Acknowledgements

This thesis is dedicated to my late parents Louis and Joy Holmes, who instilled in me the desire to work hard, strive for the best and never give up. They taught me to live by the motto “If something is worth doing, do it well.”

I would hereby like to thank:

- My husband Michael Laubscher, you never once doubted my abilities and supported me, encouraged me and believed in me throughout this journey. Thank you for always giving a hand when the load was heavy; an ear just to listen; a shoulder to lean on; for being a soundboard and for giving advice when my ideas were low; and most of all love to carry me through. Without your support, this would have been a long, lonely road.
- Prof Seugnet Blignaut, my promoter, for sharing your wealth of knowledge with me. I admire you for your dedication to your students and your passion for what you do. It has been a privilege having you as my promoter, mentor and friend for the past nine years. Thank you for believing in me and for always being there to guide, support and encourage me, beyond the call of duty.
- Prof Hercules Nieuwoudt, my assistant promoter, for being there to provide insight and to share your fountain of knowledge with me. Your fervour and enthusiasm for Mathematics education is contagious. Thank you for sharing your expertise and knowledge with me.
- Prof Dawid Jordaan, for your expertise and enthusiasm in creating the app. It was a pleasure working with you.
- Hermien Dreyer and Tertia Jordaan for being such supportive colleagues. Thank you for standing in for me during my study leave and thank you for the peer coding and evaluation of the app. Your collegiality and friendship are precious to me.
- Verona Leendertz, for the peer coding of the systematic literature review. Thank you for sharing your expertise and time with me.
- Hettie Sieberhagen for the language editing.
- The participants in this study who were always enthusiastic to meet with me and discuss issues close to our hearts.
- All my friends, family and colleagues, who always showed a keen interest in me and the study, thank you.
- And finally my Heavenly Father for carrying me through this journey. “Through it all, my eyes are on you— it is well with my soul.” Without His peace, knowledge, strength and love, I would not have completed the journey.

Abstract

Different teaching styles and approaches that are employed in a teaching environment have a huge impact on the achievement of learners. The value of using the Realistic Mathematics Education (RME) teaching approach to teaching Mathematics is evident in a number of studies. This study aimed to determine how the RME approach, facilitated by technology, could be used to enhance teaching practice. It also aimed to establish what support needs in-service Mathematics teacher-students in the South African context had with regard to using the RME approach, and it intended to yield guidelines for the effective use of technology in implementing the RME approach, thereby generating theoretically relevant knowledge to the body of scholarship. A purposeful stratified sample was used to understand what needs in-service Mathematics teachers had in terms of making Mathematics more realistic for their learners. Participants were selected from a group of in-service teachers enrolled for the BEd Honours post-graduate degree in Mathematics education at the NWU. Qualitative design-based research was an appropriate methodology for this study. I produced, evaluated and adjusted content based on the RME approach, presented by means of a mobile application to assist teacher-students in presenting learning content to their learners in a more realistic and relevant way. The first stage of the study consisted of a systematic literature review (SLR) to determine how the RME approach could be facilitated by technology to enhance teaching practice. Individual interviews with participants followed, to determine their needs in terms of effectively implementing the RME approach in their teaching practice. Thereafter iterative cycles of design and intervention took place. A mobile application (app) was used to present content to the participants, based on the needs identified in the individual interviews and the literature review. The re-design of the intervention was guided by testing different versions of the prototype of the app with various users, as well as by literature. Focus group interviews were used to establish the teacher-students' perceptions and evaluation of the app. The final stage of the study produced guidelines based on the findings of the study. Data were coded, sorted and summarised into themes using a computer assisted qualitative data analysis software (CAQDAS), ATLAS.ti™. The data analysis and interpretation were integrated with the literature review to answer the research questions. Based on these findings, guidelines for the effective use of technology in implementing the RME approach in teaching practice were designed. These guidelines were designed around the five dominant themes in the study, namely Mathematics, RME, ICT, role-players and aspects relating to the app. The guidelines will be of value to teachers, their learners, lecturers, curriculum specialists and instructional designers in the design, implementation and adaptation of mathematical content and course material.

Keywords:

Mathematics Education; Realistic Mathematics Education (RME); mLearning; Mobile App; Systematic Literature Review (SLR); qualitative data analysis; Interpretivist; ATLAS.ti™; teacher-students; open distance learning (ODL).

Opsomming

Verskillende onderrigstyle en benaderings tot onderrig het ’n geweldige impak op die prestasie van leerders. Die waarde van die gebruik van die Realistiese Wiskunde-onderrig (RWO)-benadering word genoegsaam gesteun deur navorsing. Hierdie studie het gepoog om te bepaal hoe die RWO-benadering, gefasiliteer deur tegnologie, gebruik kan word om die praktyk van onderrig en leer te verbeter. Dit het ook gepoog om te bepaal watter ondersteuningsbehoeftes praktiserende Wiskunde-onderwysers wat deeltyds studeer, spesifiek in die Suid-Afrikaanse konteks, het t.o.v. die gebruik van die RWO-benadering. Voorts het dit gepoog om ook spesifieke riglyne daar te stel vir die effektiewe gebruik van tegnologie tydens die implementering van die RWO-benadering, wat ’n bydrae sal maak tot die relevante teoretiese kennis in hierdie vakgebied. ’n Doelgerigte gestratifiseerde steekproef is gebruik om te bepaal watter ondersteuningsbehoeftes praktiserende Wiskunde-onderwysers het, om Wiskunde meer realisties te maak vir hulle leerders. Deelnemers is geselekteer vanuit ’n groep praktiserende Wiskunde onderwysers wat deeltyds studeer, en ingeskrewe BEd Honneurs-studente (Wiskunde-onderrig) by die Noordwes-Universiteit is. ’n Kwalitatiewe ontwerp-gebaseerde navorsingsmetodologie is gebruik vir hierdie studie. Ek het die inhoud geproduseer, beoordeel en aangepas n.a.v. die RWO-benadering. Dit is gedoen m.b.v. ’n mobiele toepassing wat praktiserende Wiskunde onderwysers wat deeltyds studeer, kan gebruik in ’n poging om die leerinhoud meer realisties en relevant aan te bied. Die eerste fase van die studie bestaan uit ’n sistematiese literatuurstudie om te bepaal hoe die RWO-benadering gefasiliteer kan word d.m.v. tegnologie in ’n poging om onderrigpraktyk te verbeter. Individuele onderhoude met die deelnemers is daarna gedoen met die doel om die behoeftes t.o.v. die effektiewe implementering van die RWO-benadering in die onderrigpraktyk te bepaal. Ontwerpsiklusse wat beide herhalend en ingrypend van aard was, is toegepas. ’n Mobiele toepassing wat ontwerp is na gelang van die bepaling van behoeftes soos geïdentifiseer deur die individuele onderhoude en die literatuurstudie, is gebruik om inhoud aan te bied aan die deelnemers. Die herontwerp van die ingryping is bepaal deur die toetsing en evaluasie van verskillende weergawes van die prototipe, en is voordurend aangepas na gelang van toetsing en terugvoer van verskeie gebruikers, ondersteun deur die literatuur. Fokusgroep-onderhoude is gebruik om die deelnemers se persepsies en evaluasie van die toepassing te bepaal. Die finale fase van die studie het riglyne opgelewer gebaseer op die bevindings van die studie. Data is gekodeer, sorteer en opgesom en vervat in verskillende temas deur gebruik te maak van ’n kwalitatiewe rekenaardata-analise-sagteware, ATLAS.ti™. Die data-analise en interpretasie is geïntegreer met die literatuuroorsig met die doel om die navorsingsvraag te beantwoord. Riglyne vir die effektiewe gebruik van tegnologie in die implementering van die RWO-benadering in onderrigpraktyk is ontwerp, gebaseer op die bevindings uitgewys deur die data. Hierdie riglyne is ontwerp en het gefokus op die vyf dominante temas in die studie, naamlik Wiskunde, RWO, IKT, die verskillende rolspelers en aspekte m.b.t. die toepassing. Die riglyne sal van waarde wees vir onderwysers, die leerders, lektore, kurrikulumspesialiste en onderrigontwerpers tydens die ontwerp, implementering en aanpassing van wiskundige inhoud en Wiskundige kursusmateriaal.

Sleutelwoorde

Wiskunde-onderrig, Realistiese Wiskundeonderrig, mobiele leer, Mobiele Toepassing, Sistematiese literatuuroorsig, kwalitatiewe data-analise, interpretivisties, ATLAS.ti™; praktiserende onderwysstudente, oop afstandsleer (OAL).

Chapter One

Orientation to the Research Journey

1.1 Introduction

The effective teaching and learning of Mathematics remains a priority in South Africa (Fleisch & Schöer, 2014, p. 1). Different approaches to the teaching of Mathematics influence learner achievement. The significance of using the Realistic Mathematics Education (RME) teaching approach to assist learners previously taught by traditional approaches is evident in literature. This study aims to determine the needs of in-service Mathematics teacher-students in the South African context with regard to teaching using the RME approach. It also intends to yield guidelines for the effective use of technology in implementing the RME approach; thereby generating theoretically relevant knowledge to the body of scholarship (Gravemeijer, 1999, p. 113).

The sections that follow in this chapter give an overview of the study in terms of the problem statement and motivation to do the research; a brief literature review which also highlights the gaps in the current literature; the research design and methodology; ethical issues; the way in which data were generated; and also some important terminology referred to in this study. Figure 1.1 represents an overview of what follows in Chapter One.

1.2 Motivation and Problem Statement

A primary concern of the South African Government, on which the Department of Basic Education has to deliver, is to improve the quality of basic education (DBE, 2012, p. 2). The Annual National Assessment (ANA) and the National Senior Certificate (NSC) examination play crucial roles in the Government's action plan to improve the quality of basic education (DBE, 2013, p. 6). Since the 2015 ANA tests were postponed, the NSC examinations remain the main essential measure for monitoring progress in achieving the targets that have been set in terms of learner achievement for Grade 12s.

The Annual National Assessment (ANA) which monitored learner achievement progress was implemented from 2011 to 2014. It was a diagnostic testing programme that required all schools in the country to conduct the same Language and Mathematics tests, which was grade-specific, for grades 1 to 6 and 9 (DBE, 2012, p. 2). The 2012 ANA, a huge undertaking, assessed the literacy and numeracy of more than seven million learners. The national average percentage marks for Mathematics in 2014 were: grade1: 68%, grade 2: 62%, grade 3: 56%, grade 4: 37%, grade 5: 37%, grade 6: 43%, and grade 9:11% (DBE, 2014, p. 9).

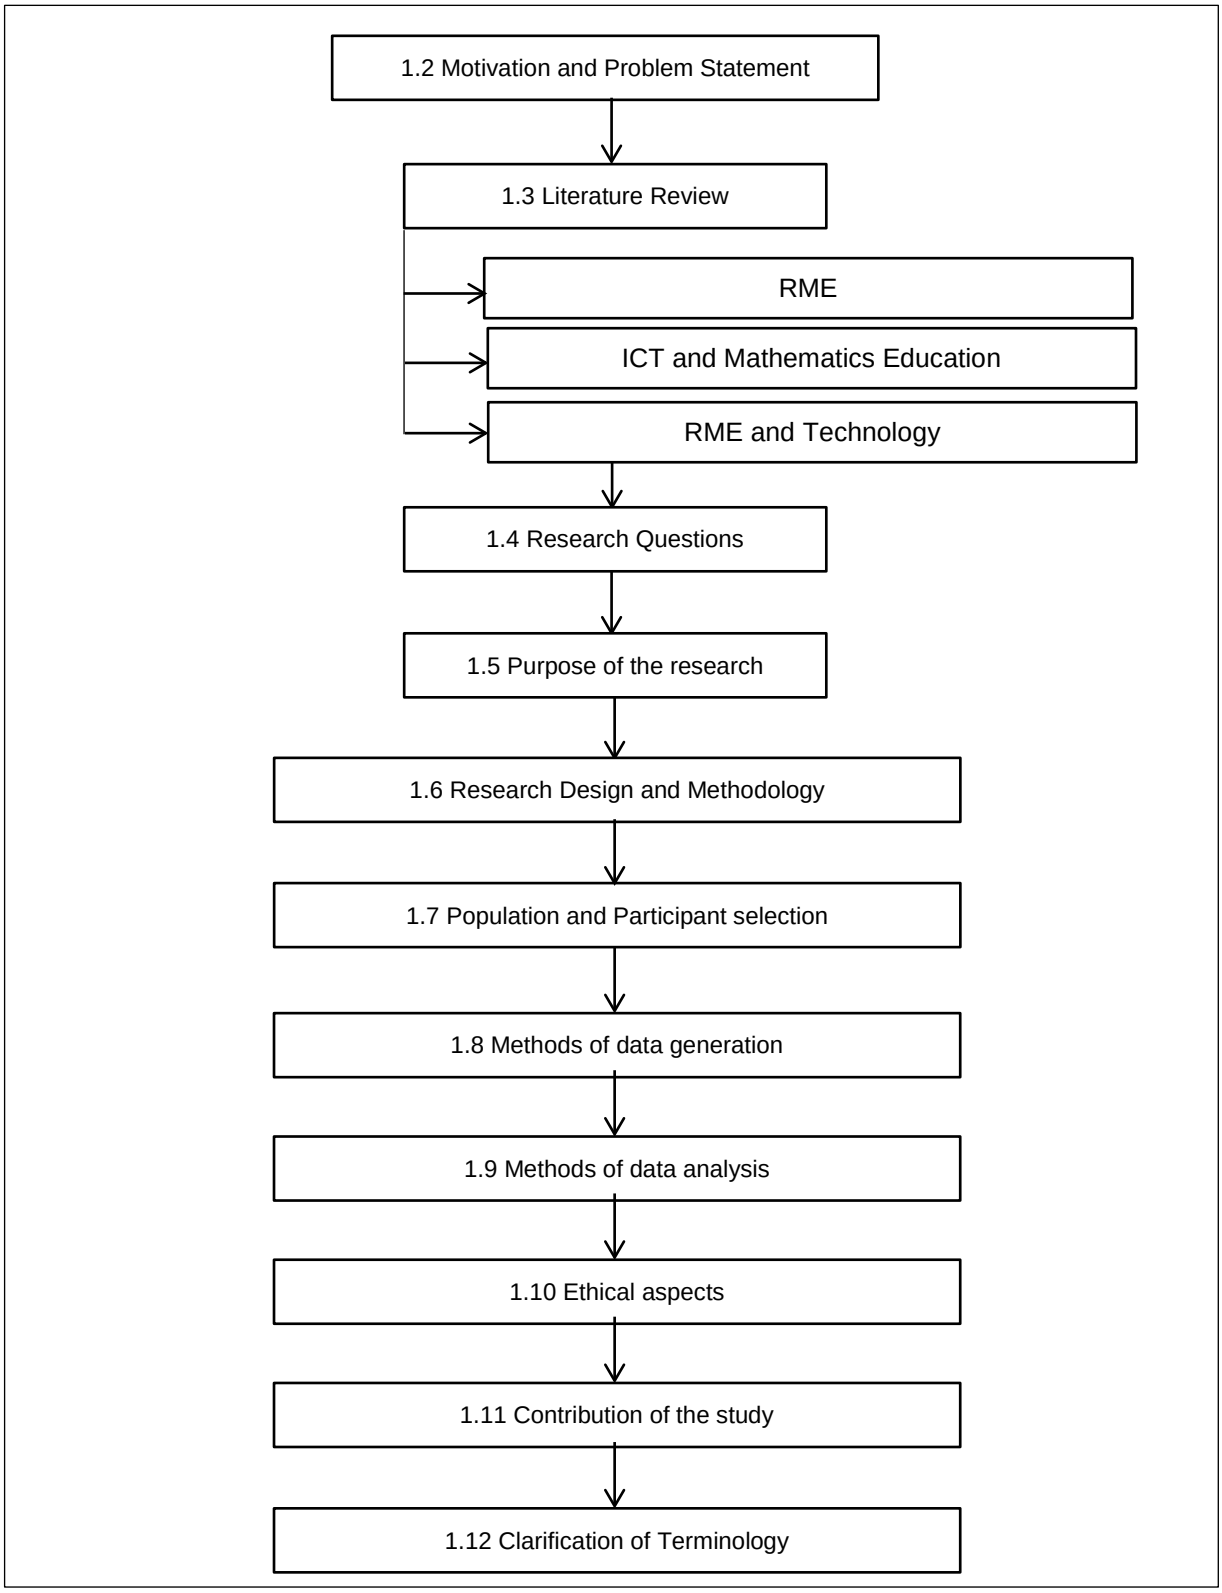

Figure 1.1: Orientation of the study

In most cases, except in grade 6 and grade 9, learners performed slightly better in 2014 than in 2013, however there remains a huge concern about the declining trend from lower to higher grades, culminating in the extremely poor results of the grade 9s (DBE, 2014, p. 9).

Not only are there concerns with the Foundation, Intermediate and Senior Phase Mathematics, but also with the grade 12s in the Further Education and Training (FET) phase. One of the targets of the government's Action Plan to 2014 was to increase the number of grade 12 learners who pass Mathematics (DBE, 2011, p. 8). The percentage pass rates for Grade 12 Mathematics for the past eight years are as follows: 2008 was 45,4%, 2009 was 46,0%, 2010 was 47,4%, 2011 was 46,3%, 2012 was 54%, 2013 was 59,1%, 2014 was 53,5% and in 2015 it was 49,1% (DBE, 2015, p. 58). Despite occasional improvement, there is still great concern about the Mathematics results.

One of the challenges identified by the government during the first five years of the implementation of the National Senior Certificate (NSC) is that there is a concern about the large numbers of candidates enrolling for Mathematical Literacy rather than Mathematics. Since the ratio at present is 2:3 of Mathematics to Mathematical Literacy for grade 10 to 12 learners, the Department of Basic Education (DBE) would like to see more learners taking Mathematics (DBE, 2015, p. 19).

Specific intervention strategies for 2013 have been devised as part of a turnaround strategy within the National Strategy for Learner Attainment (NSLA) framework. One such strategy expects teachers to, amongst other important aspects, not only ensure full curriculum coverage; provide opportunities for more written work by learners, but also improve the quality of teaching and assessment tasks given to learners (DBE, 2013, p. 14). The DBE has prioritised Mathematics, Science and Technology skills in line with the national human resource development priorities. One example of such support is the Dinaledi[1] schools' programme which provides focused support and intervention in Mathematics, Science and Technology in the form of funding for Mathematics and Science equipment, developing learning and teaching support material for Mathematics and Science and training for Mathematics and Science teachers on subject content knowledge (DBE, 2013, p. 15). Furthermore, the Telkom Masters Agreement was signed on 27 March 2012 for the first phase of the Connectivity Plan, which will provide internet connectivity to 1650 schools for a period of three years (DBE, 2013, p. 15) and aims at assisting with the learners' performance in Mathematics Science and Technology.

Different teaching styles influence learner achievement, and the selection of teaching approaches that are employed in a teaching environment, have a huge impact on the achievement of learners (Samuelsson, 2010, p. 61). Particularly, the traditional approach, where *talk-and-chalk* is the preferred teaching style, is linked to the poor quality of Mathematics education (Bishop, Hart, Lerman, & Nunes, 1993, p. 18). Often learners do not like learning Mathematics because they do not learn the Mathematics that they need in life (Fauzan, Plomp, & Gravemeijer, 2013, p. 162). Various studies have indicated that the RME approach offers great value to learners who have failed to benefit adequately from traditional teaching approaches (Barnes, 2004; Cobb, Zhao, & Visnovska, 2008; Fauzan et al., 2013; Gravemeijer & Doorman, 1999; Webb, 2011).

[1] In 2001 the Department of Education initiated the Dinaledi School Project to try to improve the number of university-entrance passes in Mathematics and Science for Grade 12 learners. The project involved selecting certain secondary schools that demonstrated potential for improving learner performance in Mathematics and Science. These schools were provided with resources and support to improve the teaching and learning of these subjects (DoE, 2009, p. 6).

The development of what is now known as Realistic Mathematics Education (RME) started in the late 1960s and is still under active development. In essence, RME is concerned with the idea of Mathematics as a human activity of making sense of reality so as for it to be useful (Freudenthal, 1973). The relevance for Mathematics education is that the subject is not a closed system, but an activity. The focus should be on the process of mathematizing reality (Freudenthal, 1968, p. 7). This process of mathematization involves providing learners the opportunity to reinvent Mathematics by reorganising or mathematizing real world situations or mathematical processes (Cobb et al., 2008, p. 105). By using technology, teacher-students can learn the RME approach as and when they wish to do so. This can happen during a guided programme or even after the completion of such a programme, since technology makes the availability of information very easy to access (Zulkardi, 2002, p. 157).

The National Council of Teachers of Mathematics (NCTM) claims in their position statement that "it is essential that teachers and learners have regular access to technologies that support and advance mathematical sense making, reasoning, problem solving, and communication" (National Council of Teachers of Mathematics, 2011, p. 1). The importance of technology in teacher education is also emphasised by the NCTM. They assert that teacher education programmes and professional development must continually update specialists' knowledge of technology and the application thereof to support learning (National Council of Teachers of Mathematics, 2011, p. 1).

Drijvers (2012, p. 1) valiantly raises the question of whether digital technology in Mathematics education works or not. Upon investigation of six cases, which are considered leading studies in the field, he reveals that both success and failure occur at levels of teaching, learning and research (Drijvers, 2012, p. 12). An important observation that is made in this study is that the integration of technology in Mathematics education does not reduce the importance of the teacher. The teacher plays an active role and needs to devise learning activities that relate experiences within the technological environment to mathematical activities (Drijvers, 2012, p. 12). Another important observation is that digital technology should be embedded in an educational context that is coherent and in which the technology is integrated in a natural way (Drijvers, 2012, p. 13). The importance of the teacher in the process of teaching with technology should not be underestimated. The role of the teacher has been acknowledged as a critical factor in the integration of technology into teaching and learning Mathematics. It is considered critical because the way in which teachers approach the use of technology has vast consequences for the effects of its use in the classroom (Drijvers, Doorman, Boon, Reed, & Gravemeijer, 2010a, p. 213). Ottenbreit-Leftwich et al. (2012, p. 400) assert that technology is an essential part of professional competency and teachers' appropriate use of technology can have positive academic benefits.

