description of these schemes leads anyway to didactical contract effects that organize the students' behavior. For that reason, I focus here only on these contract effects.
"Making one time each exercise" corresponds to students who work with the computer as they would do it with a paper exercises sheet. They consider the Internet resource as a textbook, and place themselves in the usual didactic contract, ignoring the feed-backs. By "following the computer's suggestion" the students clearly attribute to the computer responsibilities that usually belong to the teacher's domain. These students work within a didactical contract modified by the presence of the computer.
The designers of the resource clearly expected the second working pattern. It indicates a belief about the learning processes: a student learns by making several times similar exercises. It is a typical drill and practice choice. In the research mentioned here, we studied the evolution of the students' ability to identify and solve proportionality problems before, during and after their work on the computer. We observed real improvements, but no significant difference between the groups corresponding to each of the two working patterns described here. It means that students learn by drill; but they do not seem to learn more than the one who work like in a usual environment. However, we do not know what the students who practiced drill would have learnt if the scenario, or the resource banned that behavior. Further research is necessary to decide whether leaving the two possibilities has positive consequences for learning.
Conclusion
For students solving a given e-exercise, the instrumental approach provides a framework to describe instrumented action schemes associated to the "environment" artifact. It permits in particular to anticipate behaviors likely to hinder learning. 211
On the more global level of a whole session on an e-exercises resource, stable working patterns can be observed and interpreted in terms of didactic contract. It is then necessary to evaluate the consequences of these working patterns on learning. Stating such results can be useful to design further resources, or to improve the existing ones. But it can also be simply used by teachers to choose appropriate scenarios for a given resource, in order to avoid undesirable behaviors and foster learning. The scenario plays indeed a central role to determine the explicit, and some of the implicit rules of the didactic contract.

A developing agenda for research into digital technologies and mathematics education: A view from Brazil
Lulu Healy, Catholic University of Sao Paulo (PUC-SP), Brazil
lulu@pucsp.br
This article aims to introduce the research agenda that is currently guiding activities in the group Tecnologias e Meios de Expressão em Matemática
23
(TecMEM) of
PUC-SP. It describes how wide scale attempts to insert digital technologies into Brazil's public schools system have tended to emphasise the computer as a catalyst for pedagogical change, without acknowledging the epistemological and cognitive dimensions associated with such change or the complexity associated with the appropriation of tools into mathematical and teaching practices. To focus research efforts on learning ecologies as complex interacting systems, the paper presents how our group is adopting as a research strategy the involvement of teachers and students in the process of collaborative tool design.
Integrating (?) Technology in the Brazilian Education System
In the late 70s and early 80s, university researchers in Brazil started to develop studies relating to the use of the computer as an instrument in the processes of teaching and learning. Their experiments were based on the use of programming languages inspired by the evolving constructionist perspective of Papert (1980). The introduction of computer technology into the public sector of the Brazilian Education system began later in the 80s, when the Ministry of Education (MEC) funded projects such as EDUCOM and FORMAR. In these projects, the role attributed to the computer was that of catalyst for pedagogical change (Valente & Almeida, 1997). The idea being that the possibilities offered by computer technology would enable innovative approaches to education, helping to form reflective citizens who would use exploit technology in the search, selection and interrelation of information and in the construction of knowledge and hence enable them to better understand and transform their own socio-historical context. A huge challenge given that the dominant pedagogical approach of the time almost exclusively focussed on teaching as transmission of ideas.
Despite, or perhaps because of, the innovative nature of the Brazilian proposal for the insertion of computer in the education system, none of the government-funded programs have yet resulted in the intended transformations in educational approach. The pedagogical aspects implicit in the use of the computer have turned out to be much more complex than originally predicted and, in practice, compounded by the fact that, within the public education system in Brazil, access to technological resources continues to be sporadic and unevenly distributed throughout the country's

23
Technology and Media for Mathematical Expression214
schools. One important result, however, has been the recognition of the critical need
to understand the role of the teacher in every step of the integration process.
It is important to stress that although research in mathematics education has
been a part of the insertion process described above, its role has not been central. In
attempts to prepare teachers to make use of technology, there seems to have been less
emphasis on what to teach – or even what is being taught – and much more on how it
could/should be taught. Epistemological concerns regarding mathematics (or indeed
any other curriculum area) or the meanings for mathematics constructed during
technology-mediated activity seem to have been largely absent from the debates
concerning the integration of computers into the Brazilian education system. Indeed,
in the official guidelines for the Brazilian Mathematics Curriculum published by
MEC (PCN, 1998), again it is principally pedagogical concerns that figure in relation
to the use of digital technologies in the mathematics classroom. The use of
technological resources (such as calculators, video and computers) is one of a set of
three pedagogical approaches emphasised, the other two being the use of historical
resources and games.
Digital tools and mediated agency
It seems that the privileging of the (supposed) impact of digital technologies
on pedagogical approach in the Brazilian context had the result of largely ignoring
the important reciprocal relationships between technology and thinking – that the
resources available for the negotiation of meanings for mathematics, both shape and
are shaped by these developing meanings. According to Borba (2000), the same
could be said of much of the work generated by Brazilian researchers working
specifically in the field of mathematics education. He suggests that, until recently,
investigations of the role of different media in the teaching and learning of
mathematics have been limited to treating technological tools as didactical aids
which might help (or not) the learning of particular material. Drawing from the work
of Levy and Latour, Borba suggests that rather than individual learners we should
focus our attention on the collective "seres-humanos-com-mídias" (people-withmedia), a construct reminiscent of the socio-cultural unit of analysis proposed by
Wertsch and Toma (1994), individual(s)-operating-with-mediational-means or
mediated agency. According to this perspective, the inclusion of the (any) tool in
activity alters the course both of the activity and of all the mental processes that enter
into the instrumental act.
This suggests that in order to understand learning ecologies that include digital
resources, it is important to consider the ways these resources interrelate with both
epistemological and cognitive dimensions. Recent research has also emphasised the
need to theorise more precisely about the ways in which learners come to make use
of the technological resources available in the learning environments in which they
interact or, to put it in the terms of Verillon and Rabardel (1995), to understand the
process of instrumental genesis by which artefacts become transformed into 215
instruments
24
. The potential role of digital tools cannot be expected to be transparent
– neither to teachers nor to learners – and if they are to be integrated in a significant
form into mathematics classrooms, an understanding of how to engender the process
of instrumental genesis is crucial. It could be conjectured, then, that one of the
weaknesses of the Brazilian teacher education programs was (and largely still is) that
little attention was given to the process by which the digital artefacts introduced
might be appropriated by teachers and integrated into their practice. In the case of
teacher education, it may even been that the instrumental genesis process is yet more
complex since its ends become twofold: artefacts need to become instruments not
only in the mathematical practices of teachers but also in their didactical practices.
Research into the use of technology in mathematics education within Brazil,
and more specifically the emerging research agenda of the group Tecnologias e
Meios de Expressão em Matemática – TecMEM has begun to take on board these
issues our research is increasingly focused on what meanings for the mathematical
objects concerned are afforded (and constrained) as particular tools are appropriated,
how these meanings evolve as the tools are transformed by their users in practice and
how both tools and the meanings associated with them impact upon the way we think
about the mathematics in question. In considering the constraints and affordances of
particular resources, as we bring epistemological and cognitive questions into play,
and as sociocultural perspectives on tool mediation come to the fore, we believe it is
important not to relegate pedagogical aspects to a second plane. The challenge is to
focus on the learning ecology as a whole, considering the interactions between
different dimensions – epistemological, technological (or perhaps instrumental),
cognitive and pedagogical – concomitantly.
Approaches to tool design
TecMEM is a research group of the programme of post-graduate studies in
mathematics education of the Catholic University of Sao Paulo (PUC-SP).
Geographically, the group is based in the university's Centre of Exact Sciences.
Because of this location, the group counts on participants from a diversity of
backgrounds: researchers in mathematics education and mathematics teachers are
joined by computer scientists and engineers. As a group, we are involved in
understanding the processes by which mathematical knowledge is constructed in the
presence of digital technologies, while building learning environments that support
engagement in these processes. Given the particular background of the group, it is
perhaps not surprising that tool design represents a significant aspect of the group's

24 Verillon and Rabardel (1995) use term artefact to describe a given human-made object. For
any individual person, the artefact becomes an instrument as he or she develops a set of schemes
associated with its use, allowing the artefact to be appropriated and integrated into the
individual's practices. As Trouche (2004; p. 285) puts it "an instrument can be considered as an
extension of the body, a functional organ made up of an artefact component (an artefact, or the
part of an artefact mobilized in the activity) and a psychological component". 216
work. To a certain extent, we have come full circle back to the constructionist
beginnings of computer use in education in Brazil, and underlying our research is a
continued desire to design tools that will provoke changes in the way mathematics is
experienced in Brazilian schools. But the theoretical basis which informs our
research has developed considerably, opening new windows through which to
investigate mediating between learners' personal knowledge of mathematics and the
official mathematical discourse they are supposed to learn.
In terms of tool design, it is possible to distinguish between two contrasting
approaches to supporting connections between conventional and personal
mathematics, usually described using the metaphors top-down and bottom-up.
Software designed from the top-down have their genesis in expert practice, in
"crystallised expert mathematical knowledge" as Gravemeijer (1997) puts it. They
offer to learners a set of tools to enact conventional techniques or methods. Examples
include Computer Algebra Systems, many educational statistical packages (see,
Biehler, 1997, Konold, 2002). Dynamic geometry systems can also be included
within this group: Laborde and Laborde (1995), for example, describe how Cabrigéomètre, was designed to bring students in touch with a model as close as possible
to traditional Euclidean Geometry. On the other hand, are software designed from the
bottom-up, their basis in the learners' practices and reasoning, perhaps the most
classic example of which is Turtle Geometry, which "started with the goal of fitting
children" (Papert, 1980; p. 53) and the hope that students would bring what they
know about their own bodies and their movements to bear as they learn a formal
geometry.
A problem with these metaphors is that they place learners, mathematics
always on a lower plane. The devaluing of individual knowledge in favour of the
conventional can be avoided if instead the terms filling inwards (FI) and filling
outwards (FO) are employed (Healy, 2002). This has the added advantage of
stressing a major difference between constructivist and sociocultural approaches: the
primacy assigned to the individual or the cultural in the learning process. Hence,
these approaches are not limited to tool design considerations and can be interpreted
more generally as two different didactical models. Filling outwards approaches
correspond to constructivist-rooted approaches to mathematical teaching (such as
realistic mathematics education, didactical engineering and the emergent approach of
Cobb et al., 1997, for example), which emphasise an outwards flow whereby
interventions are intended to guide personal understandings gradually towards
institutionalized knowledge, with mathematically significant issues arising out of the
student's own constructive efforts. A reverse filling-inwards flow of instruction
characterises sociocultural accounts of teaching, with interventions aimed at
supporting learners in internalising institutionalized knowledge to construct new
understandings, hence enabling mathematically significant issues to become
appropriated during the learner's constructive efforts. 217
Returning to the issue of tool design, it might be hypothesised the process of
instrumental genesis is rather different according to whether a filling outwards or
filling inwards approach is adopted. For experts, the integration of FI-based tools into
their mathematical practices might be relatively straightforward, but for those less
fluent in the expert practice, the path from artefact to instrument might be more
tortuous. In contrast, FO-based tools might be more easily incorporated into learner's
activities since they have been designed on the basis of what they can be expected to
know. But in this case, facilitating the process of instrumental genesis may not have
the effect of guiding towards conventional mathematical expression. This results in a
somewhat paradoxical situation. When we design tools on the basis of the practices
of learners rather than experts, enabling learners to express their own meanings in
ways that do not necessarily match conventional expressions, teachers are not always
willing to accept the validity of the tools. On the other hand, when our design
decisions are guided by conventional mathematical expressions instead of what we
know about learners' understandings, although the legitimacy of the tools we design
is less likely to be questioned by teachers, the tools themselves do not always enable
learners to interact with the mathematics in question.
Our current research agenda
So the challenge the participants of *TecMEM* are currently confronting is how
to design tools that make sense to learners, connect with their points of view and
resonate with what they already know, while, at the same time enabling them to
express their ideas in ways that are considered mathematically legitimate by their
teachers. Tools that illuminate the mathematical structures and relationships
embedded in them to learners and to teachers alike.
We are choosing to concentrate our design efforts particularly in areas of
mathematics whose current coverage has been highlighted as problematic in the
Brazilian context. This includes, for example, statistics and probability, whose
emphasis in the official mathematics curriculum has significantly increased in recent
years
25
, geometry, pinpointed as a domain that mathematics teachers have a tendency
to avoid, and proof, an aspect of mathematics considered rarely, if at all, in the
mathematics classrooms of the public school system
26
. Because of the make-up of
our group, it would be possible to divide the research tasks, with researchers and
computer programmers responsible for task and tool design respectively and the
mathematics teachers involved principally in implementing these activities in their

25 A description of some of the mathematically issues that emerged in the design of tools for
the simulation of data distributions, see Healy (in press).
26 We are currently engaged in a CNPq funded project, AProvaME (Argumentação e Prova na
Matemática Escola, No. 478272/2004-9) which is involving 26 mathematics teachers from public
schools in the state of sao Paulo in investigation the strategies of proof and justification of their
students and in building technology-intergrated learning scenarios to support these students in
further developing their competencies in proving.218
classrooms. The problem is, if teachers bypass the design phase, they will not
necessarily come into contact with either the epistemological, didactical or cognitive
considerations that contributed to the conception of the activities. Without this
contact, teachers may not feel ready to come up with new activities of their own or
even to adapt existing activities according to the particular needs of their students.
The strategy we are investigating, then, is to involve all group members not
only in the design of activities to support mathematical reasoning, but also in the
design of the computational environments which form the context in which this
reasoning is to take place. Our aim is not that we create well polished "finished"
softwares, rather that, in line with the constructionist agenda that continues to guide
our work, we create microworlds that represent our tinkering and can be
subsequently tinkered with by others (Papert, 1991). In our strategy, the process of
instrumental genesis begins with the genesis of the artefact itself, that is, it could be
said that, for the designer, the artefact is always an instrument. The conjecture that
drives the projects currently underway is that the design of digital tools for
mathematics learning will necessarily involve participants in making explicit their
own knowledge about the mathematical issues concerned, their beliefs about the
learning trajectories their students follow and their thinking about how best to
mediate between their students' (and perhaps their own) personal knowledge and the
mathematics they are aiming to teach. As such, in relation to the integration of digital
technologies into mathematics classroom, the questions to which we are seeking
evidence are:
• Will participating in design of tools for simulating data sets encourage designers
as learners to reflect upon mathematics concepts incorporated in the tools under
development?
• Will participating in the design process encourage designers as teachers to reflect
upon the kinds of representations that might permit their students to access and
explore these same ideas?
• And what didactical approaches do designers as researchers build into the
learning scenarios in which their developing tools are embedded?
So, one strand of our research work involves mathematics teachers in the
collaborative design of tools for mathematics learning. A second strand involves the
students themselves in this collaborative design process.
In this second strand, we are working with learners whose developmental trajectories
are not yet well represented in the research literature: blind learners and learners with
severe visual impairments. As researchers, we recognise that we still know relatively
little about the mathematical interpretations developed by blind learners and whether
the mathematical meanings they construct and the narratives through which they
make sense of mathematical problems follow significantly different patterns to those
of sighted learners. However, in Brazil, there is currently a strong drive within the
public education systems towards the inclusion of learners with special needs into

mainstream schooling. Because of this policy, a number of the mathematics teachers 219
of TecMEM are already facing the challenge of teaching classes in which one or
several of the forty or so students are blind. One of the particular difficulties is that
not only can the learners not see the inscriptions of mathematics presented to the rest
of the class, the mathematics teachers cannot, in general, read the inscriptions
produced by their blind learners, until they are translated from Braille, making. This
makes it extremely hard to know if and when to intervene, and especially to adopt a
filling-outwards didactical approach. We are currently working on the design of
musical microworlds and microworlds composed of speaking and conversing
mathematical objects, which, combined with tactile tools, aim to allow blind learners
to explore, express and communicate mathematical ideas associated with rational
numbers, function and geometry. Although this work is only beginning, we are
finding that the participation of the learners, right from the conception of the tools is
critically as we simply do not know enough about the stories they construct to make
sense of the mathematics they encounter to proceed without them
27
.
A final word
From the beginning, the attempts to insert digital technologies into Brazilian schools
did not represent a response to an expressed need from the grass-roots of the
classroom. To a greater or lesser extent this continues to be true today. On the other
hand, it might be that digital technologies do have considerable potential to offer in
confronting current challenges at the chalk face. Our research seeks to involve
teachers and their students in the process of collaborative tool design, in order that
they might assess and, where appropriate, begin to harness this potential to resolve
the particular complexities of the classrooms in which they work. By its very nature,
our approach, not unlike the process of instrumental genesis, is complex, timeconsuming and linked to local considerations such as the characteristics of the
learning setting, and the participants' activities, knowledge and former methods of
working.

Functionalities of technological tools in the learning of basic geometrical
notions and properties
Verónica Hoyos
CAEMTIC, Universidad Pedagógica Nacional, México
vhoyosa@upn.mx
This contribution presents the comparisons made by two students, each the most
advanced in their classes, of the relative functionality of a variety of technological
tools, the ones they had used to learn basic geometric notions and properties. This
work is part of a line of investigation specializing in the functionality of artifacts
involved in teaching sessions (Verillon and Rabardel, 1995) and the development of
classroom discourse (Sfard, 2001). It revisits the case of "Guillermo" (Hoyos, 2003),
a junior high school student who learns the topic of geometric transformations via
utilization of Cabri-II and pantographs or articulated machines. Also reviewed is the
case of "Marcel", a sixth grade student which takes up problem resolution involving
the notions of angle, turn, and their measurement via Logo and Cabri-II. The paper
argues for complementarity between the tools utilized for the construction of use
schema, which objectified certain mathematical notions involved; and for the
internalization of instruments in use (Mariotti, 2002).
Theoretical Framework
As Mariotti (2002, p. 697) argued, since school use of computers and new
technologies is on the rise, it becomes urgent to identify key points around which to
organize their use in fostering diverse educational processes.
In addition to incorporation of computers in schools, she and other Italian researchers
(Bartolini et al., 1998; Boero et al., 1997; Mariotti et al., 1997) particularly have
recommended using artifacts and contexts of geometric practice which employ
mechanical or jointed models of drawing and tracing machines as a school's way to
generate complex mathematical ideas or notions.
28

28
As an example, in the case of the study of geometrical transformations, each one of the used
machines was made of a set of articulated metal bars mounted on a wooden stage in accordance
with different geometrical configurations representing the elemental geometric principles of
reflection, symmetry, translation, and dilation. The bars are fifteen to twenty-five centimeters long,
the wood base measures about fifty by sixty centimeters. One of the more well-known pantographs
may be the one that enlarges or reduces a drawing by a given ratio. This research employed this
artifact, as well other similarly constructed, which were designed to study symmetry, reflection, and
translation. The materials were originally constructed by the University of Modena (UNIMO), in
Italy. For further detail on the pantographs and other UNIMO instruments, refer to
www.mmlab.unimo.it 222
Actually, current investigations have focused on incorporating use of diverse
technological tools, with the idea of comparing the results from manipulating
different learning environments (cf. Hoyos, Capponi and Genèves, 1998; Vincent et
al., 2002; Hoyos, 2002; Hoyos, 2005) or in the attempt to overcome difficulties
associated with solving mathematical complex tasks, like the proof of geometrical
basic properties. (See Vincent et al., 2002; Hoyos, 2005)
For example, participant observation of sixth grade students (Hoyos, 2005) revealed
that, although Logo's turtle (figure 1) can move forward in any direction, it does so
linearly in such a way that it is not evident for children that the same turn procedure
is being applied both forward and backward.
Fig. 1
Mathematical turn rules are usually referred to clockwise, and using Logo it might
not be evident to children that the turtle procedure of turning to the right (the rt
command) could be associated with clockwise motion, and counterclockwise in the
case of left turns (the lt command). We predict that a broader significance assigned to
turns implemented by this tool would aid students to improve their handling of Logo.
Based on these considerations, and thinking about the advantage of having interactive
tools that could measure the various magnitudes presented in the problems, we used
other materials in addition to Logo, particularly the Cabri-II computer environment.
Briefly, all the technological tools used in that context would provide specific,
functional features to enable students to efficiently leave behind drawing difficulties
related with giving the turtle convenient instructions – a task which requires
anticipating turtle turn direction.
Verillon and Rabardel (1995, p. 77) affirmed the potential for artifacts to address
particular learning difficulties related to the functionalities of the artifacts in play.
Among the most important contributions these authors offer is to point up the
substantial differences in the products of knowledge derived from unlike
manipulation experiences. On the one hand are those (cf. Piaget and Inhelder, 1958)
in which the subject manipulates various sizes and shapes of metal bars or liquids 223
transferred between containers, and on the other are those that involve exploration or
use of technologies, such as activating a robot.
Concerning use of Cabri-II dynamic geometry software in both exploratory studies,
one of the central hypotheses (Hoyos, 2006) was that if from the beginning of the
activities the learners had available a formal language they had not yet used or
experienced
29
, it would permit tracking their progress in mathematic discourse, as far
as they construct or assign meaning to these referents.
Sfard (2001) takes as an instance of the development of mathematic discourse a
classroom interaction in grade seven on the learning of negative numbers. She shows
how disorganized the information becomes when these numbers had only recently
been introduced, as well as the students' shallow comprehension. Sfard argues that
this type of basement is insufficient to immediate advancement toward capitalization
in, for example, operational handling of the new terms. For Sfard (2001, p. 28), the
"introduction of new names and new signifiers is the beginning rather than the end
of the story."
Sfard emphasizes that the introduction of new symbols acts as a piston, driving and
creating new semantic spaces which appeal to the needs for new meanings and new
discursive habits (ibid, p. 32).
This author identifies the act of communication with the act of thinking, and thus the
development of discourse in a two phased process. The first phase is characterized by
the use of terms with a template at hand and the second by objectification or
objectified use of the symbols.
Finally, from the approach Sfard proposes to learning as the development of
discourse, it becomes interesting to obtain descriptions of student identifications of
the symbols or terms in use, given that learning some topic creates the capacity to
extend discursive capacities so that in some moment the learner will be able to
communicate on the theme. (Ibid, p. 26)
Aims, Methodology, and Some Results
The two case studies reviewed here (Hoyos, 2003; Hoyos, 2005) were constituted on
the basis of the productions made by the most advanced students in each of the
classes observed. Different technologies were alternated in both cases so that the
learners would be able to strengthen or compare the results from manipulating
distinct learning environments (cf. Vincent et al., 2002; Hoyos, 2002; Hoyos, 2003).

29
Note that Cabri-II includes a Help command that displays a legend at the bottom of
the screen. This legend gives the students a formal description of the geometric
construction in turn, just as is the case with the menu for geometric transformations.
In fact, that legend constitutes a formal guide for the student in order to execute the
required construction or action. 224
During the first case study, "Guillermo" (Hoyos, 2003), a very advanced student in a
ninth grade Math class (fifteen years old, approximately), was introduced to explore
Cabri-II and pantographs as a means to approach the theme of basic geometrical
transformations.
With ease and accomplishment he worked all the tasks presented in a long series of
practical activities implemented in the classroom (Hoyos, 2006). Video logs were
obtained of all of Guillermo's movements, especially because he was asked to
describe what they had done at the end of each assigned activity. At the end of the
reflection and translation learning activities, during his description of what he had
done, Guillermo makes reference to the various moments of the activities performed
during the two learning stages that were set.
Here it is going to be briefly mentioned what happened using Cabri-II when he
activated the Reflection command. The student describes it as making the initial and
image objects "move in opposite directions":
Guillermo (hereinafter G): What we saw with this machine [the jointed machine for
reflection or axial symmetry] was the same as for axial symmetry, what we were
seeing, for example ... Like if we took these by the movement points [manipulates
the jointed machine, moving its drawing guide] they go opposite ways. Like [what]
we were seeing in the Cabri software...
What we were proving here [with the jointed machine] was that axial symmetry is
practically a reflection of the original figure, if we move [the guide] to the left ... It's

like when we move the original figure from left to right, the reflection goes … From right to left.
As can be clearly observed from the work report Guillermo wrote after have finished the work sessions with the software, he was able to quite coherently express the properties of dilation. For example, it is presented here his answer to the question "Give a general definition of dilation", which was on the scripted worksheet for the computer exploration:
G: The image [is] on another scale, with proportional movements to what you do [in relation with the initial figure].
The final passage that is going to be presented here concerns with comparison of tools in use. In the last interview with Guillermo he was asked to offer his opinion on the work he carried out in all the sessions.
I: Let's see, Guillermo, tell me how you feel about these work sessions.
G: Yea, well, alright. 225
I: Right. Has what we've done been interesting for you?
G: Yea, because it made us think awful hard.
I: Yes. Did you like the computer work?
G: Yea, just that it's easier with the computer than doing it here, firsthand.
I: But the work with the machines [the pantographs], does it seem productive? I mean, it leaves you with something. Interesting, isn't it?
G: You learn more [there], than with computers, cause you do the work.
I: You learn more with computers, is that what you think?
G: No, you learn more there, [points to the pantographs] cause here you do the work and the tracing, and on the computer the only thing you do is guide it.
Along the second case study (Hoyos, 2005), the hypothesis was advanced that Logo and Cabri-II functions were complementary when applied to the learning of angle and turn. Activities based on manipulating these learning environments and other concrete materials permitted the students to overcome difficulties with the direction of turn and the measurement of angles greater than 180°.
In the previous to the last session it was introduced Cabri-II as a teaching technique, because it was likely to allow the students to overcome the difficulties still demonstrated in the Stage 4 of that study, which had to do with measuring angles greater than 180° and the direction of turns.
The Cabri-II activities may be briefly characterized as simulating both directions of clock movement by placing the hands in various positions and using its Angle command to measure angle sizes, especially those greater than 180°. At this juncture it is worth noting that Cabri's Angle command only works with angles less than or equal to 180°, requiring reflection or planning on how to calculate those of greater dimension. These may be the reasons why comprehension about measuring that kind of angles might finally be achieved.
In sum, what happened during the work session with Cabri-II was that the children were asked to measure an angle like that indicated by an arc in greater than 180°. Nonetheless, the measurement the software displays when one selects three points -- one on the little hand, one in the center of the circumference, and one on the big hand-- (as Angle measurement shows in the Help legend,) is a measurement of 148.9°, which is less than 180°!
Instructor (I): So, what's up with the measurement the machine is giving us [that of 148.9°]? How can I do to know how much the angle labeled by the arc is?
Marcel (M) [The most advanced student in that study case-]: Do you know why it's showing up like that? [He is referring to the software] What the computer is doing is, what I suppose, is it isn't marking on this side, but from here to here [M points to the other side of the angle, which in effect measures less than 180°]. 'Cause it wasn't labeled exactly. [You, sir] put the three points, but the computer can make mistakes, [it doesn't know] if it's to here or to here [M successively indicates each of the two 226 dos angles determined by the clock hands simulated in Cabri-II]. It didn't label right which angle to go to.
I: Marcel is right, since you have to label three points to measure an angle, as the legend in Help says, the angle the software is looking at could be the one marked by the arc or its opposite. Perfect.
I… What should I do to measure the angle labeled by the arc?
M: I see how I can do it. 360°-148.9°, this is the angle labeled by the arc, [because] the 148.9° is the one that the arc didn't label. So, if this is what this angle measures, it's less 360, and so we get the other degrees left over. That's why we know what [that, the result from subtraction] the other angle is.
Briefly, at the conclusion of the work sequence on problem solving with Logo, the instructor asked the children their opinion on working with Logo, or Cabri-II, and whether they had enjoyed working with these programs:
M: Cabri seems easier to me, 'cause there you go to your tools and you get everything. But here [with Logo] you have to calculate 'n' everything. It looks harder to me. It's a bit harder for a kid … Because there you gotta be calculating degrees … But in that one [Cabri] you've got your tools 'n' everything. So for a kid it's easier to get what you need from the tools, not in that one [Logo], you gotta be calculating 'n' everything [gestures to his head].
Towards a Conclusion
One of the lines of research into the question of semiotic mediation (Mariotti, 2002) looks into the cognitive processes of instrumental genesis, with the source of its analysis being the self-same nature and manipulation of the artifacts employed.
Preliminary results obtained in both explorations indicate that, in effect, coordination is possible between all technological instruments deployed. Besides, the working hypothesis that appears to gain credence on the basis the comparison the children made between the instruments used (Cabri-II and pantographs in the first study; Logo and Cabri-II in the second one) is that students might naturally tend to assign greater value to tools and to learning gained once an objectification process has taken place, as they will contrast their current capacities against those they had been able to perform during a previous stage.
In addition, both cases would appear to be evidence of an accomplished internalization process (Mariotti, 2002), because it is probable that idiosyncratic use of contextual terms to evaluate used tools might be evidence of cognitive attainment that probably is only reached through accomplished internalization of instruments in use. 227

Tools rather than Toys: Fostering mathematical understanding through ICT in primary mathematics classrooms
Diana Hunscheidt & Andrea Peter-Koop, Dept. of Mathematics
University of Oldenburg, Germany
hunscheidt@mathematik.uni-oldenburg.de
peter-koop@mathematik.uni-oldenburg.de

The proposed paper addresses the theme "teachers and teaching" by reflecting how far a new methods course on the use of technology in primary mathematics prepares pre-service teachers to critically select and use digital and electronic technologies in classrooms. While the motivational benefit with respect to the use of ICT in classrooms is certainly an important issue, this paper seeks to highlight in how far the careful selection and reflected implementation of technologies in classrooms can help to extend mathematical understanding beyond mathematics teaching and learning with traditional classroom materials. The paper focuses on two learning environments that have been developed in the context of a university methods course and trialed in the form of teaching experiments in grade 4 classrooms by pre-service teachers. The two learning environments go beyond the use of special software designed for (primary) mathematics classrooms and involve a robot and a monitoring device. Both learning environments will be briefly introduced in terms of their technical description. In addition, selected tasks from the teaching experiments, classroom observations and examples of students' work will be presented. More detailed information as well as an evaluation of the pre-service teachers learning processes (currently in progress) would be provided during the conference presentation.
The context: An ICT module within the teacher preparation programme at the University of Oldenburg
The teacher preparation programme focussing on future primary mathematics teachers at the University of Oldenburg
30
involves a compulsory 4-hour-module on
the use of digital and electronic technologies in the primary mathematics class-room. The course is based on research findings that students learn more mathematics, more deeply with the use of technology (e.g. see NCTM 2000) and the understanding that technology does not replace the mathematics teacher (e.g. see Way & Beardon 2003).

30 All teacher preparation programmes at the University of Oldenburg have been re-developed in the last two years in order to meet the criteria of the Bologna declaration (UNESCO-CEPES 1999). For future primary and lower secondary teachers the University of Oldenburg offers a three-year bachelor programme (Bachelor of Arts/Science) focussing on two subjects and educational studies followed by a one year master-programme (Master of Education). 229
The more theoretical parts of the course critically reflect the current international literature on the impact of ICT on the teaching and learning of primary mathematics with respect to the following questions:
- How far can ICT improve the learning of mathematics?
- How can ICT support effective mathematics classroom practice?
- How far does the use of ICT effect mathematics contents?

In the more practical oriented parts of the course, pre-service teachers are given the opportunity to explore ICT such as teaching and learning software, construction and logo programmes, small robots and monitoring devices in small groups in order to understand their functions and their role as essential tools for mathematics learning. However, while critical theoretical reflections and practical investigations are seen as crucial elements of the course, they are not regarded as sufficient in terms of teacher preparation.
Guskey's (1985) investigation of teachers' professional development processes suggests that in-service teachers' classroom practice is a critical variable for classroom change. He argues that teachers predominantly define their professional success through the improvement of their students' learning. Hence, the opportunity to explore ICT in mathematics classrooms and to observe and assess students' learning processes is seen additionally as a critical factor for teacher pre-service training. In order to facilitate these classroom experiences, the course also involves the development, classroom implementation and evaluation of appropriate learning environments in primary mathematics.
The development of the learning environments is guided by the paradigm that ICT serve as tools not toys in the classroom (Buchanan 2003) which foster the extension of mathematical understanding and the introduction of new content areas.
Two examples of ICT based learning environments
In the following paragraphs two innovative examples of ICT tools suitable for primary mathematics are introduced. Both have been chosen because they support the extension of mathematical understanding beyond traditional classroom materials.
Introducing Pip
„Pip" is a small robot on wheels which can be programmed to move in centimetres, turn in degrees and wait in tenths of a second. It can be programmed via a keyboard - overall a maximum of 48 commands can be entered in one programme. A pen can be attached through the whole in the centre of the device which allows to record its movements on a 230 sheet of paper for subsequent analysis.
When it is first introduced, many primary students (and pre-service teachers) get the impression that Pip is a great toy and they certainly enjoy "playing" with it. However, pre-service teachers in the methods course have been challenged to develop a learning environment based on Pip that enables fourth graders active discovery of new mathematical contents, such as angles.
Using Pip to teach angles
Primary mathematics curricula in Germany require that students in grade 4 get to know and understand the 90° angle. This is usually taught introducing a protractor. More innovative approaches would also include suitable paper folding activities.

However, Pip allows the introduction of the angle concept in a hands-on and discovery based environment that involves and challenges the exploration of a number of angles other than 90° and their relationships.
Goal of the learning environment developed by the pre-service teachers was the understanding of 90°, 180° und 360° angles as a basis for finding and estimating other angles in between.
For the classroom exploration a drawing of a circle with 10° intervals on a large piece of paper was prepared and Pip was positioned in the centre of the circle with the arrow facing 0°/360°.
The grade 4 students were given the following tasks:
Exploring different sized angles with Pip
1) Program Pip so that it turns 90°/ 10°/ 180°/240°/360° clockwise (anticlockwise).
2) Program Pip so that it turns 40°/60°/20° clockwise. To which degree is the arrow pointing, when it would then turn 60°/30°/180° anti-clockwise?
3) The degrees of the circle are hidden: We want Pip to turn 45°/135°/ 70° clockwise. Show where it will stop! 231
Another task aimed at the understanding of the 90° angle with respect to the concept of perpendicular. A pen was attached so that Pip's movements created a drawing.
Constructing 90° angles
1) Program Pip so that it turns 40° anti-clockwise going all the way to the circle's outline, then turns 180° again going to (the opposite side of) the circle's outline.
2) Then program Pip so that it draws a perpendicular line through the centre of the circle.
3) Finally program Pip so that it draws a parallel line to the perpendicular line.
Apart from understanding and programming different angles and finding and programming the right length, these tasks require reasoning and anticipatory mathematical thinking.
In this context, Pip is either an effective addition or an alternative to the use of the protractor that fosters experimentation and visualisation. Mistakes quickly become obvious and are generally understood in a constructive way. Through empirical approaches and "trial and error" Pip enabled the students to independently control and – if necessary – advance and correct their thinking and modify their actions. They could develop estimation skills with respect to the size of different angles beyond 90° and deepen their understanding of the angle concept.
Overall, Pip provided an enjoyable and stimulating approach to angles for primary students. This frequently lead them to 'invent' and explore their own tasks, e.g. by imagining that the circle line is a clock: Can we program Pip so that the clock shows 5 o'clock (2 o'clock, 9 o'clock …)?
Using Pip to explore lengths 232
Using Pip in the context of length measurement encourages children to estimate distances and to check their estimates. Challenging tasks might also involve the combination of angles and lengths with respect to estimation:
Practising estimation
1) Program Pip so that it goes to the child that is sitting directly opposite to you.
2) Program Pip so that it goes to Anne/Tom/Erkan .
Path diagrams created by Pip are another opportunity to combine the estimation of lengths and angles. Depending on their prior knowledge and individual capability students can be challenged to program Pip so that it follows given path diagrams (either with 90° or other size angles).
Pip has also been used successfully in grade 4 classrooms with respect to the following topics: Axial symmetry, sum of angles in quadrilaterals, features of geometric shapes.
Understanding graphs with the „Ranger"
The „Ranger" is a monitoring device (data logger) that allows the monitoring of movement in a straight line. In combination with the computer programme LogIT it provides the construction of graphs that show the relationship between time and distance.
In using the Ranger primary students can develop basic knowledge about graphs in an experimental environment. They observe and discover how the Ranger reacts to their movements and learn to interpret graphs by developing their understanding of the relationship between time and distance. 233
In traditional approaches to the development and understanding of time – distance graphs without the computer, children would walk forward and backwards between points A and B, timing themselves with stop-watches, then draw a graph of their results. But it would be difficult to understand and correct misconceptions, e.g. wrong distances or a graph that implies that one could go back in time.
With the aid of the Ranger and LogIT the movements can be monitored and recorded as graphs which can then be compared with the graphs predicted by the children.
Introductory activities could involve the following tasks:
Recording time – distance relationships with the Ranger
1) Stand 3 metres in front of the Ranger. Cross your arms and then slowly walk towards it.
2) Stand 3 metres in front of the Ranger. Cross your arms and then quickly walk towards it.
3) Stand 3 metres in front of the Ranger. Cross your arms and then slowly walk a few steps forwards and backwards.
Then the three graphs can be compared by analysing the time-distance relationship that they display.
The computer programme also allows children to overlay. This is useful if one wants to set up a walk beforehand and ask others to copy.
Alternatively, peers can orally describe a given walk that one child has to copy without seeing the graph.
Another activity involved given graphs that had to be interpreted by the students, for example by telling or writing the 'story' belonging to the graph (see picture on the bottom left). The examples chosen by the pre-services teachers deliberately included graphs that do not describe a time-distance relationships and require children's reasoning why these graphs cannot be reproduced by the Ranger. Other groups of children had been given little stories and the students were encouraged to draw the graph that would capture the story. 234

Concluding Remarks
The tasks and classroom examples introduced above refer to very recently conducted teaching experiments during the current winter semester. Pre-service teachers involved in the classroom explorations are in the process of documenting their experiences and reflecting their professional learning. In addition, they have been given a questionnaire that seeks to investigate their knowledge, beliefs and attitudes with respect to the use of ICT in primary mathematics.
In the next couple of months this data will be analysed with respect to the key questions identified in the introductory section of this paper. Findings and artefacts from these analyses would be provided during the presentation at the Study Conference.
With respect to the question in how far ICT might effect mathematics contents, the two learning environments based on "Pip" and "Ranger" illustrated increased mathematical understanding with respect to angles and graphs.
Without the introduction of Pip, the treatment of angles most likely would have been limited to the isolated introduction of the 90°, 180° and 360° angles. The construction of perpendicular lines that form a 90° angle as shown in photos above, certainly would not have been included. While perpendicular lines can easily be drawn by using a protractor, this task rather requires procedural understanding. The construction of perpendicular lines as described above by using Pip, in contrast requires a conceptual understanding of angles. The pre-service teachers involved in the teaching experiments were clearly surprised that grade 4 children were able to demonstrate that level of understanding.
Furthermore, the understanding of time – distance graphs is not a topic that is frequently dealt with in grade 4 classrooms in Germany. Traditional approaches to graphs in grade 7 are often based on text book tasks that do not involve student experiments. But even more innovative approaches so far were limited to hand drawn graphs of movements between two points A and B timed with stop watches. However, while these drawings would reveal students' misconceptions, it would be difficult for students to understand and correct their mistakes due to a lack of empirical experiences. In this context, the Ranger enabled fourth graders to explore, monitor and record time – distance relationships and hence to develop a deep understanding of graphs. 235
While both devices certainly were seen as fun toys by many children, 'playing' with these toys in suitable learning environments turned them into powerful tools for mathematics teaching and learning.
Acknowledgement
We wish to express our gratitude to Audrey Elliot who introduced us to "Pip" and "Ranger" in the context of our joint Sokrates-Comenius 2.1 programme "COSIMA – Communicating Own Strategies in Primary Mathematics". Her classroom ideas and experiences have greatly supported the development of the learning environments described in this paper as well as the contents of the methods course.

Dynamic Geometry Activity Design for Elementary School Mathematics
31
Nicholas Jackiw, KCP Technologies, Inc., USA
Nathalie Sinclair. Michigan State University, USA
njackiw@keypress.com, nathsinc@math.msu.edu
Based on our research in designing mathematics activities for the grade 3-5 classroom, we outline central issues confronting the deployment and integration of Dynamic Geometry software in the elementary school curriculum. We remark in particular on contributions of the elementary setting to specific theoretical and pedagogic issues confronted in Dynamic Geometry use in real classrooms not directly instrumented through researcher interventions, and to specific effects of Dynamic Geometry technology on students' mathematical understanding and practice.
Introduction
In this paper, we report preliminary findings from our work using The Geometer's Sketchpad (Jackiw, 2001) to design mathematics activities for use in grade 3-5 classrooms in the United States. We emphasize how our emerging understanding of Dynamic Geometry's reception and impact differs in this situation (age-group, curriculum, and classroom setting) from the upper-middle-school and secondary mathematics settings more commonly addressed by Dynamic Geometry research (see King and Schattschneider, 1997).
Background and examples
The context of these remarks is Sketchpad for Young Learners of Mathematics (SYL), a research and materials development initiative that grew out of a 2003 conference on uses of visualization software in the early grade levels. The research focus of this project is on technology-supported curriculum design models; the development focus is on a collection of classroom materials using Sketchpad to support, specifically and concretely, several curricular programs in current widespread use in the United States (the National Science Foundation "reform curricula" such as Everyday Mathematics (UCSMP, 1998), and the Connected Mathematics Project (Lappan et al., 1995)). The project aims for impact at national scale, and thus emphasizes the conditions of widespread adoptability of project materials and sustainability of their dissemination and reuse by teachers without direct project support in the way of additional tools, professional development, or

31
Portions of this work were funded by the National Science Foundation (Dynamic Mathematics Visualization, ESI#02-43196, 2003, and Sketchpad for Young Learners of Mathematics, DMI-0339703/0521981, 2005). Opinions expressed here are those of the authors, not the Foundation. More information: www.keypress.com/sketchpad/syl/. 237
other resources. Design therefore proceeds as much in reference to practical, cultural, and political exigencies of the intended user community as in reference to theoretical models of cognition, social interaction, or educational formation. Activities from the early phases of the effort are freely available; through the end of 2005, more than three thousand school teachers had requested and received them.
In this section, three representative activities illustrate the project's output and establish a context for our subsequent discussion. Each activity features one or more sketches—interactive Dynamic Geometry microworlds—as well as teacher discussion documents and student activity sheets. Their discussion here suffers from the typical problem of describing dynamic imagery and interactive technology in static print—we make do with a few representative screen shots and verbal remarks, but in doing so mourn the loss of some of the sketches' dynamic character.
Grouping. In this activity, designed for whole-class participation, students encounter a population of wandering bugs—green dots on the screen—that can be marshaled into group formations, and make predictions and observations about the bugs and their groupings (see Figure 1). Initially (a) the screen contains an unsorted collection of insects, two buttons (123 and Redlight), and an editable number statement: group size = 5. Pressing the 123 button (b) causes the insects to wander randomly across the screen, but pressing Redlight causes them to sprint into (c) organized groups of the

same number of bugs.
32
As students orient themselves to the environment, the
activity asks them to begin mathematizing it. How many groups of bugs are there?
How many bugs in each group? How many left over? (One group in (c) has only four
members!) How many bugs are there, in total? Either through experience with earlier
activities, or through explicit teacher prompting, students discover they can alter the
value of the group size parameter, and that this value controls the size of the groups
into which bugs cluster. Image (d) shows the bugs frozen by Redlight with a group
size of three. More questions explore this idea of variation: if grouping by five made
four leftovers, what other group sizes will have four leftovers? Students in grade 4
are very concerned with fairness: how can you group them so that no bugs are left
over? Further questions and oriented discussion seek more subjective responses: how
could you group them to best show that there are exactly 24 bugs?

32
The names for the buttons here come from a popular children's game—"red light, green light"—
where players move as far and as fast as possible during a count (1, 2, 3…); then stop still on the
cry of "red light!" 238
(a) a "large" collection of bugs… (b) wander aimlessly about the
screen…
(c) until students "collect" them
into groups…
(d) whose size is determined by the
given parameter.
Figure 1. Grouping
Jump Along. This second activity (figure 2) resituates the ideas of Grouping in a
more familiar representation—the number line (a)—governed by two parameters, a
number of jumps and an amount to jump by. Pressing Jump Along causes a point
to hop rightwards (from zero) by the number and size of jumps requested by the
parameters. In (b), six jumps of four units lands on 24. Activity questions seek first
concrete and then generalized descriptions of observed patterns and inferred rules of
the environment. How else might you land on 24? Image (c) shows a related pattern
(four jumps of six) superimposed on the first (six groups of four). Thus the
commutative principle emerges from students' exploration of co-variation of the two
parameters (both land on 24—six fours equal four sixes), while visual imagery
retains the obvious distinction between these two propositions (six fours is not the
same thing as four sixes). Further development in the activity strives to build
additional "visual personalities" for number and number properties through the
jumping metaphor. A destination like 24 ultimately accumulates a denselyoverlapped set of jump factors, while prime numbers emerge with an equally distinct
visual signature (numbers that can be reached only by the smallest jumps). 239
(a) the basic number line… (b) shows n jumps of m
units…
(c) for student choices of n
and m.
Figure 2. Jump-counting along the number line
Flatland. This third activity provides an interactive model of the universe of
Edwin Abbott's 1884 parable of higher-dimensional visualization. Abbott's
protagonist, A. Square, is a two-dimensional being living inside the plane. He thus
perceives other inhabitants of his world always "edge-on:" objects appear with width
but no height, and their depth can only be sensed through relative brightness.
(Ambient gloom in Flatland causes things farther away to appear darker.) Where
Abbott's masterpiece develops these optical principles in analogic pursuit of three-
and higher-dimensional thinking, the grade 5 Sketchpad activity focuses on twodimensional visualization and the development of intrinsic geometry perspectives.
The Sketchpad microworld (Figure 3) is divided into two panels—a "spaceland
view" looking down on the plane from above and a "flatland view" looking across
the plane from within it, specifically from the vantage of the brown square. In (a), the
spaceland view at top shows the square looking (in the direction of its lower left
vertex) at the plane's other inhabitant, a triangle of separately-colored sides. The
flatland view at bottom—the broad horizontal stripe—shows the triangle as the
square sees it: only its red and blue edges are visible, and they occupy roughly the
same amount of the square's field of view. (But they are not equally long! The righthand edge fades to a much darker red at its extremity, indicating that edge recedes
sharply into the distance.) The sketch is also interactive. Students control the position
and orientation of the square either by dragging it (and its "eye") directly with the
mouse, or by navigating indirectly through turtle-like controls. The most important
button, Hide Spaceland, eliminates the top-down view and leaves only the edge-on
view of the triangle. Guided exercises develop students' footing in the flatlandscape,
and then probe their understanding. In the square's view (a) of the triangle, can you
determine with certainty whether the red and blue edges meet at all, or if one simply
eclipses the other? What maneuvers might improve or disprove that conjecture?
What other shapes could masquerade as perspective (a)? Eventually the activity
moves offline: without recourse to trial-and-error experiment, what sort of spaceland
geometries could lead to the four flatland perspectives shown in (b)? 240
(a) Corresponding views of a
triangle in Spaceland (top,
viewed from above the plane)
and Flatland (bottom, viewed

Curriculum: discrete vs. continuous
In contrast to the content domains in which Dynamic Geometry is widely studied at
the middle school and higher levels (notably geometry, but also others), much of the
mathematics at the elementary level is discrete in nature. Students begin with whole
numbers, then move to integers, fractions, and decimals—which themselves appear
not as markers of a real continuum, but rather as another counting system of
somewhat smaller steps. At first blush, these discrete concepts and representations
seem at odds with the continuous motions and visualizations that form the heart of
Dynamic Geometry dragging. To rephrase as a challenge: what relevance has a
technology fundamentally about continuous evolution and dynamic manipulation of
geometric shape, to curricula focused on discrete counting systems and number
representations?
Three possible responses are evident in the SYL activities. We note the most
obvious first: not all of the elementary curriculum in the US concerns number.
Informal geometry (particularly the study of shape properties and hierarchies) is
pursued intermittently through qualitative and relational approaches that—because
non-quantitative—avoid the discrete formulations so common elsewhere. Thus
activities like Flatland, which centrally feature continuous variation and deformation
of shape, remain relevant. While such activities may appear as novel Sketchpad
treatments in terms of their intended age level, their use of Dynamic Geometry is
conventional.
A second observation is that some common discrete mathematical representations
that appear at these grade levels are conventions of, rather than essential to,
conceptual objects of study. This opens up the possibility of substituting, in the 241
dynamic environment, continuous for discrete representations, while remaining
focused on shared underlying mathematical concepts. Within our project, such
substitutions were well-accepted by field-testing teachers provided that the alternate
representations themselves were not identified as "properly belonging" to other
locations within the scope and sequence of their curriculum. In an attempt, for
example, to reinterpret a textbook lesson in data analysis, a draft Sketchpad activity
placed several draggable data markers on a horizontal axis. Each marker displayed its
numeric value, and bright arrows displayed the location and value of the mean and
median of the data set. Where the corresponding textbook activity depicted only
integer-valued data, the sketch displayed values to two decimal places, to provide
suitable numeric feedback to the act of dragging values left and right on the axis. But
these values led to the draft's rejection by field-testing teachers, under the stronglyheld conviction that this was intended as—and that the curriculum called for—an
activity about central tendency, not an activity about decimal numbers. A subsequent
draft removed numeric values from the dynamically-displayed data-markers and
central measures, and relied instead on graphical and positional visualizations of
these quantities. This draft—substituting a continuous, visual representation for the
integerized textbook illustration—met with greater teacher ratification. Thus in many
of our field-test classrooms, the mathematical role of technology is clearly to
innovate within parameters well established by an external curriculum framework—
both in terms of what it may address and what clearly it must avoid.
33
Provided
Dynamic Geometry respect that principle, from our teachers' perspectives,
continuous representations though often new were not per se judged inappropriate
(see also Assude and Gelis, 2002). From students' perspective, such substitutions
tended to de-emphasize counting and computation skills, and re-emphasize
qualitative behaviors and comparative relationships.
A final response is that the general-purpose tools such as Sketchpad provide
sufficient capabilities to permit advanced users—in this case, curriculum
developers—to simulate discrete or quasi-discrete representations out of the
continuous ones that come easily in Dynamic Geometry. For example, step-functions
can be used to round or truncate the decimal portion of real quantities, and settings
for the preferred number of visible decimal digits can be adjusted to display these as
whole numbers. In addition, one can take advantage of subtly discrete behaviors that
already exist in the software's mathematics.
34
Pursuing "highly authored" activity
design through such techniques of course has its own consequences in terms of the

33
Since there is no national curriculum all schools most follow in the US, this "external curriculum
framework" in many cases was defined simply by the classroom textbook, or by school- or districtwide teaching policies and content expectations.
34
For example, an intersection of two line segments continuously moves, in Sketchpad, as a result
of motion of the segments—until they no longer intersect, at which moment the intersection point
"blinks out" of existence. Thus on top of the continuous phenomenon of point location is layered a
discrete notion of point existence. Sophisticated users manipulate such behaviors as constructive
building blocks of other discrete and categorical phenomena or effects. 242
software's use and instrumentalization by students. We develop some of these
consequences in the next section, and in our presentation will discuss further the
Sketchpad software functionality we found particularly adaptable to, or relevant in,
young learner activity design.
To close this discussion of the discrete and the continuous, we note similar issues
impact Dynamic Geometry experiences at all levels, not just in the elementary
setting. An example so common it deserves a name of its own—the "defective
triangle defect" problem, perhaps—strikes most users when they first measure the
interior angles of a dynamic triangle, and sum the resulting values. The sum appears
as exactly 180°. But inspection shows that hand-adding the three displayed addends
themselves gives a different answer—180.1° or 179.9°. The issue, of course, is not
one of internal software accuracy, but of decimal representation and measurement.
The three angles are continuously-varying geometric quantities; there may be no
finite number of decimal digits that measures them exactly. Thus the individual
values display rounded to some adjustable, but finite, precision. Their summed result,
on the other hand, is exactly representable in whole-number decimal degrees. The
heart of the issue is how one's assumptions have been fed by prior textbook
illustrations of triangles in which all angles "happen" to have exact whole-degree
magnitudes. In the infinite bestiary of possible triangles one encounters in dynamic
geometry, such triangles are vanishingly rare, and one confronts the realization that
although discrete decimal numbers can usefully measure—that is, estimate—an
arbitrary angle's magnitude, they infinitely rarely describe it exactly. These sorts of
tension between the discrete and the continuous are fundamental to the mathematical
domain itself; but they are brought into particular focus by Dynamic Geometry's
novel and accessible representation of mathematical continuity. At the elementary
school level, occasionally-weaker content knowledge combines with greater
curricular emphasis on whole number operations to make their outbreak more
frequent, unless steps are taken in curriculum design to anticipate and manage their
consequences.
Students: pre-algebraic thinking, motion, and instrumental genesis
While we have yet to study student learning and engagement with these activities
directly, our field-test observations of classrooms and discussions with teacher
research participants identify several distinct features of the young learner
appropriation of Dynamic Geometry tools and activity settings.
The object known within Sketchpad as a "parameter" seems strongly implicated
in students' proto-symbolic thinking. Parameters consist of two attributes—a textual
name and a (possibly dimensioned) numeric value. (Group size = 5, in the Grouping
activity, and number of jumps = 4 and jump by = 6 in the Jump Along activity, are
parameter objects.) When users create a new parameter, they specify initial values for
both halves, which subsequently display together, as in the arrangements of Figures 1
and 2. Users then access a variety of tools to change the halves separately: a textediting tool, for renaming the parameter; a number-editing tool, for typing-in a new 243
numeric value; an adjusting tool, for incrementing or decrementing a present value;
and an animating tool, for varying the value continuously across some preset numeric
domain. The dual name/value appearance of Sketchpad parameters scaffolds
students' conception of variation and, more generally, of "variables." Many SYL
activities involve changing parameter values. Thus both over time within the
activity's unfolding on a single computer, and at any single moment in time across
multiple computers (in a lab or class cluster), the "same" parameter appears with
different values. In communicating with each other and with a teacher, students move
from referring to parameters by value—"let's change the three to a four"—to
referring to them by name: "change jump by to four." In these pre-symbolic uses,
the name clearly acts both a placeholder for a current value and as a summary of all
possible values (as in: "jump by can be as big as you want"—elementary students
like big numbers!—"but you don't necessarily wind up on the same spot").
From a broader pre-algebraic perspective, we note students at this age display
greater degrees of comfort and dexterity negotiating technical formalisms imposed

by constraints of interaction with a computer program than with those imposed by teachers. Where a definition, rule, or requirement stated by a teacher may vex students as arbitrary, insufficiently justified, or otherwise opaque, students appear to expect inflexible responses from machines. The Sketchpad command to measure, for example, requires a student to pre-select two points identifying that distance. This requirement operates as a mathematical formalism that students navigate to proceed in an activity. If a student incorrectly proposes that distance might be measured as a property of a single point, the software simply refuses to cooperate: the command stays disabled. Because this response has none of the overtones of error, fault, and correction that would accrue to similar human responses (by teachers or other authorities), students view it less as a rebuke than as a challenge: "how do I get the computer to do it?" Where students encounter computational representations and operations that parallel mathematical representations and operations, the software milieu offers unique opportunities to support their acquisition.