1.2.1 Gaps in the Existing Literature

A study concerning the design, development and evaluation of a learning environment (an RME course created with web support) for student teachers in Indonesia revealed important results (Zulkardi, 2002, p. 46). This learning environment could assist the student teachers in learning the mathematical, didactic and practice part of the RME course, thus promoting their understanding about RME and supporting student teachers in learning how to redesign lesson material for the classroom (Zulkardi, 2002, p. 168). The learning environment also had a positive impact on developing student teachers' performance, and on increasing the positive attitude of pupils in the secondary school towards Mathematics (Zulkardi, 2002, p. 168).

A research project (Widjaja & Heck, 2003) conducted at an Indonesian Junior School which investigated the effects of teaching and learning in an RME-based and Information and Communication Technology (ICT)-supported learning process revealed that teachers in general considered the experience as positive. The teachers believed that the chosen approach proved to be advantageous for both teachers and learners. Learners obtained results from their own efforts, rather than receiving descriptive material from the teacher, they were acquainted with new technology and their abilities and skills were explored and encouraged (Widjaja & Heck, 2003, p. 41). Advantages for the teacher included, amongst others, that the teachers did not have to spend much time and energy on explanations (Widjaja & Heck, 2003, p. 41). Some recommendations made in the study suggest that this idea should be developed within teacher-training institutes, more material should be provided for teachers and stronger networks among teachers and teacher-students should be established (Widjaja & Heck, 2003, p. 47).

A local study performed at UNISA also reports the successful adoption of the RME theory to teach introductory Calculus concepts within the context of Distance Education (Kizito, 2012b, p. 3). Some important recommendations in this study include that the concepts and mathematical structures that are to be represented should be carefully selected, and the learning activities should be researched, tested and developed by a team of experts which should include mathematicians and Mathematics subject didacticians (Kizito, 2012b, p. 3).

Some limitations highlighted by the studies listed above include the further need to investigate the extent to which the learning environment, which comprises a RME course with Web support, will improve the perceptions and Mathematics learning outcomes of pupils after they have been taught by prospective teachers using the RME approach with Web support (Zulkardi, 2002, p. 172). Additionally, Kizito (2012b, p. 284) suggests that intervention which involves mobile learning (mLearning) requires an institutional approach in order to be effective. Widjaja and Heck (2003, p. 45) also propose that the changing roles of teachers and learners need to be further researched.

Despite a few similar studies in the field, as summarised in Table 1, the need arises to investigate the use of the RME approach facilitated by a variety of technologies, for in-service Mathematics teacher-students in the South African context, with the aim to enhance teaching practice.

Table 1.1: Comparison of similar studies relating to Realistic Mathematics Education, Design-based research and technology

Key Factors	UNISA study	Indonesian study	Erkki Sutinen	Andreasen	Current Study
RME	Yes	Yes	Yes	Yes	Yes
Technology	Mobile	Web-based	Mobile	No technology	Mobile
Target	Undergraduate Mathematics	Undergraduate Education	Non-students	Undergraduate Mathematics education	In-service
Mode of delivery	Distance Education	Full-time	Incidental	Full-time	Open and Distance Learning (ODL) and face to face
Design	Design-based research	Design-based research	Action Research	Design-based research	Design-based research

1.3 Overview of the Literature

1.3.1 Realistic Mathematics Education

Mathematics is of such a general nature that it applies to a richer variety of situations than any other teaching subject (Freudenthal, 1968, p. 5). Many learners are not able to apply their Mathematical classroom experiences in the most trivial situations in daily life (Freudenthal, 1968, p. 5). Freudenthal (1968, p. 5) distinguishes between two attitudes to teaching Mathematics, namely teaching Mathematics without any relation to its use other than hoping that learners will apply it when necessary; and the opposing attitude which is to teach useful Mathematics. Freudenthal (1973) believes that learners should be allowed to reinvent Mathematics by mathematizing real world situations. RME is rooted in Freudenthal's interpretation of Mathematics as a human activity, which implies an activity of looking for and solving problems, and also an activity of organising subject matter (Freudenthal, 1973).

Mathematizing is distinguished as having a horizontal and vertical component (Treffers, 1993, p. 94). In general terms, these components can be described as follows. In horizontal mathematization, learners devise mathematical tools which can help to organize and solve a problem in a real life situation. Vertical mathematization is the process of reorganization within the mathematical system itself, e.g. finding shortcuts and discovering connections between concepts and strategies and applying these discoveries (van den Heuvel-Panhuizen, 1998). Horizontal mathematization is a process in which learners transform problem situations that they perceive as realistic into a mathematical system (Widjaja & Heck, 2003, p. 9). In RME mathematization takes place in both

directions by means of a process of reinvention which is guided by the teacher and the instructional materials (Widjaja & Heck, 2003, p. 10).

In RME, Mathematics is considered to be a human activity connected with reality, where contextual problems are used as a starting point in learning (Widjaja & Heck, 2003, p. 3). Three basic RME heuristics have been identified by Gravemeijer, Bowers, and Stephan (2003, p. 52). These provide designers with information to assist in supporting learners within the cycles of design-based research. They include the following:

1. sequences must be experientially real for learners (learners must be able to engage in personally meaningful activity, the sequences must be realistic in learner terms);
2. guided reinvention (after the designer has engaged in planning, a sequence of instructional activities are developed);
3. emergence of learner-developed models (learners' modelling activity is developed to support the reinvention process) (Gravemeijer et al., 2003, p. 52).

These three heuristics work together to assist learners to participate in activities that will develop sophisticated mathematical practices (Gravemeijer et al., 2003, p. 52).

Besides the three heuristics, RME is also characterised by five types of activities (Gravemeijer, 1994, p. 451; Kizito, 2012b, p. 103):

1. *Phenomenological exploration*: Teaching learners ways to manipulate the means of organising phenomena that need to be organised.
2. *Using models and symbols for progressive mathematization*: Attention is given to models, model situations and schemata that arise from problem-solving activities.
3. *Learner contributions*: Learners are encouraged to create their own constructions and productions.
4. *Interactivity:* A learning process is constructed where learners' informal methods are used to negotiate, intervene, discuss, co-operate and evaluate.
5. *Intertwining:* Problem-solving consists of an interlinking of learning strands.

As far as possible, these activities should be included in a RME approach.

The notion of guided reinvention is closely associated with RME. As Freudenthal (1973) points out, Mathematics is an activity where the most important activity is mathematization, which implies a form of organization from a mathematical perspective. This organisation or mathematization is how the learners can reinvent Mathematics, but it is important to note that learners are not meant to reinvent on their own. Freudenthal (1973) refers to guided reinvention, where the emphasis is not on the invention, but rather on the process that takes place (Gravemeijer & Doorman, 1999, p. 116). The process starts where real life situations are mathematized, and continues where reinvention takes place in which learners also mathematize their own mathematical activity (Gravemeijer & Doorman, 1999, p. 116). In practice this would mean that specific contextual problems are given to learners where they are given the opportunity to create solutions within the given context. The reinvention

takes place when learners use their everyday language to structure the given problems into both informal and formal mathematical forms (Barnes, 2004, p. 56).

In order to apply the principles of RME, the development of a Hypothetical Learning Trajectory (HLT) is required. Simon (1995) refers to HLT which represents a framework for teachers to adapt instructional sequences that suit their needs in the classroom. An HLT comprises three components: the teacher's goal or aim for learner learning that determines the direction, the actual mathematical tasks that will be used to promote learner learning, and a predicted view or hypothesis regarding the process of learner thinking, learning and understanding that will shape in the context of the learning activities (Baroody, Cibulskis, Lai, & Li, 2004, p. 231; Simon, 1995, p. 133). HLT is the course along which learning might proceed, as predicted by the teacher. The creation and on-going modification and refinement of these learning activities form a cyclical process. As teachers evaluate learners' thinking and learning, new ideas for learning activities can be planned. These learning activities depend on the teacher's hypotheses about the development of learners' thinking and learning (Simon, 1995, p. 136).

A number of key aspects play a role in the teaching process. These aspects include: the teachers' knowledge of Mathematics, their views about learners' cognitions, their theories about Mathematics teaching and learning, their knowledge of learning with respect to specific mathematical content, and their knowledge of mathematical representations, materials and activities (Simon, 1995, p. 133). These ideas are reinforced by research done on Mathematical Knowledge for Teaching (MKT).

Mathematical Knowledge for Teaching (MKT) is defined as the "mathematical knowledge needed to perform the recurrent tasks of teaching mathematics to learners" (Ball, Thames, & Phelps, 2008, p. 399). As an extension to the work of Shulman (1986), Ball et al. (2008, p. 403) distinguish between different domains for mathematical knowledge for teaching, namely subject matter knowledge and pedagogical content knowledge, which in turn are subdivided into the following categories: common content knowledge, horizon content knowledge, specialised content knowledge, knowledge of content and learners, knowledge of content and teaching and knowledge of content and curriculum. When referring to the mathematical knowledge that teachers need to teach, Ball et al. (2008, p. 395) consider "teaching" to entail the following activities: planning the lessons, evaluating learners' work, designing and assessment, explaining classwork to parents, designing and managing homework and dealing with equity. Mishra and Koehler (2006) also expand on the work of Shulman (1986) by introducing the knowledge of technology as an essential knowledge domain. The Technological Pedagogical Content Knowledge (TPACK) framework presents the three main components of teachers' knowledge: content, pedagogy and technology. Not only are these aspects important, but the interactions between them which are represented as PCK (pedagogical content knowledge), TCK (technological content knowledge), TPK (technological pedagogical knowledge) and TPACK (technological pedagogical content knowledge) are essential (Mishra & Koehler, 2006, p. 62). The role of a teacher's MKT is therefore vital in his or her construction of an HLT.

1.3.2 Information and Communication Technology and Mathematics Education

The positive effects of using technology in teaching and learning situations are becoming more apparent (Bennison & Goos, 2010, p. 31; Chinnappan, 2003, p. 35; Li, 2003, p. 72; Mistretta, 2005, p. 18). Training teachers to integrate technology in the classroom and continuing to investigate the effects of technology on teaching and learning are two ways to empower technology-based learning environments (Mistretta, 2005, p. 23). The need to assist both pre-service and in-service Mathematics educators to develop the ability to effectively make use of technology in their classrooms is becoming more pronounced and important. It is suggested that technology is best learned in context and should thus be integrated into coursework and field experience (Li, 2003, p. 62). Li (2003, p. 62) believes that teacher-students should see their professors modelling or demonstrating the use of technology.

In a study that explored the use of the Internet (discussion forums, online material, e-journaling, computer games) in a Mathematics education course, teacher-students felt that instructional technology could be an effective tool for their own learning. They also indicated that the use of the Internet in the course assisted them with aspects like improving communication with one another, which in turn could enhance their understanding of educational theories. Other advantages of using instructional technology that they mentioned, include that it gives time for synthesis, it enhances learning by providing visual and interactive experiences, and it saves time (Li, 2003, p. 72).

Although teachers use technology to display or present content, many are not aware of the potential that technology has to promote concept development in the Mathematics classroom (Serow & Callingham, 2011, p. 161). The role of the teacher in integrating technology in Mathematics education is extremely important. The teacher has to coordinate learning by creating technology-rich activities, use appropriate tool techniques and relate the experiences in the technological environment to mathematical activities. To achieve this, a process of professional development is needed (Drijvers, 2012, p. 12). Serow and Callingham (2011, p. 171) who conducted research on the use of the Interactive Whiteboard (IWB) in teaching primary school Mathematics, suggest that Mathematics teachers require time to explore and develop teaching materials and should be allowed to work with a mentor from an early stage when it comes to effective professional development.

Facebook was originally designed as a social networking website, but has proceeded to be used in educational settings as well. Grossecka, Branb, and Tiruc (2011, p. 1426) review characteristics from literature concerning learners and teachers. The learners recommend Facebook as a tool that has the potential to contribute significantly to the educational arena. For the learners, some advantages include the following: to be involved in achieving learning tasks; to develop communication, cognitive and social competencies; to create their own learning path by establishing links and connections; to consolidate self-confidence and self-esteem and to communicate with the teacher outside the class.

For the teacher, the following benefits are highlighted: to practise a differential pedagogy in the best interest of the learners; to perform mentoring; to interconnect learning experiences; to expand the communicative experience with the learners concerning didactic issues and to give up on old behavioural patterns (Grossecka et al., 2011, p. 1427).

GeoGebra is freely-available open-source dynamic Mathematics software which incorporates Geometry, Algebra, Calculus and a spread sheet into a single software package. To merely provide teachers with technology is not enough for them to successfully integrate the technology into their teaching (Hohenwarter & Lavicsa, 2007, p. 49). Hohenwarter and Jones (2007, p. 130) assert that, apart from online collaboration, teachers should also be offered professional development in terms of the use of technology in their teaching and also research activities should be coordinated, especially in relation to GeoGebra.

1.3.3 Realistic Mathematics Education and Technology

As the TPACK framework of Mishra and Koehler (2006) suggests, ICT is a suitable means to promote the realization of alternative approaches to Mathematics, such as the realistic approach (Widjaja & Heck, 2003, p. 3). In their study which focused on the applicability of ICT-supported lessons, based on a RME approach, Widjaja and Heck (2003) reported that learners were both positive towards the use of ICT in lessons before and after implementing different ICT related tasks. Not only did learners' performance improve in this study, but 77% of the group agreed or strongly agreed that doing activities using a computer was interesting and exciting and looked forward to making use of ICT in their next Mathematics lessons.

A study which explores teachers' views on Mathematics education and the role of technology therein, and was guided by RME principles, reveals that teachers see technology as a means to stimulate interaction in the class, a key principle in RME (Drijvers et al., 2010a, p. 222). The study also revealed that teachers see technology as an effective means to achieve their teaching goal in Mathematics; they believe that ICT could help learners to develop understanding; and that technology is a suitable and useful means to provide scaffolding for learners with mid-ability who benefit from clear demonstrations and explanations in a structured manner (Drijvers et al., 2010a, p. 223).

A literature study to explore the existing body of knowledge with regard to the adoption of a RME approach, facilitated by technology to enhance teaching practice, was conducted. A systematic literature review was performed to not only limit bias (Petticrew & Roberts, 2006, p. 9), but also to summarise the existing evidence relating to the topic, to identify any gaps in current research to suggest possible areas for further investigation and to provide an appropriate background to position new research (Kitchenham, 2004, p. 2). Although not a common feature, systematic literature reviews have been used in the social sciences for many decades and are increasingly used to not only direct new research, but to support practice and policy (Petticrew & Roberts, 2006, p. 23).

The systematic literature review was done with the aid of the databases Scopus, EBSCOHost, Web of Science, Science Direct, MathSciNet, and Google Scholar. Various combinations of the following keywords were used to perform the searches: realistic* or RME, teach* or learn* or educat*, math*, tech* or ict or educat* tech*.

1.4 Research Questions

The study aimed to address the following main research question: *What are the guidelines for the effective use of technology in implementing the RME approach in teaching practice?* In order to effectively answer this research question, two sub-questions were also posed to gain insight on the main question. These questions were:

1. How can the use of the RME approach, facilitated by technology, enhance teaching practice?
2. What support needs do teachers have in order to effectively implement the RME approach in their teaching practice?

1.5 Purpose of the Study

The purpose of the study was to:

- Develop an understanding of how the RME approach, facilitated by technology, can enhance teaching practice;
- Establish support needs of teachers in order to effectively implement the RME approach in their teaching practice;
- Develop guidelines for the effective use of technology in implementing the RME approach in teaching practice.

1.6 Research Design and Methodology

Each researcher brings with him or her certain beliefs and philosophical assumptions to their research, which are instilled in them through different influences (Creswell, 2013, p. 15). Philosophical ideas are often hidden in research, yet they still influence research practice. A worldview or paradigm is a researcher's orientation about the world and the nature of research (Creswell, 2009, p. 5). The significance of a paradigm is that it gives meaning to the world as we see it. The selected paradigm for this research was the interpretive paradigm. From an interpretive perspective, the focus is on describing, understanding or interpreting an experience (Merriam, 2009, p. 11).

Creswell (2013, p. 15) suggests that a qualitative researcher highlights the importance of understanding these beliefs and assumptions and also actively writes about them in a study, and this I have duly done in the study. The interpretive paradigm is "characterised by a concern for the individual" and aims to understand the "subjective world of human experience" (Cohen, Manion, & Morrison, 2011, p. 17). Interpretive approaches start with individuals and aim to understand those individuals' interpretation of the world around them (Cohen et al., 2011, p. 18). Interpretive research is the most common type of qualitative research and works from the premise that reality is socially constructed; and that there is no single observable reality, but rather multiple realities (Merriam & Tisdell, 2016, p. 9).

Researchers with interpretivist goals describe and attempt to explain the meaning or implications of phenomena related to educational factors such as teaching, learning, performance, assessment and social interaction (McKenney & Reeves, 2012, p. 29). Design experiments aim to support the composition of an empirically grounded local instruction theory. They also aim to place classroom events in a broader context and serve as the context for the development of theoretical frameworks that entail new scientific categories, which can be useful in generating, selecting and assessing design alternatives. The interpretive framework serves as an innovation for interpreting classroom discourse and communication, and also shows what norms to aim for to make the design experiment successful (Gravemeijer & Cobb, 2013, p. 80). The interpretive framework has a dual purpose: it acts as a lens for making sense of what is happening in a real world setting, and acts as a guideline for instructional design. It also offers guidelines on the characteristics of the classroom culture(Gravemeijer & Cobb, 2013, p. 89).

Qualitative research is a "situated activity that locates the observer in the world" and consists of interpretive practices that make the world visible (Denzin & Lincoln, 2011, p. 6). The qualitative researcher studies "things in their natural settings, attempting to make sense of or interpret phenomena in terms of the meanings people bring to them" (Denzin & Lincoln, 2011, p. 6). Merriam and Tisdell (2016, p. 15) point out that qualitative researchers are concerned with "understanding the meaning people have constructed; that is, how people make sense of their world and the experiences they have in the world." Qualitative researchers are concerned with "the meanings people attach to things in their lives" and identify with the people they study so as to understand how they see things (Taylor & Bogdan, 1998, p. 7).

As was the case in this study, various other qualitative studies including those of Baumann et al. (2013, p. 25); Juuti and Lavonen (2013, p. 49); Nathans and Revelle (2013, p. 164), have made use of a design-based research approach. Educational design-based research is an innovative and promising approach in which the iterative progression of solutions to complex problems provides the backdrop for scientific investigation (McKenney & Reeves, 2014, p. 131). Researchers who work with design-based research not only attempt to solve significant real world problems, but seek to unfold new knowledge (McKenney & Reeves, 2014, p. 131). The common features of design-based

research include the following: theories on learning and teaching are produced; it is interventionist; it is iterative and takes place in real life settings (Barab & Squire, 2004, p. 2). Design-based research is concerned with using design to develop models of how people think, know, act and learn; as well as to uncover, explore and confirm theoretical relationships (Barab & Squire, 2004, p. 5).

1.7 Population and Participant Selection

The teacher-students that participated in this research were enrolled at the North-West University (NWU) Potchefstroom Campus in South Africa. The NWU has three campuses across South Africa: Mafikeng Campus, Potchefstroom Campus and Vaal Triangle Campus. The Unit for Open Distance Learning (UODL) is situated on the Potchefstroom Campus and services in the region of 30 000 students who are registered to study various courses through distance education. The majority of these students are in the Faculty of Education Sciences, and are teachers who are under- or unqualified and who want to upgrade their qualifications (Pienaar, 2016, p. 1). The UODL has 65 study centres in South Africa, Namibia and other countries. Lectures are broadcast to these centres where students can attend contact classes and have access to a mini-library equipped with computers with Internet access (Spamer, 2016, p. 1). Figure 1.2 illustrates the location of the various study centres in South Africa and Namibia.

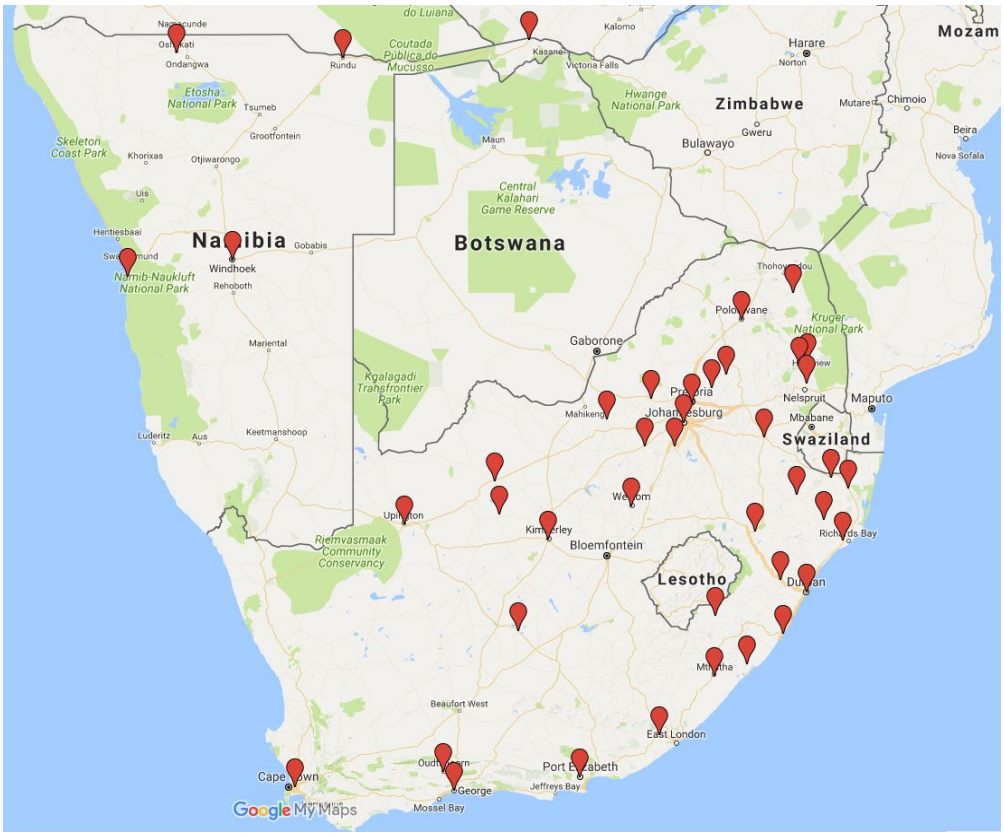

Figure 1.2: Distribution of NWU Study Centres across South Africa and Namibia

Many of the teacher-students are from disadvantaged schools and are women (Kok, 2009). They live in areas that range from deep rural areas where there is often no electricity or running water to fully urbanized communities such as Johannesburg and Cape Town. Many teacher-students work in classrooms that are often not well-equipped and teach large groups of learners (more than forty in a classroom). Despite these circumstances, the teacher-students still have the desire to improve their qualifications.