We turn to consider the role of motion. If motion--particularly, the mathematical motion of geometric objects under dragging or animation--is the most signal ingredient of Dynamic Geometry experiences, it appears motion takes on somewhat different functions in elementary activities than in the standard class of triangle-dragging activities well-studied by the Dynamic Geometry literature. First we note several different categories of motion within the activities described in Section 2. In Jump Along, the motion of jumping particles is strictly determined by given parameters, and exactly replicable for any setting of them. Students choreograph and explore this motion only indirectly, by setting parameter values and then "jumping." The Grouping activity combines this sort of deterministic motion (the grouping formations) with the more organic motion of freely-wandering bugs. Students impose the former on the latter, which they may initiate (by pressing 123) and terminate (Redlight) but not otherwise control. In Flatland, motions are open-ended and entirely under the agency and direction of the student, who may move, position, and 244 spin objects either through direct manipulation of their physical shapes or through a variety of indirect controls.

These diverse types of motion sustain diverse roles and functions of motion within SYL activities. An important purpose of motion in activities like Jump Along and Grouping is to invest some form of continuous dynamics to traditionally or fundamentally discrete mathematical representations and concepts (see Section 3). Continuity in turn endows changing mathematical forms with durable identities, and temporalizes abstract relations and propositions, thus literally animating mathematical representations. The central idea of jumping, in Jump Along, takes place in time and space: motion interprets 24 = 6 x 4 as six jumps (in time) of four units each (in space). Thus student discussion of systems in motion focus on the behavior of mathematical situations rather than on their properties or attributes. Secondarily, we find in the SYL project that motion frequently defines the narrative matrix of an activity's story or context (see Sinclair, 2005). The Grouping activity's bugs "feel like" bugs not because of the precision of their frozen Redlight arrangements but because of their ant-like perambulations when 123 wandering. Such story contexts themselves play multiple roles in an activity. As authors, we hope they motivate and sustain student engagement in problem spaces (but are aware of how often such contexts strike older students as sham devices, to be stripped and discarded as the first step of solving "real" problems). Perhaps more importantly, we see that story contexts provide a mechanism for teachers and students alike to transport discoveries, experiences, and conclusions formed within the technology activity milieu into other contexts and situations. Weeks after encountering the Grouping activity, a student struggling with division may not be able conveniently to return to Sketchpad. His teacher asks "remember what had to happen for the bugs to group up with nobody left out?" and resurrects, through story, the situated activity experience. Finally, we note that where direct motions and manipulations--dragging a vertex, rotating a polygon--provide the most immersive form of free geometric inquiry, activity situations in which motion is initiated and determined indirectly--for example, by pressing buttons--often leads students to patterns of more explicit conjecture formation and evaluation.

Our last observation concerns students' and teachers' instrumentalization of the software. An intellectually exhilarating ingredient of many users' first encounter with the dynamic geometry "behavior" of a simple construction--say, of a triangle and its centroid--is the shortness of the distance between one's perception of what one confronts, and the conviction that you could construct it yourself. (We see this shortness as a central feature of what Hoyles and Noss (2003) call "expressive technologies.") An initial concern in this project, then, was that the authoring techniques required to develop microworlds such as Grouping or Flatland were sufficiently advanced--in terms of both mathematical sophistication and Sketchpad technique--as to be indistinguishable from the advanced techniques required to program a dedicated Flash or Java-based applet of the sort that exist in great number on the web. The internal construction defining the dynamic behavior of Grouping or 245 Jump Along is not trivial; and a desirable degree of transparency--how does this work?--is lost. Happily, though, we find frequent evidence of the dynamic geometry environment's classroom remaining value even when used in conjunction with microworlds whose assembly techniques are ultimately opaque. Even where the mechanisms behind a microworld may appear as a black-box, the available and interesting mathematics emerging from that microworld, as well as the questions and techniques students bring to probing it, are not confined to such boxes. Since over the course of multiple activities, students become exposed to a general stable of Sketchpad techniques (e.g. changing a parameter, measuring a distance, coloring an existing shape or constructing a new one), over time these techniques develop into vertical skills that users re-apply even in contexts not intentionally structured for them. When a student--departing from an activity script--recolors one of the green bugs red, to trace its migration from group to group under different group size values, she expresses her acquisition of the software as an intellectual tool, rather than merely as an activity-delivery environment; and alters her relation to both the activity and its setting. A teacher responding to a spontaneous student question by measuring some quantity within an activity sketch similarly demonstrates vertical appropriation of the software. While novice users certainly remain distinguishable from Sketchpad experts, both exist in continuum and in flux, rather than in fixed camps of activity-producing developers and activity-consuming users. Teachers, students, and curriculum developers alike appear across the usage spectrum.

On-line professional development for mathematics educators: Overcoming significant barriers to the modelling of reform-oriented pedagogy

Daniel H. Jarvis, University of Western Ontario,London, Ontario,Canada
djarvis3@uwo.ca

As noted in the ICMI 17 Discussion Document, much has changed since the original ICMI 1985 study. The advent of highspeed Internet and web-based technologies has in many ways revolutionized the educational project, touching all areas of research and practice. For example, on-line course offerings in continuing teacher education are rapidly becoming standard features for faculties of education involved with the profesional development of in-service teachers. However, instructors of mathematics education courses which are offered in a full-distance context must navigate certain formidable obstacles in the planning and delivery of their on-line learning experience. In an era of reform-oriented mathematics education (National Council of Teachers of Mathematics, 2000; Ontario Ministry of Education, 2005), which emphasizes the increased use of manipulatives, technology, groupwork, and communication, the "virtual" instructor must develop creative methods for modelling these important aspects of teaching and learning. Based on three years (eight courses) of instructor/course evaluation feedback and on the author's own observations, the following paper presents four key strategies for bridging this technological gap in the delivery of quality on-line professional development for mathematics educators. In addressing both professional development and distance education, this paper speaks to specific questions found in both the Teachers and Teaching (3) and Connectivity and Virtual Networks for Learning (7) themes, and approaches these in terms of digital technologies and the role of the teacher.

Introductory

On-line learning is quickly becoming a commonplace feature of the postsecondary education landscape (Varnhagen, Wilson, Krupa, Kasprzak, & Hunting, 2005). This reality is clearly, and in an ever-expanding manner, evidenced within pre-service and in-service teacher training programs across North America. Fulldistance education has both benefits and drawbacks for the candidate and for the online instructor. Mathematics education, by the very nature of the its content and delivery, brings with it a unique set of obstacles and opportunities when taught online, particularly from a reform-oriented perspective such as that encouraged by the National Council of Teachers of Mathematics (National Council of Teachers of Mathematics, 2000).

While teaching in an Additional Qualifications (AQ) on-line learning environment for the past three years at the University of Western Ontario in Ontario, Canada, I have attempted to develop several strategies that I believe, based on candidate feedback and my own observations as facilitator, enhance the overall 247 professional learning experience for mathematics educators who are enrolled in such teacher development courses. I would like to share with you four of the most effective strategies in this article.

Building Community with Class Profiles

Like in any regular classroom, the first few instructions given and interactions experienced within the on-line forum are of extreme importance in terms of setting the tone or "creating the ambience" for learning (Kimball, 1995, p. 55). Adult learners enrolled in my Honours Specialist Mathematics courses are first asked to "sign in" on-line within the "Aftermath Café" folder, sharing various details about their professional experiences and personal interests. After several days, I have found it very useful for both myself and the candidates to take the time to collate this data in two forms: a simple table or chart (see Table 1) with columns highlighting their location, school, courses taught, years teaching, and other miscellaneous information; and a geographical map (see Figure 1) upon which each individual is situated according to location and name. These files are shared with candidates on-line, and I ask them to provide me with feedback regarding any possible errors or omissions. As the second and sometimes third drafts are created and posted, I, as instructor, am already modelling collaboration, interest, and direct involvement within the course.

Table 1. Class Profile Chart of Professional and Personal Information

Imran Toronto, Ontario	AASS Mathematics/Business 2a	Worked in Business; MBA;	likes new technologies	
Jean-Jacques Montreal, Quebec	BBSS Mathematics/Computers 18a	Physics/Science background;	enjoys cycling and climbing	
Elizabeth Ottawa, Canada	CCSS Mathematics/Visual Arts 7a	Black belt in karate; loves to	sketch, paint, and integrate	

The table or chart provides the instructor with instant access to important facts which often become helpful throughout the course in terms of mentally "locating" an individual, asking good questions, and mindfully drawing upon candidate expertise as one extends or redirects on-line interaction. The map serves to actually situate learners within a visual context, allowing them to obtain a general "feel" for what the course looks like in terms of geographical representation, and rendering a sense of "place" in an otherwise distant or disconnected context. One obvious benefit of on-line learning is that it allows the learner to not only participate at her/his leisure, but also permits she/he from studying at great distances or while on the move. I've had candidates take my London-based mathematics education courses while teaching in China, working in western Canada, and touring Europe with a backpack and laptop. 248

Figure 1. Class Profile Map of Candidate Locations.

Because the instructor and course participants are often denied the visual element (i.e., as in onsite settings or teleconferencing situations) in much of distance education, this chart/map class profile is very much a part of building community and constructing individual "portraits" of each learner. Mounted near my monitor for the duration of the course, the class profile provides for quick identification regarding who is who, and who is where.

Engaging Minds with Rich Problems

The second strategy which I've found to be very effective is that of posting engaging mathematics problems throughout the course and asking candidates to delay sharing their ideas/solutions concerning these problems until a specified date, thereby allowing all participants more time to grapple with a given problem (see Figure 2 for sample problem and related instructions; this is a classic ratio problem rewritten using Tolkien's Lord of the Rings characters in order to provide a more interesting context).

249
Problem: Strider and Boromir are sitting at a back table in a dark, smoky tavern of
Middle Earth known as the Prancing Pony. Strider has three loaves of bread; Boromir
has two. Just before they eat, however, in walks Bilbo Baggins, obviously famished,
and asks if he may share their meal. They agree, and each of the three characters eat
equal amounts of bread. Before departing, Bilbo pulls out five identical gold coins
and says, "Please accept these few coins as thanks." Strider and Boromir watch the
hobbit depart but then become puzzled as to how they should distribute the gift.
Unable to solve the riddle, they take it to Gandalf the Grey and ask him for advice.
As this represented a difficult "two-pipe" problem, they had to wait some time
outside the wizzard's dwelling. Finally, he emerged from the interior, and delivered
his recommendation.

Question: What was Gandalf's conclusion, and why was it the only fair and just way
to divide up the golden coins? Further, think of as many different ways (at least
three) to tackle this mathematical problem as possible. What role would the teacher
play in these? At what grade levels might this problem be appropriate, and where
might it be used in terms of curriculum?
N.B. Again, please wait until Monday July 18th before posting
solutions/ideas/comments, so that all of the hobbits will have a chance to think
through the problem. (N.B. If you are not a Tolkien fan, you can substitute other
names or leave the characters anonymous.)
Figure 2. Sample Engaging Problem, Question, and Response Posting
Instructions.
These problems and subsequent response posts are located in a separate
folder and are thereby kept organized and easily accessible. Four or five such
problems are selected for the course, one being featured for each of the on-line
modules which may last one or several weeks, depending on the course structure. Not
only does this process model the use of rich problems in mathematics classrooms, but
the multiple solutions that are often presented by candidates lead to important
pedagogical discussions surrounding issues of mathematical communication, teacher
questioning, consolidation of learning, and the encouragement of invented algorithms
and novel approaches to problem solving among students.
Creating Anticipation with Live Technology Tutorials
A third on-line teaching strategy is the use of scheduled chatline technology
tutorials in which candidates meet virtually, at scheduled dates/times to share
comments/questions/insights regarding the many software/website resources and
related explorations that I, as instructor, have posted earlier in the course. Like with
the math problems, I have found it beneficial to maintain a separate folder 250
specifically focussed on mathematics technology, in which I can post these various
resources and links. Candidates are asked to have relevant software "up and running"
and/or available during the virtual class sessions wherever possible, and to have
specific questions/comments prepared in advance. During the scheduled tutorials, the
instructor acts as facilitator, sometimes answering specific questions but more often
than not simply guiding the conversation and offering insights where possible.
As technology is now such a vital part of reform-oriented mathematics
education (Gadanidis, Gadanidis, & Schindler, 2003; National Council of Teachers
of Mathematics, 2000, pp. 24-27; Ontario Ministry of Education, 2005, pp. 27-28;
Richards, 2002; Sinclair, 2005), and since on-line learning prohibits the use of
technology software/hardware in an actual classroom, this teaching strategy serves to
address this important area of pedagogy within the distance education forum. I
currently have candidates examine five areas of technology (see Figure 3) with
related introductory activities (e.g., graphing calculators and spreadsheets; dynamic
geometry and data software; on-line learning objects [Interactive Applets] and virtual
manipulatives; Statistics Canada's E-Stat on-line learning resources; and various
websites related to the teaching and learning of mathematics).

Figure 3. Sample Web-Based Resources for On-line Technology Explorations.
The web-based resources are obviously widely available, and the Key
Curriculum Press software titles listed above (i.e., Sketchpad and Fathom) are
licensed for Ontario teachers under the Ontario Software Acquisition Program and
are also available to candidates as free downloadable evaluation copies. Therefore,
apart from the graphing calculators--most teachers taking Honour Specialist courses
either have purchased their own machine or can borrow one from their school for the
duration of the on-line course--all of these technology resources are readily
available, and so access is not an issue. 251
To date, I have only made these chatline tutorials optional/voluntary, in
terms of candidate participation, and they have therefore not been assessed as part of
the course evaluation. However, I could see incorporating these sessions as a formal
requirement, thereby encouraging all candidates to explore the posted activities
beforehand and to offer comments/questions during the virtual gatherings.
Depending on the configuration of the distance education system, it may be to the
instructor's advantage to divide up the participants into smaller groups based on
software/hardware topics and/or the most convenient gathering times for candidates.
For those not able to join the group on-line during selected dates/times, transcripts of
the sessions are converted to PDF and posted for everyone following the chatline
sessions. As one teacher shared following the tutorial: "I found the on-line chat the
most fun part of the course. It was quite engaging and I would encourage you to
include more live chat sessions."
Providing Specific and Ongoing Feedback with Candidate Assessment Files
Like all students, adult learners desire meaningful and ongoing feedback
throughout the on-line learning experience. I have found that the best way to respond
to this need in a consistent and appropriate manner is to construct what I've simply
labelled as "Candidate Assessment Files (CAFs)." Sent privately to each participant
via the on-line MailBox, all four instalments of this CAF provide candidates with
both general and individual comments regarding course progress and assignment
achievement, respectively. These CAFs are Word files with each candidate's name
typed on a title page with course information and colourful graphics. Inside, each
course module is briefly synopsised and then individual comments are made
regarding the modular assignments. Particularly effective, in terms of feedback, is the
copying and pasting of specific quotations made within the candidates' assignments,
accompanied by related instructor comments, questions, and/or suggested readings.
Even in the very first instalment of the CAF, all modules and assignments
are represented in blank outline form. Also included are rubrics for major
assignments (i.e., the cells of which are simply shaded to indicate achievement upon
assessment), a "Course in Review" page with all assignments listed and their
respective value (i.e., these left blank for the moment), and a copy of the university
grading scales (e.g., what characteristics constitute a mark of "A" or "B+"). This
complete CAF, although primarily blank at the point of first instalment, provides
each candidate with a clear framework for assessment in the on-line course. They can
be confident that there will not be any surprises in terms of how or when they will be
evaluated. By providing both general (i.e., course reading and on-line discussion
highlights) and individual (i.e., referencing specific assignment quotations and online participation tracking) comments, not only is the instructor more likely to be in
tune with all participants and the course in general, but candidates are reassured that
their instructor is carefully monitoring all that transpires. 252
Towards On-line Teaching Excellence
When I first started teaching on-line courses in the spring of 2003, I assumed
that they would be very limiting in terms of possible interaction with candidates and
my ability to deal, in any meaningful way, with the immensely important area of
technology within mathematics education. In looking back now, however, and
comparing my eight university courses taught on-line with the same number taught
onsite in faculty of education classrooms, I must honestly say that not only have I
enjoyed the on-line immensely, but that in developing and implementing the abovedetailed strategies, I have been much more "connected" to candidates and able to
closely monitor what and how they were thinking as a given course progressed.
Although I could not "see" them, in the end I felt that I actually "knew them" better.
By creating detailed class profiles, posting rich and engaging mathematics
problems, hosting virtual technology tutorials, and providing ongoing and
meaningful assessment files, I have grown as an instructor and feel that I've been
able to provide mathematics educators with quality on-line professional
development. On-line learning does have its inherent limitations, to be sure; yet the
opportunities it affords the "virtual" instructor of mathematics education, and the
participating candidates, are indeed worth investigating.

Theoretical perspectives on the design
of dynamic visualisation software
Keith Jones, University of Southampton, UK
d.k.jones@soton.ac.uk
Constantinos Christou, University of Cyprus
Marios Pittalis, University of Cyprus
Nicholas Mousoulides, University of Cyprus
Designing learning environments entails drawing on theoretical perspectives on
learning while, at the same time, being cognisant of the affordances and constraints
of the technology. This paper reflects on the design process through utilising
evidence from the design stage of the development of a dynamic visualisation
software environment called 3DMath. During the development of 3DMath, a dynamic
three-dimensional geometry microworld aimed at enabling learners to construct, observe
and manipulate geometrical figures in a 3D-like space, the key elements of visualisation
– covering mental images, external representations, and the processes and abilities of
visualisation- were taken into consideration. The aim of this paper is to illustrate how
the design of this particular software was informed by these elements of visualisation, as
well as by theories related to the philosophical basis of mathematical knowledge and by
semiotics. The paper illustrates how the features of software may be designed to take
account of relevant theoretical notions and to satisfy the characteristics of instructional
techniques that are appropriate to theoretical perspectives on learning.
Introduction
A prime aim of the 8
th
World Conference on Computers in Education, held in July
2005, in Stellenbosch, South Africa, was to develop and produce a "global vision for ICT
in education". The vision document produced at the conference, known as the
Stellenbosch Declaration (IFIP, 2005), sets challenges for all stakeholders in ICT in
education - teachers, practitioners, researchers, academics, managers, decision-makers
and policy-makers- all with a view to increasing the access to education for everyone
around the world.
While acknowledging that the development of well-designed ICT-based
educational material is growing, the Stellenbosch Declaration sets out a radical agenda
for research, specifying the need for the research community both to bridge the gap
between technology and pedagogy, and to ensure the development of solid theoretical
frameworks for software design and utilisation. This is because, the Declaration argues,