Stratified purposive sampling entails that participants are selected according to preselected criteria relevant to the research question (Nieuwenhuis, 2010c, p. 79). I selected this sampling method because I wanted to understand what needs in-service Mathematics teachers had in terms of making Mathematics more realistic for their learners. In this study, I selected participants from a group of in-service teachers enrolled for the BEd Honours post-graduate degree in Mathematics education at the NWU, which is delivered by both the dual face to face and ODL mode. The criteria for selection were as follows:

(i) teacher-students enrolled at the NWU for the BEd Honours degree through either face to face or ODL mode
(ii) teacher-students who attended contact classes for the degree in question
(iii) teacher-students who are currently teaching Mathematics in any Phase
(iv) male and female teachers at various schools.

1.8 Methods of Data Generation

After the systematic literature review had been completed, I designed an interview schedule for a semi-structured interview with teacher-students in order to establish what needs they had in relation to making the Mathematics content more realistic for their learners. Mathematics teaching that is related to real life has proved to enhance learners' understanding (Fauzan et al., 2013, p. 174) and can stimulate and address alternative conceptions of learners (Barnes, 2004, p. 63). I facilitated the semi-structured interviews with four teacher-students. When I coded and categorised the data, using ATLAS.ti™, I was able to determine two important aspects in this study: what areas of the curriculum were problematic to the teacher-students and also to their learners; and what areas they found difficult to present in a real life context. With the help of a programmer, I designed an application (app) to guide teacher-students in how to present mathematical content using the principles of RME. Teacher-students were given the opportunity to work with the app, and gave feedback at a follow-up focus group interview. These interviews were also coded with the aid of ATLAS.ti™.

1.9 Methods of Data Analysis

The data obtained through the interviews were transcribed and the documents were assigned to the Computer Assisted Qualitative Data Analysis Software (CAQDAS), ATLAS.ti™, where they were coded. ATLAS.ti™ offers a variety of tools to explore the phenomena concealed in the data. ATLAS.ti™ provided me with an environment in which to manage, compare, explore and reassemble meaning from the data in a systematic manner (Friese, 2014a, p. 10).

1.10 Ethical Aspects of this Research

The following ethical principles were applied throughout the project, namely that the participants were protected from any harm and the research data would at all times remain confidential (Fraenkel & Wallen, 2003, p. 57). The necessary ethics application form was completed and submitted to the North-West University's ethics committee, and permission was attained to commence the research. The ethical clearance number for this study is: NWU-HS-2014-0267. Participants were requested to complete a letter of consent, providing me with permission to continue with the project. The letter ensured participants that their participation was voluntary, their identity would remain anonymous, all information would be treated as confidential and that their decision whether to participate in the project or not, would not jeopardise their studies in any way.

1.11 Contribution of this Study

This contribution of this study would be to develop, implement and evaluate the use of the RME approach supported by technology, as presented to in-service teacher-students enrolled for a post-graduate degree in Mathematics education. The aim was to provide guidelines for the effective use of the RME approach, facilitated by technology, to enhance the usefulness of Mathematics in the classroom, and improve teaching and learning practice. The study contributed towards the subject area and discipline of Mathematics by providing insight into the needs of Mathematics teachers in terms of making Mathematics more realistic for their learners. The findings of this study could assist curriculum experts and lecturers in the designing and adaptation of study material that is more relevant for teaching practice. It could also assist teachers and learners by making the mathematical content more relevant and realistic for them. The study also produced guidelines as to how the RME approach could be successfully facilitated by technology to improve teaching and learning practice.

1.12 Clarification of Important Terminology

Table 1.2 presents the clarification of some important terminology used in the study.

Table 1.2: Table for Clarification of Terminology

Term	Clarification of term
Mathematics	Freudenthal (1968, p. 4) argues that Mathematics has proved indispensable for the understanding and the technological control of both the physical world and the social structure. Mathematics has been described by some as a static discipline developed abstractly, while others see it as a dynamic discipline constantly changing due to new discoveries (Dossey, 1992, p. 39). Other authors describe Mathematics as the science of pattern and order, which challenges the view that Mathematics is merely a discipline dominated by computation (Van de Walle, Karp, & Bay-Williams, 2013, p. 13). Mathematics is also described as a human endeavour in which ordinary people construct concepts, discover relationships, invent methods, execute algorithms, communicate and solve problems posed by the real world (Cangelosi, 2003, p. 7).
Realistic Mathematics Education (RME)	Realistic Mathematics Education (RME) is rooted in the work of Freudenthal (1973). Freudenthal views Mathematics as a human activity of sense-making where learners should be given the opportunity to reinvent Mathematics by organising or mathematizing real world situations. The basic principles of RME view the learning of Mathematics as a progressive reorganisation of real world situations or mathematical processes (Cobb et al., 2008, p. 107).
Learning technology	Learning technology is defined as the application of technology for the enhancement of teaching, learning and assessment (Rist & Hewer, 1996, p. 3). Learning technology is viewed as not only a technical skill or as a means of improving learning effectiveness, but also a way of shifting goals and processes of education (Law et al., 2008, p. 14).
Technology	Technology has the potential to promote generalisation and justification by enabling fast and accurate computation, collection and analysis of data (Goos, Galbraith, Renshaw, & Geiger, 2003, p. 74). It is also able to provide learners with rich learning environments, which allows them to adopt a wide range of perspectives on complex issues and cater for individual differences (Sang, Valcke, van Braak, & Tondeur, 2010, p. 103).
Student teacher	Student teacher refers to pre-service students who are studying in the field of education.
Teacher-student	Teacher-student refers to teachers, who are currently in the profession, but who are furthering their qualifications on a part-time basis, the mode of delivery could be either face-to-face or open-distance learning (ODL).

Chapter Two

Research Design and Methodology

2.1 Introduction

The literature offers various definitions for research. One such definition is that research is a step by step process of collecting and analysing information to increase our understanding of a topic or issue (Creswell, 2014, p. 17). Merriam and Tisdell (2016, p. 3) state that what most of these definitions have in common is the idea of "inquiring into, or investigating something in a systematic manner." Research is important because its adds to our knowledge, it improves practice and it informs policy debates (Creswell, 2014, p. 18). Researchers bring their own beliefs and philosophical assumptions to their research projects. There is a close connection between the philosophy that researchers hold and how they advance to use a framework to encompass the investigation (Creswell, 2013, p. 15).

Educational research is important because it helps us in understanding educational processes, guides our decision making and can enhance classroom, school and system accountability (McMillan & Schumacher, 2014, p. 11). This research aims to produce guidelines for the effective facilitation of technology to facilitate Realistic Mathematics Education to enhance teaching practice.

This chapter in detail describes the choices I made during my research journey and it informs all subsequent chapters in terms of the world view of the researcher, the design and methodology for this study, choices regarding research strategies, intervention strategies and the consequent guidelines. Figure 2.1 illustrates the research design and methodology that has been used in this study.

The study is driven by the research question as discussed in § 1.4, namely: *What are the guidelines for the effective use of technology in implementing the RME approach in teaching practice?* The two sub-questions that were posed to gain insight on the main question were:

1. How can the use of the RME approach, facilitated by technology, enhance teaching practice?
2. What support needs do teachers have in order to effectively implement the RME approach in their teaching practice?

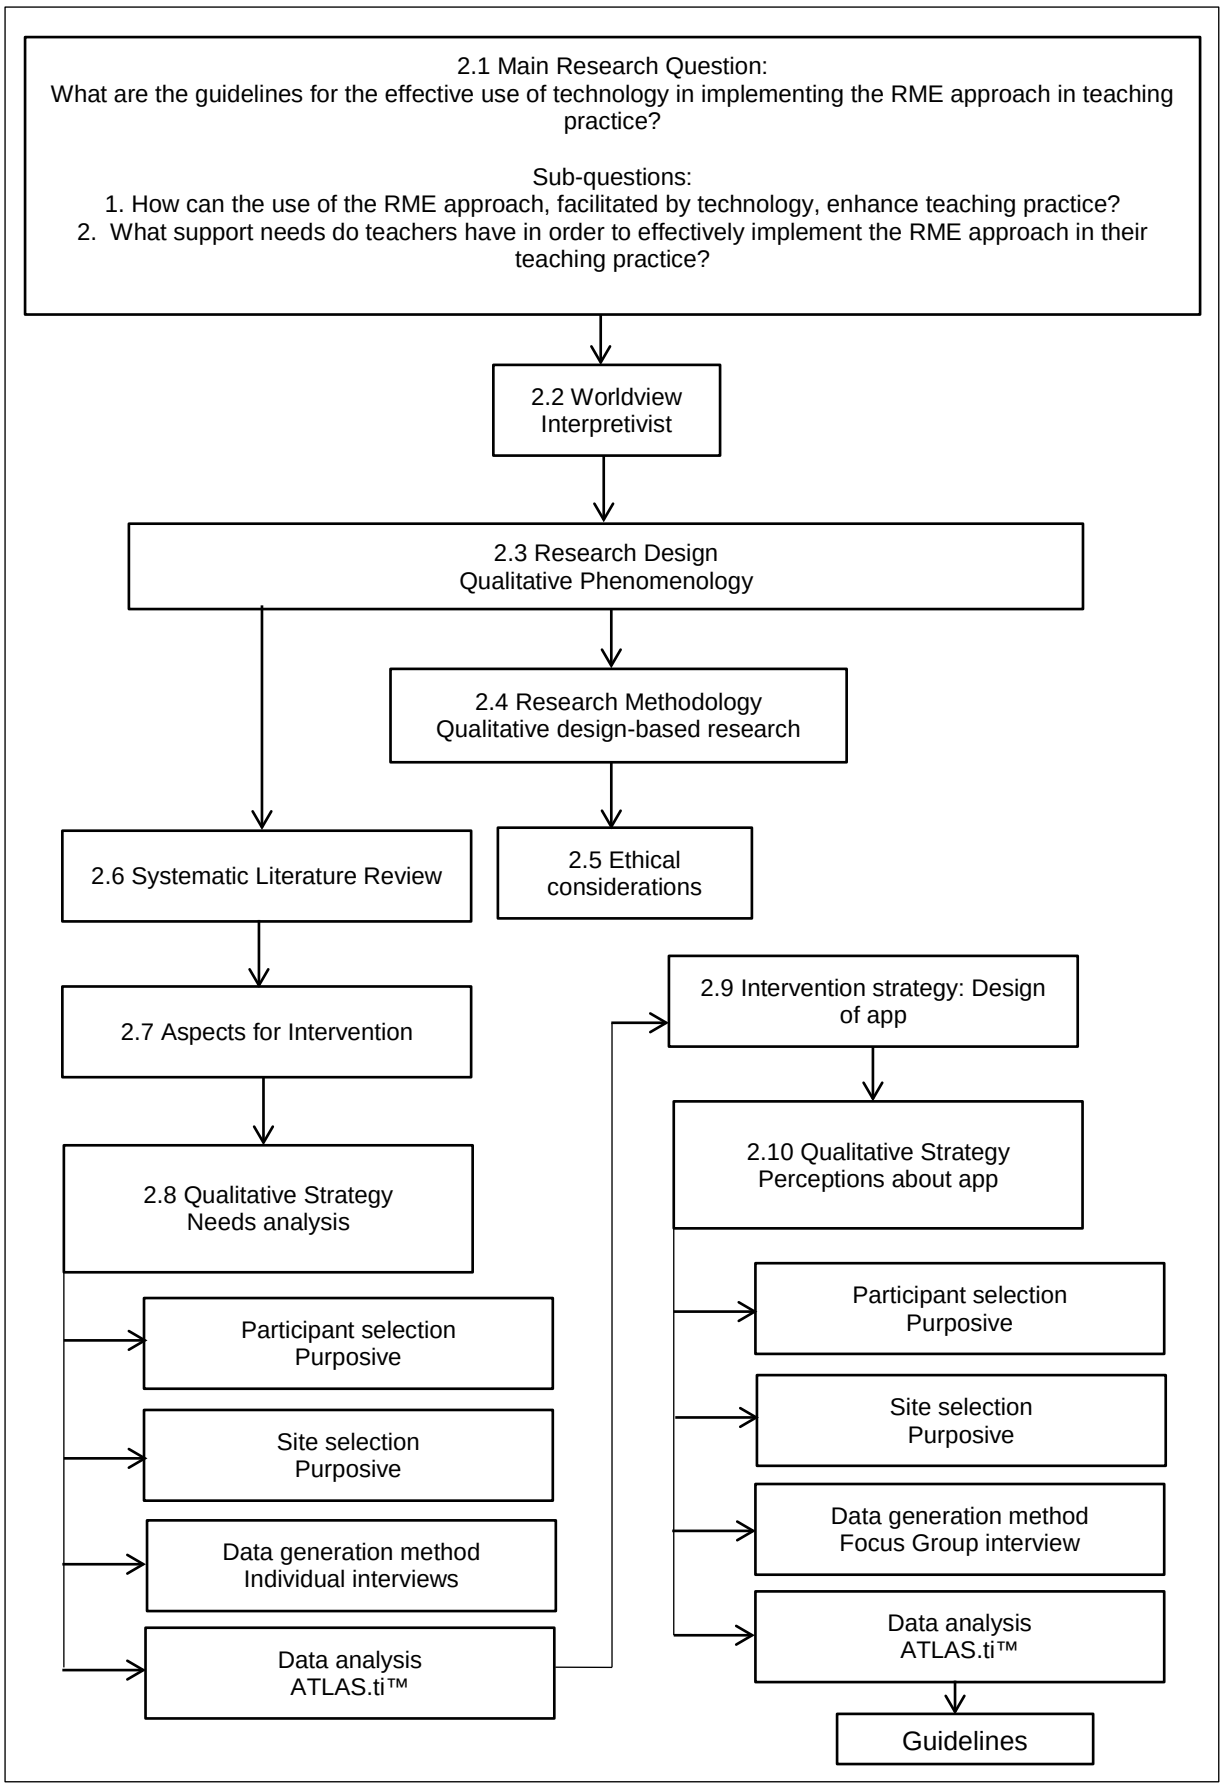

Figure 2.1: Research Design and Methodology for this Study

2.2 Worldview of the Research

Social scientists have particular assumptions about the nature of the social world, and they approach their subject with this in mind. These assumptions are of an ontological, epistemological, human, and methodological nature (Burrell & Morgan, 1994, p. 1). Burrell and Morgan (1994, p. 2) refer to assumptions of an ontological nature as the very essence of the phenomena being investigated; assumptions of an epistemological nature as the "assumptions about the grounds of knowledge," how one can understand the world and communicate this knowledge to others; and assumptions about human nature as the relationship between human beings and their environment. The three sets of assumptions directly impact the methodological nature. Different models of ontology, epistemology and human nature direct social scientists to different methodologies (Burrell & Morgan, 1994, p. 2).

As Merriam (2009, p. 8) and Creswell (2013, p. 19) aptly explain, there is little consistency regarding the philosophical foundations of qualitative research. As is typical of qualitative research, different authors make sense of the philosophical influences each in his or her own way. Various terms and descriptions are used such as: paradigms; philosophical assumptions; traditions and theoretical underpinnings; theoretical traditions and orientations; theoretical paradigms; worldviews and epistemology; and theoretical perspectives (Creswell, 2013, p. 19; Merriam, 2009, p. 8). In essence they are beliefs about ontology (the nature of reality), epistemology (what counts as knowledge and how knowledge claims are justified), axiology (the role of values in research) and methodology (the process of research) (Creswell, 2013, p. 20). These beliefs shape how the qualitative researcher views the world and acts in it (Denzin & Lincoln, 2013, p. 26). Berman and Smyth (2013, p. 6) suggest a model to illustrate the alignment of ontology, epistemology and methodology within a doctoral study.

Table 2.1 Pedagogical Model for the use of Conceptual Frameworks in a Doctoral Study (Berman & Smyth, 2013)

What is your conceptual framework?		
WHAT ontology	HOW methodology	WHY epistemology
Context for the research problem	Research theme(s)	New knowledge
Key concepts	Explicit research questions	New theorising
Relationships	Research design	Extent (limits) of generalising
Establishment of terminology and common language	Methodology (data gathering, organising, analysing, interpreting)	Implications for practice
Boundaries for conclusions and theorising	Validity (conceptual, practical ...)	

They refer to these aspects as the *what, why* and *how* of research and represent the alignment of ontology, epistemology and methodology. The ontology, or *what* is being researched, refers to the reality of the context of the research problem; it must be clear and confined so that a solid foundation for shared meaning can be established (Berman & Smyth, 2013, p. 6). These ontological concerns are linked to the meaning of the research, or the epistemology (the *why* of the research). As new knowledge is generated from comprehensive abstract thinking, epistemological outcomes can be

produced which could have both theoretical and practical implications. The higher order thinking and conceptualisation of reality and knowledge and the specific epistemology guides the nature of the methodology (the *how* of the research) (Berman & Smyth, 2013, p. 6).

2.2.1 Ontology

In classical philosophy, ontology referred to the science of being; however, the meaning has evolved during the contemporary era (Given, 2008, p. 577). Ontology is in essence a form of questioning (Given, 2008, p. 580) and refers to the nature of reality and its characteristics (Creswell, 2013, p. 20; Ormston, Spencer, Barnard, & Snape, 2014, p. 2; Willis, Jost, & Nilakanta, 2007, p. 9). Different ontological perspectives reflect different prescriptions of what can be real and what cannot be real (Willis et al., 2007, p. 9). One's beliefs about the nature of reality or ontology is an indication of one's philosophical positioning (Merriam, 2009, p. 8), which means that different researchers, the individuals being studied as well as the readers of the qualitative study, embrace different realities (Creswell, 2013, p. 20). The aim of qualitative research is to report these multiple realities using varied evidence in themes where actual words of different individuals are used to present different perspectives (Creswell, 2013, p. 20).

2.2.2 Epistemology

Epistemology is an essential part of a philosophical study that "includes the sources and limits, rationality and justification of knowledge" (Given, 2008, p. 264). It refers to the nature of knowledge (Merriam, 2009, p. 8) and how it can be acquired (Ormston et al., 2014, p. 2); theories of knowledge and perceptions in science (Flick, 2014, p. 536); the relationship between the inquirer and the known (Denzin & Lincoln, 2013, p. 26) or otherwise phrased, as the nature of the relationship between the researcher and what can be known (Terre Blanche & Durrheim, 2006, p. 6). Epistemology is concerned with what we know about reality and how we get to know it (Willis et al., 2007, p. 10). When doing a qualitative study, the researcher tries to get as close as possible to the participants being studied in order to accumulate subjective evidence based on individual views (Creswell, 2013, p. 20). The subjective experiences of people create knowledge, which means that studies need to be conducted in the field, where participants live and work (Creswell, 2013, p. 20).

The interpretive paradigm is informed by a concern to understand the world as it is, and strives to explain the world within the participant's frame of reference, rather than that of the observer (Burrell & Morgan, 1994, p. 28). Interpretive research starts out with the assumption that reality can only be accessed through social constructions like language, consciousness and shared meanings. Interpretive research is guided by a set of beliefs and emotions about the world and how it should be understood and studied (Denzin & Lincoln, 2011, p. 12). Interpretive studies attempt to understand phenomena through the meanings that people assign to them, and aim to offer a perspective of a

situation and analyse a situation to provide insight into the way in which a particular group of people make sense of their situation (Nieuwenhuis, 2010b, p. 60).

Burrell and Morgan (1994) have done extensive work relating to different approaches to social theory. They identify four paradigms for the analysis of social theory (Figure 2.2).

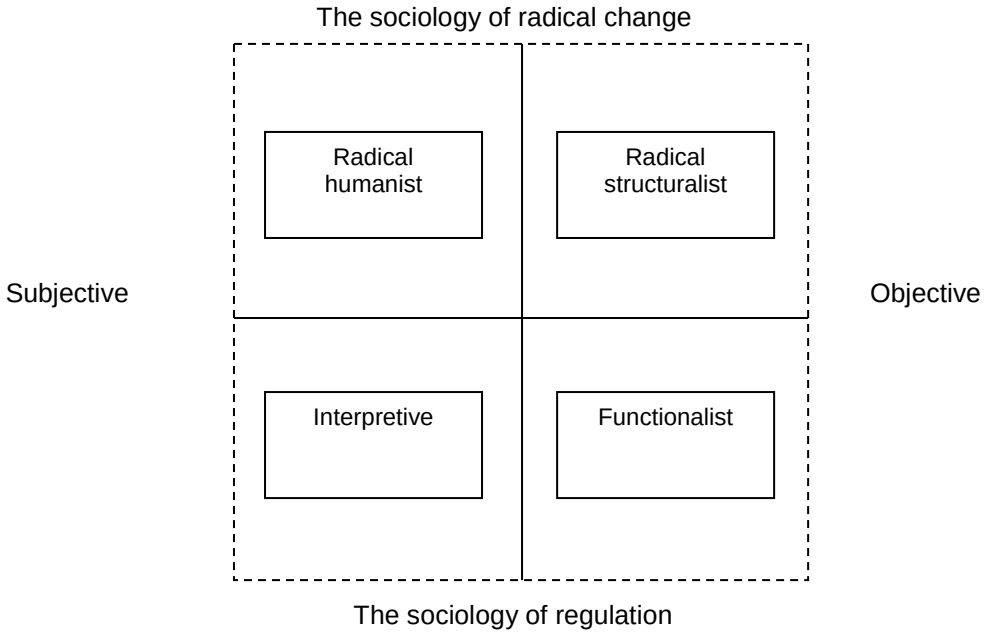

Figure 2.2: Four Paradigms for the Analysis of Social Theory (Burrell & Morgan, 1994, p. 22)

The four paradigms describe overlapping, but fundamentally different perspectives for analysing social phenomena (Burrell & Morgan, 1994, p. 23). These four paradigms represent four sets of basic assumptions in social theory, and they define four views of the social world based on different assumptions with regard to science and society (Burrell & Morgan, 1994, p. 24). When located in each different paradigm, the world is viewed in a particular way. The functionalist paradigm represents a perspective which approaches its subject matter from an objectivist point of view. It is rooted in the sociology of regulation. This paradigm is concerned with explaining the following issues: the status quo, social integration, solidarity, need satisfaction and actuality. These concerns are approached from an outlook that is realist, positivist, determinist and nomothetic. In general this paradigm provides rational explanations of social affairs; it is pragmatic in nature and is concerned with understanding society in a way which produces knowledge (Burrell & Morgan, 1994, pp. 25-26).

Since this study is rooted in the Interpretivist paradigm, this paradigm will be discussed in detail in § 2.2.3. The radical humanist paradigm is concerned with developing a sociology of radical change from a subjectivist point of view. It sees the social world from a nominalist, anti-positivist, voluntarist and ideographic perspective. In this paradigm social theorising is designed to critique the status quo.

In this paradigm, the greatest emphasis is based on radical change, modes of domination, emancipation, deprivation and potentiality (Burrell & Morgan, 1994, p. 32).

The radical structuralist paradigm promotes a sociology of fundamental change. It is dedicated not only to radical change, but also to emancipation and potentiality, and emphasises structural conflict, modes of domination, contradiction and deprivation. This paradigm approaches these issues from a realist, positivist, determinist and nomothetic perspective. The rational structuralist focuses on structural relationships within a realist social world (Burrell & Morgan, 1994, p. 34).

2.2.3 Interpretivist Paradigm

The interpretivist paradigm is driven by a concern to understand the world as it is, to understand the fundamental nature of the social world. It strives to explore the realm of individual consciousness and subjectivity within the participant's frame of reference. The interpretivist paradigm's approach to social science is nominalist, anti-positivist, voluntarist and ideographic. It views the social world as a developing social process, created by the concerned individuals (Burrell & Morgan, 1994, p. 28). Interpretivist theorists strive to understand the basis and source of social reality. Their stance is backed by the assumption that the world of human affairs is cohesive, ordered and integrated. Issues like conflict, domination, contradiction, potentiality and change do not feature in their framework. Their concern is with understanding the social world "as it is" and is involved with issues relating to the nature of social order (Burrell & Morgan, 1994, p. 31).

Interpretivist research is guided by specific beliefs and feelings about the world and how it should be understood and studied (Denzin & Lincoln, 2013). For interpretivists, the meaning of the world for the person or group being studied is critically important to good research in social sciences (Willis et al., 2007, p. 6). Denzin and Lincoln (2013, p. 27) categorise the interpretivist paradigm as positivist and postpositivist, constructivist-interpretivist, critical and feminist-poststructural. A core belief of this paradigm is that the reality we know is socially constructed (Merriam & Tisdell, 2016, p. 9; Willis et al., 2007, p. 95), which implies that researchers only have access to a socially constructed reality (Willis et al., 2007, p. 97). This serves as a justification as to why social constructivism is also known as interpretivism (Creswell, 2013, p. 24), and that there is no single observable reality (Merriam & Tisdell, 2016, p. 9). Understanding the context in which the research takes place is crucial to the interpretation of the data that are gathered (Willis et al., 2007, p. 98).

The purpose of interpretivist research is to understand a particular situation, and not to discover universal laws (Willis et al., 2007, p. 111). There is not a so-called "correct way" of viewing a particular situation, it is rather an understanding of multiple perspectives on the topic (Willis et al., 2007, p. 113). Individuals develop subjective meanings, which are directed towards certain objects, of their experiences. The meanings are many and diverse, which means that the researcher needs to seek the complexity of the views, rather than limit the meaning into a few selected categories (Creswell,

2013, p. 24). This kind of research addresses the process of interaction between individuals. The contexts in which people live and work need to be considered when attempting to understand the historical and cultural setting of the participant. The researchers' own backgrounds, such as their own personal, cultural and historical experiences, shape the way in which they interpret the research (Creswell, 2013, p. 25). Interpretivists do not consider any form of research to be completely objective and tend to prefer data sources that are close to the point of application because context is so important in the interpretation of data (Willis et al., 2007, p. 111). Qualitative research is most often located within an interpretive paradigm, which assumes that reality is socially constructed and that there are numerous realities or interpretations of a single event (Merriam, 2009, p. 8).

2.3 Research Design: Qualitative Phenomenology

Research design refers to the decisions about how research is conceptualised, the conducting of a research project and the type of contribution the research is envisioned to make to the body of knowledge (Given, 2008, p. 761). The process in which a research design is developed entails three related components, namely the theoretical, methodological and ethical considerations, which all shape the design and what the research is aiming to achieve (Given, 2008, p. 761). A research design describes a flexible course of action that links theoretical paradigms to two aspects, namely strategies of inquiry and methods of collecting empirical data (Denzin & Lincoln, 2008, p. 33). It also positions the reader in the empirical world and connects him or her to specific locations, persons, groups, organisations and forms of relevant interpretive material such as documents and archives (Denzin & Lincoln, 2008, p. 34).

2.3.1 Research Approach: Qualitative Design

One of the most generic definitions for qualitative research is offered by Denzin and Lincoln (2008, p. 4), namely that it is "a situated activity that locates the observer in the world." Qualitative research can be used to explore a problem or issue, to empower individuals to share their experiences, and/or to develop theories when partial or inadequate theories need to be further explored (Creswell, 2013, p. 48). It aims to thoroughly describe "life-worlds" from the participants' points of view and strives to create a better understanding of social realities (Flick, von Kardoff, & Steinke, 2010, p. 3). It involves the collection of different kinds of empirical material that describes moments and meanings in individuals' lives (Denzin & Lincoln, 2013, p. 7).

Qualitative researchers are concerned with understanding how people interpret their experiences, how they create their worlds and what meaning they ascribe to their experiences (Merriam & Tisdell, 2016, p. 6). They accentuate the importance of both understanding and writing about the beliefs and theories that inform their research (Creswell, 2013, p. 15); they collect data in a natural setting and are sensitive to the people and places that are being studied. The final report presents "the voices of the

participants, the reflexivity of the researcher, a complex description and interpretation of the problem, and its contribution to the literature" (Creswell, 2013, p. 44). Creswell (2013, p. 44) emphasises the process of research, namely the philosophical assumptions, interpretive lens, and the procedure for studying human or social problems.

Creswell (2013, p. 45) describes an extensive list of characteristics of qualitative research, which include the following aspects: the research is conducted in a natural setting; the researcher acts as a key instrument in data collection; it involves the use of multiple methods; complex reasoning through inductive and deductive logic is used; it focuses on participants' perspectives and meanings; it is situated within the context of the participants; it involves an emergent and evolving design; it is reflective and interpretive and sensitive to the researcher's background; and it presents a holistic, complex picture of the issue being studied. Flick (2014, p. 14) narrows this list down to the following essential features, namely: the correct choice of appropriate methods and theories; recognising the perspectives of the participants and their diversity; the researchers' reflections on the research (reflexivity); and the variety of approaches and methods in qualitative research. Qualitative research should be used when an issue needs to be explored and we need a detailed understanding of the issue, and to develop theories (Creswell, 2013, p. 47).

Qualitative research is concerned with understanding the meaning people have constructed, which means it has to do with how people make sense of their world and the experiences they have in the world (Merriam, 2009, p. 13). Although various characteristics have been explored to understand qualitative research, Merriam (2009, p. 14) highlights four characteristics that stand out as most important in understanding qualitative research. These are: the focus is on the process, understanding and meaning; the researcher is the main instrument in collecting and analysing the data; the process is inductive, and the product is richly descriptive.

Nieuwenhuis (2010b, p. 50) refers to qualitative research as research that attempts to collect rich descriptive data about a particular phenomenon or context in order to develop an understanding of what is being observed. The focus is on how individuals and groups view and understand the world and construct meaning from their experiences. Qualitative research is concerned with understanding the processes and the social and cultural contexts which underlie behavioural patterns. It studies people or systems by interacting with and observing the participants in their natural environment, the focus being on their interpretations and meanings. The emphasis of qualitative research is on the quality and depth of information, rather than on the scope or the breadth of the information. (Nieuwenhuis, 2010b, p. 51).

The most important concern is therefore to understand the phenomena being researched from the perspective of the participant rather than the researcher. In order to effectively understand the phenomena, it makes most sense that the researcher acts as the primary instrument to collect and analyse the data, since he or she could expand his or her understanding through verbal and non-

verbal communication, by processing data immediately, summarizing material, making certain that interpretation is accurate by checking with participants and exploring responses that were unusual or unexpected (Merriam, 2009, p. 15). Qualitative research is concerned with gathering data to build concepts, hypotheses or theories instead of deductively testing hypotheses. The product of qualitative research is abundantly descriptive because words and pictures rather than numbers are used to express what has been discovered about the phenomenon (Merriam, 2009, p. 16).

2.3.2 Qualitative Approach to Inquiry: Phenomenology

Phenomenology emphasises the subjectivity and relativity of reality and highlights the need to understand how humans view themselves and the world around them (Willis et al., 2007, p. 53). It is the study of the way in which people perceive the world, rather than trying to learn what the world is. The focus is on understanding from the perspective of the person(s) being studied (Willis et al., 2007, p. 107). Phenomenology focuses on the lived experience and how being subjected to an experience is converted into consciousness (Merriam & Tisdell, 2016, p. 26). The task of the phenomenologist is to portray the quintessence of the experience, which can often be an intense human experience (Merriam & Tisdell, 2016, p. 26).

A phenomenological study describes the mutual meaning for a number of individuals, of their lived experiences of a concept or a phenomenon, the focus being on the description of what participants have in common as a particular phenomenon is experienced (Creswell, 2013, p. 76). A study such as this produces a "composite description that presents the 'essence' of the phenomenon" (Creswell, 2013, p. 82). It refers to the study of the perceptions of the person being studied (Willis et al., 2007, p. 108). Phenomenology serves to reduce an individual experience with a phenomenon to an account of the universal principle. It is in many ways the study of consciousness (Willis et al., 2007, p. 172) and is ideally used in the social sciences (Creswell, 2013, p. 77). Two types of phenomenology exist, namely hermeneutic phenomenology; and empirical, transcendental, or psychological phenomenology. Hermeneutical phenomenology is research that is directed towards lived experiences where the transcripts of life are interpreted (Creswell, 2013, p. 79).

2.4 Research Methodology: Qualitative Design-based Research

A researcher's philosophical stance and paradigm informs the methodology used, including the research design and techniques used to gather, analyse and interpret the data (Creswell & Clark, 2011, p. 38). Methodology refers to the way in which we approach problems and look for answers (Taylor & Bogdan, 1998, p. 3); how we know the world or gain knowledge of it (Denzin & Lincoln, 2011, p. 12); the process of how we look for new knowledge (Lincoln, Lynham, & Guba, 2013, p. 213). Methodology is interwoven with and develops from the nature of a particular discipline and perspective (Lincoln et al., 2013, p. 200). The methodology of qualitative research is considered to be inductive,

emerging and guided by the researcher's experience in collecting and analysing the data (Creswell, 2013, p. 22).

Qualitative research served as a suitable approach within design-based research methodology in a number of studies (Guler & Altun, 2010, p. 118; Gunn & Lefoe, 2013, p. 45; Nathans & Revelle, 2013, p. 164). Design-based research is a suitable approach for a short-term project such as a PhD provided the relevant phases are followed and the required outcomes are achieved (Pool & Laubscher, 2016, p. 10). It necessitates a significant literature review and theory generation and makes use of different data analysis and collection methods which are used in quantitative or qualitative research, and is considered to be an effective and efficient approach to investigate processes in educational settings (Wang & Hannafin, 2005, p. 6). Design-based research is considered to be a series of approaches set on producing new theories, artefacts and practices that can have an impact on teaching and learning (Barab & Squire, 2004, p. 2).

The design-based research approach is rooted in two approaches in the teaching of Mathematics, namely the socio-constructivist approach and the RME approach (Gravemeijer & Cobb, 2013, p. 74). The theory of RME offers design heuristics and also functions as an interpretivist framework to interpret student activity in the learning of Mathematics (Gravemeijer & Cobb, 2013, p. 89). Plomp (2007, p. 13) describes educational design-based research as "the systematic study of designing, developing and evaluating educational interventions (such as programmes, teaching-learning strategies and materials, products and systems) as solutions for complex problems in educational practice, which also aims at advancing our knowledge about the characteristics of these interventions and the processes of designing and developing them." Design-based research in education is described as research in which the design of materials such as computer tools or learning tasks forms an essential part of the research. The design of learning environments is interwoven with the developing of theory (Bakker & van Eerde, 2012, p. 2). Design-based research is defined by the goals of those who pursue it, rather than by its methods (McKenney & Reeves, 2012, p. 28). Plomp (2007, p. 11) distinguishes between different research functions which characterise design-based research, namely to describe, to compare, to evaluate, to explain or to predict, to design and develop. The focus of design-based research is on understanding (Gravemeijer & Cobb, 2013, p. 74).

Wang and Hannafin (2005, p. 6) define design-based research as a systematic and flexible methodology aimed at improving educational practices through iterative analysis, design, development and implementation. This collaboration takes place between researchers and practitioners and real world settings. Design-based research is a series of approaches where the aim is to produce new theories, artefacts and practices that can impact teaching and learning (Barab & Squire, 2004, p. 2). It is further described as being a means to capture social interaction, and is considered to involve flexible design revision (Barab & Squire, 2004, p. 3). Amiel and Reeves (2008, p. 35) claim that, due to the intentions and lifecycle proposed by a design-based framework, it is in a position to address the complexities that are characterised by educational technology research. Researchers not only design

research processes, but also design and implement interventions systematically to improve designs and advance pragmatic and theoretic aims (Wang & Hannafin, 2005, p. 6).

The research process in design-based research is cyclical in nature. Activities involving analysis, design, evaluation and revision are iterated (Plomp, 2007, p. 13). Authors represent this process of design-based research in different ways, one such representation by Amiel and Reeves (2008, p. 34) (Figure 2.3), is as follows:

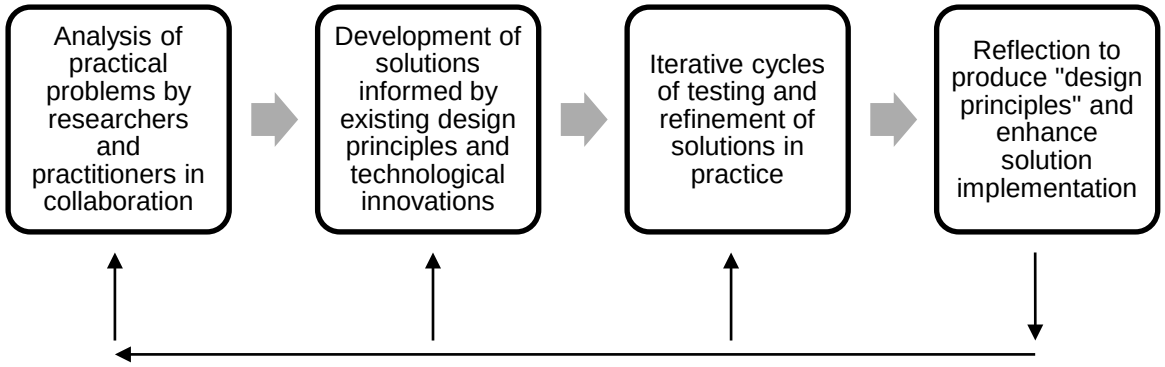

Figure 2.3 The Process of Design-based Research (Amiel & Reeves, 2008, p. 34)

Another illustration is presented by McKenney (2001, p. 12) and is presented in Figure 2.4.

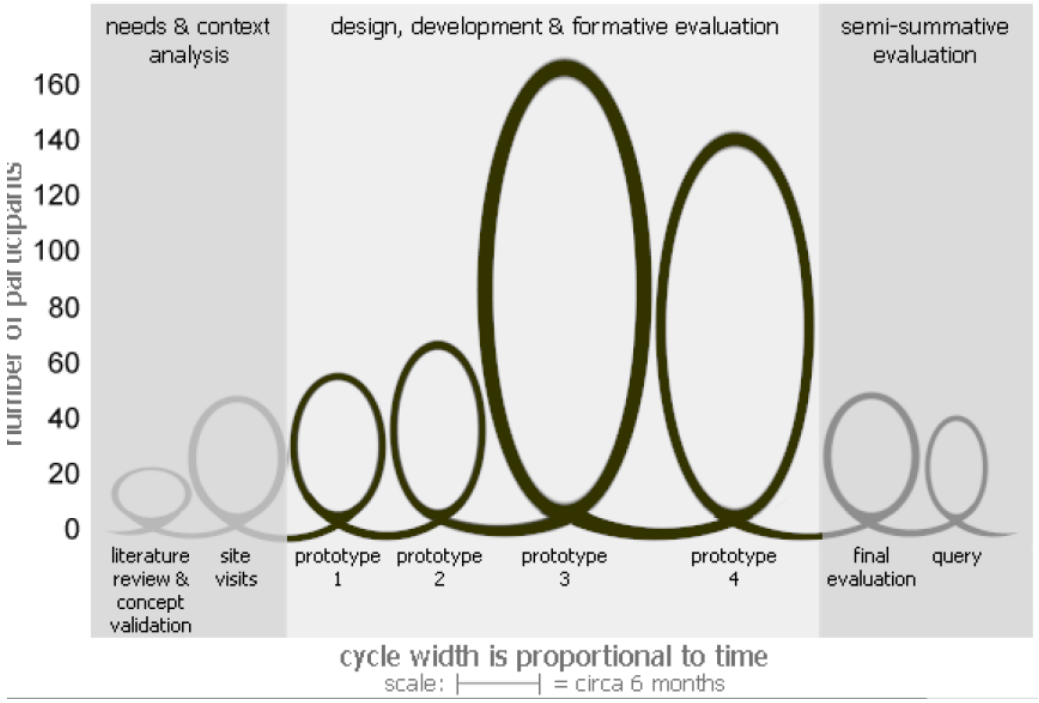

Figure 2.4 Illustration of the CASCADE-SEA Study by McKenney (2001, p. 12)

As illustrated in Figure 2.4, McKenney (2001, p. 12) indicates that design-based research features three main phases, namely needs or contextual analysis, design or formative evaluation of the prototype tools and a summative assessment of the final product. These phases are represented on

the horizontal axis. Each phase consists of a number of cycles of activities which involve different groups of participants, which could include experts or users. The vertical axis represents the number of participants in relation to the phases of the research. Although authors represent the design-research process in different ways, there are essentially three main stages in the process: preliminary research, prototyping and assessment. Throughout these stages researchers will perform systematic reflection and documentation to produce the required scientific harvest in the form of theories or design principles (Plomp, 2007, p. 15). An adapted version of the illustration presented by McKenney (2001, p. 12), specific to this study, will be discussed later in this section.

McKenney and Reeves (2012, p. 76) build on models such as these, and represent a visual model (Figure 2.5) that depicts the overall process from the point of view of the researcher.

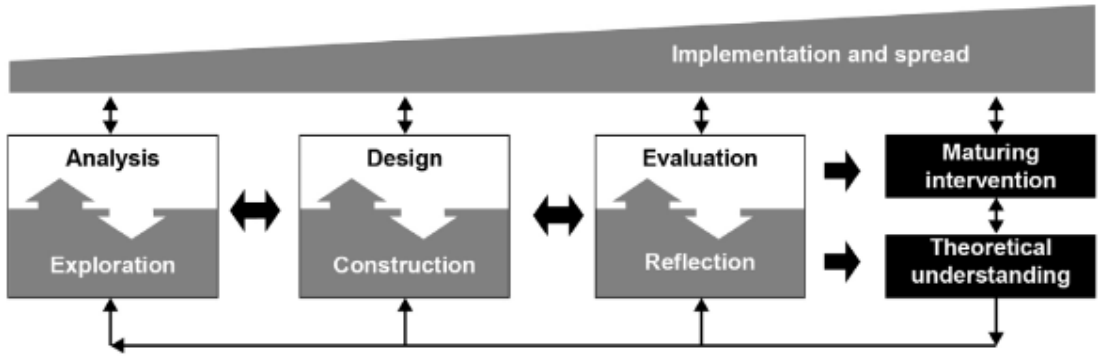

Figure 2.5 Generic Model for Conducting Design Research in Education (McKenney & Reeves, 2012, p. 77)

The three core phases of their model are: analysis and exploration; design and construction and evaluation and reflection, followed closely by a fourth output phase which includes maturing intervention and theoretical understanding. The iterative nature of the process is emphasised by the arrows between the different components. As is emphasised by various specialists on design-based research, McKenney and Reeves (2012, p. 77) also accentuate both the iterative and flexible nature of design-based research. The process is iterative because results from certain elements lead into others on a continual basis, and flexible because many different routes can be followed. The output that is produced in such a process is both theoretical and practical. The implementation and spread referred to in the figure indicate the increasing interaction with practice (McKenney & Reeves, 2012, p. 77).

The process of design-based research starts with an analysis of the problem that exists in educational practice. In this step expertise is pursued in the form of a literature review to establish theoretical contributions that help to understand the problem and context. The literature also helps to develop a scientifically related approach for the study (McKenney & Reeves, 2012, p. 78). Once a solid understanding of the problem and context has been established, an unrestricted exploration can take place in which similar problems and their solutions are explored (McKenney & Reeves, 2012, p. 79).

In this study, the poor Mathematics results in South Africa in particular, and the influence of a teaching approach on learners' achievement in Mathematics, created the need to investigate the effect of using technology to implement the principles of the RME approach in teaching practice. In this study, the systematic literature review (§ 2.6) which focused on the literature relating to RME, Mathematics education and ICT, explored current work on existing design principles and technological innovations. This first step was further explored by doing a needs analysis of the teacher-students (§ 2.8) to establish which areas of the curriculum they found problematic to teach and also in which sections they had difficulty applying the principles of RME.

The second step in the process of design-based research is to develop solutions informed by existing design principles and innovations in technology (Amiel & Reeves, 2008, p. 34). In this stage, an articulate process is followed and recorded in which a tentative solution to the problem is sought (McKenney & Reeves, 2012, p. 79). Here a conceptual model is created—during design, solutions to the problem are "generated, explored and considered" and eventually charted (McKenney & Reeves, 2012, p. 79). It is important here as well that the guidelines for the actual building of solutions are defined. Construction is where the ideas of the design stage are applied to manufacture a potential solution (McKenney & Reeves, 2012, p. 79). In this study, the design phase was realised by the development of a mobile application tool that aimed to address the needs expressed by the teacher-students. A detailed description of the design process is presented in Chapter Five.