"in the field of ICT-supported learning, pedagogy and technology have often been treated separately: pedagogy often being based on what the technology appears to permit, rather than fully integrated as a basis for technological design" (emphasis added) and that "the possibility of relying on solid theoretical frameworks is one of the key factors that can 254 enable conception of the many positive experiences already taking place in order to reach the definition of reliable innovative reference models" (ibid, p4, emphasis added). The Declaration also insists that "the output of research should be made widely available, as open source, for improving practice, decision-making, and resources development".
This paper is offered as a modest contribution to meeting the challenges to research set out in the Stellenbosch Declaration. It does this by reporting on the theoretical perspectives underpinning the design of a dynamic visualisation software environment called 3DMath (Christou et al, 2006) aimed at enabling learners to construct, observe and manipulate geometrical figures in a 3D-like space.
Theoretical Perspectives on Design
Traditionally, three-dimensional geometry is taught using static pictures of geometric solids presented in textbooks. Students, however, are known to have difficulty reasoning from two-dimensional representations of three-dimensional objects (Raquel, 2002: Parzysz, 1988). Moreover, developing visualization skills is difficult in a traditional lesson environment using the standard chalkboard because representing 3D objects by a 2D sketch is complicated and time consuming. Such difficulties remain even when commonly available 2D dynamic software is used. For example, Dixon (1995) showed that 2D software can be effective in improving students' two dimensional visualisation but was not effective in improving students' three dimensional visualisation.
In an attempt to overcome these difficulties, and to take account of relevant theory, this paper reports on the design of a 3D software named 3DMath. The main objective of the software development project is to develop a dynamic three dimensional geometry microworld, which enables students to construct, observe and manipulate geometrical figures in 3D-like space on the computer screen. To meet these purposes, the design of the proposed software followed three major fields of educational theory:
(a) the constructivist perspective about learning which argues that learning is personally constructed and is achieved by designing and making artifacts that are personally meaningful (Kafai & Resnick, 1996),
(b) the semiotic perspective about mathematics as a meaning-making endeavour which argues that any single sign (e.g. icon, diagram, symbol) is an incomplete representation of the object or concept, and thus multiple representations of knowledge should be encouraged during learning (Yeh & Nason, 2004), and
(c) the fallibilist nature of mathematics which argues that mathematical knowledge is a construction of human beings and is subject to revision (Ernest, 1994).
In addition, the aim of developing the 3DMath software was to develop abilities and processes in students that are closely associated with the idea of visual imagery as a mental scheme depicting spatial information (Presmeg, 1986). It is generally accepted that learning 3D geometry is strongly associated with spatial and visual ability (Dreyfus, 1991) and that incorporating spatial visualisation and manipulation into learning activity could improve geometry learning (Tso and Liang, 2002). 255
Spatial ability has had many definitions in the literature. For example, Tartre (1990) defines spatial ability as the mental skills concerned with understanding, manipulating, reorganizing, or interpreting relationships visually, while Linn and Petersen (1985) defines it as the process of representing, transforming, generating, and recalling symbolic, non-linguistic information. Lohman (1988) proposes a three factor model for spatial ability, including "spatial visualization", "spatial orientation", and "spatial relations". "Spatial visualization" is the ability to comprehend imaginary movements in a three-dimensional space or the ability to manipulate objects in imagination. "Spatial orientation" is defined as a measure of one's ability to remain unconfused by the changes in the orientation of visual stimuli that requires only a mental rotation of configuration. "Spatial relation" is defined by the speed in manipulating simple visual patterns such as mental rotations and describes the ability to mentally rotate a spatial object fast and correctly.
The core visual abilities that should be taken into account in developing 3D dynamic geometry software could be said to be the following (following Gutiérrez, 1996):
(a) "Perceptual constancy", i.e., the ability to recognize that some properties of an object are independent of size, colour, texture, or position, and to remain unconfused when an object or picture is perceived in different orientations,
(b) "Mental rotation", the ability to produce dynamic mental images and to visualize a configuration in movement,
(c) "Perception of spatial positions", the ability to relate an object, picture, or mental image to oneself,
(d) "Perception of spatial relationships", the ability to relate several objects, pictures, and/or mental images to each other, or simultaneously to oneself, and
(e) "Visual discrimination", the ability to compare several objects, pictures, and/or mental images to identify similarities and differences among them.
In addition, given Yakimanskaya's (1991) claim that the creation of mental images is possible because of the accumulation of representations that serve as the starting point, 3D dynamic geometry software should aim to provide the learner with a variety and richness of spatial images.. The richer and more diverse the store of spatial representations, the easier is to use images in solving problems.
Design Principles for 3DMath
Based on the above theoretical perspectives, and the rich concept of visualisation noted above, the following guided the design and the construction of the 3DMath software:
(a) The software needs to allows students to see a geometric solid represented in several possible ways on the screen and to transform it, helping students to acquire and develop abilities of visualization in the context of 3D geometry.
(b) Given Gutiérrez's (1996) view that when a person handles a real threedimensional solid and rotates it, the rotations made with the hands can be so fast, 256 unconscious, and accurate that the person can hardly reflect on such actions, then the software could usefully place some small limits on the directions and speed of rotation, thus forcing students to devise strategies of movement and to anticipate the result of a given turn.
(c) The interface of the software needs to be intuitive and to provide an open and generative environment that enables learning to learn through making and designing personally meaningful artefacts. It also needs to employ rich semiotic resources that enable multiple perspectives and representations for mathematical meaning-making (for example, students need to be able to represent a solid in 3D, or its correspondence in 2D).
(d) The software needs to be designed to provide the means for students to focus on the mental images they create, and the processes and abilities of visualization they use to solve problems. Given that a mental image is any kind of cognitive representation of a mathematical concept by means of spatial elements, 3DMath needs to makes it straightforward for students to construct different solids and perceive them in a concrete or pictorial form. This is because the repetition of this process helps students to formulate a "picture in their mind's eyes" (Presmeg, 1986). In addition, the software needs enables students to see solids in many positions on the screen and consequently gain a rich experience that allows them to form richer mental images than from textbooks or other static resources.
(e) In terms of external representations, a visual representation means the manipulation of visual images and the transformation of one visual image into another (Bishop, 1980). The form of software developed by the 3DMath project aims to be rich in the ability to manipulate and transform solids - see Christou et al (2006) for an example of how the 3DMath software aids the user in distinguishing between a representation of a pyramid and an octahedron.
(f) Bishop (1980) identified two relevant processes of visualisation: interpreting figural information and the visual processing of abstract information; the translation of abstract relationships and non-figural data into visual terms, the manipulation and extrapolation of visual imagery, and the transformation of one visual image into another. The 3DMath software incorporates Bishop's ideas by focusing on the processes of observation, construction and exploration (see Christou et al, 2006, for examples) in that
- observation allows students to see and understand the third dimension by changing the spatial system of reference (axes), choosing perspective and displaying visual feedback on objects. The 3DMath software is being designed so that students can rotate a geometric figure in reference to the three axes and thence obtain a holistic view of it. The speed and the direction of the rotation are e controlled by the user of the software and the drawing style of the object can be in a solid colour view or in a transparent line view. Students can select, label and colour the edges and faces of the objects.
- construction entails providing users with the facilities to allows a dynamic construction of geometrical figures from elementary objects (points, lines, planes) and 257 construction primitives (intersection, parallel, etc.). Students can also construct geometrical figures by selecting the appropriate 2D figures and then forming the solids by dynamic animations.
- exploration allows students to explore and discover geometrical properties of the figure. This is the main procedure adopted in most of the teaching scenarios being designed to accompany the 3DMath software.
(g) The 3DMath software is being designed in such a way as to accommodate the development of the following visualisation abilities (see Gutiérrez, 1996): (a) the figure-ground perception, (b) perceptual constancy, (c) mental rotation, (d) perception of spatial positions, (e) perception of spatial relationships, and (f) visual discrimination.
The following features are that are thought to contribute to the development of the abilities are being integrates into the software:
- the dragging capability of the software is being designed to enable students to rotate, move and resize 3D objects. Rotation can be executed in all directions by controlling a rotation cursor and determining the speed of the rotation. In addition, students can resize proportionally all the dimensions of the object or resize it only in one dimension, according to the requirements of the problem.
- tracing is a particular instance of the interface where only parts of the figure are displayed. The intended purpose of this feature is to provide the learners with a way to perform a visual filtering of the main construction represented on the screen, i.e., to allow them to extract and observe parts of the construction in an independent view.
- as in 2D dynamic geometry software, students can carry out useful measurements, in the case of 3DMath measures of the length of edges, the area of faces, and the volume of a solid. All measurements are dynamic as solids are resized by dragging. The dynamic characteristic of the measurement facility allows the exploration of properties within and among figures e.g. users can measure the volume of a cone and then double its height and see how its volume is altered.
- a textual feature, which represents the declarative description of the figure, provides the learners with a textual and chronological list of all the geometrical objects involved in the construction of the figure. Additionally, the History file can be used as input to the system. For example, a History file created by one student in one country can be used by another student in another country to reconstruct (or re-use) the same model. Using this feature, it would be possible to construct not only Interactive models, but also Declarative models (by importing History files) and Interactive Programming models.
- a diagrammatic feature provides a representation of the structural dependency graph of the figure.
(h) Other features being developed include:
- the ability to export constructions as images (BMP, JPEG, etc), or in other rendering format (PS, XML, etc). This should help teachers to create supporting educational materials, preparing reports, printed material, etc. 258
- the locking/unlocking of features (primitives), making them hidden from view. For example, the primitive to find the distance from a point to a plane might be initially locked (or hidden). To find that distance, students must solve the problem by making appropriate constructions. Once they do this correctly, the primitive may be unlocked (or made visible) so that it can be used freely in further constructions.
Concluding Comments
As illustrated by this paper, the design of 3DMath is informed by theories based on philosophy of mathematical knowledge, such as constructivism, and by semiotics. The main purpose of 3DMath is to enhance students' understanding of 3D geometry with an emphasis on visualisation. Thus, during the developmental process the key elements of visualization, as defined by Presmeg (1986), Bishop (1980), Clements (1982) and Gutiérrez (1996) (mental images, external representations, processes, and abilities of visualization), are carefully taken into consideration.
In developing the 3DMath software we are seeking to bridge the gap between technology and pedagogy, and develop solid theoretical frameworks that inform the software design. This is so that the pedagogy is fully integrated as a basis for technological design, rather than the pedagogy, as is often the case, being based on what the technology appears to permit a The output of this research, as the IFIP (2005) declaration recommends, is to be made widely available, as open source, for improving practice, decision-making, and resources development in mathematics education.

Designing for diversity through web-based layered learning:
a prototype space travel games construction kit

Ken Kahn, Richard Noss, Celia Hoyles and Duncan Jones
35
Stanford, USA University of London, UK
Kahn@csli.stanford.edu r.noss@ioe.ac.uk, c.hoyles@ioe.ac.uk

We present a Space Travel Games Construction Kit designed to enable students to learn while building a computer game. Games are built in the context of a metagame that provides motivation, structure, guidance, and background in game making. A key design decision was to encourage layered learning through specially-designed program fragments, which the students could customise and assemble. We present some scenarios and report on the results of testing a version of the kit with students, which suggest that designing levels in the game is an avenue for further development.

Introduction and design principles

In this paper, we discuss the hypothesis that learning of a subject domain can be deep and richly interconnected if it involves exploration within a computer game which combines designing and building as well as game playing. Additionally, we will argue that this approach to learning could potentially widen access to the possibilities of digital technologies, given that it allows diverse layers of engagement and exploits the interconnectivity available on the web.

Our prior research concerning computer games (Noss & Hoyles, in press) has indicated that games designed for learning authored by students tend not to suffer the difficulty noted with educational games more generally around poor production values. In the case of constructed games, even if they are relatively simple and crude, the students become dedicated to their creations. However acquiring the skills to make computer games requires a major investment in time and effort. Here, we present some novel design research that will illustrate an approach that is designed to reap the advantages of learning by programming games without the disadvantages of having to know a priori how to program.

Our starting point derives from the principle that the most powerful way for students to learn mathematics is through their long-term engagement in collaborative projects for which they take responsibility individually and collectively (see, for example, Harel & Papert, 1991). From this basis we have developed the following principles for designing for this learning:

sequenced activities that can engage students at a variety of levels in what we name layered learning;

35
We acknowledge the funding of the BBC, and the helpful comments of colleagues in the London Knowledge Lab, notably of Gordon Simpson and Diana Laurillard 261

flexible tools that have adjustable parameters, can be combined in different way and can be also be programmed, and thus allow students to investigate each activity for themselves

36

,

collaborative interactions as part of the activity sequence through which students discuss their emerging ideas in the context of their game design and finally multi-player game playing either at one computer or over the web.

The second design requirement is worthy of particular attention, as it implies that designers can both empower and constrain students by offering a set of components or modules that can be customised to suit diverse students' goals, as well as tuned to the knowledge domain. Programmable modules have the added advantage of providing a consistent way to combine and modify tools, in the control of the learner. There have been numerous attempts to design a programming-based approach to learning over the years. The most successful have achieved tangible learning outcomes across various topics (music, mathematics, language, physics (some of these are discussed in Noss & Hoyles, 1996). They have also provided important pointers to the possibilities of learning that transcends the procedural and superficial by encouraging a playful – yet mindful – spirit of enquiry on the part of learners, aiming to break down the curricular silos that so often characterises traditional schooling. For the most part, what has been missing has been generalised success in tapping into students' own interests on a wide scale and engaging them in debate, investigation and production. To achieve this aim, we have built and tested a space travel construction kit along with a narrative 'metagame' to assist learners in navigating their way through the sequence of activities of design and game playing.

Description of the game environment

The Space Travel Games Construction Kit

We began by considering the classic computer game of Lunar Lander. In the process of trying to land upon the moon, a player engages with the laws of motion, playing in a virtual world where the laws of gravity and momentum are not obscured by friction or atmospheric drag as they are on Earth. We have built and tested a Space Travel Games Construction Kit (using Imagine Logo, Blaho A., Kalas I., 2001) that can be used to build a variety of games similar to Lunar Lander. The construction kit provides small program fragments together with tools for customising and composing them. Thus the software extensions allow layered exploration appropriate for populations of students with differing backgrounds and ages; that is, users can choose how far to delve into the workings of the tools.

The innovative aspects of the software include:

36
In the current research aiming to involve groups spread geographically it was important that the tools could be accessed through a web browser - although this is not a 'principle'. 262

1. A child-friendly interface for the composition and parameterisation of pre-built program fragments;
2. An underlying computation model that has been simplified and made composable by building upon multiple independent processes. This is critical for the deeper levels of engagement where students inspect and edit program code;
3. An underlying physics model based upon conservation of momentum that is simpler than the one commonly used based upon first and second derivatives of position and the first derivative of momentum. Yet it is capable of modelling the same phenomena;
4. The concept of a "metagame" where games are made within an overarching narrative game structure.

The narrative metagame

The metagame starts with the player being hired as a game developer at a game company. The player receives help from a team of simulated experts including a programmer, a scientist, a historian, an assistant game designer, and an animator. A player may skip over all this and jump into game making, but the metagame provides structure, background information, guidance, and a gradual introduction of new features and capabilities.

The metagame embodies the design of a learning sequence. The learners are presented with a goal and need to interact with their virtual teammates in order to acquire both the needed components and the knowledge to proceed. The response of each teammate to a visit by the player is scripted but also depends upon both the current state of the game being constructed by the player and the history of the player's interactions with all the teammates. This gives the player freedom to visit the teammates in any order and with any frequency. Furthermore, each game component has an associated help button. When a component's help button is pressed, the player is informed which teammates have something to say about it. For example, the programmer, the scientist, the historian, and the game designer all have a unique perspective when giving an explanation of the component which implements gravity.

The Activity Sequence

Phase 1: exploration of game making

Moving in outer space: An astronaut is adrift and needs to reach her space ship.

Build a game by acquiring program fragments and artwork, which can be accomplished using only components involving horizontal motion that is achieved by 'throwing' rocks (previously collected by the astronaut).

Agreeing some constraints: for example, will the astronaut get back safely? Is she going too fast when she hits the spaceship? 263

Creating a new game: Now invent a new game. For example, the space ship has started to move off in a vertical direction. Can the astronaut reach it now? The final challenge in this sequence involves making the game into a cooperative game between two players over a network.

Phase 2. Building and playing a Lunar Lander game

To proceed to this phase, all the required game-making tasks in Phase 1 need to be performed. Here gravity is introduced.

Landing on the Moon: for example, what speed constitutes a safe landing? At this point we introduce dynamic configurable gauges to measure speed, acceleration, mass etc which monitor and graph these values and can help in the task of landing safely on the moon. Added challenges are introduced: do not use too much fuel.

Using the Autopilot: The settings of any 'manual' landing that is all the variables and how they are changed can be captured by an autopilot. The next challenge is to construct the best autopilot program, by recording what is deemed a good landing and then tweaking the parameters of the recorded landing to produce an optimal landing.

Multiplayer game over the web: Players can compete for example to land with the safest landing speed using the least amount of time or fuel. Students are also challenged to invent new games to play.

The potential layers of learning

Both the metagame and the construction kit were designed to support layered learning. At the first layer, engagement is mainly through reading, watching and making conjectures based on observation and for example describing a motion and reflecting on it. The tools for this layer are basic, perhaps only a handful to control a simulation on video, or the timing of movement. At a second layer, the learner can begin to manipulate motion and predict and test out the effects of different values. At a third layer, the learner might explore further how variables relate to each other, for example position, velocity and acceleration, by reference to the values set by sliders. And finally, a fourth layer that engages with these relationships either by modifying existing programming code or by writing new programs or fragments of programs.

Game construction: the interface

When the player is ready to build the game, a game panel with images of the astronaut and lander is presented (see Figure 1). Beside it is a control panel with a start button. Pushing the start button initially does nothing, since none of the game elements have been given programs. The control panel also has a button that causes the behaviour gadgets panel to appear (Figure 2). It contains behaviour gadgets that consist of one or more code boxes. A picture can be given a behaviour by placing a behaviour gadget on its back. The behaviour can be altered by setting sliders on the gadget's settings page. The code boxes of a behaviour gadget can be removed, whereupon they expand to display the code that implements the behaviour. Portions 264 of the code that can safely be edited without programming expertise are colour highlighted.

Figure 1. The initial game construction page

Figure 2. Behaviour gadgets can be dragged from the Behaviour Gadgets Panel. Initially, the behaviour gadgets panel contains only a horizontal velocity gadget and a horizontal rock throwing gadget. As the metagame progresses, the behaviour gadgets panel acquires more elements.

The total mass of rocks (i.e., total fuel), the largest rock (the maximum rate of fuel

usage), and the rock velocity (the propellant velocity) can all be adjusted by moving sliders. As one does so, the system makes calculations to show derived values such as force and to perform unit conversions. These parameters reflect real engineering tradeoffs. For example, adding more rocks/fuel does increases the duration of manoeuvrability but at the cost of a greater total mass and hence a smaller acceleration from identical rock throws.
Limitations of space prevent us from illustrating a range of further panels, behaviours and other objects that control instrumentation (for example, gauges that monitor any of 13 values in graphical or numerical displays, including velocity, acceleration, remaining fuel, total mass, the application of thrust (by throwing rocks out in the opposite direction), autopilot facility (a recording of all the changes to thrusters made manually), and a two-player version of the Lunar Lander game typically involving a race to be the first to land safely on the moon.
Figure 3 - A snapshot of game play with three active gauges.
Alternative epistemologies underlying design
When designing a toolkit to be used to construct scientific models (and games based upon these models) one needs to determine the underlying ontology of the system. How should time be modelled? How should concurrent processes behave? What are 265 the primitive notions of motion and space and which concepts are to be constructed from those primitives? Are the usual ways of conceptualising the laws of motion that are based upon algebra and calculus optimal for computational modelling?
Here we simply discuss the epistemological question is how to model forces. Should forces define acceleration, which in turn defines velocity, which defines position? A sequential program that models all the processes could be built this way. But it would lack the modularity and composibility of the concurrent processes that we rely upon, and although this provides a coherent epistemological perspective, it may not be optimal for learning. Consider the difficulties that would arise if one process implemented gravity by setting the acceleration to the appropriate value, while a thruster process implemented force by adding to or subtracting from the current acceleration. Clearly, the order in which the gravity process and the thruster processes run will drastically affect the model.
Instead, we chose to build upon the conservation of momentum, rather than F = ma. One reason for this is that it provides a concrete and discrete way to think about forces. It is likely to be more accessible than the alternative, which relies upon a notion of continuous rates of change. It also makes the mechanism underlying rocket thrust transparent. Throwing a one kilogram rock once per second is the same mechanism as real rocket thrusters that "throw" a trillion trillion molecules ("rocks") per second. Force is the derivative of momentum and as such is a more complex and difficult notion than the discrete change in momentum that we build upon.
Some illustrations of learning
We now very briefly outline some of the learning issues that are emerging from the iterative design/test cycle with three groups of students: two drawn from a large, urban comprehensive school (one "Year 7" class aged 11-12; one "Year 8" class, aged 12-13) and a small group of 3 students (aged 12-14) from a second school in an after-school setting.
Developing understandings of Newton's third law: In the first task the Year 7 students began with a relatively low knowledge of the physics concepts involved. For example, R suggested, "you could throw some rocks away and that would make her lighter so she would move." They were unaware that the effect of gravity in space is negligible (in the terms in which the software was devised). Through the course of the activity and experimentation with the horizontal rock thrower they appeared to develop an understanding that throwing a rock would develop an opposite movement proportional in velocity. Indeed, later in the session two of the students worked with the theory that "throwing larger rocks makes her move faster."
Minimising time (of astronaut to spaceship, or lander to moon) proved a motivating task, particularly for the Year 7 students. Most students used an iterative strategy e.g. Tom and Alex were delighted to refine their strategy again and again by optimising the use of the horizontal rock thrower against the speed of reaching the spaceship. 266
Using the gauges: Throughout the sequence much use was made of the gauges and interpretation of their output. Students found this relatively easy to put in place and tended to refer to them constantly as a guide to their use of the rock thrower or thrust. When landing on the moon some students applied far too much thrust causing the lander to move upwards and disappear off the screen. Reading the vertical velocity gauge which they had set up for the lander they predicted how the lander would "keep on getting slower until zero. Then it will fall back again because of gravity." In the 2 player game the ability to attach gauges to the opponent's lander was a particularly successful feature, enabling one group to make a close comparison with the other and to adjust the strategy second by second.
Composing horizontal and vertical velocities: Coming up with the hypothesis that to achieve diagonal movement a combination of horizontal and vertical thrusts would be needed, appeared almost effortless and was tested by, for example, using both horizontal and vertical rock throwers to the astronaut and using both simultaneously.
Gravity: The Year 7 students did not immediately make a connection between the rock throwing astronaut and the rock throwers for the lander, although Year 8 needed no prompting. The Year 7s also only had a more sketchy concept of gravity. Only two - Tess and Alex - volunteered that the lander game would be different from the astronaut in that there would be a gravitational pull (Alex) near the surface of the moon.
Collaboration, competition and motivation: Beating previous best scores proved highly motivating, especially for the team of Year 7 boys. Collaboration centred around agreeing what the two teams should have in common; the total mass of the projectiles, an agreed safe landing action, a value for gravity and the vertical starting position of their landers, for which they sought and found a new gauge, previously not used.
Attempts to minimise fuel use became more sophisticated. The boys realised that with their agreed safe landing speed of 30 metres per second, they needed only to keep just below this figure to ensure a safe landing and minimal fuel consumption. Before this they had been trying to reduce the velocity to the minimum regardless of fuel use.
In summary, the competitive element of the two-player version was an enormous motivation to the students: they loved seeing the opposition's ship on their screen and being able to monitor its progress through gauges. The students became wildly excited during landings.
Reflections on design
Overall the software did allow access to diverse students at many layers of learning. It stimulated huge interest and discussion and students used quite sophisticated ideas in pursuit of their game making and playing. The students evaluated the sessions and were all positive: but came up with many ideas for improvement. For example, they 267 suggested the need to reduce the amount of reading required in the initial stages and simplify some terminology that was too complex in places. The students suggested that a choice should be offered between reading and listening to instructions and that more complex instructions might be communicated through demo buttons or tutorials - for example showing them how to set up a gauge or to use a behaviour gadget.
Perhaps the most interesting suggestion was that the software might be structured into what they described as "levels", such as those commonly found in computer games.
Where the lunar lander software failed to meet the initial expectations was in giving students easy access to the programming code and in creating situations where they would want to analyse and adjust that code. It would seem possible that if the software were remodelled into a series of levels - corresponding in some way to the previously defined expected layered learning model - analysis and use of the relationships inspectable in the programming code or as recorded by the autopilot could become not just a real possibility but an integral part of the game.

IT in Singapore Mathematics Education
Kho Tek Hong, Ministry of Education, Singapore
KHO_Tek_Hong@moe.gov.sg
Introduction
The Singapore's second Masterplan for IT in Education (2002 - 2008), following the first masterplan
37
, provides the overall direction on how schools can harness the possibilities offered by IT for learning. For mathematics education, the emphasis is increasingly on using IT to enable and support the teaching and learning. To achieve this would require curriculum and pedagogical changes, the professional development of teachers, and a paradigm shift in teaching and learning.
Integration of IT and Pedagogy
The Singapore school mathematics framework has 5 inter-related components, namely, Concepts, Skills, Processes, Attitudes and Metacognition. (As shown)
The framework was developed in 1990, and has been updated in 2000 and 2005.The new emphases include "Reasoning, communication and connections" and "Application and modelling". IT can play an important role in supporting the development of these.

37
The first masterplan (1997 - 2002) has created an IT-enriched learning environment. All schools have an IT infrastructure with a good range of learning resources. Teachers generally have acquired basic proficiency in IT knowledge and skills.

A Pedagogy-Driven Model
The development of IT-supported learning resources involves 3 aspects, namely, pedagogy, technology and resources. A successful development would depend much on an effective integration of IT and pedagogy. We would like to propose the following pedagogy-driven model for the development of learning resources for mathematics:
The model involves the development of IT tools to support certain pre-determined pedagogical approaches. Students will use the IT tools to help them understand mathematics concepts and processes. The tools, in turn, will allow students to construct mathematics concepts and models, and to share and discuss their constructions, and the system will provide feedback to facilitate the learning process. Thus students will be actively engaged in an interactive and collaborative learning environment.
Conclusion
We are constantly improving the way we teach mathematics, paying greater attention to the processes of learning mathematics. For example, the Concrete-PictorialAbstract approach
38
, grounded in Bruner's theory of constructivism
39
and Vygotsky's
theory of zone of proximal development
40
, has proven to work in our Primary Mathematics curriculum. This approach is now extended to learning algebra, for the development of conceptual understanding through carefully planned, developmentally- and age-appropriate strategies. With IT support and enhancement, students will develop not only deep understanding of algebra concepts and processes, but also the skills of reasoning and communication, which are required by our school mathematics framework. The aim is to prepare students to meet the challenges of the 21
st
century.

38
This approach was developed by MOE in the 1980s, and has become the basis of our mathematics education. It was inspired by Bruner's classical book: The Process of Education (1960) in which he presents three levels of representation of knowledge: enactive, iconic and symbolic representations.
39
Bruner defines constructivist learning as an active process in which learners construct new ideas or concepts based upon their current and past knowledge.
40
Vygotsky defines the zone of proximal development as the distance between the actual developmental level for independent problem solving and the level of potential development with adult guidance or with more capable peers.