The third step in the process of design-based research is that of evaluation and reflection where iterative cycles of refinement of solutions in practice are performed (Amiel & Reeves, 2008, p. 34). Evaluation refers to the empirical testing of the design or constructed intervention. Reflection comprises "active and thoughtful consideration of what has come together in both research and development" in order to produce theoretical understanding (McKenney & Reeves, 2012, p. 80). As one reassesses and reflects upon the data, new designs are created and employed to produce an on-going cycle of design-reflection-design. In this study the evaluation and reflection took place throughout the design process. Various prototypes of the app were created and tested by novices, experts in the field of Mathematics education, an expert in the field of RME as well as the design team, which consisted of an expert programmer who is experienced in the design of mobile applications; my promoter who is an expert in the field of using technology in teaching and learning; my co-promoter, an expert in Mathematics and Mathematics education; and myself, who took on the role of content specialist.

In the output phase, design principles are produced and the implementation of solutions are enhanced (Amiel & Reeves, 2008, p. 34). The ultimate outcome of design-based research is to produce a set of design principles which are empirically derived and richly described (Amiel & Reeves, 2008, p. 35). In Figure 2.5, McKenney and Reeves (2012, p. 80) depict two main outputs from design-based research, namely maturing interventions, which contribute to practice; and theoretical understanding, which is

produced through (usually several) micro- and meso-cycles of design-based research. In this study the design-based research produced guidelines for the effective use of technology in implementing the RME approach. The guidelines are presented in detail in Chapter Seven. These guidelines contribute to practice by presenting ideas and suggestions for using technology to reinforce the principles of RME in teaching practice.

For the purposes of this study, it was necessary to adapt the illustration by McKenney (2001, p. 12) to suit the design-based process that was followed. Figure 2.6 presents this adapted illustration.

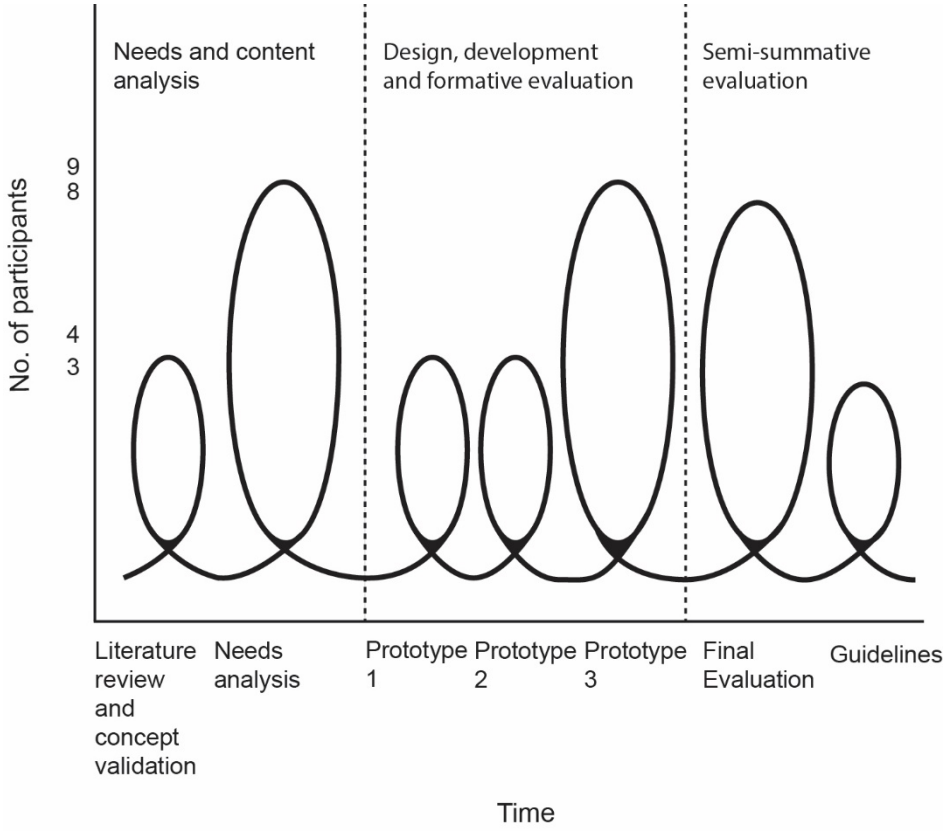

Figure 2.6: The Design-based Research Process Specific to this Study, adapted from McKenney (2001, p. 12)

In this study, the three phases as suggested by McKenney (2001, p. 12) were also relevant: needs and content analysis; design, development and formative evaluation; and semi-summative evaluation. Time is represented on the horizontal axis and the phases are also represented on the horizontal axis. The phases entailed the following activities: a systematic literature review in which concepts were validated; a needs analysis of the teacher-students' needs relating to their teaching practice; the development of three different prototypes of a mobile app; a final evaluation of the mobile app; and finally guidelines for the effective use of technology in implementing the RME approach. On the vertical axis, the number of participants, which include users and experts, are represented. The cycles had varying numbers of participants. This is illustrated in Table 2.2.

Table 2.2 The Participants that Played a Role in each Cycle of the Study

Cycle	Participants	Number of Participants
Literature review and concept validation	Myself, Promoter, Assistant promoter, Expert in Mathematics education and Systematic Literature Reviews	4
Needs analysis	Myself, Promoter, Assistant Promoter, four Participants, Two Experts in Mathematics education	9
Prototype 1	Myself, Promoter, Assistant Promoter, Expert Programmer	4
Prototype 2	Myself, Promoter, Assistant Promoter, Expert Programmer	4
Prototype 3	Myself, Promoter, Assistant Promoter, Expert Programmer, Two Experts in Mathematics education, three Novices	9
Final evaluation	Myself, Promoter, Assistant Promoter, Expert Programmer, four Participants	8
Guidelines	Myself, Promoter, Assistant Promoter	3

The emphasis on design-based research should be on the premise that the researcher should generate evidence-based claims about learning that addresses theoretical issues and generating theoretical knowledge in the field, rather than on showing that a particular design works (Barab & Squire, 2004, p. 6). This study aimed to determine what support needs in-service teacher-students had with regard to teaching using the RME approach, and it intended to yield guidelines for the effective use of technology in implementing the RME approach, thereby generating theoretically relevant knowledge to the body of scholarship.

One of the characteristics of design-based research is that it is interventionist, which means that the goal thereof is to design interventions in a real world setting, thus building a stronger connection between educational research and real world problems (Amiel & Reeves, 2008, p. 34; Joseph, 2004, p. 235; Plomp, 2007, p. 15). Other characteristics include: it is iterative—cycles of analysis, design and development, evaluation and revision take place; it is process oriented—the emphasis is on understanding and improving interventions. Additionally it is utility oriented—the value of a design is partly measured by how practical it is for users in real contexts; it is theory oriented—the design is partially based on a conceptual framework and theoretical proposals, and the evaluation of the prototypes in the intervention contribute to building theory. Added to that the involvement of practitioners is important—the active collaboration with and participation of practitioners increase the chances that the intervention is relevant and practical (Barab & Squire, 2004, p. 2; Plomp, 2013, p. 20).

This study was interventionist in that the interventions were not only designed in the real world setting of the Mathematics classroom, but the content that was designed was focused specifically on the real life application of Mathematics. The process was iterative in that a number of prototypes of the app were created and tested by novices and experts. The design of the intervention was grounded in the theory of RME. The five characteristics of RME were adhered to and the three principles of RME formed the foundation of the design. Each prototype was grounded in guided reinvention, focused on the use of models and adhered to the principle of didactical phenomenology. The experts who tested the app as well as the participants in the research played the role of practitioners. The experts were

all actively working in the field of Mathematics education, and IT education at a higher education institution (HEI), and dealt with Mathematics and technology in education on a daily basis. The participants were actively involved in Mathematics education at secondary school level. Following their needs analysis and opinions of the use of the RME approach in teaching Mathematics aided by technology, a suitable and appropriate intervention, in the form of the app, was designed to assist them in their teaching practice. The relevance of this intervention is discussed in detail in Chapter Six.

Design-based research is said to have a dual purpose (Plomp, 2013, p. 22), namely to develop prototypical products (curriculum documents and materials) along with experimental evidence of their quality; and to generate methodological directions for the design and evaluation of such products (Fauzan et al., 2013, p. 163). In developmental studies, not only should the research based intervention be functional and effective in addressing the solutions to the complex problem, but it should also contribute to the body of knowledge in the field as well, typically in the form of re-usable guidelines for addressing educational problems (Barab & Squire, 2004, p. 5; Plomp, 2013, p. 22). This links closely to the characteristic of theory orientation as discussed above.

Plomp (2013, p. 22) distinguishes between three types of design-based studies, namely developmental studies, validation studies and implementation studies. In developmental studies, the foundation is the identification of educational problems in which there are few validated principles available to structure and support the design and development activities (Plomp, 2013, p. 22). A characteristic of a developmental study is that the study is informed by prior research through a review of the literature. Researchers, together with practitioners, design and develop feasible and effective interventions by studying consecutive versions of the interventions in the relevant contexts. The final stage of a developmental study in design-based research is when a period of reflection follows where the researcher and practitioner reflect on the research process in order to produce design principles for developing innovative interventions which are significant for educational practice (Plomp, 2013, p. 22).

In validation studies the focus is on designing learning trajectories or environments in order to develop and validate theories about learning. The research goal is to develop or validate theory and it also has a dual purpose, namely to design learning environments with the purpose to validate design principles and to develop and validate theories about learning and learning environments (Plomp, 2013, p. 23). In such studies, researchers work in natural settings such as the classroom, rather than controlled settings (Plomp, 2013, p. 23).

Gravemeijer and Cobb (2013) distinguish between three phases in validation studies: preparing for the experiment; designing the experiment; and retrospective analysis. These phases are similar to those in developmental studies (Plomp, 2013, p. 26). In practice, it is possible that the design-based research may combine a developmental and validation study. Plomp (2013, p. 26) uses the work of Fauzan et al. (2013) as such an example. This research involved the development of a geometry

course based on the RME principles (developmental study) and also investigated the validity of design principles in a different context (validation study).

The findings in design-based research cannot be generalised to a larger universe. The researcher should try to generalise the design principles to form part of a broader theory. In order to do this, the design principles must be tested through a number of repetitions in various contexts (Plomp, 2013, p. 34).

2.5 Ethical Considerations

Given (2008, p. 273) describes ethics as "the part of human philosophy concerned with appropriate conduct and virtuous living." Because qualitative research revolves around human endeavours, it is viewed by scholars as moral ethical endeavours. The ethical principles as suggested by Christians (2008, p. 192), namely informed consent; free of deception; privacy and confidentiality; and accuracy, were applied throughout the project. The necessary ethical application was completed and submitted to the North-West University's ethical committee, and permission was obtained to commence the research. The ethical clearance number is: NWU-HS-2014-0267 (Addendum 2.1). The participants were provided with a letter describing their potential role in the research, which spelled out exactly what would be expected of them in the project. They were requested to complete a letter of consent, providing me with consent to continue with the project. This letter (Addendum 2.2) ensured the participants that participation was voluntary, that they were free to withdraw from the project at any time, that withdrawal would not jeopardise their studies in any way, and that all information would be treated as confidential. Names were not required at any point during the data generation which ensured that the participants remained anonymous.

2.6 Qualitative Systematic Literature Review

Kitchenham (2004, p. 1) defines a systematic literature review as "a means of identifying, evaluating and interpreting all available research relevant to a particular research question, or topic area, or phenomenon of interest." Systematic literature reviews also serve as a "method of making sense of large bodies of information, and a means of contributing to the answers to questions about what works and what does not" (Petticrew & Roberts, 2006, p. 2). They are also a method of mapping out areas of uncertainty, and can indicate where new studies are necessary (Petticrew & Roberts, 2006, p. 2). Systematic literature reviews are used in a variety of fields including medicine, health care, social policy and education (Briner & Denyer, 2012, p. 1).

The most common reasons for performing a systematic literature review is: to summarise the existing evidence concerning a treatment or technology; to identify any gaps in the existing research; to

provide a framework in which to position new research; to examine the extent to which hypotheses are supported or contradicted by empirical evidence; or to assist in the generation of new hypotheses (Kitchenham, 2004, p. 1).

One of the advantages of doing a systematic literature review is that it provides information about the effects of a phenomenon across a wide range of settings (Kitchenham, 2004, p. 2). Systematic literature reviews are increasingly replacing traditional narrative reviews because they attempt to bring the same level of rigour to reviewing evidence as should be present in producing the evidence (Hemingway & Brereton, 2009, p. 1). Systematic literature reviews are suitable ways of examining quantitative or qualitative evidence (Hemingway & Brereton, 2009, p. 1).

Systematic literature reviews should adhere to a number of core principles. They should be: systematic and organised, transparent, replicable and updatable. They should also be able to synthesise and summarise the evidence relating to the research question (Briner & Denyer, 2012, p. 3). Important features that differentiate between a systematic literature review and a traditional literature review are: systematic reviews start by defining a review protocol that specifies the research question being addressed as well as the methods that will be used to do the review; systematic reviews are based on a defined search strategy with the purpose of detecting as much relevant literature as possible; systematic reviews document the search strategy to verify its rigour and completeness; systematic reviews require explicit inclusion and exclusion criteria when assessing potential material; systematic reviews specify the information to be obtained from each primary study as well as quality criteria by which the material will be evaluated (Kitchenham, 2004, p. 3).

2.6.1 Process and Documentation for a Systematic Literature Review

Although quite similar, different authors have varied opinions about the key steps to follow when doing a systematic literature review. Hemingway and Brereton (2009, p. 1) classify the following steps: identifying the relevant evidence; selecting studies or reports for inclusion; assessing the quality of these reports or studies; synthesising the findings in an unbiased way; interpreting the findings, and presenting a balanced, impartial summary of the findings. Kitchenham (2004, p. 3) provides a more expanded version and identifies three main phases, each of which encompasses a number of stages. The phases are: planning, conducting and reporting the review. The planning phase includes the stages of identifying the need for a review and developing a review protocol. The phase of conducting the review includes the stages: identifying the research, selecting the primary studies, quality assessment of studies, the extraction and monitoring of data, and data synthesis. The final phase of reporting the review consists of a single stage (Kitchenham, 2004, p. 3). Briner and Denyer (2012, p. 3) identify the following five key steps: (i) planning the review, (ii) locating studies, (iii) appraising contributions, (iv) analysing and synthesising information, and (v) reporting evidence. Khan, Kunz, Kleijnen, and Antes (2003, p. 118) also identify five steps. These are (i) framing the question, (ii)

identifying relevant publications, (iii) assessing study quality, (iv) summarising the evidence, and (v) interpreting the findings.

For the purposes of this study, I have made use of the following steps to perform the systematic literature review:

i) Identify the need for a review (Kitchenham, 2004)
ii) Identify the relevant evidence (Hemingway & Brereton, 2009)
iii) Select studies and reports for inclusion (Briner & Denyer, 2012; Hemingway & Brereton, 2009; Khan et al., 2003)
iv) Assess quality of contributions (Briner & Denyer, 2012; Hemingway & Brereton, 2009; Khan et al., 2003; Kitchenham, 2004)
v) Analyse and synthesise information (Briner & Denyer, 2012; Hemingway & Brereton, 2009)
vi) Interpret findings (Hemingway & Brereton, 2009; Khan et al., 2003)
vii) Present a balanced, impartial report (Briner & Denyer, 2012; Hemingway & Brereton, 2009; Kitchenham, 2004).

2.6.2 Search Process Documentation

The systematic literature review was documented in detail (Briner & Denyer, 2012, p. 4; Kitchenham, 2004, p. 3). All searches were recorded in detail, including the date, keywords used, the database in which the search took place, and the number of hits. With reference to the inclusion and exclusion criteria (Kitchenham, 2004, p. 3), documents were identified. In total, thirteen searches were performed independently and in collaboration with expert librarians.

The systematic literature search was done using the following keywords: realistic* or RME, teach* or learn* or educat*, math*, tech* or ict or educat* tech*. Various combinations of these keywords were used to perform the searches. The databases that were used were: Scopus, EBSCOHost, Web of Science, Science Direct, MathSciNet, and Google Scholar.

The initial searches on the various databases were done using different combinations of the keywords. A record of this process was tabulated (Addendum 2.3). Thereafter, author maps for six authors who were dominant in the search results were drawn on each of the databases. An additional 36 searches were done. The six dominant authors were LM (Michiel) Doorman, Paul Drijvers, Koeno PE Gravemeijer, AJP (André) Heck, PBJ (Peter) Boon and Nicholas Zaranis. Table 2.3 summarises each of these authors' field of expertise.

Table 2.3 The Dominant Authors and their Fields of Expertise

The Dominant Authors	Field of Expertise
Prof Dr Michiel Doorman	Interests are context-based Mathematics education; Modelling as a lever for learning Mathematics; Inquiry based learning and Coherency between

The Dominant Authors	Field of Expertise
	Mathematics and science learning.
Prof Dr Paul Drijvers	ICT in Mathematics education; Algebra education; Teachers' professional development; Curriculum development; Mathematical thinking
Prof Dr Koeno Gravemeijer	Mathematics; Computer Science; Public and Law Administration; Educational theory
Dr Andre Heck	Research on ICT aspects of Mathematics and Science education; Development of ICT tools; Development of curriculum material
Prof Dr Peter Boon	Educational technology; Teaching methods; Mathematics education; Online learning; Teaching and learning; Didactics
Prof Dr Nicholas Zaranis	Computers in Education; Educational software; Internet in Education; Teaching of Mathematics by using new technologies

2.6.3 Selection Process Criteria Documentation

After the searches had been performed, documents were screened for their aptness for this study. In total 318 documents were perused and evaluated for their suitability. The process was recorded in detail in nine different Excel sheets (Addendum 2.4). The research revolved around four main concepts: i) Realistic Mathematics Education, ii) ICT, iii) Mathematics/teacher/education, and iv) Mathematics education, and documents were screened for content relating to these themes. Initially the title and abstract were perused for suitability. Thereafter the full text was read to determine its appropriateness for this study. Only documents that related to all four themes were selected. As discussed above, the author search was done and ten additional sources were included for analysis. Six articles were hand-picked and also included.

Once the coding and analysing of the documents took place, and I began to document the literature, I realized that the key authors in the field were regularly referred to by the identified sources. It was therefore necessary to include six core articles that relate specifically to the study. These sources are authored by the key role players of the RME movement in the Netherlands, namely Hans Freudenthal, Adrian Treffers and Martin Simon. Table 2.4 indicates each of these authors' field of expertise.

Table 2.4 The Key Role players of the Realistic Mathematics Education Movement

Key Role players of RME movement	Field of expertise
Prof Dr Hans Freudenthal	Known as the father of RME
Prof Dr Adrian Treffers	Mathematics curriculum researcher at Freudenthal Institute
Prof Dr Martin Simon	Mathematics taught with a constructivist mind set; how teachers and learners understand their mathematical knowledge

The additional sources were coded and included in the systematic review for consideration.

2.6.4 Quality Assessment of Primary Documents

In order to select suitable documents for inclusion in the review, I studied all documents that were identified in the various searches and applied the quality assessment. The assessment of the

documents was done in collaboration with peers in the field of Mathematics education who acted as additional independent reviewers. The criteria for the selection of documents related to documents that:

- addressed at least four of the key concepts encompassed in this research
- related to qualitative, quantitative or mixed-method research
- published in books, accredited journals or conference proceedings
- were published between 2000 and 2015.

Figure 2.7 presents the process that was followed to assess and select the final documents for inclusion.

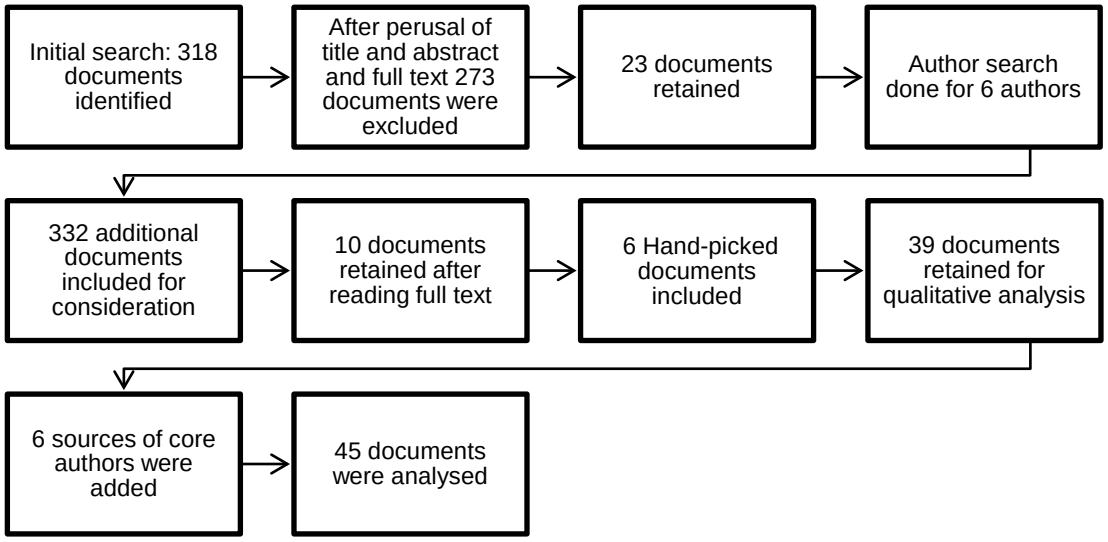

Figure 2.7: The Process of Primary Document Selection

2.6.5 Data Analysis for the Systematic Literature Review

When doing the systematic literature review, I used ATLAS.ti™ to code, sort and analyse the data. ATLAS.ti™ is part of the genre of Computer Assisted Qualitative Data Analysis Software (CAQDAS) (Friese, 2014b, p. 1). Software such as ATLAS.ti™ offers many advantages such as: it allows for easier systematic data analysis; large volumes of data and different media types can be structured and integrated quickly; it increases the validity of research results; codes and concepts can be modified as the analysis progresses (Friese, 2014b, p. 1). The three basic aspects of computer-assisted analysis are preparing data and creating a project file, coding the data, and using the software to sort and structure them with the aim of discovering patterns and relations (Friese, 2014b, p. 15). ATLAS.ti™ has very domain specific terminology that describes different aspects and processes of the software; this terminology is presented in Table 2.5.

Table 2.5 Domain Specific Terminology in ATLAS.ti™

Terminology	Meaning
Hermeneutic unit (HU)	A data file that stores everything that gets done to the data (Friese, 2014b, p. 37). The container that keeps track of all your data (Friese, 2015, p. 7). It helps to structure the data for each project (Friese, 2014a, p. 14).
Primary document	As documents are added to the project, ATLAS.ti™ creates a primary document (Friese, 2014b, p. 37). The primary document represents the data that you are analysing in your project (Friese, 2014a, p. 14).
Codes	Often a researcher-generated word or phrase that assigns a particular attribute to a portion of data (Saldaña, 2013, p. 262). A word or string of words used to name a category in data analysis (Boeije, 2010, p. 95). Keywords that are normally linked to quotations (Friese, 2014b, p. 36)
Categories	A group or cluster used to sort parts of the data during analysis (Boeije, 2010, p. 95) The aim of having a system to code data is to organise the data into categories and subcategories. Main category codes are developed by the process of conceptualisation, comparing and contrasting data segments (Friese, 2014b, p. 158).
Coding	Coding is the basic activity you engage in when working with ATLAS.ti™. It is the basis of everything else that you do further in ATLAS.ti™. It refers to the procedure of allocating categories, concepts or codes to sections of information that is of interest to your research goals (Friese, 2015, p. 7).
Quotation	Quotations are marked data segments that have a defined start and end point (Friese, 2014b, p. 38). A quotation refers to coded segments (Friese, 2015, p. 18).
Theme	That which the data are mainly concerned with (Boeije, 2010, p. 95).
Memos	Memos are places to write down all sorts of thoughts and ideas (Friese, 2014b, p. 37). Memos are independent objects that can stand alone or be connected to other objects (Friese, 2015, p. 36).
Code families	Code families are used to group codes together that belong together (Friese, 2014a, p. 234).
Network views	Network views allow one to visualise different aspects within the data. A few examples of what can be visualised are: your codings; relationships between codes; relationships between quotations; relationships between memos and quotes and many more (Friese, 2014b, p. 37).

There are a number of basic steps that need to be followed when working with ATLAS.ti™. As is illustrated in Figure 2.8, the process for this study began by creating a hermeneutic unit (HU), which contains the primary documents, quotes, code words, notes, memos, links, code families and network views (Friese, 2014b, p. 24).

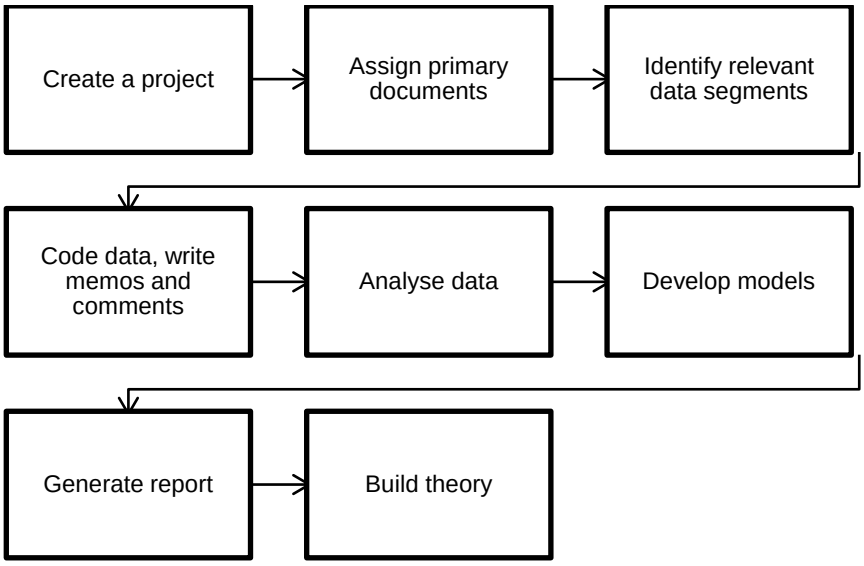

Figure 2.8 The ATLAS.ti™ Workflow Process adapted from Friese (2014a, p. 27)

It is not important that all the steps follow sequentially, logic dictates which can be shifted out of order (Friese, 2014a, p. 27). I did not follow all these steps sequentially. The six additional documents that were not assigned to the project initially were added to the project at a later stage as the need arose. I created the HU with the title "Systematic literature review relating to the use of ICT to facilitate the principles of Realistic Mathematics Education to enhance teaching practice." The 45 primary documents that were assigned to the HU included 29 journal articles, seven conference proceedings, six conference papers, one book section and two books. Relevant segments of the data were identified and coded. I did not use a pre-determined list of codes, and created codes as the different themes emerged in the data. I coded the data and created memos where necessary. Quotations, codes, categories and network views were created. I made use of inductive data analysis, since I did not have a pre-determined set of coding categories. This requires of the researcher to be immersed in the text until themes and concepts emerge from the data (Hesse-Biber & Leavy, 2006, p. 311).

As described in Table 2.5, a code is a word or phrase that assigns an attribute to a portion of data (Saldaña, 2009, p. 3). Codes are the building blocks for the construction of theory and models and form the basis of the analyst's argument; they exemplify the assumptions on which the analysis is built (MacQueen, McLellan, Kay, & Milstein, 1998, p. 31). Codes can be developed from existing theory or concepts; from raw data and from a project's research goals and questions (DeCuir-Gunby, Marshall, & McCulloch, 2011, p. 138). I created 58 codes in the process of analysing the documents.

A codebook is the compilation of the codes, the description of the content and a short data example for orientation (DeCuir-Gunby et al., 2011, p. 138; Saldaña, 2009, p. 21). Codebooks are especially critical when multiple team members work together on a project (Saldaña, 2009, p. 21). MacQueen et al. (1998, p. 32), who work with team-based qualitative analysis, describe the structure of the codebook as consisting of the following six components: "the code, a brief definition, a full definition, guidelines for when to use the code, guidelines for when not to use the code, and examples." DeCuir-Gunby et al. (2011, p. 138) on the other hand use only three components, namely "code name/label, full definition (an extensive definition that collapses inclusion and exclusion criteria), and an example."

Coding enables researchers to engage in reducing and simplifying the data and converting these into meaningful units. This allows researchers to make connections between ideas and concepts (DeCuir-Gunby et al., 2011, p. 138). DeCuir-Gunby et al. (2011, p. 141) describe the steps for developing theory-driven data as follows: generating the code; reviewing and revising the code and establishing the reliability of the code and coders. I followed this process when doing the systematic literature review. I generated codes (Table 2.6); reviewed and revised the codes within the context of the data; and established the reliability of the codes and coder by inviting a peer who is an expert in the field of Mathematics education and Systematic Literature Reviews to peer-code two articles of the systematic literature review. This will be discussed further on in this section.

Table 2.6 Codebook Table

Code	Description	Example
HLT	A hypothetical learning trajectory refers to what the teacher predicts about the path by which learning might progress(Simon, 1995, p. 135).	"The development of an HLT and the design of instructional activities are closely related: the HLT guides the design of the instructional activities, but choices made in the design process may lead to reconsideration of the HLT" (Bakker, Doorman, & Drijvers, 2003).
Design of activities	Activities or tasks that are designed based on the principles and characteristics or RME.	"Task design is widely recognized as an important, but complex and subtle activity" (Drijvers, Boon, Doorman, Bokhove, & Tacoma, 2013, p. 1).
Didactical phenomenology	One of the three key principles or heuristics of the design of teaching. It confronts students with phenomena that need to be organised by mathematical structures (Bakker et al., 2003, p. 5).	*"Didactical phenomenology* concerns the relation between the thought object−the 'nooumenon'−and the phenomenon–the 'phainomenon'−from the perspective of teaching and learning. In particular, it addresses the question how mathematical 'thought objects' can help in organizing and structuring phenomena in reality" (Drijvers et al., 2013, p. 1).
Emergent modelling	One of the principles of RME. Problem situation are used that lead to models that initially represent the problem situation, but that have the potential to develop into general models (Bakker et al., 2003, p. 5).	"According to the *emergent modeling* perspective, a model may play different roles during different phases of activity. Initially, a model is context-specific: it refers to a meaningful problem situation that is experientially real for the student, and is a model of that situation" (Drijvers et al., 2013, p. 1).
Guided reinvention	A principle of RME where students are given the opportunity to experience a process similar to how a topic was invented (Drijvers et al., 2013, p. 1).	"The principle of guided reinvention seems to apply well to digital design. ICT offers opportunities for exploration and investigation, and in this way for reinvention" (Drijvers et al., 2013, p. 7).
Advantages of using RME	Any positive aspect related to the implementation or use of RME characteristics and principles.	"The teacher also mentioned the fact that in the school's final assessment, the pupils involved in this research outscored those in the other class who he had taught the same topic in the traditional way and who he considered to be stronger in mathematics" (Widjaja & Heck, 2003, p. 20).
Characteristics of RME	The attributes or tenets of RME.	"The five characteristics of RME are: the use of contextual problems; the use of models; the use of pupils' contributions; interactivity; and intertwining of learning strands" (Widjaja & Heck, 2003, pp. 4-5).
Content easy to relate to real life	Teacher-students expressed their views on which content in the curriculum is easiest to relate to real life situations.	"Uhm, in Financial Mathematics as well. Through and through it every day life situation where you talk of borrowing, investments and other areas of activities" (P61:12).
Content where need help to relate to real life	Teacher-students discussed which areas of the curriculum they felt they needed help in relating the content to real life situations.	"I think exponents is problematic and algebra, functions" (P59:60).
Disadvantages of using RME	Any negative aspect related to the implementation or use of RME characteristics and principles.	"It should be noted that starting with real situations and real data is not at all easy" (Widjaja & Heck, 2003, p. 22).
Human activity	Freudenthal viewed Mathematics as a human activity, where reality is used as a foundation of mathematization.	"According to Freudenthal (1991), mathematics as human activity and mathematics must be connected to reality. Therefore, students should be able to understand the concepts of mathematics and its application in the real world" (Cahyono, 2012, p. 71).
Mathematization	Mathematization is the process of developing Mathematics concepts that originated in the real world (Cahyono, 2012, p. 72).	"It is based on the view of Freudenthal (1991) that mathematics is a human activity and that reality can be used as a source for mathematization." (Widjaja & Heck, 2003, p. 4).

Code	Description	Example
Principles of RME	The theory of RME produced three principles according to which activities are designed, namely: guided reinvention, didactical phenomenology and emergent modelling. (Drijvers et al., 2013, p. 1).	"this brief exploration of the issue suggests that the three RME principles are valuable for digital design, even if some appropriation is needed compared to the design of paper-and-pencil tasks, such as taking into account the constraints of the digital tools and the fact that the technological environment forms an additional 'world' to the student" (Drijvers et al., 2013, p. 7).
Real life	Situations that are linked to reality; experientially real, everyday life phenomena.	"In RME pupils learn mathematics based on activities they experience in their daily life; pupils have a big opportunity to construct their knowledge by themselves, etc." (Fauzan et al., 2013, p. 172).
Recommendations for RME based lessons	Any suggestions and recommendations presented in the literature for lessons based on the RME approach.	"The pupils could use the student book without any difficulties and they could learn the topic Area and Perimeter as intended according to the RME point of view. The teacher guide was useful for the teachers in implementing the RME-based geometry course" (Fauzan et al., 2013, p. 172).
RME tasks	Tasks and activities specifically designed using the principles and characteristics of RME.	"Gravemeijer and Doorman (1999) stressed that research on the design of Realistic Mathematics Education (RME) based activities has shown that the use of personalized contexts improved word problem solving by increasing the meaningfulness of contexts and enhancing student motivation" (Mousoulides, Sriraman, & Christou, 2007, p. 29).
Advantages, disadvantages and recommendations for RME	Positive and negative critique about RME as well as suggestions and commendations regarding RME.	"RME is a guide for student learning that focuses on the development of abstract thinking" (Fitzallen & Watson, 2014, p. 263).
Aspects of RME	These include features of RME other than the three principles or five characteristics, such as real life; human activity etc.	"According to Freudenthal (1983), mathematics is a human activity and therefore it must constitute a human value, must be close to reality of fact, be close to children and have a relationship with society" (Zaranis, Kalogiannakis, & Papadakis, 2013, p. 5).
RME	RME is the acronym for Realistic Mathematics Education which is a "domain specific instruction theory for the teaching and learning of Mathematics" (Drijvers et al., 2013, p. 1)	"In the concept of RME, mathematics is a human activity connected with reality" (Widjaja & Heck, 2003).
RME theory	The theoretical framework of Realistic Mathematics Education	"The Realistic Mathematics Education (RME) approach was the key theoretical framework for the design of the software and of the instructional material, and for the flanking educational research" (Heck, Boon, Bokhove, & Koolstra, 2007, p. 2).
Approaches to teaching Mathematics	Various teaching approaches such as the traditional approach, constructivism, problem-solving approach and RME.	"The traditional way of teaching had a negative influence on the pupils' attitudes towards mathematics which means that most pupils did not like to learn mathematics, and that some of them were even afraid of mathematics" (Fauzan et al., 2013, p. 161).
Modelling	This refers to mathematical modelling which can take on various forms such as physical models, equations, dynamic systems etc.	"The idea is to look for models that can be generalized and formalized to develop into entities of their own, which then can become models for mathematical reasoning" (Doorman et al., 2008, p. 2).
Learner reasoning	The process that learners go through where they ponder on and evaluate ideas.	"The RME philosophy also suggests instruction should build students' reasoning gradually from the concrete to the abstract, through the use of manipulatives, diagrams, and other imagery to reinforce students' reasoning" (Fitzallen & Watson, 2014, p. 264).
Learner understanding	When learners are given the opportunity to learn with deep	"The results of research in the Netherlands showed that the RME has shown satisfactory results. RME

Code	Description	Example
	understanding.	has the potential to improve students' understanding of mathematics (Streefland, 1991)" (Cahyono, 2012, p. 72).
Mathematics education	All aspects that relate to the teaching and learning of Mathematics.	"For over two decades, many stakeholders have highlighted the potential of digital technologies for mathematics education" (Drijvers, 2013, p. 1).
Maths strategies	Learning and teaching strategies used in Mathematics education.	"Context problems are selected, offering the students the opportunity to develop situation-specific representations and strategies" (Doorman et al., 2008, p. 2).
Meaningful learning of Maths	When that which is learned is fully understood in whole and related parts.	"active participation is promoted when students make artefacts that are meaningful and useful to them" (Fitzallen & Watson, 2014, p. 264).
Problem areas to teach/learn	Teacher-students discussed the areas of the content that they found problematic to teach and the areas that their learners found difficult to learn.	"Learners do have a problem with algebra and integers in fact. If they do have a problem with integers, it is going to give them a problem when dealing with algebra" (P59:12).
Teaching methods and strategies	General teaching methods and strategies	"This nation-wide reform now has an established record (Vos, 2010) that speaks directly to the building of mathematics competence, but also addresses issues of ways of working, cooperation, problem solving and metacognition"(Gordon, Rey, Siewiorek, Vivitsou, & von Reis Saari, 2012, p. 21).
Factors that influence teaching and learning	Any factor or aspect that plays a role in teaching and learning	"Another factor that is not so much elaborated in the case descriptions but is important to mention here, is assessment, which should be in line with the students' activities with technology; not doing so would suggest that in the end the use of digital technology is not important" (Drijvers, 2013, p. 15).
Learner aspects	Any aspect that influences the learner specifically in relation to the learning of Mathematics, with particular attention to learner understanding and learner reasoning	"The effectiveness of the RME-based geometry course had also to be investigated in order to show its effect on the pupils' learning" (Fauzan et al., 2013, p. 171).
Mathematics	Freudenthal (1968, p. 4)argues that Mathematics has proved indispensable for the understanding and the technological control of both the physical world and the social structure. Mathematics has been described by some as a static discipline developed abstractly, while others see it as a dynamic discipline constantly changing due to new discoveries (Dossey, 1992, p. 39). Other authors describe Mathematics as the science of pattern and order, which challenges the view that Mathematics is merely a discipline dominated by computation (Van de Walle et al., 2013, p. 13). Mathematics is also described as a human endeavour in which ordinary people construct concepts, discover relationships, invent methods, execute algorithms, communicate and solve problems posed by the real world (Cangelosi, 2003, p. 7).	"This is also in line with the objective of realistic mathematics education (RME), where instructional design is aimed at creating optimal opportunities for the emergence of formal mathematical knowledge from situation specific reasoning" (Doorman et al., 2008, p. 1).

Code	Description	Example
Mathematics content	Content areas at any level of the Mathematics school curriculum. Both formal and informal Mathematics is included in this category.	"Within this perspective, we can distinguish between formal and informal by denoting formal mathematical reasoning as a form of reasoning that builds on arguments that are located in the newly formed mathematical reality. Seen this way, the distinction between informal and formal is a relative distinction-a distinction that is relative to a certain topic and that can be made especially from an observer perspective" (Gravemeijer, 1999, p. 160).
Community	One of the role players that can influence the teaching and learning of Mathematics as expressed by the teacher-students.	"But, maybe only, let me say ten per cent of our children have got a good background, they have got a satellite dish. So mostly they are from shacks, where they do not have electricity, you know..." (P60:211).
Context	Another factor that the teacher-students identified that serves as a role player in the teaching and learning of Mathematics.	"Ja, last time when we were using the overhead projectors, but now the state of our school we cannot, we have so many projectors here, but they are not functioning" (P49:76).
Learner	Learners also are role players in the teaching and learning of Mathematics. Teacher-students voiced their opinions about the role that learners play.	"You see, most of our learners they are not, how can I say it, they are not familiar with the situations" (P49:38).
Role players	Any person or aspect that plays a role in the teaching and learning of Mathematics.	"Involving different stakeholders and especially teachers in the design process is a key factor for an innovative learning activity to find its way to teachers' everyday practice" (Perez, 2012, p. 21).
Teacher	Teacher-students expressed their views about teachers as role players in the teaching and learning of Mathematics.	"Then, recently we have Euclidean geometry which has been introduced. Uhm, it's also a major problem, but I think the problem is not the learners but maybe the majority of teachers who are teaching that, they did not even do it during their times at school. It's something that was brought in as a crash programme for teachers to be taught as well. So, those are the main three areas: Euclidean geometry, trigonometry and functions" (P61:6).
Integration across strands	One of the characteristics of RME. This deals with the integration of content across the curriculum.	"So this is how now I'm learning, right from grade twelve. Because if you're teaching it at grade twelve, there are some of the concepts that you don't know at the grade eleven and grade ten level" (P49:18).
Learning environment	The atmosphere and space that is created in which learning can take place.	"Yes, the learners present and they present it so well, they present it so well. In the meantime they are also learning, you understand? They are also learning. So, I also tell some other learners they must also do it, because you gain more knowledge by just standing there and going home to prepare the topic to do it. They come prepared and then they do it so nicely" (P60:235).
Student support	Support that is rendered to the students in terms of their learning.	"While pre-enrolment testing establishes learner readiness for participating in a course, the pre-course diagnostic testing is conducted to determine the amount and level of support a learner will require to advance successfully within the course" (Kizito, 2012a, p. 39).
Distance education	Distance learning that offers students flexible learning opportunities at their convenience.	"In the South African distance education environment, where the majority of students simply cannot afford access to web-based learning, the use of a mLearning strategy seems to be a viable and rational alternative for providing instructional support" (Kizito, 2012a, p. 39).
Motivation	Factors that encourage and inspire teachers or learners in the process of teaching and learning.	"In our opinion, digital assignments and diagnostic testing add to the motivation and performance of students in mathematics education" (Heck et al., 2007, p. 18).

Code	Description	Example
Pedagogy	An aspect that has to do with the theory and practice of education.	"even if the digital technology´s affordances and constraints are important design factors, the main guidelines and design heuristics should come from pedagogical and didactical considerations rather than being guided by the technology´s limitations or properties" (Drijvers, 2013, p. 15).
Social aspects	Any social aspect in the teaching and learning of Mathematics. This can include social norms and social interaction.	"The third level of the teaching procedure included activities using appropriate social interaction to refine the models of the problem" (Zaranis, 2014a, p. 62).
TPACK	The three main components of teachers' knowledge: content, pedagogy and technology. These aspects, as well as the interaction between them are important.	"To be able to do so, a process of professional development is required, which includes the teacher's own instrumental genesis, or, in terms of the TPACK model, the development of his technological and pedagogical content knowledge" (Drijvers, 2013, p. 15).
Challenges when working with ICT	Any aspect relating to ICT that is problematic.	"There are some disadvantages, too. When a school already uses a VLE, with all kinds of communication facilities such as email and bulletin board available, it could be considered cumbersome that yet another environment is added to the already long list" (Heck et al., 2007, p. 8).
ICT systems: virtual learning environment (VLE)	Various ICT systems and virtual learning environments are represented here.	"As technology for teaching mathematics the Freudenthal Institute's *Digital Mathematics Environment* (DME) is used. The DME integrates a content management system, a learning management system and an authoring environment. The content consists of online modules in the form of Java applets. The learning management system offers means to distribute content among students and to monitor student progress" (Drijvers et al., 2013, p. 2).
Teacher-student ICT factors	Factors relating to ICT that play a role in the teacher-students' teaching environment.	"Ja, we could prepare in advance. And then presently we've got only one projector in the school, so it is difficult to use the laptop when teaching. And some of the classes do not have electricity. That's another problem" (P49:80).
Technology as educational tool	An aspect where technology is used as an educational tool or has potential to be used as an educational tool.	"Yes, they have the tablet. We have the interactive whiteboard, but we the teachers are still struggling to use the interactive whiteboard. Most especially for Maths" (P60:22).
Value of using ICT	The advantages or benefits of using ICT in the educational arena.	"In our opinion, digital assignments and diagnostic testing add to the motivation and performance of students in mathematics education" (Heck et al., 2007, p. 18).
Devices	Any technological device that can be used in educational practice, e.g. mobile phone, laptop, tablet.	"Observation of the students' behavior during the experimental lessons supports the premise that the graphics calculator can stimulate the use of realistic contexts, the exploratory and dynamic approach to mathematics, a more integrated view of mathematics, and a more flexible behavior in problem solving" (Drijvers & Doorman, 1996, p. 425).
ICT	This refers to the broad, encompassing term that includes all information and communication technology.	"In order to help teachers to benefit from technology in everyday mathematics teaching, therefore, it is important to have more knowledge about the new teaching techniques that emerge in the technology-rich classroom and how these relate to teachers' views on mathematics education and the role of technology therein" (Drijvers et al., 2010a, p. 214).
Tools	Technology tools that aim to help teachers teach learners more effectively, such as software programmes,	"Two kinds of applets can be distinguished: model applets, which help to develop mathematical understanding (concepts), and exercise applets, which support the development of mathematical

Code	Description	Example
	applications, websites etc.	skills" (Heck et al., 2007, p. 2).
Methodology	Different methodological approaches used in the literature, e.g. design-based research; action research.	"The three studies that are discussed in this paper combine the methodology of design research with a prominent role for the Hypothetical Learning Trajectory as a research instrument in all phases of design research (design, teaching experiment, retrospective analysis)" (Bakker et al., 2003, p. 1).