The discrete continuous interplay. Will the last straw break the camel's back?
%%%
Ivy Kidron, Thierry Dana-Picard,
Department of Applied Mathematics,
Jerusalem College of Technology, Israel
ivy@jct.ac.il, dana@jct.ac.il
We investigate the influence of the technology and in particular the influence of the discrete continuous interplay, which can be demonstrated by the technology, in enhancing students' mathematical thinking. We analyze how students' awareness of the limitation of discrete numerical methods, combined with error analysis, lead to a better understanding of the continuous methods. We identify the new potential offered by the instrumented work, the way students are influenced by their interaction with the Computer Algebra System and the presence of mental images created by this interaction, even when the computer is turned off. We also identify the inability of some students to differentiate between error due to mathematical meanings and error due to meanings specific to the "instrument". Our intention is to employ the possibilities offered by the technology, to elaborate activities based on the discretecontinuous interplay and to investigate their influence on students' thinking processes in relation to the notion of limit in the derivative concept.
Introduction
The cognitive difficulties that accompany the learning of concepts that relate to the continuous such as limit and derivative are well known. Our empirical approach leads us to consider the interplay between the continuous and the discrete, and to examine how to use it to help students enhance their conceptual understanding of these central notions. The discrete continuous interplay is not new. It existed before the computer age. The founders of the mathematical theory developed numerical discrete approaches to better understand dynamic continuous processes. In the last decade, the use of technology, especially the Computer Algebra Systems (CAS), offers a new mean in the effort to overcome some of the conceptual difficulties. We focus on the "instrumentation process" (i.e. how the tool becomes an effective instrument of mathematical thinking for the learner) in analyzing students' reactions in the context of activities based on the complementary aspect of discrete and continuous approaches.
The instrumentation theory
The instrumental approach is a specific approach built upon the instrumentation theory developed by Verillon and Rabardel (1995) in cognitive ergonomics and the

%

anthropological theory developed by Chevallard (1992). The term 'instrumentation' is explained in Artigue (2002): The "instrument" is differentiated from the object, material or symbolic, on which it is based and for which the term "artifact" is used. An instrument is a mixed entity, in part an artifact, and in part cognitive schemes which make it an instrument. For a given individual, the artifact becomes an instrument through a process, called instrumental genesis. This process leads to the development or appropriation of schemes of instrumented action that progressively take shape as techniques that permit an effective response to given tasks.
The instrumentation theory focuses on the mathematical needs for instrumentation, on the status of instrumented techniques as well as on the unexpected complexity of instrumental genesis (Artigue (2002), Guin and Trouche (1999), Lagrange (2000)). We can take advantage of the new potentials offered by the instrumented work, for example, by means of discretization processes. Artigue (2002) warns us that the learner needs more specific knowledge about the way the artifact implements these discretization processes. Thus, it is important to be aware of the complexity of the instrumentation process. Working with a CAS introduces the learner to a system of "double reference" (Lagrange, 2000): on the one hand, he is introduced to mathematical meanings; on the other hand, he is introduced to meanings that are specific to the constraints of the instrument. Being aware of the limitation of the instrument might be helpful. Steiner and Dana-Picard (2004) demonstrate how to make advantage of the analysis of the error due to the limitation of the CAS to help students understand the theory of integration.
As a background to the present study, we present some cognitive difficulties that accompany the understanding of the limit concept.
Conceptualization of the continuous
In previous studies concerning the way students conceived real numbers, Kidron & Vinner (1983) observed that the infinite decimal is conceived as one of its finite approximation " three digits after the decimal point are sufficient, otherwise it is not practical" or as a dynamic creature which is in an unending process- a potentially infinite process: in each next stage we improve the precision with one more digit after the decimal point. This is not in accord with the mathematical view as expressed by Courant (1937). Courant wrote that if the concept of limit yielded nothing more than the recognition that certain known numbers can be approximated to as closely as we like by certain sequences of other known numbers, we should have gained very little from it. The fruitfulness of the concept of limit in analysis rests essentially on the fact that limits of sequences of known numbers provide a means of dealing with other numbers which are not directly known or expressible. Thus, the limit concept should lead to a new entity and not just to one more digit after the decimal point.
The derivative function is defined as
h
f x h f x
f x
h
( ) ( )
( ) lim
0
+ !
=
&
. By means of
animation and elementary programming in a Computer Algebra System, students can 272
visualize the process of
h
f(x + h) ! f(x)
approaching f (x) for decreasing h. The
dynamic picture might reinforce the misconception that one can replace the limit by
x
y
'
.
for 'x very small. How small? If we choose 'x =0.016 instead of 0.017, what
will be the difference? There is a belief that gradual causes have gradual effects and
that small changes in a cause should produce small changes in its effect (Stewart,
2001). This belief might explain the misconception that a change of, say, 0.001 in
'x will not produce a big change in its effect.
The discrete continuous interplay
We were interested in a counterexample that will demonstrate that one cannot replace
the limit "
x
y
x'
.
' &0
lim " by
x
y
'
.
.
for 'x very small and that omitting the limit will
change significantly the nature of the concept. The counterexample was found in the
field of dynamical systems. A dynamical system is any process that evolves in time.
The mathematical model is a differential equation dy/dt = y' = f(t,y) and we
encounter again the derivative
t
y
y
t'
.
=
' &0
' lim . In a dynamical process that changes with
time, time is a continuous variable. Using a numerical method to solve the differential
equation, there is a discretization of the variable time and the passage to a discrete
time model might totally change the nature of the solution. In the following
counterexample (the logistic equation), the analytical solution obtained by means of
continuous calculus is totally different from the numerical solution obtained by
means of discrete numerical methods. Moreover, using the analytical solution, the
students use the concept of the derivative
x
y
x'
.
' &0
lim . Using the discrete approximation
by means of the numerical method the students use
x
y
'
.
for small 'x . We will see
that the two solutions, the analytical and the numerical, are totally different.
The design of the learning experiment
The learning experience is described in a pilot study (Kidron, 2003). We report it
here for the convenience of the reader. The students (first year College students in a
differential equations' course) were given the following task: a point (t y,) 0 0
and the
derivative of the function dy/dt=f(t,y) are given. Plot the function y(t). The students
were asked to find the next point (t y,) 1 1
by means of (y y)/(t t) f(t y,) 1
! 0 1
! 0
= 0 0
. As t
increases by the small constant step t t □t 1
! 0
= , the students realized that they are
moving along the tangent line in the direction of the slope f(t y,) 0 0
. The students
generalized and wrote the algorithm: y □t f(t ,) n 1 n n n
y = + y +
for Euler's method. They
were asked how to better approach the solution. They proposed to choose a smaller
step □t . 273
The logistic equation dy/dt = r y(t) (1-y(t)), y(0) = 0
y was introduced as a model for
the dynamics of the growth of a population. An analytical solution exists for all
values of the parameter r. The numerical solution is totally different for different
values of □t as we can see in the graphical representations of the Euler's numerical
solution of the logistic equation with r = 18 and y(0)=1.3.
Fig. 1
In the first plot, the solution tends to 1 and looks like the analytical solution. In the
second, third and fourth plot, the process becomes a periodic oscillation between two,
four and eight levels. In the fourth plot, we did not join the points, in order that this
period doubling will be clearer. In the fifth and sixth plot, the logistic mapping
becomes chaotic. We slightly decrease □t in the seventh plot. For the first 40
iterations, the logistic map appears chaotic. Then, period 3 appears. As we increase
□t very gradually we get, in the eight plot, period 6 and, in the ninth plot period 12
and the belief that gradual causes have gradual effects is false! The fact that a
small change in a parameter causes only a small effect, does not necessarily imply
that a further small change in the parameter will cause only a further small change in
the effect. We knew this long ago. We just did not realize there was a mathematical
consequence. Take, for example, the proverb: the last straw breaks the camel back
(Stewart, 2001)
Findings and Discussion
First year college students in an innovative differential equations' course (N=60),
were the participants in the research. The first author taught the course. The students
interact with the Mathematica software in the exercise lessons which were held in the
PC laboratories. Mathematica was also used during the lectures for demonstrations.
We examined the students' reactions when they realized that the approximate
solution to the logistic equation by means of discrete numerical methods is so
different from the analytical solution. The students were given written questionnaires 274
before and after being exposed to the logistic equation. Some of the students were
also interviewed and invited to explain their answers. We present the analysis of the
students' reactions in the light of the instrumentation theory.
Awareness of the limitations of the numerical method
Before being introduced to the logistic equation, the students were asked if a very
small value for the step size □t in Euler's method will assure a good approximation to

the solution: 80% of the students claimed that a small value for □h might be not small enough. They connect their claim to the limitations of the numerical method. Some students also pointed out the fact that the error in the numerical method accumulates.
The influence of previous experiences in the PC lab on the students thinking processes
The students were influenced by previous experiences in the PC lab even if these experiences took place in other courses.
Irit: We worked on several examples in which we noticed that the more points, the smaller □h and the better the approximation BUT I think that not every function will behave this way. We encountered in the lab, in relation to another subject, a function with a special behavior: In spite of the fact that we added interpolation points, the function did not behave the way we expected. I think it was
( )
2
1
1
( )
x
f x
+
= . Usually,
the more points, the better is the approximation but it is not always the case.
Irit referred to Runge's example. The students worked in the lab looking for polynomial approximations to the function with equidistant interpolation points.
The belief that gradual causes have gradual effects
Before being exposed to the logistic equation, the students were asked to express their opinion about the following statement:" If in Euler's method, using a step size □h = 0.017 we get a solution very far from the real solution, then a step size □h = 0.016 will not produce a big improvement, maybe some digits after the decimal point and no more". The belief that gradual causes have gradual effects was expressed in 53% of the students' answers "it seems to me that if with □h = 0.017 we didn't get a good solution, then □h = 0.016 will not produce a big improvement either". 31% of the students who claimed that gradual causes have no necessarily gradual effects explained their answer by the fact that "There are functions which oscillate very quickly" or by means of the accumulating effect 275
"I think that we use an iterative procedure to find yk+1
, namely, we perform the
algorithm on yk
in order to find yk+1
and so on… After several iterations, we
accumulate differences in the value of yk+1
that might be significant therefore we
might get a big improvement even with a slightly smaller □h ".
The (in)ability to differentiate between error due to mathematical meaning and error due to the instrument
After being exposed to the logistic equation, the students were asked to characterize the source of error in Euler's method. We investigate whether the students realize that the source of error is the fact that in the numerical method the limit has been omitted in the definition of the derivative.
• The students' attention might be distracted by the round off error
The students' attention might be distracted by the round-off error especially if in previous experience with the computer they encountered such kind of round off error. This happened to a student, Hadas, which atributed the error to the round-off effect
Hadas: I remember from an exercise in the Calculus course that the solution with Matlab was 0 but the solution using the symbolic form was 0.5. When we tried to understand why this happened we realized that MatLab computes only 15 digits after the decimal point.
Hadas refered to an episode in the Calculus course in which the students were given the function
6 12
f(x) = -1 (cos(x))/x and they had to explain why some graphs of f might
give false information about lim f(x) xß0
. The limit is " but both Mathematica and
MatLab give the answer 0 when we evaluate the function for x = 0.01. Working the exercise in the PC lab, the students understood that the computer with its limited precision gives the incorrect result that -1 cos(x)
6
is 0 for even moderately small values
of x.
By means of error analysis, we planned to help the students to better understand the continuous methods and the concept of limit. But, working with a CAS, there are other unexpected effects that are directly linked with the "instrument" and the way it influences the students' thinking. In addition to the error due to the discretization process, to the fact that an algorithm that belongs to a numerical method is used to solve the logistic equation in place of the analytical method, there are other sources of error that are directly related to the "tool".
• The students' attention might be distracted by the accumulative effect
22% of the students explained the error by means of the accumulative effect.
• Round off and accumulating effect could not be the only source of error but the students cannot find the exact source of error
This view was expressed in answers like the following: 276
"The software has some limitation concerning the number of digits after the decimal point and it seems that this fact has enough strength (due to the accumulative effect) to influence the solution with Euler's method. But this fact by itself could not cause the crazy behavior of the function" or:
"The round-off is not the crucial part. There is a change in the analytical behavior. We do expect for a change due to the round off, but we expect to a change "in numbers" not in the qualitative behavior".
• The students relate the error to discrete - continuous considerations, but without a mention of the limit or of the formal definition of the derivative.
23% of the answers expressed well developed qualitative approach to differential equations, adequate to explain why there is an error, but inadequate to give a formal account how the discrete method employed the derivative concept.
• The students relate the error to the fact that in the numerical solution the limit is omitted in the definition of the derivative.
This was expressed in 19% of the answers. Some students reached this conclusion by means of mental images created by previous experiences with the instrument. These images were also present when the computer was turned off. This is expressed in the following:
"We have worked this week an exercise that demonstrates that a small change in the initial condition of a differential equation might cause a large change in the solution. Maybe the small error made in the Euler's method induced big changes in the graph of the solution curve also in our case" or:
"A difference of 0.001 might be crucial if it leads to the crossing of an equilibrium solution and therefore to a transition to a zone with totally different slopes like in the example.."
The student related to a figure describing a previous experience in the lab
"In the absence of an equilibrium solution, the error would have increased but there would not have been crucial changes. The error increased but we noticed it only because the equilibrium solution". In connection to the metaphor of the straw and the camel's back, the student added: if there was no equilibrium line, the camel would not have fall down!
Concluding remarks
The emphasis in this research study is laid on the way we take advantage of the discrete continuous interplay to identify the new potentials offered by instrumented work but also on identifying the constraints induced by the instrument. The "instrument" plays a very important role. It enables the students to "see" the significant difference between the discrete and the continuous methods. It also helps 277 the students to analyze qualitatively the behavior of the solution and to connect it with former experiences. Mathematica enables to change very slightly the value of a parameter and to plot the solution. The role played by the instrument is very important and enable the new potentials offered by the instrumented work. However, the percentage of students who did not find the source of error in the numerical method, demonstrated that it might have not been enough to expose the students to a counterexample. Students have to be faced with the necessity of developing schemes that will help them to differentiate between error due to mathematical meanings and error due to meanings specific to the instrument (Artigue, 2002).

The study presented in this report is part of a larger project on the intertwining coemergence of technique and theory within a CAS-based task environment for learning algebra, which also includes paper-and-pencil activity. The theoretical framework consists of the instrumental approach to learning mathematics with technology, in particular Artigue and colleagues' adaptation of Chevallard's anthropological theory. The theme presented herein is that of equivalence, equality, and equation. Two 10
th
grade classes were taught by the same mathematics teacher during two successive years, using project materials designed by the research team. Classroom observations, student interviews, student activity sheets, and posttest responses were the main data sources used in the analysis. Findings attest to the intertwining of technique and theory in algebra learning in a CAS environment. In addition, the data analysis revealed that probably the most productive learning took place after the CAS techniques provided some kind of confrontation or conflict with the students' expectations, based on their previous theoretical knowledge. Even if such conflicts in applying CAS techniques may seem to be hindrances to students' progress, in fact our experience suggests that they should be considered occasions for learning rather than as obstacles. However, a precondition for these conflicts to foster learning is their appropriate management in the classroom by the teacher.
Introduction
School algebra has traditionally been an area where technique and theory collide, with technique usually claiming victory. While a parallel with the terms skills/procedures and concepts may suggest itself, both technique and theory are broader in meaning than procedures and concepts (Artigue, 2002). The notion that school algebra can be an arena for the interaction of both theory and technique has not taken hold until recently. The advent of computer algebra systems (CAS) technology in schools, along with the development of theoretical frameworks for interpreting how such technology becomes an instrument of mathematical thought, have both been contributing factors.
The instrumental approach to tool use encompasses elements from both cognitive ergonomics (Vérillon & Rabardel, 1995) and the anthropological theory of didactics (Chevallard, 1999). An essential starting point in the instrumental approach is the distinction between an artifact and an instrument. Whereas the artifact is the object 279 that is used as a tool, the instrument involves also the techniques and schemes that the user develops while using it, and that guide both the way the tool is used and the development of the user's thinking. The process of an artifact becoming an instrument in the hands of a user -- in our case the student -- is called instrumental genesis. The instrumental approach was recognized by French mathematics education researchers (e.g., Artigue, 1997; Lagrange, 2000; Trouche, 2000; Guin & Trouche, 2002) as a potentially powerful framework in the context of using CAS in mathematics education.
As Monaghan (2005) pointed out, one can distinguish two directions within the instrumental approach. In line with the cognitive ergonomic framework, some researchers (e.g., Trouche, 2000; Drijvers, 2003) see the development of schemes as the heart of instrumental genesis. Although these mental schemes develop in social interaction, they are essentially individual. Within the schemes, conceptual and

technical elements are intertwined. More in line with the anthropological approach, other researchers focus on techniques that students develop while using technological tools and in social interaction. The advantage of this focus is that instrumented techniques are visible and can be observed more easily than mental schemes. Still, it is acknowledged that techniques encompass theoretical notions. The focus on techniques is dominant in the work of Artigue (1997, 2002) and Lagrange (2000) in particular.
The study
Theoretical framework: Task-Technique-Theory
Chevallard's anthropological theory of didactics, which incorporates an institutional dimension into the mathematical meaning that students construct, describes four components of practice by which mathematical objects are brought into play within didactic institutions: task, technique, technology, and theory. (By technology, Chevallard means the discourse that is used to explain and justify techniques; he is not referring to the use of computers or other technological tools.) In their adaptation of Chevallard's anthropological theory, Artigue and her colleagues have collapsed technology and theory into the one term, theory, thereby giving the theoretical component a wider interpretation than is usual in the anthropological approach. Furthermore, Artigue notes that technique also has to be given a wider meaning than is usual in educational discourse.
Lagrange (2003, p. 271) has elaborated this latter idea further: "Technique plays an epistemic role by contributing to an understanding of the objects that it handles, particularly during its elaboration. It also serves as an object for a conceptual reflection when compared with other techniques and when discussed with regard to consistency." It is precisely this epistemic role played by techniques that is a focus of our study, that is, the notion that students' mathematical theorizing develops as their techniques evolve. It is noted, as well, that our perspective on the co-emergence of theory and technique is situated within the context of technological tool use, where 280 the nature of the task plays an equally fundamental role. Thus, the triad TaskTechnique-Theory (TTT) served as the framework not only for constructing the tasks of this study, but also for gathering data during the teaching sequences and for analyzing the resulting data.
Aim of the study
The research study, of which this report is a part, is an ongoing one. It has as a central objective the shedding of further light on the co-emergence of technique and theory within the CAS-based algebraic activity of secondary school students. Because of severe space restrictions, this report will highlight the design and findings from one task set, that of equivalence, equality, and equation.
Participants
The research involves six intact classes of 10
th
graders (15-year-olds) in Canada and
Mexico, as well as a class of older students in Oregon. Five of the 10
th
grade classes
were observed during the 2004-05 school year; the sixth class, the following year.
Two of these 10
th
grade classes are featured in this report – one from the 2004 study
and the other from the 2005 study. Both classes were taught by the same teacher, with five years of experience. He is a teacher who, along with encouraging his pupils to talk about their mathematics in class, believes that it is useful for them to struggle a little with mathematical tasks. He elicits students' thinking, rather than quickly giving them answers. The students in this report had already learned a few basic techniques for solving linear and quadratic equations during their 9
th
grade mathematics course
and had used graphing calculators on a regular basis; however, they had not had any experience with the notion of equivalence, one of the theoretical ideas developed in the project materials, nor with symbol-manipulating calculators (i.e., the TI-92 Plus CAS machines used in this project).
Data sources
All project classes were observed and videotaped (12-15 class periods for each of the seven project classes). Students were interviewed, alone or in pairs, at several instances -- before, during, and after class. A posttest involving CAS was administered after the task set on equivalence had been completed. All students were pretested. Thus, data sources for the segment of the study presented in this report include the videotapes of all the classroom lessons, videotaped interviews with students, a videotaped interview with the teacher, the activity sheets of all students (these contained their paper-and-pencil responses, a record of CAS displays, and their interpretations of these displays), written pretest and posttest responses, and researcher field notes.
Task design 281
The research team created several sets of tasks that aimed at supporting the coemergence of technique and theory. Because paper-and-pencil techniques were a fundamental part of the algebra program of studies of the schools where the research was carried out, and because we believe in the importance of combining the two media, they too were included in the teaching sequences. Task sets were planned to take from one to five periods. For the task set described in this paper, one class took three periods, and the other, four. Each task set involved student work, either with CAS or paper-and-pencil or both, reflection questions, and classroom discussion of the main issues raised by the tasks. In designing the tasks, we took seriously both the students' background knowledge and the fact that these tasks were to fit into an existing curriculum; but we also did our best to ensure that they would unfold in a particular classroom culture that reflected a certain priority given to discussion of serious mathematical issues. Tasks that asked students to write about how they were interpreting their work and the related CAS displays aimed to bring mathematical notions to the surface, making them objects of explicit reflection and discourse in the classroom, and clarifying ideas and distinctions, in ways that simply "doing algebra" may not require.
The task set on equivalence, equality, and equation
The underlying motive of this task set is the subtle relationship between arithmetic and algebra: on the one hand, the numerical world is the most important motive and model for the world of algebra, on the other hand algebra goes beyond the numerical world, which is in fact part of its power. This two-sided relationship is reflected in the notion of equivalence of algebraic expressions (see Kieran & Saldanha, 2005; Saldanha & Kieran, 2005). Equivalence of two expressions relates to the numeric as it reflects the idea of 'equal output values for each of an infinite set of input values.' However, equivalence of two expressions also relates to the algebraic in that the expressions can be rewritten in a common algebraic form.
At the start of the teaching sequence, numerical evaluation of expressions by using CAS and comparison of their resultant values are used as the entry points for discussions on equivalence. One of the core tasks here aims at students' noticing that some pairs of expressions seem to always end up with equal results, and thus evokes the notion of equivalence based on numerical equality. The algebraic expressions included in the task were fairly complex so as not to permit the evaluation of equivalence by purely visual means. The task is followed by a reflection question on what would happen if the table of values were extended to include other values of x. The task and the CAS substitution technique lead to the following definition of equivalence of expressions, with deliberate inclusion of the idea of a set of admissible values:
We specify a set of admissible numbers for x (e.g., excluding the numbers where one of the expressions is not defined). If, for any admissible number that replaces x, each 282 of the expressions gives the same value, we say that these expressions are equivalent on the set of admissible values.
The impossibility of testing all possible numerical substitutions to determine equivalence motivates the use of algebraic manipulation and the explicit search for common forms of expressions in the second part of the task set. Different CAS techniques can be used: Factor, Expand, Automatic Simplification. An additional technique is the "Test of Equality," which involves entering an equation, followed by the Enter button. In this test, the CAS checks both sides of the equation for equivalence, by means of automatic simplification and other 'black-box' means. The CAS will come up with 'true' in cases of equivalence (see Figure 1). Restrictions are ignored, just as with Automatic Simplification. The Test of Equality technique has probably the most 'black-box' character, and the output it produces is the most difficult to interpret, especially for cases of non-equivalence. This CAS technique was deliberately introduced in the design of the tasks so as to provoke student questioning of its output.
Fig.1: Illustration of the "Test of Equality" and the way that the
TI-92 neglects restrictions
In the next part of the task set, the relation between two expressions being equivalent or not, and the corresponding equation having many, some, or no solutions is explored in both CAS (Solve now introduced) and paper-and-pencil tasks. For example, students are asked to generate a pair of equivalent expressions, and, in a similar follow-up task, two non-equivalent expressions. The ensuing reflection question concerns the relation between the nature of an equation's solution(s) and the equivalence or non-equivalence of the expressions that form the equation.
Analysis of student activity
Three theoretical elements were found to be intertwined and related to the techniques and tasks of this segment of the data analysis, and thus serve to organize the discussion of results: i) The numeric and algebraic views on equivalence; ii) The issue of restrictions; and iii) Coordination of the notions of equivalence and solution of an equation. 283
The numeric and algebraic views on equivalence
Students seemed to have an intuitive idea of equivalence as having always the same numerical value, even if this was sometimes expressed in an informal way. This notion was clearly supported by the CAS substitution technique, which makes numerical substitutions easy to carry out. The repeated substitution with the CAS presented the students with the phenomenon of equal values, which invited algebraic generalization. Still, the relation between the algebraic and the numeric was somewhat vague. The Factor, Expand and Automatic Simplification techniques are on a more algebraic level, but seem to foster the notion of common form as 'simple' form. That is, some students tended to interpret the simplified forms produced by these commands as ordinary or basic or common, and thought that this was what we meant when we asked them to express a pair of expressions in a common form. The Test of Equality technique is probably the most interesting one from the conceptual point of view, as it seems to act at the borderline between the numeric and the algebraic. This technique provides 'true' in cases of equivalence, but just returns the (sometimes transformed) equation in other cases. The latter was difficult to understand for many students, as they would have expected something like 'false'; whereas returning an equation -- so two expressions with an equal sign in between -- unjustly suggested equivalence to them.
The verbatim in Figure 2 illustrates that Suzanne found the output of this CAS test surprising. She tried to interpret it by means of her existing theoretical thinking, but was unable to do so satisfactorily. In spite of the confusion that she expresses in the last line, we appreciate that she takes it as an incentive to rethink about her conceptions. In fact, that is what the tasks and techniques, if dealt with properly by the teacher, can provoke: a rethinking of the theoretical knowledge. The classroom discussion that followed did help to move Suzanne's thinking forward.
Suzanne Uhm, I entered the problem (20)(3 2)1 3( )(1)(2)5
2 2 2
x + x! x + x! = x! x ! x! x+ and it
gave me pretty much the same problem back, but rearranged, it's the same answer. When you think that the other one said "true," it is kind of puzzling. … The answer that it gave me. I figure that that's this statement, like the first expression equals the second expression is true. … When I see an equal sign, I figure they are equivalent, the same.
[…]
Interviewer How would you now interpret such a display when you enter in two expressions like that?
Suzanne Uhm, that it can be right sometimes, but isn't always right. With specific numbers, it is correct.
Interviewer So, when you mean correct?
Suzanne That you would get the same number in the end on both sides. But only sometimes. 284
Interviewer Only for some numbers.
Suzanne Yah.
Interviewer So how do you feel about that?
Suzanne I'm still confused. With the "true"s and the "="s, to me it all has sort of the same meaning. I guess I just have to change my way of thinking.
Fig. 2. Confusion about the CAS returning the equation for the case of nonequivalence
A second issue that is related to the role of techniques in the evolution of the students' thinking about equivalence concerned the coordination of different techniques as a means to check consistency. In several cases, students used different techniques, both paper-and-pencil and CAS, to verify the consistency of their theorizing. Surprising CAS results in some cases gave rise to conflicts that invited reasoning. For example, at first Andrew was puzzled when the CAS simplified 2(! x)(1! 2x) as (x ! 2)(2x !1). After some thinking about this, he found a justification that involved the technique of substitution:
"I think since it's switching them both that it works out. Let's just say x was represented by 6, -4 times -11, which is 44. And the other one it's 6 2, which is 4 □ times 11, which is also 44. It's just two negatives, since it's switching both of them it's OK."
By the way, this verbatim shows the student's returning to the numerical to check algebraic relations -- not a bad habit of course. Still, when so asked, Andrew indicated that he had several means to check algebraically the equivalence of 2(! x)(1! 2x) and (x !)(2 2x !)1 , such as entering the corresponding equation or expanding them both. The other students also used these CAS techniques to check their consistency with by-hand results.
The issue of restrictions
The question of how to deal with restrictions, both with CAS and paper-and-pencil techniques, played a role in the algebraic view on equivalence. It also disclosed limitations in certain students' thinking about zero in fractions and dividing by zero. This was the case for Andrew when dealing with the equivalence of two particular