Interrater reliability was calculated using Cohen's kappa. This is an index of interrater reliability which is used to measure the level of agreement between two sets of ratings (Cohen, 1960, p. 37). Kappa is the portion of agreement between raters (Fleiss & Cohen, 1973, p. 613). Kappa ranges between -1.00 and +1.00, where a negative value indicates poor agreement, and a positive value indicates better than chance agreement (Fleiss & Cohen, 1973, p. 613). A kappa of zero indicates a random level of agreement or disagreement (Wood, 2007, p. 7). Wood (2007, p. 6) states that for research purposes, the kappa should be at least 0.60 or 0.70. For making applied decisions about a particular individual like doing intelligence tests, the kappa should be at least 0.80 or 0.90. The Cohen's Kappa for the systematic literature review was calculated to be 0.98 (Addendum 2.5).

2.6.6 Validity and Reliability in the Systematic Literature Review

The validity and reliability of a study to a large degree depend on the ethics of the researcher (Merriam, 2009, p. 228). If the ethical standards of the researcher are not acceptable, it will negate the reliability and validity of the study. I have at all stages of the research adhered to the strict ethical standards of the NWU (§ 2.5), as well as conducted all aspects of the research in an ethical manner.

The importance of producing valid and reliable results and knowledge in research is invaluable (Merriam, 2009, p. 210). Validity is an important key to effective research (Cohen et al., 2011, p. 133). The following terms are extensively embraced in qualitative research: credibility, transferability, dependability, conformability (Merriam, 2009, p. 211), trustworthiness, authenticity and plausibility (Given, 2008, p. 909). Reliability refers to the replicability of research findings which in essence in social sciences is problematic, since human behaviour constantly varies (Merriam, 2009, p. 220).

Reliability is often referred to as the "dependability, consistency and/or repeatability of a project's data collection, interpretation, and/or analysis" (Given, 2008, p. 753). To put these into practice, authors propose techniques such as spending extensive time in the field, triangulation and the use of thick description (Creswell, 2013, pp. 203-204).

Given (2008, p. 753) lists three of the commonly cited indicators of credibility and dependability that qualitative researchers use to demonstrate systematic attention to reliability issues as: i) methodological coherence, which refers to the appropriate and thorough collection, analysis and interpretation of data; ii) researcher responsiveness, which refers to the early and on-going verification of findings and analyses with participants; and iii) audit trails, which refer to the transparent

description of all procedures and issues relating to the research project. Creswell (2007, p. 206) suggests, amongst others, the following strategies to ensure validation in qualitative research: Prolonged engagement and persistent observation in the field; and rich, thick description, which helps readers make decisions about transferability. The manner in which I have complied with the indicators as suggested by Given (2008, p. 753) and Creswell (2007, p. 206) is illustrated in Table 2.7.

Table 2.7 Indicators of Credibility and Dependability in the Systematic Literature Review

Indicator	Description
Methodological coherence	I followed a scientific procedure to select relevant documents. The selection process was discussed in detail in § 2.6.1 – 2.6.3. Data analysis was systematically done with the aid of ATLAS.ti™.
Researcher responsiveness	The interpretation of the data was verified by a peer in the field of Mathematics education, who is also an expert in performing systematic literature reviews. Cohen's Kappa was calculated to verify the interrater reliability (§ 2.6.5)
Audit trails	All procedures that were followed in the selection, analysis and interpretation of the documents were described in detail in § 2.6.
Prolonged engagement	Over a period of a year, I selected, coded, analysed and documented the systematic literature review.
Rich, thick descriptions	I made use of an extensive scientific process that was documented and described in detail as to how documents were selected, coded and analysed. A detailed analysis of the literature follows in Chapter Three.

2.6.7 Limitations of the Systematic Literature Review

Although the systematic literature review has many benefits (§ 2.6), there are limitations involved in its use as well. Most importantly, systematic literature reviews can be performed badly (Hemingway & Brereton, 2009, p. 6). To overcome this problem, researchers should rigorously follow the steps documented for successful systematic literature reviews by various authors (§ 2.6.1). The most obvious limitation of a systematic literature review is the limited key words used in the search, the limited data-bases that were selected, as well as the limited time period of publication. The systematic literature review is a complex, intensive, rigorous and time-consuming method of doing a literature review. Despite these aspects, it still proved to be a suitable method for deriving a theoretical framework for the study.

2.7 Aspects for Intervention

The research questions and the exposition of the systematic literature review provided guidance and insight with regard to various aspects that required intervention. This overview was an ideal starting point which offered valuable insight into strategies that could be used to intervene. From this point the qualitative strategy, which took the form of a needs analysis, could be further used to refine the intervention process and assist the teacher-students in addressing their specific needs.

2.8 Qualitative strategy: Needs Analysis

One of the sub-questions posed to gain insight on the main research question for this study was: *What support needs do teachers have in order to successfully implement the RME approach in their teaching practice?* To answer this question, it was necessary to schedule a meeting with the teacher-students to establish what needs they had in terms of making the Mathematics content more realistic for their learners. I also used this opportunity to determine their views on what type of technology would be most suitable to address these needs.

2.8.1 Participant Selection

Two basic types of sampling can be used, namely probability sampling and nonprobability sampling. Nonprobability sampling is the most suitable choice for qualitative research, and the most common form of nonprobability sampling is purposive or purposeful sampling (Merriam & Tisdell, 2016, p. 96). Nonprobability sampling implies that the researcher targets a particular group knowing full well that it does not represent the wider population, it merely represents itself (Cohen et al., 2011, p. 155). Small-scale research often makes use of nonprobability sampling because the samples are less complicated to achieve, are considerable less costly and can prove perfectly adequate when researchers do not intend to generalise their findings, despite the disadvantages that can arise from the non-representativeness (Cohen et al., 2011, p. 155). Purposive sampling (participant selection) allows the researcher to select individuals and sites because they can provide an understanding of the research problem and principal phenomenon in the study (Creswell, 2013, p. 156). The number of participants in the sample varies, depending on the research. In phenomenology, the range of the number of participants can be from one to hundreds (Creswell, 2013, p. 157).

As mentioned in Chapter One, in this study, participants were selected from a group of in-service teachers enrolled for the BEd Honours post-graduate degree in Mathematics education at the NWU, which is delivered by means of both the face to face and ODL modes. The criteria for selection were:

(i) teacher-students enrolled at the NWU for the BEd Honours degree by means of either face to face or ODL mode,
(ii) teacher-students who attend contact classes for the degree in question,
(iii) teacher-students who are currently teaching Mathematics in any phase and
(iv) male and female teachers at various schools.

At the contact sessions in Potchefstroom, I made contact with the students who attended the presentations for the Mathematics modules in the course. I enquired of these students who would be willing to take part in this research, and collected their contact information. I approached these students for the initial interviews.

2.8.2 Site Selection

The selected site for this research was the Potchefstroom Campus of the North-West University. Part-time students enrolled at the Faculty of Education Sciences at the above-mentioned campus, for the BEd Honours post-graduate degree, specialising in Mathematics education, were invited to participate in the research.

There are a number of types of purposive sampling; the most appropriate for this study was convenience sampling. In convenience sampling, otherwise known as accidental or opportunity sampling (Cohen et al., 2011, p. 155), a sample is selected based on time, money, location and availability of sites or respondents (Merriam & Tisdell, 2016, p. 98). This sampling involves choosing the nearest individuals to serve as respondents until the sample size has been obtained (Cohen et al., 2011, p. 155). The advantage of using convenience sampling is that it saves time, money and effort, but this can impact on the information received and the credibility (Creswell, 2013, p. 158). Captive audiences like students or student teachers often serve as participants in convenience sampling (Cohen et al., 2011, p. 156). The researcher in this type of sampling needs to be particular about reporting that the parameters of being able to generalise are negligible (Cohen et al., 2011, p. 156). I made use of purposive sampling to select the site. Two of the interviews took place at the Potchefstroom Campus of the North-West University, which is a familiar terrain for the student-teachers as they regularly attend contact classes at this site. The third interview took place in the HOD's office at one of the participant's school in Potchefstroom. The fourth meeting took place at a coffee shop in Ventersdorp.

2.8.3 Methods of Data Generation or Collection

Interviews allow participants to discuss their interpretation of the world in which they live and to express their opinions on situations from their perspective (Cohen et al., 2011, p. 349). As Cohen et al. (2011, p. 349) describe it, the interview is "not simply concerned with collecting data about life: it is part of life itself, its human embeddedness is inescapable." I made use of semi-structured individual interviews with the teacher-students to establish their needs in terms of making Mathematics more realistic for their learners. The RME approach has proved to enhance and improve learners' understanding in Mathematics (Fauzan et al., 2013, p. 174). I also made use of observations of the participants' classroom practice to establish the teacher-students' needs with regard to making the curriculum content relevant for their learners. Individual as well as focus group interviews were used to further generate data. Focus group interviews should be used when interviewees are similar and the interaction between the interviewees will yield the best information (Creswell, 2007, p. 133). The interviews allowed me to gain in-depth knowledge of how teacher-students experience the intervention that is presented to them by means of different technologies, based on the RME approach. In order to ensure validity and reliability, the following measures were used: prolonged engagement and

persistent observation in the field, the use of thick, rich description and feedback from others (Creswell, 2007, p. 207).

2.8.3.1 Initial Testing of the Informal Discussion and Needs Analysis

An initial informal discussion was scheduled with a teacher with whom the researcher is familiar, to test the effectiveness and accuracy of the questions in the informal discussion. The teacher is currently teaching Mathematics at a rural secondary school in the Potchefstroom area. Some of the lecturers who are involved with distance education at the Faculty of Education Sciences at the NWU have since 2011 been involved in a school support programme with a particular school in the area. The support involves assisting grade 11 and 12 teachers and learners with Mathematics, via an Interactive White Board (IWB). The researcher is familiar with this teacher because of this support programme, since he is one of the Mathematics teachers at the school, and she is one of the lecturers involved in the support programme.

The initial informal discussion was recorded and transcribed. I together with my promoter coded the informal discussion with the aid of ATLAS.ti™. The existing codes that were created in the systematic literature review were used as well as a few additional codes that were necessary to create in the coding process. To ensure that the coding was done in sufficient detail, and to determine whether the questions were unambiguous and clear, the researcher and two peers perused the transcription again, and added additional codes where necessary. The two peers that assisted with this further coding are full-time Mathematics lecturers at the Faculty of Education Sciences at the NWU.

2.8.3.2 Individual Semi-structured Interviews

One of the most common ways of collecting qualitative data is the interview, which is used by researchers when they “cannot observe behaviour, feelings or how people interpret the world around them” (Merriam & Tisdell, 2016, p. 108). In the SAGE Encyclopaedia of Qualitative Research Methods, Given (2008, p. 422) distinguishes between different types of interviews. Merriam and Tisdell (2016, p. 109) use the same classification, namely structured, semi-structured and unstructured interviews. In-depth or semi-structured interviews are interviews in which participants are encouraged to talk in depth about a topic. The interview can be considered to be semi-structured, since the researcher maintains some control over the content and direction of the discussion, however participants are free to expand on their ideas and move the discussion into new but related directions (Given, 2008, p. 422). The conversation fluctuates between the researcher’s introduction of the topic, the participant’s description of his or her experiences and the researcher’s examining of these experiences for additional information (Given, 2008, p. 422). In a structured interview, the participant responds to a list of pre-determined topics or questions, and in an unstructured interview there are no preconceived topics or questions (Given, 2008, p. 422).

Four participants were approached to take part in the study. Individual semi-structured interviews were scheduled with each participant and an appropriate location was decided upon to do the interview. An interview schedule was loosely followed (Addendum 2.6). The questions in semi-structured interviews are flexibly worded and the interview is a mix of more or less structured questions (Merriam, 2009, p. 90). The main part of the interview is guided by a list of questions or issues that need to be explored. This allows the researcher to react to the situation as it arises (Merriam, 2009, p. 90). The first interview took place at the North-West University (NWU) Potchefstroom Campus.

The interviews were coded using ATLAS.ti™. Open-coding was used to code the interviews as this allowed me to explore ideas and meaning that were contained in the raw data (DeCuir-Gunby et al., 2011, p. 139). Codes that are driven by data involve five steps in order to create the codebook , namely: raw data are reduced; subsample themes are identified; themes are compared across subsamples; codes are created; and the reliability of codes is determined (DeCuir-Gunby et al., 2011, p. 141). These five steps were used in the study; firstly I perused paragraphs of the data to identify appropriate codes. The existing codes which were created in the systematic literature review were used, and where necessary, additional codes were created which were suited to the context and content of the data. This constituted step two, three and four. The final step to establish reliability was done by inviting two peers who are experts in the field of Mathematics education to peer code an interview. The Cohen's Kappa for the individual interview was calculated to be 0.99 (Addendum 2.7).

Data saturation occurs when "continued data collection produces no new information or insights into the phenomenon you are studying" (Merriam & Tisdell, 2016, p. 199). By the third and fourth interview, no new information emerged in this study. Another indication of data saturation is concerned with the analysis of the data—if the categories, themes or findings are robust enough to cover what emerges in later data, then saturation occurs (Merriam & Tisdell, 2016, p. 199). When coding in ATLAS.ti™, no new codes or themes were added in the third or fourth interview, so I deemed four a sufficient number of participants for the study.

2.8.3.3 Data Analysis

Data were coded, sorted and summarised into themes or patterns which would aid the understanding and interpretation of what is emerging (Nieuwenhuis, 2010a, p. 99). This analysis was done with a Computer Assisted Qualitative Data Analysis Software (CAQDAS), ATLAS.ti™. Based on these findings, I could establish what sections of the curriculum the teachers and learners found most problematic, and also with which sections they needed help to relate the content to real life situations. As a result of what was revealed in the interviews, I could also decide on the appropriate use of technology to present the intervention, which was based on the principles and characteristics of RME.

2.9 Intervention Strategy: Design of the App

The needs analysis revealed two important aspects that directed the rest of the study (a detailed discussion is presented in Chapter Four). Firstly, participants needed assistance with ideas on how to make the Mathematics more realistic for their learners; and secondly, they were keen to use technology, specifically mobile technology, as a tool to learn how to apply the principles of RME in their teaching practice. It was therefore necessary to devise a strategy to intervene, that could address the issues raised. This intervention strategy took the form of an app that was designed for Android. With the help of a programmer and specialist in the design of applications, we designed an app for the teacher-students that could help them to make the content more realistic for their learners. The design process is documented in detail in Chapter Five.

2.10 Qualitative strategy: Participants' Perceptions about the App

When the intervention tool, the Financial Mathematics app, had undergone various stages of refinement in the form of improved prototypes and it was completed, the programmer made it available on Google Play Store as a free app. It was necessary to make this app available to the teacher-students so as to establish their perceptions and opinions about the app.

2.10.1 Participant Selection

The same students that were selected for the initial interviews were approached for the follow-up focus group interview. One of the students that took part in the initial interview was not able to attend the focus group interview and an additional student who complied with the criteria in § 2.8.1 was approached to attend the focus group interview. This student was informed of the research process up to that point and agreed to take part in the focus group interview.

2.10.2 Site Selection

The same site was used as discussed in § 2.8.2. I met with teacher-students at an appropriate venue at the North-West University Potchefstroom Campus and made sure that all participants were comfortable.

2.10.3 Methods of Data Generation or Collection

A focus group interview was selected as the method of data generation. A focus group interview is an interview with a group of people who have a common interest or knowledge in a topic (Merriam, 2009, p. 93). It is beneficial when the interaction between the interviewees will produce the best information,

when the participants are similar and when they are willing to cooperate with each other (Creswell, 2007, p. 133). I decided to make use of the focus group interview for two reasons. Firstly, because I hoped that the interaction between participants would yield the most fruitful information. Secondly, I was also aware that the teacher-students were familiar with one another because they were studying the same course and attended contact classes together, so I hoped that that fact would encourage active cooperation between them. I designed an interview protocol (Creswell, 2007, p. 133) with ten questions. These questions were based on the literature review. The systematic literature review produced five main themes (Chapter Three), namely Mathematics, RME, ICT, role players and methodology. I designed questions which incorporated these themes in the process of evaluating and commenting on the app (Addendum 2.8).

2.10.3.1 Focus Group Interviews

Initially I planned to do one focus group interview with the four selected teacher-students. When contacting the students for a viable date and time to meet, I noted that one of the teacher-students was not able to attend the focus group interview at the same time as the others for logistical reasons. I decided to divide the group in two and proceeded with two focus group interviews, each attended by two students.

The purpose of the focus group interview was to introduce the teacher-students to the app on Financial Mathematics and to determine their views and opinions about it. The app was available for teacher-students to download free of charge on Google Play Store. I allocated time for them to familiarise themselves with the app before the scheduled questions (Addendum 2.8) were discussed. In this time, I was available to assist in any way they needed assistance. We then progressed to a discussion about the app and addressed the scheduled questions in the discussion. A detailed analysis of this discussion was presented in Chapter Six.

2.10.3.2 Data Analysis

I transcribed the two focus group interviews and analysed the data with the aid of ATLAS.ti™. The data analysis and interpretation were integrated with the literature review to answer the research questions. Based on these findings, guidelines for the effective use of technology in implementing the RME approach in teaching practice were designed. The detailed guidelines were presented in Chapter Seven.

All the data in the study were analysed in the same Hermeneutic Unit (HU) in ATLAS.ti™. The final list of codes as well as the code density, or the number of times each code was noted, is indicated in Table 2.8.

2.10.4 Validity and Reliability in the Qualitative Inquiry

As discussed in § 2.6.6, unless a researcher is able to show the audience that the procedures that were followed to ensure that his/her methods were reliable and his/her conclusions were valid, there is no point in trying to conclude a research dissertation (Silverman, 2007, p. 209). I used the same criteria to ensure validity and reliability in the qualitative inquiry as I used in the systematic literature review. A detailed description of the theoretical underpinnings is given in § 2.6.6.

The manner in which I have complied with the indicators as suggested by Given (2008, p. 753) and Creswell (2007, p. 206) in the qualitative inquiry is illustrated in Table 2.9.

Table 2.9 Indicators of Credibility and Dependability in the Qualitative Inquiry

Indicator	Description
Methodological coherence	The initial test interview was peer coded to ensure validity and reliability of the coding (§2.8.3.1) All data analysis was systematically done with the aid of ATLAS.ti™. The design of the app followed nine systematic and coherent steps in the design and development phase (§ 5.5.2)
Researcher responsiveness	The interpretation of the interview data was verified by two expert peers in the field of Mathematics education. Cohen's Kappa was calculated to verify the interrater reliability (§ 2.8.3.2)
Audit trails	All procedures that were followed in the collection, analysis and description of the qualitative data were described in detail in § 2.8-2.10. The detailed analysis of the individual interviews was done in Chapter Four and the detailed analysis of the focus group interviews was done in Chapter Six.
Prolonged engagement	There was a period of nine months between doing the initial needs analysis of the teacher-students and the follow-up focus group interviews. In this time, myself and various other role players spent extensive time in conceptualising, developing and testing the mobile app, before meeting with the teacher-students for the second time.
Rich, thick descriptions	Chapters Four and Six present detailed analyses of the qualitative data. The actual words of participants were used to reinforce the analysis and findings. Reference is constantly made in these chapters to the conceptual framework from the literature review (Chapter Three) as well as the process that was followed in the research methodology of qualitative design-based research.

2.11 The Role of the Researcher

Denzin and Lincoln (2013, p. 8) describe the qualitative researcher as a "bricoleur," a person who engages in the construction of something from a wide range of available things, an amateur who is able to do practical repairs of any kind (Given, 2008, p. 65; Gravemeijer & Cobb, 2013, p. 78). Denzin and Lincoln (2013, p. 11) are of the opinion that qualitative researchers should be proficient in performing a large number of assorted tasks which include interviewing and rigorous self-reflection, and should read widely about the many interpretive paradigms. Gravemeijer and Cobb (2013, p. 78) state that the way a design-based researcher goes about doing things resembles the way a "bricoleur" works. The qualitative researcher should understand that the research is an interactive process which is shaped by not only his/her own personal history, biography, gender, social class, race and ethnicity, but also those of the people in the setting (Denzin & Lincoln, 2013, p. 11). The researcher is the

primary instrument for collecting and analysing data (Creswell, 2013, p. 45; Merriam & Tisdell, 2016, p. 16).

When discussing the process of design-based research, Amiel and Reeves (2008, p. 35) discuss the liaison between researchers and practitioners. They suggest that researchers rarely engage directly with practitioners as far as the design process is concerned. The design-based research should start with negotiations between researcher and practitioner regarding the research goals. The practitioner's role is to partner the researcher in establishing research questions and identify problems that need to be investigated (Amiel & Reeves, 2008, p. 35).

One of the requirements of a researcher in design-based research is that he or she should be "humble in approaching research by recognising the complexity of interactions that occur in real world environments and the contextual limitations of proposed designs" (Amiel & Reeves, 2008, p. 35). According to Plomp (2013, p. 43) the researcher needs to be adaptable, and the researcher needs to be adaptable in the following ways: in addition to being researcher, the researcher should be willing to take on the role of designer, advisor and facilitator; be tolerant with regard to role distinctions; and be willing to allow the study to be partially influenced by the role players (McKenney, Nieeven, & van den Akker, 2006, p. 84).