expressions: (3x !1)(x
2
! x ! 2)(x + 5) and
(x
2
+ 3x !10)(3x !1)(x
2
+ 3x + 2)
x + 2
. At first, he had
difficulties with identifying the restriction of x = !2 . The question to consider the denominator revealed a misconception: "If x were -2 then the denominator would be - 2 plus 2, which is zero and anything over zero is equal to zero. One over zero equals to zero," he said. After some intervention, Andrew concluded that the result of division by zero is undefined, but it remained unclear about whether another zero might appear somewhere. To check this out, he substituted x = !2 into the first expression and got -84 as a result, clearly not zero. So, he concluded: "Basically, it 285 will work with everything except the !2." Then he substituted x = !2 into the expanded form of the first expression, which of course gave !84 once more. This seemed to be a check for consistency, although he was not completely sure about what to expect. Then he wondered about the value of the second expression when x = !2 would be substituted. He expected -84, but the calculator displayed 'undefined.' He explained this as follows:
"That's what I figured out that it should be, undefined, but I didn't think the calculator would show it. Just based on all the other results, just based on the fact that this came out to -84, and this came out to -84. … Well like it substitutes it and then it fills everything in and anything divided by zero is undefined, no matter what the equation is on top, it's still divided by -2 plus 2, so it's undefined."
Andrew's fuzzy thinking about rational expressions, division by zero, and substitution of inadmissible values into the numerator interacted with his expectation of a certain CAS output. He was, however, eventually able to provide a technical interpretation that made sense to him about how the CAS produced 'undef' – as disclosed by his last comment.
Coordination of the notions of equivalence and solution of an equation
Results concerning the coordination of solutions and equivalent/non-equivalent expressions were mixed. For example, after students had generated a pair of equivalent expressions and were asked what they could say about the solutions of the equation formed from this pair -- but without actually solving the equation -- half the students' responses included true, equal, equivalent, and did not refer explicitly to solutions of the equation. Furthermore, the word solution itself seemed problematic. While some students were able to relate the set of equation solutions to the equivalence of the two expressions involved, this remained unclear for others. The Solve technique in itself was not a problem for the students; but its coordination with the other techniques on equivalence required a change of perspective, which was not easy. Evidence suggests that a language issue is involved here as well: students use the word 'solve' for any operation leading to a result, the result being called the 'solution.'
Concluding remarks on equivalence, equality, and equation
If we consider our findings on the task set of equivalence, equality, and equation in retrospect, two main issues come to the fore: the relation between students' theoretical thinking and the techniques they use for solving the proposed tasks, and the specific role of the confrontation of CAS output with students' expectations. To elaborate on the first point, our findings suggest that the relation between Theory and Technique, as it is established while working on appropriate Tasks, can hardly be underestimated. On the one hand, the development of students' theoretical thinking was guided by the techniques that the tasks invited; on the other hand, students' 286 conceptions influenced the development of these techniques. More specifically, students' numerical view on equivalence of expressions was found to be related to three techniques: the numerical substitution technique, and, to a lesser extent, the Test of Equality and the Solve technique. The fact that students seemed to give priority to a numerical view on equivalence was tied to their use of the numerical substitution technique to check equality. In the emergence of an algebraic view on equivalence, the CAS techniques Factor, Expand, Automatic Simplification, and Test of Equality played important roles, even to the extent that the factored and expanded forms were considered as common forms. Finally, with regard to relating the numeric and the algebraic views on equivalence, students had difficulties with the coordination of the Solve technique and the techniques on equivalence; nevertheless, classroom discussion of these techniques turned out to be quite productive.
To elaborate on the second point, the data analysis revealed that probably the most productive learning took place after the CAS techniques provided some kind of confrontation or conflict with the students' expectations, based on their previous theoretical knowledge. The students' seeking for consistency evoked theoretical thinking and further experimentation. Also, the fact that the CAS Automatic Simplification technique and the Test of Equality both neglect restrictions led to an increasing awareness of the importance of these 'exceptions.' Finally, the CAS just returning an equation in cases of non-equivalence struck the students, and gave rise to interesting discussions on the interpretation of the output, as did the interpretation of 'true' and 'false' in cases of numeric or algebraic application of the Test of Equality. Even if such complications in applying CAS techniques may seem to be hindrances (see Drijvers, 2002) to students' progress, in fact our experience suggests that they should be considered occasions for learning rather than as obstacles. However, a precondition for these complications to foster learning is their appropriate management in the classroom by the teacher.
Acknowledgments
The research presented in this report was made possible by a grant from the Social Sciences and Humanities Research Council of Canada – INE Grant # 501-2002-0132. We express our appreciation to the two classes of students, and teacher, who participated in the research. In addition, we are grateful to Texas Instruments for providing the TI-92 Plus calculators and view screens used in the study. The impact of the use of graphics calculator on the learning of statistics: a malaysian experience
Kor Liew Kee Lim Chap Sam
MARA University of Technology University Science Malaysia
korlk564@kedah.uitm.edu.my cslim@usm.my
Educational tool such as the graphics calculator (GC) is increasingly being used in school and college mathematics worldwide. In Malaysia, the Ministry of Education together with a couple of GC distributing companies (such as CASIO and TEXAS INSTRUMENTS) has conducted a series of GC workshops to train the secondary school mathematics and science teachers. To date, undergraduate mathematics integrating the use of GC has already been offered in the local universities. This paper emphasizes on the impact of GC in the learning of statistics. Even though many research findings have reported favourable use of GC in the teaching and learning of mathematics, the effect and the impact of GC however, could be different in a diverse learning environment. In the study conducted, students' thinking and feeling towards engaging GC in their learning process were explored through observation, students' written self-reflection and interviews. Analysis of the data highlighted three major changes in the students' learning process that engaged the use of GC. These three changes are students' perceived value of GC, changes in the norm classroom practices and changes in the perceived peer status.
Background
Educational tool such as the graphics calculator (GC) is increasingly being used in school and college mathematics worldwide. New ideas for graphing technologies are continuously being featured at international conferences as well as published in mathematics educational journals. The integration of such innovative technology in the mathematics classroom is anticipated to bring about changes in the approach in completing a mathematical task. Studies over the past (Arcavi & Hadas, 2000; Selinger & Pratt, 1997) have shown that GC can be used in ways that can promote and enhanced learning of mathematical concepts through visualization, symbolic, algebraic and graphic presentations. In addition, there are studies (Cedillo, 2001; Ruthven, 1990) that shown using of GC might enhance students' thinking skills in mathematics such as analyzing, reasoning and translation to algebraic or symbolic form.
In Malaysia, the integration of GC in the teaching and learning of mathematics has received much attention from the Ministry of Education (MOE), though the pick up is still slow. Since mid-2003, the MOE has been sponsoring educational officers and mathematics teachers to attend short-term GC training courses or workshops as part of their professional development program. With the support of the MOE and the initiative given by a couple of GC distributing companies (such as CASIO and 289 TEXAS INSTRUMENTS), a series of GC workshops was conducted to train the secondary mathematics and science teachers in 388 schools throughout Malaysia. Besides these training, each participating school was given a classroom set (40 units) of GC from the MOE. This program is planned to continue until the majority of the mathematics teachers are familiar to the practice of using the GC technology. In addition, the teachers training colleges have also taken drastic measure to gain access to the portable mathematical tool in order to equip more trainee teachers with the GC knowledge.
To date, undergraduate mathematics applying the GC knowledge has been offered in certain local universities (Rosihan et. al, 2002; Rosihan & Kor, 2004). However, the use of GC in mathematics at school level is still very limited. Nevertheless, more and more schools and higher institutions throughout Malaysia are encouraged to use GC in the teaching and learning of mathematics. For example, the latest curriculum specification of the Secondary Mathematics Syllabus 2005 has explicitly recommended the use of GC and GSP in the teaching and learning activities. Consequently, new mathematics textbooks that incorporate graphing technologies as part of the solution steps inevitably help to provide impetus to intensify the use and integration of graphing technologies in the present mathematics classroom.
Rationale of the study
Statistical literacy is vital to all aspects in our lives that deal with data based information. The importance of statistical literacy can be seen by the recent move taken by all colleges and universities in Malaysia to require their undergraduates to pursue compulsorily a first course in statistics regardless of their future profession. Even though many research findings (Kissane, 2004; Rosihan & Kor, 2004) reported favourable use of GC in the teaching and learning of mathematics, the effect and the impact of GC however, could be different in a diverse learning environment. Apparently, the Malaysian mathematics classroom that comprises of Asian students with a different learning culture is a worthwhile case to study. A study of this kind complies with Koc's (2005) assertion that awareness of cultural differences in technology could help instructional designers and trainers to build more culturally and socially sensitive materials for educational purposes. With these in mind, this study was conducted to examine how students' engagement with GC changes the

norm practice of their learning of statistics.
Method
The respondents in the study comprised of 76 second year Diploma in Business students. All were non-mathematics majors who had no prior classroom experience in using the GC. The statistics course in this study was conducted using the TI-83 Plus. 290 The topics taught were Measures of Central Tendency, and Correlation & Simple Linear Regression. The researcher conducted the whole course in twelve lessons. One lesson was two hours long and there were two lessons a week.
Students were required to write down their reflection corresponding to five openended questions given after each lesson. Interviews were conducted twice during the twelve lessons to explore students' thinking and feeling towards engaging GC in their learning process. Four independent facilitators were also employed to observe the classroom climate. Respondents' written reflection, the audio taped interviews and observation notes were collected, transcribed and analyzed.
Results and discussions
Analysis of the data highlighted three major changes in the students' learning process that engaged the use of GC. These three changes are students' perceived value of GC, changes in the norm classroom practices and changes in the perceived peer status.
(A) Changes in students' perceived value of GC
(i) GC as a technological tool
During the interview, the respondents expressed that they were not too convinced of the capability of the GC at the beginning of the lesson. They thought it would be just another calculator with more advance features and is solely used to assist them in doing more complicated computation. After a few lessons, many respondents were very impressed with the many functions a GC can perform. They were especially attracted to the graphs that appeared on the screen at the press of a button. The respondents responded by saying,
The first time we see a GC, we did not expect it to be able to draw graphs like what we do now… you just need to key in the right data and press the right button and there is the graph.
Another group found that the GC enriched their understanding on a set of data by presenting the data in different forms because "we saw that the same set of data can be represented in many different forms". These students' responses highlighted the significance of GC as a tool for learning. They learned that data is not just about a set of numbers but can be presented in many different forms within the switch of the GC screens.
However, there were some who dislike the use of GC voiced different view about GC such that, "learning to use GC is very difficult. There are so many steps to follow… 291 so many functions to remember…very confusing … cannot tell us if we have keyed in the wrong data or have pressed the wrong button!"
(ii) Use of GC provides a new approach in learning statistics
An appropriate use of technological tool such as GC has the potential to bring about students' cognitive activities rather than just to amplify their human capabilities. There was description about using GC to "work backwards" with the existing data when there is an uncertainty in solving a particular problem. One average achiever who favours GC presented a refreshing perspective by saying that
Sometimes I used GC to find the answer to a problem that I am not sure of doing … use the answer to work backwards to get the solution… like a box plot looks… can use GC to plot the box plot with the data I had and then use the "TRACE" key to locate the points and transfer these points to my graph paper to complete a box plot.
One group mentioned that they worked out the solutions with GC repeatedly until the final correct answer was achieved. They elaborated further, "To locate a point on a regression line for example, we can zoom repeatedly and trace the point that is not in the range until we get it."
(iii) Perceived personal gains
Interestingly, respondents' views about the new GC-enhanced statistics lessons were a mixture of great expectation and cynicism. Some respondents expressed that GC enhanced their learning, they said, "… there is reinforcement when we learn to solve a problem in two different methods: the calculator and the manual methods. By doing it twice we can remember better."
In addition, some related their bad experience when using GC such as, "It is very difficult to remember the functions in GC. We cannot see anything meaningful on the GC screen as compared to learning with manual method." One facilitator observed that, "The students seemed to show disappointment when they failed to follow the instructions on how to use the GC to plot a regression line."
(B) Changes in the norm classroom practice
(i) Classroom learning atmosphere
Before the GC engagement, the study sample was observed to be serious and followed the lessons passively. They were seen taking notes from the white board and occasionally exchanging words in a whisper with their neighbours. The learning atmosphere was solemn. However, the inclusion of GC seemed to change the classroom norm. It was observed that the classroom atmosphere was lively and 292 cheerful. Time passed by without anyone noticing as most of the respondents were busy sharing their findings with each other. One facilitator strongly believed that the invigorating classroom climate reflects that learning is in progress as she commented, "The class was noisy but it is a good sign of learning because they were busy asking questions. Discussions were seen among the students and between students and lecturer."
(ii) Students' learning attitudes
In general, the engagement of GC in the statistics lessons had motivated students' interest in statistics as well as improved their confidence in the learning process. A typical remark that explains the transformation was,
I find that I work harder now in this subject… always rush to finish off the given exercises in the classroom. I would try out again and again if I fail to get the answer… want to get it done because nobody can offer you help on GC other than the lecturer …all of us are still new to this thing.
Another respondent reported the excitement when using GC as, "I can draw frequency polygon faster than the traditional method. I am excited …using GC to learn is really interesting."
However, some expressed difficulties in using GC to learn because they could not concentrate on doing two things at the same time.
… need to listen to the instruction given by the lecturer and at the same time we need to understand the concepts…it's very difficult…we could not catch up with the others. We were always left behind in the lesson. It creates tension and phobia in us.
(iii) Classroom participation
Compare to the normal class, more respondents were seen offering peer tutoring among themselves. It was recorded by the facilitators that, "When they (respondents) were confused in receiving instruction from the lecturer, they overcome this by encouraging and helping each other."
The learning process was dynamic. Group discussions and didactic conversation between lecturer and students and among students were a common sight. One group explained the reason why they asked more questions than the normal class. They said, "We are forced to ask many questions because there are many new things that we do not know about GC." 293
Conversely, weak students who dislike using the GC revealed their problems that kept them from active participation. This is because, "We were hardly active in the group discussion… we were not confident of contributing anything about GC. We were afraid that we might say the wrong thing… we just kept quiet and let the others do the talking."
(c) Changes in perceived peer status
Some respondents seemed to associate GC with the state-of-the-art modern electronic device. They were optimistic that GC as a new technological gadget can create an appeal to the future statistics classroom. They developed a sense of pride from the knowledge gained from GC. There were two groups of respondents who used the analogy of "hand phone" while another two groups used "computer" to describe the GC. There were groups who felt that learning statistics with GC is compatible with the present computer age. These respondents considered themselves as technology savvy and more knowledgeable after learning how to use GC in statistics. They said, "GC is like a hand phone … when we compare ourselves to those without the GC knowledge, we are more professional and proficient in doing statistics."
Conclusion
The findings of this study suggest that GC can bring changes to the statistics classroom culture of learning. These changes include the cognitive changes in the pattern of learning and doing statistics, the norm classroom practice and changes in the students' perception and feelings about the new tool and the new GC knowledge. Although there were reports that the respondents were confused in the process of handling GC, the number was relatively small in the study sample. Apparently not all respondents in the study recommended highly the engagement of GC in doing and learning statistics. Nevertheless, majority admitted that GC enhanced their understanding through visualization and multiple representations. One of the most common complaints among the respondents was the frustration they faced in mastering the GC skills. Inevitably, respondents who were incompetent in GC skills often encountered with technological problems. As a result, the weak students often find using GC annoying.
In fact, the success of GC implementation depends much on tool competency of the users. Poor mastery of GC could lead to high frustration and subsequently reduce learners' motivation to learn the subject. Consequently, this study advocates strongly that the more experiences the learners have with GC prior to instruction, the more likely they are to perform better through the course. This study also shows that many weak students did not possess the necessary GC skills and sound understanding of 294 the statistics content that allowed them to work collaboratively in a group. Therefore, it is pertinent that special attention must be taken when including a GC into a mixedability classroom. This study supports Lindsay's (2003) attestation that studentcentred activities, inquiry-based approaches of mathematics teaching might be more suitable for average and high-achievers only. For weak students, it is important that their skills in handling GC should always be evaluated and monitored throughout the learning period. Furthermore, the facilitator must provide ample guidance and gives immediate feedback to reinforce the learners' short-term memory.
In sum, we observed that the Malaysian students' experience in engaging GC to learn statistics was not far different from the global norm. However, it remains our concern on how to exploit the use of educational tools such as GC so as to make the learning of mathematics more enticing and motivating to students of all abilities.

Analysis of effects of tablet PC technology in mathematical education of future teachers
Olga Kosheleva, Ana Rusch, Vera Ioudina
University of Texas at El Paso, United States
olgak@utep.edu, arusch@utep.edu, vioudina@utep.edu
This paper presents description of authors' current and proposed work using Tablet PCs mobile computer lab in future teachers' preparation classes. Faculty from the Colleges of Education and Science at the University of Texas at El Paso worked together to study the effects of incorporating Tablet PC technology in pre-service teachers' math education. We assessed the significance of the technology by evaluating and comparing students' final project and course grades. We did a statistical comparison of two groups: the treatment group where students extensively used Tablet PCs to work on mathematical investigations and lesson plans and the control group where students worked on identical math investigations and created lesson plans without utilizing any technology. The outcome shows a greater improvement in the treatment group's mathematical content knowledge versus that of the control group's. Current and future work involves evaluation of the change in acquiring mathematical pedagogical knowledge by pre-service teachers. Future teachers (in both groups) are asked to create original math lessons using unique manipulatives and hands-on activities. Students in the treatment group are required to use Tablet PCs to create hands-on activities. Groups' pedagogical knowledge will be compared using pre/post tests, questionnaires and knowledge and attitude surveys.
Introduction
The concept of a "digital divide" separating those with access to computers and communications technology from those without is simplistic.
Research (Peslak, 2005) shows that computers per students and total number of computers in a school significantly effects student learning, but surprisingly there is a negative impact of this metric on standardized reading and math scores.
Another study (Warschauer, 2005) shows that kindergarten through 12th grade students from a higher socioeconomic status are more likely to use computers for experimentation, research and critical inquiry; students from a lower socioeconomic status usually engage in less challenging drills and exercises that do not fully utilize the advantages of computer technology.
To benefit from computers teachers should have access to good educational software and be familiar with the available software. Ideally teachers should be able to use appropriate software to create math activities that guide students to higher order

thinking. Pre-service (future) teachers should be confident and knowledgeable about effective instructional strategies that incorporate variety of digital technologies. 296
Located on the Rio Grande River in the far western edge of Texas along the borders of Mexico, New Mexico and Texas, El Paso is a bustling urban area of 700,000 people, more than 74% of whom are Mexican in origin. Widely known as a major passageway for land travel through the mountains from Mexico to the U.S., El Paso sits in close proximity to the Mexican City of Juarez, with a population of more than 1.2 million; together El Paso and Juarez represent the largest metropolitan along the 2,000- mile U. S. /Mexico border. Generations of Mexicans and Mexican-Americans view El Paso as a place where they can pursue their hopes, aspirations, and dreams. Almost a quarter of El Paso's population is foreign born, and more than 50% of El Paso's households speak Spanish as the language of preference. The University of Texas at El Paso prepares a large number of bilingual educators to work with the growing Hispanic population.
In the beginning of 2004 the team of researchers from the College of Education and College of Engineering received a grant from Hewlett Packard that allowed UTEP to organize a mobile Tablet PC lab. This lab was readily available for use in the math and math methods classes taught in a Field-based environment. It was this HP grant which provided us the necessary technology for this study.
In this paper we present the study on the effects of Tablet PC technology on mathematical content knowledge of pre-service teachers. We also in the process of collecting data and evaluating students' math pedagogy, attitudes toward digital wireless technologies, and effects of this technology on collaborative learning of mathematics. Thus, the scope of this paper addresses the following research questions (from Discussion Document http://www.math.msu.edu/~nathsinc/ICMI/):
roles of different technologies in teaching and learning mathematics, assessing learning of mathematics using digital technologies, and how can technologyintegrated environments be design so as to capture significant moments of learning.
The significance of Tablet PCs: recently, at Technology Review's Emerging Technologies Conference held at MIT, Nicholas Negroponte, a founder of MIT's Media Lab, showed off a laptop design he hopes can be sold for just $100. These small laptops work similarly to Tablet PCs, using "digital ink" thus providing students the opportunity to write on the screen using a specially designed stylus pen. With the affordability of these computers, schools will be able to provide every child with a computer.
The Study
In spring semester of 2005, 38 pre-service elementary teachers were enrolled in math content and math methods courses. These students were also enrolled in internships at local elementary schools. The students' internships and class placement was random.
Our study focused on two groups of students. The treatment group consisted of 15 students that regularly met in a professional development school where they were provided with 14 Tablet PCs for use in their math and math method classes. The control group consisted of 23 students who were enrolled in the same courses with 297 the same instructor but met at different times and location. In this control group Tablet PCs were not used.
All math and math methods classes were team taught using a series of rich math investigations, in-depth discussions on topics in the methods textbook (Van de Walle, 2004) and group lesson preparations and implementations. Specifically, math and math methods course were designed to foster conceptual understanding of mathematics and pedagogy in the following major strands: rational numbers, geometry, algebra, number theory, and functions. All projects were designed to include open-ended problems that required thorough investigations to achieve successful solutions. Instructors utilized collaborative learning and inquiry based methodology while students worked in small groups.
The treatment group used Tablet PCs to explore the investigations or projects. This technology allowed students to explore each activity fully without being limited to paper and pencil drawings. The real time feedback in the various programs and websites used gave students a good evaluation tool of their problem solving methods. In addition, the ability to iterate calculations allowed students to focus on the "big" picture without getting bogged down with repetitive calculations.
Besides the rich investigations, students from both groups planned individual/group lessons and implemented them in local elementary schools. Students created these lesson plans by applying the concepts investigated in their math and math methods courses. Students in the treatment group successfully implemented Tablet PCs in their individual and group teachings allowing pupils to engage in meaningful technology based activities.
By the end of the four month period both groups had completed and presented several investigations. The students' final exam was an oral presentation covering the functions and algebra investigation. The students' final grade was a cumulative grade indicative of the students' performances in each investigation, presentation, teaching and methods review.
Implementing the Tablet PCs in a technology-enhanced classroom
Tablet PC's are fully functional PC's running an enhanced version of Windows XP Professional. One of their most interesting feature is the "digital ink" that allows a user to write on the screen using a stylus pen. The same pen is also used as a mouse. The handwriting recognition software allows the written text to be converted to digital text in Microsoft Word. Traditional keyboard and mouse are also available. Tablet PC's also have built-in wireless connectivity, so they can communicate with each other even if there is no internet connection present (ad hoc mode). They can also wirelessly connect to the internet. In newer Tablet PCs battery life can be up to six hours, however in our case our Tablets only have a battery life of three hours.
Students had the opportunity to utilize the Tablet PC during their presentations by connecting the Tablets to a data projector. In addition since we had 14 Tablets and 15 students, then students were able to work with the Tablet PCs individually or in small groups. Faculty used special software to communicate with the students. First, using 298 VNC software (http://www.realvnc.com/what.html) and internal wireless capability, faculty could connect to any of the students' Tablet PCs and check their work, help them and project their successful solution on the screen. Second, Discourse software (www.ets.org/discourse) was used for assessment. Using this software, faculty is able to ask various types of questions including open-ended or multiple-choice questions. Each question can be accompanied by an image guiding students to explore this particular question. In addition to images, faculty can guide students to a specific internet site relevant to the question. Students can answer their questions concurrently or on their own pace.
The faculty is also able to simultaneously monitor each student's answer in real time. Some of the students prefer typing the answers; others can open a writing pad, and record their answer on the pad. This writing pad automatically converts it to digital text. Also, students can have discussions using the "chat" option (that can be disabled by faculty).
Pre-service teachers employed the Tablet PCs in their university courses and during their internship teaching in a number of ways. The most popular program was a program called Microsoft Journal, which comes free on Tablets and is used as an electronic whiteboard. The Power Point program was extensively used for presentations and for the creation of animated virtual manipulatives. The students were very successful in creating virtual manipulatives for solving word problems, place value tasks, fractions, and geometrical designs. Similarly, Kidspiration and Inspiration software was used for the creation of math activities and games. Students also used this software to create concept or mind maps.
Variety of specialized free software was also used. One of the most interesting software is Java Bars
(http://tt.uga.edu/tt/jwilson.coe.uga.edu/olive/welcome.html) that provides a creative workspace to explore fractions. Another software used extensively was the Tangram editor that will no longer be available for free. Excel was used in mathematical projects by utilizing the different spreadsheet capabilities such as graphing and formula calculator. Another interactive site used for fractions was Cynthia Lainus' website from Rice University where students could explore fractions with pattern blocks. Students also used a variety of internet sites such as the National Library of Virtual Manipulatives, NCTM Illuminations, Math Playground and InterMath Investigations. Preservice teachers used a WebCT portal provided to all students by the university to submit their work for grading and discussion as well as for submitting questions outside of class time.
Results, Conclusions and Future Work
We statistically compared the effectiveness of our technology enhanced method for mathematics, using the Tablet PC, to the standard inquiry based method. This comparison is based on the results of two distinct items. The first is the students' Final Exam given at the end of a 4 month learning period. The second is the students' Final Grades which is a cumulative grade based on all the investigations throughout 299 the semester. Of a random sample of 38 students, 15 were taught by the technology enhanced method and were considered our treatment group. The other 23 students were taught by the standard inquiry-based method and were considered out control group. All 38 students were taught by the same qualified instructors under similar conditions.
We computed students' grade point average (GPA) using only their previous mathematics courses. The average math GPA for the treatment group is 2.99 while the average math GPA for the control group is 2.98. This indicates that both groups had approximately the same mathematical background and content knowledge prior to the study. We developed descriptive statistics for both samples and both teaching methods see (Table 1).

Final Exam Final Grade Group	n	Mean X	Var 2 (	St.Dev.	n	Mean X	Var 2 (	St.Dev.
Treatment	15	90.8	14.31	3.78	15	93.04	8.95	2.99
Control	23	84.9	77.55	8.81	23	87.70	42.49	6.52

Table 1: Sample's Descriptive Statistics

Based on our observations during the previous semesters, we expected that the new teaching method is more effective. If we can show a statistically significant difference between these groups, we can conclude this observation to be valid. To do this, we set up a null hypothesis that the two sample means are the same (or the two groups come from the same population), and attempt to reject that hypothesis.
The standard approach for this situation is to use the small-sample t-test. The first theoretical assumption about the independency of observations is satisfied, based on the information provided about the sampling procedure. The second assumption is about Normality (the histograms of all four distributions are bell-shaped and approximately symmetric). To verify the Normality in more rigorous way, we used the
2
- test for the Final Exam and Final Grades for both groups. The results of four tests are represented in (Table 2).
The test shows that for all four distributions the calculated value chi-square is less than the critical value for the indicated degrees of freedom and . There is insufficient evidence to reject the null-hypothesis about the Normal distribution for given samples. Consequently, each sample data set appears to come from a 300 population that is approximately Normal. Moreover, as we know, the t-test is robust to moderate departures from Normality.
The third and weaker assumption is that the two samples come from distributions with approximately the same variance.
For our samples we can see that the ratio of the larger to smaller standard deviation is greater than two, so the unequal variance test should be used. In the case where the sample sizes and variances are different (n1 n2 and 1
2
2
), an approximate smallsample test can be obtained by modifying the standard deviation and the degrees of freedom associated with the t-distribution.

Final Exam Group	n	2	df	critical
Treatment	15	3.53	1	0.05 3.84
Control	23	4.37	1	0.025 5.02

Final Grade Group	n	2	df	critical
Treatment	15	1.52	1	0.05 3.84
Control	23	0.78	2	0.05 5.99

Table 2: The Results for

Table 3 (test results) shows that the t-values for both tests are much bigger than the
critical value of the t-test with the 5% Type I Error. The table of t-distribution
(J.Devore, 2004, p.747) shows that the area under the 32 degrees of freedom t-curve 301
to the right of 2.851 for the Final Exam test is 0.0035. So the p-value for the uppertailed test is also 0.0035, that corresponds to the probability 0.35%. For the Final
Grade test the p-value is only 0.001 or 0.1%.
t df □t Confidence Interval critical
Lower limit Upper
limit

Final Exam
2.851 32 0.05 1.694 2.40 9.45
Final Grade
3.418 33 0.05 1.693 2.70 8.00
Table 3: The results of the Small-Size t-test
With a confidence level 0.95, we estimate the difference in the mean of the Final
Exam scores between treatment group and the control group to fall in the interval
(2.40, 9.45). This means that with 95% confidence we estimate the mean Final Exam
score for the new method to be anywhere from 2.40 to 9.45 points more than the
mean of the Final Exam score for the standard inquiry-based method.
The 95% confidence interval for the Final Grade is (2.70, 8.00), so we estimate the
mean of the Final Grade for the new method to be anywhere from 2.70 to 8.00 points
more than the mean of the Final Grade for the standard inquiry-based method. In
other words, the new method is associated with higher mean scores.
Therefore there is enough evidence to indicate that (□1 - □ 2) differs from zero and that
(□1 - □ 2) > 0. Using a significance level of 0.05, we can reject the null hypothesis that
the two sample means are the same in a favor of the alternative hypothesis which
states that the treatment group mean is significantly bigger then the control group
mean for the both the Final Exam and the Final Grade.
Consequently, the statistical analysis of the data collected shows that the technology
enhanced group achieved significantly higher mean scores than the control group.
These higher mean scores obtained by the treatment group translates into the
treatment group having a greater understanding of math content when compared to
the control group. This greater understanding can be directly contributed to the
effective implementation of the Tablet PC technology in the math and math methods
courses. Thus, we simultaneously achieved two goals. We increased students' math
education software literacy and math content knowledge.
This study was conducted in math and math methods classes. The natural extension
of our work is to evaluate the change in acquiring mathematical pedagogical
knowledge by pre-service teachers. Future teachers (in both groups) are asked to
create original math lessons using manipulatives and hands-on activities. Students in
the treatment group are required to use Tablet PCs to create hands-on activities and
virtual manipulatives. Groups' pedagogical knowledge will be compared using
pre/post tests, questionnaires and knowledge and attitude surveys. Preliminary 302
observations show that even students who did not improve significantly their math
content knowledge benefit from using Tablet PCs in terms of mathematical
pedagogy. They become more creative in developing hands-on activities, become
very confident in searching the Internet and develop good skills to critically analyze
existing mathematical activities posted on the Internet.
Another important aspect that will be studied is how well the collaboration helps preservice teachers to learn mathematics and pedagogy. Collaboration is recognized as
an important forum for learning (Bransford, J. D., Brown, A. L., Cocking, R. R.,
Eds., 2000.), and research has demonstrated its potential for improving students'
problem-solving and learning (Slavin, R. E, pp. 145-173, 1992, Johnson, D. W. and
Johnson, R. T., pp. 23-37, 1990). In both treatment and control groups students are
working in teams. However in the treatment group Discourse software is extensively
used for teaching, learning and assessment by both faculty and students. Important
feature for collaboration evaluation is "chat" option. Students are encouraged to chat
only on the topics discussed in the class session. These chats can be saved in the
archive file and then be analyzed to evaluate the level of cooperation, team members'
participation in collaborative work on the project as well as level and complexities of
content questions asked.

What can be learned from metacognitive guidance in mathematical online
discussion?
Bracha Kramarski
School of Education, Bar-Ilan University, Israel
E-mail: kramabr@mail.biu.ac.il
This study compares two mathematical online learning environments: Online learning supported either with
explicit metagognitive guidance (MG) or with no metagognitive guidance (NG). The metacognitive guidance
was based on three aspects: Using the IMPROVE self-metacognitive questioning method for problem solving
(Kramarski & Mevarech, 2003), discussing features of mathematical explanations, and practicing ways of
providing online feedback. The effects were compared between mathematical online problem solving of a
real life task and students' mathematical and metacognitive discourse. Participants were 79 ninth-grade
students in Israeli junior high schools. Results showed that MG students significantly outperformed the NG
students in online problem solving with regard to mathematical explanations. We also found that the MG
students outperformed their counterparts in various criteria of mathematical and metacognitive discourse.
The practical and theoretical implications of supporting online learning with metacognitive guidance will be
discussed at the conference.
Introduction
New advances in technology have brought challenges and opportunities to
mathematical education and instruction methods. Online environments provide
students with dynamic, interactive nonlinear access to a wide range of information
represented as text, graphics, and animation as well as to self-directed learning in
online discussion (e.g., Jacobson & Archodidou, 2000).
Discussion mediates shared meaning. Through critically examining others' reasoning
and participating in the resolution of disagreements, students learn to monitor their
thinking in the service of reasoning about important mathematical concepts (e.g.,
McClain & Cobb, 2001). Online discussion allows asynchronous exchanges and
permits both one-to-one as well as one-to-many interactions. The students exhibit
motivation, learn independently, and transfer and apply the knowledge to real-life
situations. Learning in such an environment requires students to self regulate their
learning; that is, to make decisions about what to learn, how to learn it, when to
abandon and modify plans and strategies, and to increase effort. Specifically, students
need to analyze the learning situation, set meaningful learning goals, determine which
strategies to use, assess whether the strategies are effective in meeting the learning
goal, evaluate their emerging understanding of the topic, and determine whether the
learning strategy is effective for a given learning goal. Students' need to monitor their
understanding and modify their plans, goals, and strategies (e.g., Zimmerman &
Schunk, 2001). However, research indicated that too few students are skilled at
regulating their learning to optimize self-directed learning. For the most part, studies
have found that students learn little in online environments and they do not deploy
key self-regulatory processes and mechanisms such as effective cognitive and
metacognitive strategies during learning (e.g., Azevedo & Cromley, 2004). 304
Recent research has begun to examine the role of students' ability to regulate several
aspects of their cognition, motivation, and behavior during learning environments
with explicit metacognitive guidance as self-questioning and providing feedback
(e.g., Azevedo & Cromley, 2004; Kramarski & Mizrachi, in press; Kramarski &
Mevarech, 2003).
There is little research in the field of mathematics to accurately determine the benefits
and pitfalls of new technology such as online discussion particularly when compared
to a learning environment embedded with metacognitive guidance. Gaining
knowledge about process and outcomes of online discussion with and without
metacognitive guidance, help educators and researchers to gain insight on students'
problem solving of real-life task and online discourse.
The purpose of the study is two-fold: (a) To investigate the ability to solve online
real-life tasks of students' who were exposed either to metacognitive guidance (MG)
or with no such guidance NG; and (b) to examine the online discourse of students'
who were exposed to these instructional guidance with regard to mathematical and
metacognitive aspects.
Method
Participants
Participants were 79 (boys and girls) ninth-grade students who studied in two classes
within one junior high school in central Israel. Each instructional approach was
assigned randomly to one of the classes. No statistical differenced on a mathematical
pre test were found between the two groups (M=83.30; SD=16. 80; M=80;
SD=15.70; t(78)= 2.01; p>.05).
Measurements
The study utilized two measures: (a) an online real life task; and (b) online discourse.
(a) An online real life task
A real-life task was administrated in online discussion adapted from PISA (2003).
The task describes an orchard planted by a farmer. The students are asked to find
patterns in change and relationships by comparing the growth of apple trees planted
in a square pattern and conifer trees planted around the orchard and to explain their
reasoning. Relationships are manipulated in a variety of representations, including
graphical, tabular, and symbolic.
Scoring: Each item on the task was scored from 0 (not responding, or wrong
response) to 1 point (correct answer/explanation). The scores were translated into
percents. The quality of explanations were analyzed based on two criteria of
arguments: Mathematical arguments (e.g., formal or daily arguments); and
Procedural arguments (e.g., calculation example).
(b) Online discourse 305
Students' online discourse during the solution of the real-life task was analyzed in
two aspects: Mathematical discourse and metacognitive discourse. Mathematical
discourse refers to four criteria: Number of statements, mathematical terms,
mathematical representations and final solution. Metacognitive discourse refers to
three criteria: Errors identification, process description and mathematical
explanations.
Scoring: Sum of references provided to each category during the online discussion
was calculated.
Instructions
General online discussion instructions: Students from both groups (MG & NG)
participated in an asynchronous forum based on problem solving discussion of reallife tasks. Students practiced problem solving in pairs for a four-week period once a
week in the computer lab (45 min). Three stages were implemented in the online
discussion: First, each pair were asked to solve the task and to send the solution to
another pair online as a text in the forum. Second, each pair were asked to provide
and receive feedback to the solution from a counterpart pair. During the third stage
each pair corrected the solution and sent it as a text to the forum and as an attachment
file to the teacher. The teacher encouraged students to be engaged in the whole forum

discussion by providing mathematical explanations and feedback, and resent their corrected solutions.
Metacognitive online discussion guidance: The metacognitive guidance was based on two parts: The first part was based on the IMPROVE metacognitive questioning method (Mevarech & Kramarski, 1997 and Kramarski & Mevarech, 2003) and the second part was based on practicing explicit strategies for providing mathematical explanations and feedback. The IMPROVE method utilizes a series of four selfaddressed metacognitive questions during problem solving: Comprehension, connection, strategic, and reflection.
Comprehension questions prompted students to reflect on the problem/task before solving it (e.g., "What is the problem/task all about?"); Connection questions prompted students to focus on similarities and differences between the problem/task they worked on and the problem/task or set of problems/tasks that they had already solved (e.g., "How is this problem/task different from/similar to what you have already solved? Explain why"). Strategic questions prompted students to consider which strategies were appropriate for solving the given problem/task and for what reasons (e.g., What strategy/tactic/principle can be used in order to solve the problem/task?" and WHY). Reflection questions prompted students to reflect on their understanding during the solution process (e.g., "What am I doing?"; "Does the solution make sense?").
In the second stage students were engaged in a discussion about the question "what does it mean to provide a good mathematical explanation". They were exposed to features of mathematical explanation such as, mathematical expressions, 306 representations, conclusions and clarity. In addition, students practiced how to provide feedback technique by reflecting and discussing examples. The metacognitive questions and instructions on how to provide explanations and feedback were printed on an index card and students referred to this guidance in the following circumstances: During their turn to solve the task, during the discussion about the solution, and their providing explanations and feedback regarding peers' solutions.
Results
The primary purpose of our study was to investigate students' online real-life problem solving with regard to mathematical explanations.

We performed a one-way ANOVA on real-life task scores. Results indicated that the online MG students significantly outperformed their counterparts (NG) on mathematical problem solving and providing mathematical explanations. In addition, we found that at the end of the study more MG students provided mathematical arguments than the NG students (72%; 50%, t(77) = 3.97, p<.05 respectively), whereas no significant differences were found between the two environments on procedural arguments (17%; 20%, t(77) = 0.57, p>.05 respectively).
The second purpose of our study was to examine students' online discourse with regard to mathematical and metacognitive aspects.

Similarly, Table 3 indicated that the MG students significantly outperformed their counterparts (NG) on metacognitive discourse regarding two criteria of providing feedback: Errors identification, and mathematical explanations. No significant differences were found on providing feedback regarding process description.
Discussion and conclusions
Our findings indicated that metacognitive guidance in an online learning environment might be a vehicle for students' mathematical problem solving and discourse. There are possible reasons for the beneficial effect of the metacognitive guidance. It seems, that IMPROVE guidance integrating with discussion about mathematical 308 explanations and providing feedback might help students access and interact with the content functionality, think about the deeper concepts and structure of disciplinary relations, and avoid superficial details. Our findings extend other findings in nontechnology environments which indicated that the IMPROVE method had a cognitive effect on students' mathematical reasoning (e.g., Kramarski & Mevarech, 2003).
We recognize the need to understand more about how mathematical problem solving and students' discourse emerge in different advanced technology environments. Our study focuses on questions such as how do students learn mathematics with technology and what mathematics do they learn. The metacognitive framework, findings and implications will contribute to the discussion of theme 3 (contribution to learning mathematics).

HALF-BAKED MICROWORLDS IN CONSTRUCTIONIST TASKS
CHALLENGING TEACHER EDUCATORS' KNOWLEDGE
Chronis Kynigos, Educational Technology Lab, Dept. of Education, School of Philosophy, University of Athens, Greece
kynigos@cti.gr
This paper illustrates how five teacher educators in training were challenged with respect to their epistemology and perceptions of teaching and learning mathematics through their interactions with expressive digital media during a professional development course. The research focused on their experience of communally constructing artifacts and their reflections on the nature of mathematics and mathematics teaching and learning with digital media. We discussed three different ways in which this media was used by the teachers; firstly, as a means to engage in techical-applied mathematics to engineer mathematical models; secondly, as a means to construct models for students to engage in experimental-constructivist activity; thirdly, as a means to engage in a discussion of a challenging mathematical problem.
This paper addresses theme 3 and in particular the kind of professional development programs which might be appropriate to prepare teachers for using mathematical microworlds in their classrooms. It discusses 'half-baked microworlds' as tools in tasks designed to generate teacher educators' reflection on pedagogy and mathematical ideas based on the experience of jointly constructing and reconstructing such microworlds. Half-baked microworlds are programmable pieces of software designed so that teachers would want to build on them, change them or decompose parts of them in order to carry out some mathematics for themselves or to build microworlds for students. They are meant to operate as starting points, as idea generators and as resources for building or de-composing pieces of software. They are not built and presented as ready made environments to be understood by the teachers and then used by students. Instead, the point is to change and customize them and thus to gain ownership of the techniques and the ideas behind microworld construction. A crucial characteristic of half- baked microworlds is that they invite construction and re-construction of structural parts of the software, i.e. they are not just 'containers' of content which teachers can put in or take out. They are thus based on technological platforms which allow for deep structural access (diSessa, 1997). It is the very nature of the structure and the tools for structural change which are an integral part of the mathematics at hand. The platform used in the study described in this paper is 'E-slate' (Kynigos 2004, 2002), a programmable construction kit similar to diSessa's 'Boxer', but different in that the elements for construction are generic pieces of software themselves (diSessa, 2004).
In this paper, I describe the process by which one of these E-slate half-baked microworlds was developed and changed within respective tasks in a course for 310 teacher educators, focusing on its potential for generating mathematical, pedagogical and professional reflections amongst them. The paper is a synopsis of alarger paper describing this research and including different half baked microworlds.
The study was carried out within the context of an innovative systemic initiative to employ three university sites to prepare experienced teachers to take on the role of teacher educators in the use of ICT in educational practice. At the Educational Technology Lab, , these teachers participated in courses, constructed digital artefacts and corresponding materials for student learning and engaged in teacher education courses as part of their training. A particular aspect of the pedagogical design of the course was to support these teachers to acquire some experience not only with the technology but most importantly with pedagogical knowledge about constuctionist (Papert et al, 1991) experiential mathematics and at the same time with the process of joint reflection on the practice of this kind of mathematical activity. Korthagen and Kessels (1999) discuss Aristotle's notion of episteme versus phronesis, i.e. theoretical de-contextualized knowledge applicable to a wide spectrum of situations versus situation – specific knowledge derived directly from experience within that situation and aimed at meeting a problem within the situation itself. In arguing for a realistic teacher education pedagogy, they suggest that building on teachers' phronesis is critical to their understanding a theory and most importantly in building a constructively reflective habit of mind in the teachers,

helping them perceive their profession as a developing one. Our particular focus was on the ways in which half-baked microworlds designed as tasks for doing mathematics with, were used in phronesis-generating situations, i.e. within the process of action, discussion and reflection during the course. My agenda for supporting these kind of situations was formed mainly because of the context of the Greek Education system where a frontal encyclopedic and revelatory educational paradigm coupled with minimal teacher education mechanisms makes it very hard for such mathematical activity to be understood, valued and practiced.

Context

Describing the context in which a course like this is situated is a complex thing to do, since one can select a large variety of contextual characteristics, from the macro-level of the educational system and the cultural - historical and political time in which the course took place, to the specifics of the institutional dynamics and the roles of the actors engaged in the course. The course described here, for instance, was in itself an innovation within the Greek education system.

The context of this system is characterized by a centralized nation-wide administration coupled with a single national curriculum. In this sense, the teacher is placed in the role of the technical implementer of this curriculum rather than in the role of a professional implementing a developing personal pedagogy. With such constraints, it is very hard to distinguish innovation from systemic reform, and it is difficult to imagine individual teachers involved in curriculum design and in trying out alternative teaching methods, both of which were central to the aims of the 311 course. Furthermore, at the secondary level there is almost non-existent teacher education at both pre-service and in-service levels, only some optional courses are provided in undergraduate programs, while at in-service level there is mainly a range of Masters' level university based courses. It would be thus fair to suggest that from a systemic point of view, the teacher profession is considered as that of a nondeveloping practitioner. In this kind of context, it was unlikely that teachers would start constructing things with a piece of educational technology unless this was done through starting up a program for teacher education that aimed to institutionalize not only the use of technology in schools, but also the idea of teacher professional development supported by the system.

The course was a constituent element of a middle-scale initiative from the Ministry of Education involving the installation and use of digital technologies in 10% of secondary schools ('Odysseia' project

1

, Maritsas et. al., 1992). The objective of the teacher education course described here was to train experienced teachers, selected by the Ministry of Education, to become teacher educators in the use of digital technologies for teaching and learning in their respective subject. It was one out of three such courses funded by the Odysseia project and was carried out by the (Author's site). During and after completion of the course, these teacher educators were relieved from their school duties and given the task to engage in in-service teacher education programs in 3-5 schools neighboring their own.

The course at the (Author's site) was thus designed on the premise that, from an educational point of view, digital technologies can at best provide the educational community with sources of information and media for communication and expression (Author, 2001). With respect to mathematics education, if this technology is put to educational use it may support richer learning activity based on symbolic expression, construction, experimentation, investigation, data handling. It may also support the generation of social learning modes where authentic questioning, research, use of human and artificial feedback, argumentation become recognized and valued in school. A course to train teacher educators would thus need to perceive teacher education as a systematic, life-long professional development activity addressing teachers' epistemologies, practices, pedagogies and subject-related knowledge. It would entail teachers supported to adopt the role of reflective practitioners personally engaged in co-implementing the innovation. This role for teacher educators cannot be prescribed and handed to them by their administration when it constitutes such an innovation. Rather, it needs to be actively claimed and shaped through practice.

The project (code name 'E42') involved a year - long course

2

to train 15 selected secondary teachers (five from each mathematics, science and humanities disciplines). The aim of the course was a) to provide the teachers with methods; knowledge and experience in in-service school based teacher education, and b) to educate them in the pedagogical characteristics and uses of exploratory software and communication technologies. The E42 project involved a "sandwich" course where 312 teachers would alternate between full time presence at the University and practice at in-service teacher education in three schools to which they were each assigned. The content of the course ranged from teacher education methods to teaching and learning with subject specific exploratory software. In this paper, the focus is on work with the five mathematics teachers.

Technology

During the course, the five mathematics teachers worked with four kinds of digital media for learning mathematics:

Data handling software (they used 'Tabletop', see Hanckock, 1995)

CAS software (they used Function Probe, see Confrey, 1993)

DGS software (they used Geometer's Sketchpad, Jakiw, 1991)

Programmable microworlds software (they used Turtleworlds and E-slate software, see Author, in press)

In this study, the focus is on the teachers' work towards the end of the course, when they were learning to use the fourth category. During the whole of the course, a central feature of the method used to encourage the teachers' engagement with and appropriation of the technology, was to start each time with what we called 'a halfbaked microworld'. Half-baked microworlds are pieces of software designed so that the teachers would want to build on them, change them or de-compose parts of them in order to carry out some mathematics for themselves or to build microworlds for students. They are meant to operate as starting points, as idea generators and as resources for building or de-composing pieces of software. In a sense, they operate like diSessa's toolsets (diSessa, 1997) in that they are not built and presented as ready made environments to be understood by the teachers and then used by students. Instead, the point is to change and customize them and thus to gain ownership of the techniques and the ideas behind microworld construction as outlined earlier. In this paper, I describe the process by which two of these half-baked microworlds were developed and changed through the experience of the course, focusing on its potential for generating mathematical, pedagogical and professional reflections amongst the teachers.

Method

A design research method was selected as appropriate for the study, the researcher taking on the role of participant interventionist. The data collected included research journals, the to-be educators' reports from their pilot courses with colleagues, the instructor's reports on observations of a sample of these courses, a semi-structured interview on their perceptions of mathematics and mathematics teaching with digital media and the various versions of the software they constructed. The analysis of the data is presented in the form of a story addressing a key aspect of the research findings. The research focused on the trainee teacher educators' experience of communally constructing artifacts and their reflections on the nature of mathematics and mathematics teaching and learning with digital media. The story respectively discusses the way in which this media was used by the teachers; firstly, 313 as a means to engage in technical-applied mathematics to engineer mathematical models; secondly, as a means to construct models for students to engage in experimental-constructivist activity; thirdly, as a means to engage in a discussion of a challenging mathematical problem.

A half-baked microworld: creating functional relations between number lines

The 'connected number lines' microworld consists of a series of sliders connected through Logo scripts so that moving the pointer on the first would result in a mathematically related corresponding movement on the others. The version the teachers started with had an additive relationship between first and second slider (+100), a multiplicative one between first and third (x2) and an exponential one between first and fourth (power of 2). In that sense, the first slider 'x' is the independent variable in three distinct cases. In each of these, sliders y, z and w are respectively the dependent variables in the three corresponding functional relationships. The interesting aspect of this microworld is the representation of function in one dimension rather than two in an ortho-canonical system. Since the number lines are aligned, dragging the cursor on the x slider causes simultaneous movement on the others. The additive function resembles a movement where x and y have the same velocity, the multiplicative function resembles y moving at greater but constant speed than x and the exponential one resembles acceleration. The microworld thus provides a sense of the 'effect' the independent variable has on the dependent one in each case.

So, in this teacher educator course, the strategy was not to provide the participants with exemplary tools to master, but rather to engage them in situations where phronesis (in the sense of Korthagen and Kessels, 1999) would be built, as a result of their own experiences with designing courses with the technology. The halfbaked microworld was thus designed as phronesis - generating tool, in the sense that it was not imposed on the participants as exemplary or complete case. What they would do with it was left open at the beginning, so that discussion and challenge related to constructivist learning theory would emerge from pragmatic situations.

Findings: Teachers' theoretical mathematics

The teachers were shown the half-baked connected number lines microworld. They were shown by the instructor how the sliders-number lines were connected through the E-slate authoring mechanism of writing Logo scripts defining the connections between component pieces of software, which in this case were replicates of one simple such component, the slider. The commands of the script were shown and explained and subsequently, the behavior of the software and the didactical design behind it was discussed. The idea of what the slider representations 'this is a framework which aims to engage the students in the activities through problem solving, the problem being within the framework of the curriculum... to engage students in generalization processes'. 314 show seemed interesting and teacher B referred to the idea of rate of change which he had read in a math education paper by Kaput. That is, that the slider connected with a multiplicative function seemed to go steadily faster than the independent one, whereas the one connected with an exponential function seemed to behave very differently. The teachers were then asked to think up microworlds of their own, based on the connected slider idea.

Not surprisingly, at first, focus was on re-creating a connection between two sliders so that the syntax and the mechanism would be understood. Soon however, the discussion centered on the mathematical relations between the sliders. What kind of representation do the sliders provide? How can we make something interesting happen? A teacher then had the idea of composite functions, i.e. making one slider dependent on the next and so forth. They inserted a functional relationship of x-1 between first and second slider and another of 3x between second and third and observed what happened when moving the first. In mathematical notation terms, we have: f(x) = x-1, g(x) = 3x, f(g(x)) = 3(x-1). In slider notation terms we have: sa, sb=sa-1, sc=3sb (sa, sb, sc are the slider names respectively). The discussion centered for a while on what kind of tasks we could give to students. For instance, if slider sa has a range of 30, what range should slider sb have so that the pointer covers it when we drag the pointer of slider sa the whole distance? How can I make a currency conversion machine (drachmas to euros)?

At some point, however, this style of designing exercises for their students suddenly changed. Teacher B suggested trying to create a model of an interesting mathematical investigation he himself was engaged in a short while back involving fractal geometry. Teacher B was the ultimate "bricoleur" (do it yourself) personality. He enjoyed using technology and spent a lot of time developing elaborate constructions especially with Geometer's Sketchpad. He perceived computers to be "a tool to play with ideas" as he said during the interview. Also that 'mathematics is a means for solving any problem, it's creative. It's an interplay between theory and practice'. However, he was quite overwhelmingly proficient in relation to the other teachers. This influenced his teacher education pedagogy, at least at the beginning as shown by one of the instructors' reports.

The other teachers agreed to build the model suggested by teacher B. He explained the problem, which involved the process of repeatedly forming the composition of a function with itself. He represented that by starting with an independent slider and then consecutively linking sliders, each taking double the value of the immediately previous one. What is formed in this way, is a series of

Teacher B (instructor's report): He himself organized what the topic and the precise use of the software would be. This was good because it helped focus on specific functionalities of the software. However, it did not allow the trainees to act personally and to make decisions on what functionalities they needed for the activity. 315

compositions starting from the function f(x)=2x, then onto f1(x)=2(f(x))=2

2

x, then

onto f2(x)=2(f1(f(x)))=2

3

x and so on. By placing these sliders in vertical alignment, the slider cursors represent the values of x. The formation of these cursors is equivalent to the graphical representation of plotting the number of iterations with the value of fn(x). In teacher B's representation, the variation tool was inserted (the emergent connecting of pieces of software as a microworld construction progresses is characteristic of E-slate authoring, see Kynigos, 2004) to signify the value of the parameter, in a generalization of the problem where the initial function is f(x)=ax. What was interesting and was part of teacher B's reading and investigating, is that for a given value x, changing the value of the parameter created different cursor patterns. The teachers discussed the mathematical issues in theoretical terms, away from the medium, occasionally sketching on paper. However, this whole discussion was initiated from selecting a problem which was interesting and challenging to them as mathematicians (from a mathematical, not an educational/teaching point of view), representing it with a digital medium so that it could be dynamically manipulated. The manipulation ignited discussion on the behavior of the representation which quickly went on to a discussion of the mathematics behind it.

Being immersed in an activity where the mathematics itself was a challenge may have allowed the teachers to feel what doing mathematics is like. Even though teacher D had stated that 'new knowledge comes form the teacher and the book', in

another part of the interview, he allowed for students' generation of mathematical meaning through experimentation with the tool.
In discussing his own teacher education pedagogy, he also referred to the value of teachers' experiences in using computers and in mathematical pedagogy based on experiential learning with this technology.
So, the use of this story was not to point out that such experience will in itself change teachers' beliefs in a predictable and reproducible way. Rather, stories like that constitute situations rich in potential for phronesis-style experiences to take place. This is because they are based on construction and representation activity with
Teacher D (interview): There are times when the student discovers things from trying them out on the computer and observing what happens. I've seen students, because of the tool, find solutions which were unexpected, yet they were correct. Once, the teacher I was observing scolded a student for doing his own thing. That teacher was greatly surprised when he realized that the solution was correct, after I had pointed this out to him.
Teacher D: For teacher education to take effect, the teacher needs hands-on experience with the tool.
Teacher D: I believe computers will be widely used when teachers understand that this tool differs from the classical method when everything had to do with the teacher's brain. 316
the software and on discussion related to the constructs and their designed use. An integral and crucial part of the activity was the interchange of roles played by the teachers which in this case was model constructors, microworld designers and mathematicians. Bringing these changes into awareness and turning them into material for reflection operated as a means for associations with different aspects of pedagogical knowledge. The pedagogical milieu orchestrated by the instructor is of course crucial to the emergence of clear associations with episteme style knowledge and the potential for that knowledge to be put to use in subsequent teaching.
The research shows how the emergence of these uses was a process which challenged teachers' knowing with respect to teaching and learning mathematics, but also regarding their view of the nature of mathematics itself. In a sense, it was the process of experience with the half-baked microworld which seemed to play a critical role in bringing genuine mathematical discussion and activity into the context of professional practice. In parallel, the same process encouraged reflection on mathematical teaching and learning issues. In that sense, I argue that constructionist mathematics may not necessarily be an agenda only for student tasks. There is a place for constructionist mathematics in task design in contexts where the pedagogical agenda for teacher education is the generation of knowledge based on phronesis. What this study suggests is that it might be worthwhile to consider this perspective as a design factor for tasks in teacher educator development contexts.

The question addressed by this contribution is how teachers organize the conditions for an instrumental genesis and to what extent they foster mathematics learning through an instrumental genesis, in the case of geometry learning and teaching based on the use of a dynamic geometry software. The contribution is based on a French project aimed at studying the integration processes of dynamic geometry at primary school and the beginning of middle school.
Integrating ICT into teaching and especially the teaching of mathematics is supported by official institutions for education in several countries. It is now well known that such a political will is not a sufficient condition for a real integration of digital technology into the everyday teaching practice. The present paper addresses the problems teachers are faced with in a context of institutional support of use of technology when they make practical decisions for organizing the use of technology in their teaching. This issue is discussed on the basis of a research project developed in France. There is currently in France an institutional injunction for using ICT in the teaching. However there is still a long way until teachers view technology as a tool for fostering learning. In our approach, we consider that teachers are faced with a professional problem. They must turn institutional demands into everyday decisions by making choices within a system of constraints.
The aim of our contribution to ICMI study 17 is to make explicit the constraints and conditions of integration of digital technology into the teaching practice and by means of theoretical tools to propose indicators allowing researchers to evaluate the degree of this integration in a teaching practice. The focus will be on the instrumental dimension (Artigue, 2002). We refer here to the theoretical approach developed by Rabardel and Vérillon (1995) according to which the individual must learn how to use a tool (or an artifact) for carrying out a task by means of the tool. When the tool is complex and offers the possibility of performing operations referring to theoretical domains, this process of instrumental genesis may be long and may need the help or intervention of a more expert person. What we would like to stress here is that, as

41
We are grateful to the French Ministry of Education supporting this project with the status of a Technological Research Team in Education called MAGI (Mieux Apprendre la Géométrie avec l'Informatique) 318
technology involved in mathematics education embodies mathematics, the technical and the conceptual parts are intrinsically intertwined (Artigue Ibid.): the use of technology shapes the knowledge constructed by students (Hoyles et al. 2004). The question addressed by this contribution is how the teachers organize the conditions for an instrumental genesis and to what extent they foster mathematics learning through instrumental genesis in the case of geometry learning and teaching.
Our contribution comes within the theme « Teachers and teaching » by addressing the two following questions: "What theoretical frameworks and methodologies illuminate the teacher's role in technology-integrated environments for mathematics teaching?" and "What kinds of pedagogical approaches and classroom organisations can be employed in technology-integrated environments and how can they be evaluated?"
Context of the research work
It is carried out in the frame of a national project (Technological Research Team in Education) entitled MAGI ("Mieux Apprendre la Géométrie avec l'Informatique", in English "Better Learning of Geometry with Computers"). The project is a development and research project involving twenty researchers, teacher educators and teachers divided into groups located in different places in France: It is aimed to study the integration processes of dynamic geometry software, namely Cabrigeometry, into ordinary teaching contexts at primary school and beginning of secondary school. The project consists of two parts:
designing and implementing scenarios of use of Cabri in several classes of primary and secondary schools (in about ten classes)
study of the impact of teacher preparation sessions to the use of Cabri onto their classroom practice.
Dynamic geometry is conceived in this project as a tool for helping students to move from a purely visual conception to the construction of geometrical theoretical concepts such as collinearity, perpendicular, parallel, congruence... Therefore the school levels, primary school and the beginning of secondary school, were chosen.
The entry to a « theoretical geometry » must be prepared in France at primary school and achieved in the first years of secondary school. In addition, geometry is not a favoured subject for primary school teachers who view the teaching of geometry as essentially the teaching of a vocabulary and not as the construction of a coherent model of spatial phenomena and objects. Dynamic geometry can change their view of geometry and motivate them for changing the teaching geometry. This is why it seemed particularly interesting to investigate the integration of dynamic geometry at this school level.
Theoretical framework: mode and degree of instrumental integration
Our analysis of technology integration into teaching is based on a multidimensional approach (Assude & Gélis 2002, Artigue 2001, Guin & Trouche 2004, Lagrange 319 2001, Trouche 2005) that takes into account several dimensions: epistemological, cognitive as well as instrumental, institutional and anthropological.
What do we mean by "degree of instrumental integration"? It measures to what extent mathematical knowledge and knowledge of handling a tool are intertwined in the organization of the instrumental genesis by the teacher. We could consider that it can take any value in a continuum from zero to one, zero meaning no integration at all and one the highest level of integration. However it is difficult to assign such a precise degree to an observed teacher practice and we prefer to define modes of integration, characterizing a teacher practice on a period of time, a session or part of a session, or sequence of teaching sessions.
To determine these different modes, we use several indicators:
• focus of the tasks given to pupils: is the focus on the tool or on mathematics?
• techniques for solving these tasks: do they come mainly within mathematics or technology or within both, or in other words does the task require mainly instrumental abilities (IA) or mainly mathematical knowledge (MK), or both are equally important?
• extent of the intertwining of instrumental abilities and mathematical knowledge involved in the task (IA/MK).
Until now we propose to distinguish four modes of integration: instrumental initiation, instrumental exploration, instrumental reinforcement, instrumental symbiosis. We distinguish between two cases of instrumental abilities: either pupils are beginners or novice in using the artifact (low IA or no IA) or they already have got knowledge of the artifact but they have not yet a good knowledge how handle all the facilities (average IA).
Pupils are beginners:
In the instrumental initiation, the teacher's aim is mainly that the pupils learn how to use the technology (pupils must learn some IA). Pupils are given tasks focusing on the way to use Cabri. The relation between IA and MK is minimal.
In the instrumental exploration, the teacher aims at improving both some IA and MK. Pupils explore the technology through mathematical tasks. The relationship between IA and MK can vary according to the mathematical task and to the content teacher interventions: the teacher may just give information items of how to use a specific facility of the artifact or (s)he may express links between IA and MK.
Pupils are already introduced to handle the artifact:
In the instrumental reinforcement, pupils are faced with instrumental difficulties when solving a mathematical task. The teacher gives them elements of information about how to use a specific item of the artifact to allow them to overcome the technical difficulties. The teacher's aim is improving mathematical knowledge. The relationship between IA and MK may vary according to the way the teacher formulates his/her help for using the artifact (see below § 4.1 the case of Robert on regular polygon). 320
In the instrumental symbiosis, pupils are faced with mathematical tasks that allow them to improve both their IA and MK because these ones are connected. The relation between IA and MK is maximal: each one allows the other to increase and the connection between paper-pencil work and Cabri work is strong. An example of such symbiosis is the construction of a square with given side AB. The difficulty of the task essentially lies in using a circle as a tool for transferring length and thus conceiving a circle as a set of points equidistant of a given point.
These different modes of instrumental integration led us to classify the integration practices from the lowest level (where the only instrumental integration taken into account is the instrumental initiation) to the highest level (where the different modes are taken into account according to the adequacy of the moment).
Characterizing the design of a sequence by means of degrees of instrumental integration
Part of the work carried out by the Grenoble subgroup of our team was to build a teaching sequence aimed to initiate 11 year-old pupils to deductive reasoning and to introduce them to the use of Cabri. Actually, the drag mode in Cabri-geometry provides a means for distinguishing between the properties that belong to the geometrical figure (hypotheses and their consequences) and the ones that belong are valid only for a specific diagram (a particular case). The first ones are preserved by dragging and not the second ones. Thus, Cabri-geometry seems to be a relevant tool to be used by the pupils at the very beginning of the learning of deductive reasoning.
Within this purpose, the mathematical learning objectives are strongly intertwined with the ability to use the software. In fact, the pupils give a mathematical sense to the effects of the dragging as far as they understand the geometrical properties of a figure. To reach its objectives related to deductive reasoning, the sequence has to support the instrumental genesis that turns the dragging into a pupil's instrument to state about the validity of a geometrical property. For the design of the sequence, we paid attention to create a strong interaction between the discovery of Cabri, the development of instrumental abilities and the learning of mathematics.
An example of the design of a task:
Four diagrams were displayed in Cabri. They have not been obtained by the same construction process but they were all looking like a triangle and an inscribed

quadrilateral in the triangle (Fig.1). The pupils were asked to answer questions about parallel or perpendicular lines: are lines BC and GF perpendicular? Are lines GF and DE parallel? Are lines EG and DF parallel? To answer, the pupils were supposed to move every free point of the diagram and to observe whether the property was preserved or not (Figs 2 & 3). This kind of task is possible only after a significant work about moving objects and interpreting mathematically what happens on the screen. With pupils already introduced to Cabri, this task can be considered as coming within instrumental symbiosis. The task is of instrumental and mathematical nature: pupils need to decide 1) to drag elements 2) to drag enough points elements in order to decide about the validity of mathematical properties. 321

A
B
C
D F
E G

Fig. 1 The initial state of all four diagrams Fig.2 Dragging D Fig.3 Dragging A, B or C in one of the diagrams

Dragging D is not enough to state about the parallelism of lines ED and GF. Because these lines look always parallel when A, B or C are dragged, pupils must find a mathematical reason in the construction program (obtained in Cabri with the facility Replay construction): ED and GF were both constructed as perpendicular to line BC and dragging D has no influence on the quadrilateral because F is the reflected point of D with respect to the midpoint of segment BC. However the relationship between dragging and mathematics may strongly vary according to the prior knowledge of pupils. Pupils may be attracted by the only fact that "it moves", once they drag points but do not pay attention in a more precise way to what happens while dragging or misinterpret the phenomena because they do not relate it to geometrical properties. In this case, the expected instrumental symbiosis turns into instrumental exploration since the pupils may be considered as beginners with respect to the interpretation of drag mode and the aim of the teacher becomes to reintroduce dragging as a tool for checking properties. In the same vein, the activity may turn into instrumental reinforcement, if pupils do not know how to get information on the construction program of the diagram, the teacher may give information about the existence and use of the tool "Replay construction" and extend the instrumental abilities of the pupils.

The observation of the teacher during two years showed us that the instrumentation of the drag mode takes a very long time. In the first year, it took seven weeks until pupils decide to drag points on their own with a mathematical intention.

When the gap between the planned mode of integration and its actualization in classroom is important, it reveals the incomplete instrumental genesis of the pupils and thus may be a research tool for analysing the integration of technology.

Characterizing teachers' practices with degrees of instrumental integration

Two subgroups of our project, one in Toulon and one in Amiens, worked with primary school teachers who had no knowledge of dynamic geometry before the project. They were introduced to dynamic geometry in a short training session (half a day) for The Toulon subgroup and in a longer session (one week) for the Amiens subgroup. Each group worked with three teachers, in charge of 10 year-old pupils in Toulon, and of 9 and 10 year-old pupils in Amiens. The agreement was made with the teachers that they would integrate the use of the software in relation to the whole 322 work of their class, that they were completely free to choose activities with the software and that the role of researchers was restricted to observing teachers without intervening on the choice and the design of the activities as well as on the management of the class. We wanted to bring out the conditions and constraints of integration of the software by ordinary teachers who had to construct – everything – including a relationship with Cabri. Analyses are done by means of observation notes, videos, students' notebooks, and interviews with teachers. The teachers of Toulon were observed during one year, those of Amiens during two successive years. It is interesting to note that in both subgroups, the number of sessions devoted to the use of the software varied according to the teachers: from 5 to 15 sessions in Toulon, from 3 to 11 sessions in Amiens.

Two contrasted cases in the observation of teachers

These cases were observed by the Toulon subgroup.

A low level of instrumental integration: the example of Ingrid

Teacher Ingrid

42

proposed two initiation sessions to the pupils. During these sessions pupils created and dragged successively a point, a straight line, a circle, a segment and they named points. They did it from reading a form indicating all the actions they were required to do and there was no collective institutionalization

43

of these

Instrumental Abilities. The teacher did not point at the status of points, and though pupils dragged, the teacher did not insist on the interest of dragging to check the constructions.

In these sessions, the type of task was a Cabri task whose aim was to build and drag some basic mathematical objects. The relation between IA and MK is minimal. We consider that these sessions come within an instrumental initiation. In addition, these sessions did not insist enough on the changes in the didactical contract: the function of dragging the constructions and the contribution of Cabri to an experimental approach of geometry were not expressed at all. Such an initiation is aimed at creating mathematical objects on the computer instead of emphasizing the kind of work the software allows to do with those objects. In the following sessions the teacher was reluctant to use instrumental reinforcement (although it sometimes occurred) and instrumental symbiosis.

The mode of instrumental integration was limited to an instrumental initiation and that fact leads us to make the hypothesis that during the first year during which teacher Ingrid tried to integrate Cabri software, she did not pay enough attention to the instrumental dimension (although there were initiation sessions). From this point of view the degree of instrumental integration can be estimated as low.

A medium level of instrumental integration: the example of Robert

42

Teachers are given fictitious names

43

By institutionalization we mean that the teacher is synthesizing knowledge used in the task, which is part of the official knowledge and must be learnt. 323

Teacher Robert did not propose initiation sessions to his pupils. They discovered Cabri through exploring the software tools to achieve some mathematical tasks. In such a case the IA constitute a tool for mathematical tasks (instrumental exploration) but the relation IA/MK is minimal because the link between them was not made explicit. The mathematical task proposed by the teacher was to construct the perpendicular bisector of a segment. This kind of task as well as the notion itself of perpendicular bisector was new for the pupils and the focus of the teacher was on solving problems; pupils were expected to make hypothesis on what is a perpendicular bisector of a segment by handling Cabri. They also discovered how to create a segment, a midpoint of a segment and the perpendicular bisector of a segment by exploring the menu items. As the teacher asked them to justify their answers, pupils were also faced with other IA, such as measuring a segment or checking whether a line and a segment were perpendicular. This instrumental exploration can reach its limits if the teacher doesn't institutionalize some IA at one moment or another, and if they remain under the private control of the pupils.

Later we could observe what we call instrumental reinforcement when teacher Robert brought additional information on how to measure segments when they were not created as such. The pupils had to construct a square and to check that they obtained a square: they used the Cabri tool "regular polygon and wanted to measure the sides of a square. In that case, Cabri provides the measure of the perimeter, but not the measure of the side of the square. As long as the teacher didn't inform the pupils that they needed to create segments to be able to measure them (IA), they could not perform the mathematical task.

We consider that teacher Robert carried out an instrumental integration of medium degree: he took into account several instrumental integration modes according to the pupils' mathematical needs. However he did not institutionalize the instrumental abilities needed to perform the mathematical work and he did not take into account relations between IA and MK, and relations between Cabri tasks and paper-pencil tasks.

Observation of the instrumental dimension on a teacher long term practice

In the Amiens group, teachers were observed during two years. This long term observation allowed us to observe evolution in the modes of instrumental integration.

An increase in the level of instrumental integration: the example of Sara

The first year, the objective of teacher Sara was to come back to geometrical concepts studied at the beginning of year in paper/pencil environment while using dynamic geometry and construction programs. Sara organised three types of session: an initiation session: pupils created and dragged a point, created a segment or a line from two points, created and dragged a point on a segment, created the intersecting point of two lines. Each action to perform on the software was described on a worksheet. Then pupils analyzed the constructed objects to study their properties and answer the questions. Finally teacher Sara institutionalized the three kinds of points, by linking instrumental abilities and geometrical knowledge. 324

two strongly guided sessions: pupils performed given construction programs (rightangled triangle, square) in the environment and analysed the obtained constructions;

eight less guided sessions: pupils had to use these programs to construct or reproduce simple diagrams drawn on paper. Pupils had time for searching and teacher Sara brought information only when pupils had instrumental difficulties. But Sara must bring a lot of instrumental assistance in an individual way. In a collective synthesis, Sara established the link between properties of a figure and the used functionalities of the software.

In the first year, the initiation session aimed at both exploring the software instructions and improving mathematical knowledge in interaction with instrumental abilities. It can be viewed as an instrumental exploration. Later during tasks about reflection, teacher Sara gave information to build symmetric points (instrumental reinforcement). But there was no relationship between software tasks and paperpencil tasks. Furthermore, Sara proposed only construction tasks in which the aim was just to obtain a diagram and the software did not contribute to an experimental approach of geometry. From this point of view, we consider that the degree of instrumental integration is low.

During the second year, Sara alternated software tasks and paper-pencil tasks. Unlike the first year, Sara divided the initiation phase into two parts and in the first part gave more written instructions about the use of the software. She didn't organize any collective institutionalization of these instrumental abilities. But then she articulated geometrical tasks and software tasks to approach the concepts of circle, reflection and parallelogram. The aim was to analyze figures and to make conjectures about geometrical properties. On the other hand, Sara proposed less construction tasks than the previous year.

The first part of the initiation phase can be considered as an instrumental exploration in which the ratio between mathematical knowledge and instrumental abilities became minimal. But in the following sessions, Sara changed the didactic contract: the function of dragging the constructions and the contribution of the software to support an experimental approach of geometry have been developed. Sara also organized instrumental reinforcement when it was necessary to construct new geometrical knowledge by means of the software. Even if the same modes were observed in the first year and in the second year, Sara changed the organisation of the instrumental genesis by increasing the relationship between instrumental abilities and mathematical knowledge.

The examination of Computer Algebra Systems (CAS) integration into university-level mathematics teaching

Zsolt Lavicza
University of Cambridge, United Kingdom
zl221@cam.ac.uk

Although the first ICMI study was almost exclusively concerned with the integration of technology into university-level mathematics, there has been little focus on this phase of education as technology-related research has become dominated by schoollevel studies. Computer Algebra Systems have quietly become an integral component of university-level mathematics, but little is known about the extent of CAS use and the factors influencing its integration into university curricula. School-level studies suggest that beyond the availability of technology, teachers' conceptions and cultural

elements are key factors in technology integration into mathematics teaching and learning. In this proposal I report on an ongoing project and summarize results of the first phase of this study, which is based on interviews and observations of 22 mathematicians in three countries, Hungary, UK, and US. In addition, I outline the development of the second-phase in which a questionnaire will be sent to a sample of 3500 mathematicians in the participating countries to investigate the extent of current CAS use and to examine factors influencing CAS integration into universitylevel mathematics education. My research contributes to the ICMI-17 by considering cultural diversity, reflecting on actual uses of technology and addressing potential impact of CAS upon mathematics teaching and learning in universities.

The first ICMI study in 1985 reviewed the history, the potentials, the constraints, and the impact of computers on mathematics and its teaching and learning (Churchhouse et al., 1986). Despite difficulties articulated by several of its authors, the study presented an optimistic future for technology integration into mathematics education. Some years later, due to increasing accessibility to both computers and calculators, Kaput (1992) predicted that technology would become rapidly integrated into all levels of education. However, the accumulated evidence of the last fifteen years indicates that this prediction has not been realized with technology still playing a marginal role in mathematics teaching and learning (Cuban, Kirkpatrick, & Peck, 2001; Ruthven & Hennessy, 2002).

The first ICMI study was almost exclusively concerned with the integration of technology into university-level mathematics (Holton, 2001). More recently, despite a small number of studies reporting on innovative technology-assisted teaching practices and examination of university students' learning, technology mediated mathematics education research has been dominated by school-level studies (Lagrange, Artigue, Laborde, & Trouche, 2003). 327

Papers in the ICMI-11 study discuss, inter alia, the role of technology in a variety of mathematics courses taught in universities, accounts of the ways in which technology can be used to enhance students' learning, and the impact of technology on classroom communication (King, Hillel, & Artigue, 2001). However, the study provides neither an overview of the extent of technology use in universities nor discusses the reasons for the slowness of technology integration, preferring to offer examples of particular practices in particular universities in particular countries. The totality of the report suggests that technology use remains 'cosmetic' (Hillel, 2001). Even though little is known about the state of technology use in universities, recent surveys tell us much about its use in school mathematics and the factors influencing its classroom integration at both national (Becker, 2000; Ofsted, 2004) and international levels (Gonzales et al., 2004; OECD, 2004). These studies suggest that investment in technology can enhance, but not guarantee, increased use of ICT in education, although the TIMSS 2003 study implies that funding for educational technology may not increase the actual use of ICT

44

in classrooms (Gonzales et al.,

2004). Other studies, which have investigated the cause of slow technology integration, suggest that, beyond the accessibility of technology and policy pressures, teachers' beliefs and attitudes as well as cultural aspects are vital factors influencing technology integration (Hennessy, Ruthven, & Brindley, 2005; Ruthven & Hennessy, 2002). In addition, international comparative studies have reinforced the importance of cultural aspects by demonstrating that teachers' didactical beliefs and conceptions of the subject, as well as the characteristics of their classrooms and their relation to technology, are heavily affected by teaching traditions and geographic locations (Andrews & Hatch, 2000). Results from such school-based studies may be applicable to the university setting, but a systematic investigation essential.

Aims of the study

Due to the paucity of university-level research outlined above, I designed a study to investigate the current use of technology together with the factors that influence its integration into university mathematics education. In my study, I focus on a specific technology application, Computer Algebra Systems (CAS), because this type of software package is the most widely used in university mathematics education. CAS is explicitly designed to carry out mathematical operations (not a general technology application such as a web-based homework system); and CAS has the potential to become a mathematical tool in students' future studies and career (Artigue, 2005). Specifically, my study aims to examine:

- the extent and manner of CAS use in university mathematics departments;

44

Information and Communication Technologies (ICT). Frequently used as a reference to technology (-ies) in the UK. 328

- the pedagogical and mathematical conceptions of university mathematicians regarding CAS, including the factors influencing their professional use of CAS; and
- the extent to which nationally situated teaching traditions, frequently based on unarticulated assumptions, influence mathematicians' conceptions of and motivation for using CAS.

I decided to adopt an international comparative approach in order to understand more completely different teaching traditions and subject-related conceptions (Andrews & Hatch, 2000) at the university level. The participating countries, Hungary, the United Kingdom (UK), and the United States (US), pose a variety of cultural and economic considerations. Obviously, my selection has also been influenced by my personal and professional background, as well as by my familiarity with the higher education systems of these countries. However, international comparative literature advocates the comparison of considerably dissimilar (Hungary vs. UK, US) and similar (UK, US) teaching traditions to elicit similarities and differences (Kaiser, 1999).

Methodology, methods, and preliminary results

To investigate the outlined aims I designed a two-phase study following a mixed method methodology (Johnson & Onwuegbuzie, 2004). The first, qualitative, phase of the study explored those issues that influenced university mathematics lecturers' CAS-assisted teaching. In this phase, I interviewed 22 mathematicians, observed classes, and collected course materials in Hungary, the UK, and the US. Data were analysed by means of a grounded theory approach (Glaser & Strauss, 1967; Strauss & Corbin, 1998). Building on the results of the first phase, I am designing a largescale quantitative study to further examine the issues that emerged from the analysis of the first phase data, to gauge the extent of CAS use in universities, and to uncover additional issues that did not surface in the initial phase of the study.

The analysis of the first phase data identified three clusters of issues:

1. Personal characteristics
2. External factors (institutional and technology issues)
3. Mathematicians' conceptions (of mathematics, mathematics teaching/learning, CAS, CAS teaching/learning)

Many of these issues will be further investigated in the second phase of my study, but space does not permit a detailed discussion here. (A more complete list of the subcategories of these issues can be found in Lavicza (In review). However, I highlight three of the more interesting findings of this phase below.

Firstly, similarly to results of school-level studies, academics' conceptions, proved to be a crucial factor in technology integration into mathematics teaching. Moreover, 329 their conceptions appear more important an influence than for schoolteachers because, due to the academic freedoms of university life, they are less prone to policy pressures. Also, mathematicians are less constrained than schoolteachers by prescribed curricula and uniform examinations. Therefore, mathematicians have better opportunities than schoolteachers to experiment with technology integration in their teaching. However, academics are frequently more concerned with research than teaching and so experiments with technology in their teaching may be seen as counterproductive.

Secondly, mathematicians' primary use of CAS in their teaching is to enhance the transmission of mathematical concepts. Many described using CAS to illustrate mathematical concepts and I did not encounter any instance when they referred to CAS use as a motivational tool. In contrast, school-level studies report that teachers often emphasize the use of technology as motivational and classroom management tools (Hennessy et al., 2005; Ruthven & Hennessy, 2002). This result challenges the applicability of school-level findings to university settings while presenting new possibilities for collaboration that may enhance the integration of technology at all levels of mathematics education.