I am a lecturer in the Faculty of Education Sciences at the NWU, and work specifically with programmes that are delivered to in-service teacher-students, and specialise in the field of Mathematics education. I fulfilled a multi-faceted role in this research. Firstly I acted as researcher throughout the entire process. After negotiating with teacher-students and establishing what problem areas teacher-students (who acted as practitioners in this research) had in teaching Mathematics content to their learners, my second role, as a content specialist, was to design appropriate intervention in the form of a mobile app. The latter was based on the RME approach to assist the teacher-students to make the content which they teach to their learners more relevant and related to real life. The third role that I fulfilled in the study was to act as interviewer and facilitator of the teacher-students to establish what support-needs the teacher-students had in order to effectively implement the RME approach in their teaching, as well as to determine their perceptions about the mobile app as intervention. My fourth role was to design and refine guidelines appropriate for the application of the RME approach to be implemented with the aid of technology.

2.12 Summary of the Chapter

This chapter presented the research design and methodology for this study. The research questions formed the foundation of the method that was selected. I described my stance as an interpretivist and expressed the suitability of selecting to do a qualitative phenomenological study. I explicated the methodology of qualitative design-based research as well as the suitability thereof in this study. The

ethical considerations were taken into account. I detailed the description of the systematic literature review process as well as the qualitative inquiry. Concerning both aspects I discussed the rationale behind participant selection, site selection, data generation methods and the process of analysis. I also explored my role as researcher and discussed the trustworthiness of both the systematic literature review as well as the qualitative inquiry. Chapter Three presents the systematic literature review.

Chapter Three

Systematic Literature Review

3.1 Introduction

This chapter presents the review of the current literature with regard to the implementation of RME principles, aided by the use of ICT in Mathematics education. ATLAS.ti™ was used to analyse the literature in order to create themes for discussion and interpretation. Five themes emerged in this review which related to: (i) Mathematics, (ii) RME, (iii) ICT, (iv) Methodology, and (v) Role players. These themes guide the discussion in the chapter that follows. Figure 3.1 is an illustration from ATLAS.ti™ of the five main themes that emerged from the systematic literature review.

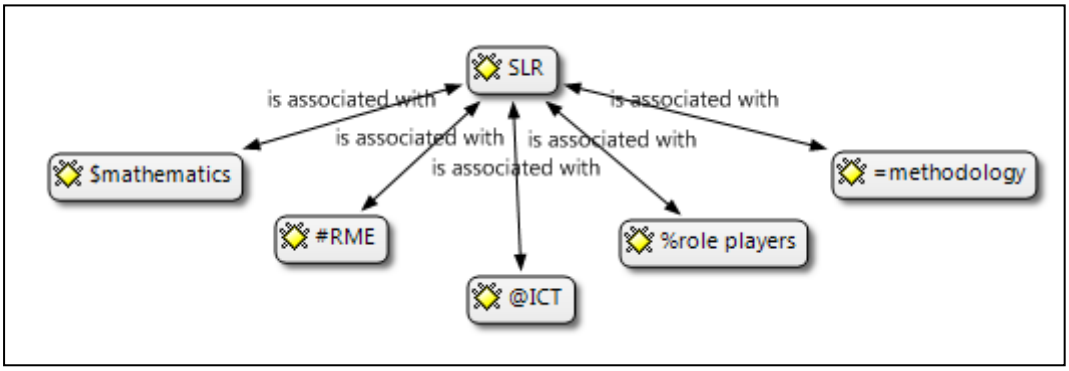

Figure 3.1: Emerging Themes from the Systematic Literature Review

Figure 3.2 presents the conceptual framework for the systematic literature review and serves as a guide for the rest of Chapter Three.

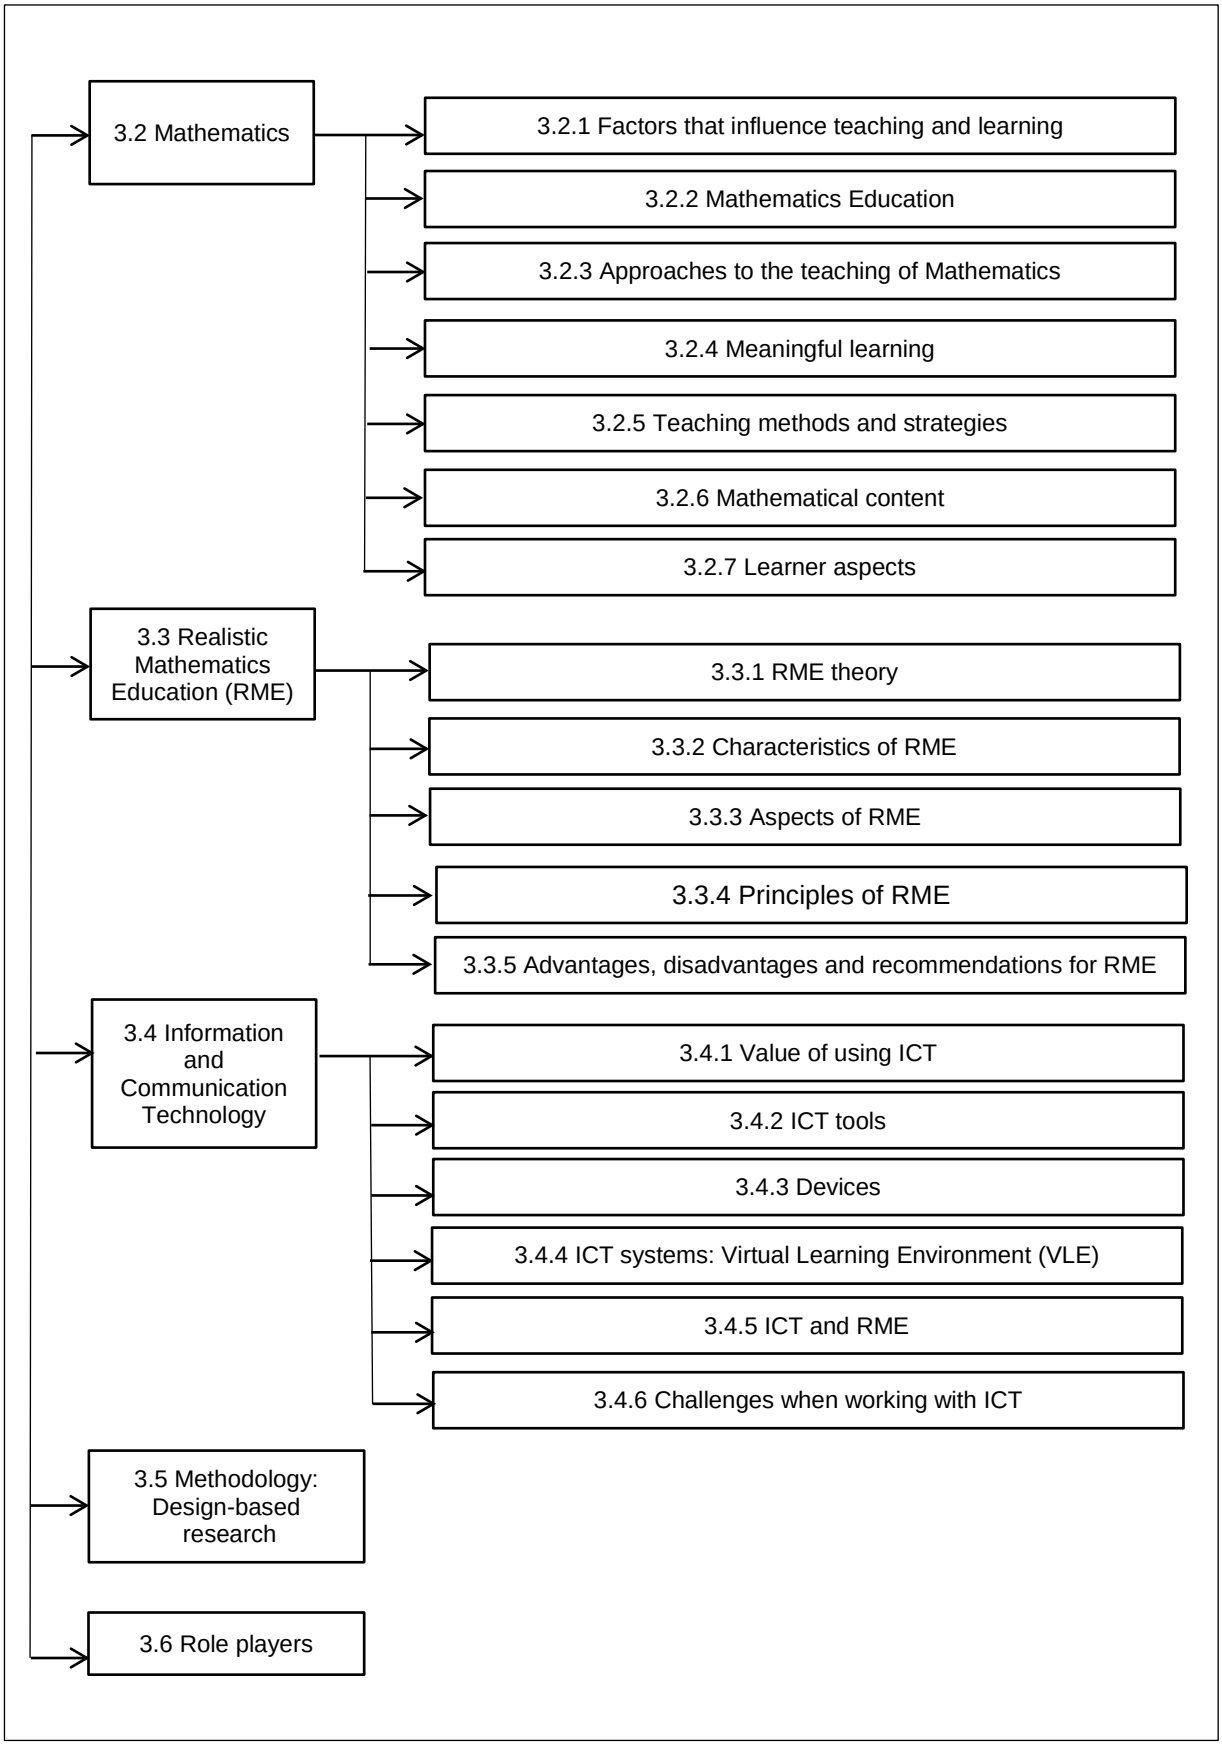

Figure 3.2: Conceptual Framework for the Systematic Literature Review

3.2 Mathematics

Mathematics is one of the main themes that arose from the systematic literature review as is illustrated in Figure 3.3.

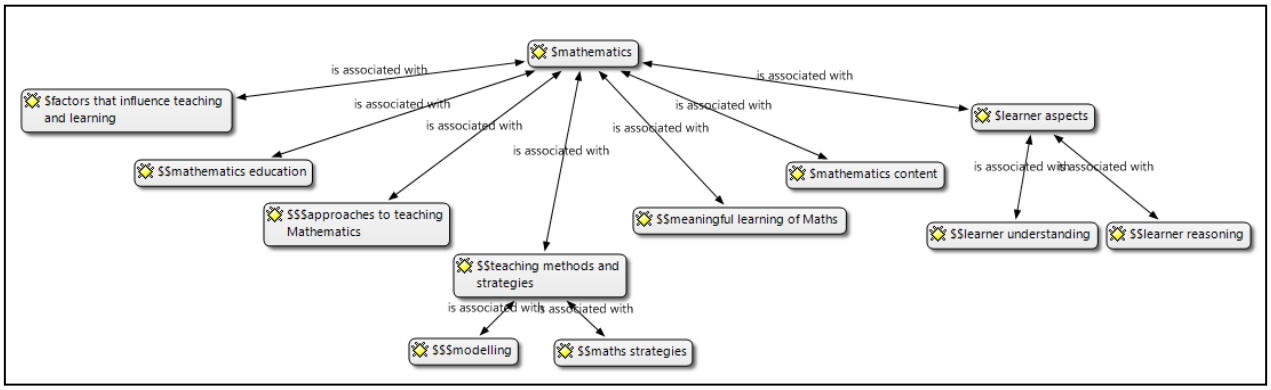

Figure 3.3: Mathematics as Theme from the Systematic Literature Review

Mathematics is not just an abstract body of knowledge, but a subject that contains skills and a way of thinking that can be applied in numerous real life situations (Domazet, Baranović, & Matić, 2013). The teaching and learning of Mathematics is a complex undertaking, but should be connected to reality in order to make sense to learners (Cahyono, 2012). One of the main expectations of Mathematics is that it will develop rational thinking, orderliness and accuracy of expression, all of which can be applied in everyday life (Domazet et al., 2013).

3.2.1 Factors that Influence Teaching and Learning

The rapidly changing information society influences the role of learners and teachers (Gravemeijer, 2012). Future jobs require what Gravemeijer (2012) refers to as 21st century skills, which include "flexibility, critical thinking, problem solving, collaboration, and communication." Gravemeijer (2012) emphasises the importance of addressing these demands by investigating educational practices that may nurture these goals. Heck et al. (2007) are of the opinion that digital assignments and diagnostic testing can increase motivation as well as performance in learners. Also, the use of real life contexts stimulate motivation because the relevance of Mathematics can then be seen in the real world (Risnawati, Kurniati, & Regita, 2014).

Mobile Learning (mLearning) is a field that is rapidly expanding and that affords new possibilities to improve learning, especially in a distance education (DE) environment (Kizito, 2012a). South Africa in particular is a suitable location to use mLearning in distance education due to its viability and affordability as opposed to web-based technology (Kizito, 2012a). Further research is required to determine how the mobile phone can effectively be used in testing in DE (Kizito, 2012a). The portability of mobile technology allows learners to work creatively and collaboratively (Zaranis et al.,

2013). When used correctly, technology could promote critical thinking, improved problem solving skills and collaboration (Stols, 2012).

Various reasons are offered for poor performance in Mathematics. These include: when topics taught seem to be removed from learners' daily lives (Fauzan et al., 2013); inaccurate learning material; inadequate and out-dated teaching methods; poor forms of assessment and learners' anxiety about Mathematics (Widjaja & Heck, 2003); and learners' negative attitudes towards Mathematics (Widjaja & Heck, 2003). The difficulties that learners experience in Mathematics in later years are associated with the inadequate development of mathematical thinking in the initial years (Zaranis, 2014c).

3.2.2 Mathematics Education

An essential goal of Mathematics education is the adoption of fundamental mathematical knowledge, the development of basic mathematical literacy and the ability to solve problems (Domazet et al., 2013). Mathematics education is not about transferring a mound of mathematical knowledge to young people, but rather about fulfilling broader social goals (Domazet et al., 2013). It is important to remember that pedagogy should guide the process of designing digital technology, rather than technology itself (Drijvers, 2013). The technology needs to be rooted in an educational context (Drijvers, 2013).

Mathematics teachers are challenged to develop Mathematics education that is in line with the dynamic conceptions of symbolising and the development of meaning (Bakker et al., 2003). The role of the teacher is essential in understanding how to teach effectively with technology (Drijvers, 2012). A teacher needs to plan for productive whole-class discussions, which demands that the teacher needs to account for differences in students. Students are at different levels of mathematical understanding, and the teacher needs to highlight problem areas in such discussions that stimulate a higher level of understanding (Gravemeijer, 2012). Tasks should be designed in such a way that students are encouraged to develop their own Mathematics. The teacher needs to guide the process and should know when to further explore a topic or concept and when to cease to investigate a topic (Drijvers et al., 2013). Digital assessment and diagnostic testing can increase the motivation and performance of students in Mathematics education (Heck, Boon, & van Velthoven, 2008).

3.2.3 Approaches to the Teaching of Mathematics

The traditional teaching approach tends to dominate in many classrooms still today (Fauzan et al., 2013). This approach is characterised by teachers' who actively explain material and provide examples and exercises, while learners listen, write and perform the tasks requested by the teacher (Gravemeijer, 2012; Widjaja & Heck, 2003). There is very little room for discussion, interaction and communication (Widjaja & Heck, 2003), and learners normally do not get involved in problem solving and reasoning (Gravemeijer, 2012). The social norms of the traditional classroom dictate that the

teachers' answers are always correct and that students should follow given procedures to reach correct answers, which are more important than reasoning (Gravemeijer, 2012). Learners are seldom given the opportunity to understand the rationale behind algorithms that are taught to them (Risnawati et al., 2014).

The traditional approach in teaching Mathematics has been labelled as a possible reason for the poor quality of Mathematics education in Indonesia (Fauzan et al., 2013; Widjaja & Heck, 2003). The reason for this is that most learners feel that they do not have the opportunity to learn significant Mathematics (Fauzan et al., 2013). Context problems in the traditional approach are used only as applications at the end of a section, rather than during the course of the teaching and learning process (Gravemeijer & Doorman, 1999).

Traditional teaching approaches tend to have a negative influence on learners, especially on their attitude towards Mathematics (Fauzan et al., 2013). Often in the traditional approach, learners work with problems that are not directly linked to school Mathematics, and they need to deal with unfamiliar situations and contexts (Mousoulides et al., 2007). Another consequence of traditional teaching is when students solve traditional word problems, high level cognitive and metacognitive processes are often absent (Mousoulides et al., 2007). The continuous change in Mathematics education is evident in the shift from traditional curricula to problem-oriented curricula (Widjaja & Heck, 2003).

A common thread of all alternative approaches is the belief that learning Mathematics should not be a process of assembling pieces of knowledge, but rather of cognitive growth (Gravemeijer & Doorman, 1999) and the development of core skills in learners (Heck, 2009). Reform from the traditional approach demands that curricula, teaching materials and assessment need to be adapted (Zulkardi, 2000). In essence, Freudenthal (1968), who is seen as the father of RME, opposes the traditional idea that the end result of the work of Mathematicians is the starting point for Mathematics education (Gravemeijer & Doorman, 1999).

Problem solving through modelling leads to the design of activities that allows for students to deal with non-routine problem situations that demand the development of important mathematical ideas that can be extended, explored and refined in other problem situations (Mousoulides et al., 2007). Technological tools create new prospects for problem solving in Mathematics (Doorman et al., 2007).

RME is a domain-specific instruction theory for the teaching and learning of Mathematics (Drijvers et al., 2013). The RME-based teaching and learning process promotes learner-centred learning (Fauzan et al., 2013). One of the cornerstones of RME is that learners are encouraged to not only receive information, but also question and process information (Widjaja & Heck, 2003), actively participate in the educational process and develop mathematical tools and insights (Drijvers et al., 2013). The RME approach can be used to address the shortcomings that the traditional approach presents, such as the remembering of facts and concepts that must be reproduced verbally, studying

computational aspects and applying formulas (Fauzan et al., 2013). RME does not aim to use abstract principles or rules in concrete situations (Widjaja & Heck, 2003).

Learners' achievements tend to improve in experimental situations, which is common to the RME approach as opposed to traditional teaching (Fauzan et al., 2013; Zaranis, 2014a) and the learners become more independent and actively involved in the teaching and learning process (Fauzan et al., 2013; Fitzallen & Watson, 2014). Learners learn by experience, and not because of what they are told by the teacher (Gravemeijer, 2012). The structure of RME is such that learners gradually reorganise their thinking toward more abstract ideas and relate those ideas to the practical context of the situation (Fitzallen & Watson, 2014). Learners reconstruct solution procedures by using problems that have meaning in their reality (Drijvers & Doorman, 1996).

Teachers are key role players in bringing about change in education. Teacher training both pre-service and in-service is therefore essential (Zulkardi, 2000). Fauzan et al. (2013) found that teachers like to use the RME approach and that they are able to implement the approach as it is intended. They do however sometimes revert back to the traditional teaching approach, perhaps because they are not yet fully familiar with the RME approach (Fauzan et al., 2013).

In the RME approach, context problems have a central role in Mathematics teaching. They are used to support a reinvention process which allows learners to come to terms with formal Mathematics (Gravemeijer & Doorman, 1999). There is an increased focus on the utility of Mathematics in daily practice. It should not be seen as a ready-made product, the emphasis should rather be on the process of doing Mathematics (Zulkardi, 2000). Mathematics that is built on everyday perceptions is in line with the objectives of RME where formal mathematical knowledge can be created from situation specific reasoning (Doorman et al., 2008).

Development in technology encourages innovation in the teaching and learning of Mathematics (Cahyono, 2012). If technology is used correctly it can enhance teaching and learning, specifically in Mathematics (Stols, 2012; Zaranis, 2014c). More specifically, a technology enriched environment helps to improve the conceptual geometric growth of learners (Stols, 2012). ICT is a good catalyst to realise activity-based approaches to teaching Mathematics such as the RME approach (Widjaja & Heck, 2003). Computer-assisted learning can contribute in developing mathematical skills and can cultivate deeper conceptual thinking as compared to teaching in the traditional approach (Zaranis, 2014a, 2014c). Digital activities are particularly effective when they are designed to examine a specific problem or to teach a specific skill (Zaranis et al., 2013). New technological tools create new possibilities for problem-solving in Mathematics since new horizons can be explored (Doorman et al., 2007).

RME instruction theory links closely to the work of Van Hiele (Gravemeijer, 1999; Treffers, 1978). The Van Hiele theory identifies five discrete levels of Geometric development that are ordered and

progressive, that are not dependent on age but rather on a learners' experience (Stols, 2012; Zaranis, 2014a). The Van Hiele theory has a significant influence on geometry education and can be used to measure the cognitive growth of students (Stols, 2012).

3.2.4 Meaningful Learning

The theory of RME can help to design activities that promote meaningful learning (Wijers, Jonker, & Drijvers, 2010). One way in which meaningful learning can be promoted in both formal and informal settings, is through playing games (Zaranis et al., 2013). The interaction between teacher and student and students with one another can provide them with opportunities to enhance their learning process through social interaction (Cahyono, 2012). This interaction also enhances reflection on work, engaging in explanations, justifying, agreeing and disagreeing, and questioning alternatives, which is an essential part of RME (Widjaja & Heck, 2003). Learners that are given the opportunity to discuss their own informal strategies in solving problems with the teacher and fellow pupils, have a greater opportunity to stimulate understanding than those who do not (Widjaja & Heck, 2003). Learning outcomes and learners' understanding can be improved as a result of collaboration in learning (Cahyono, 2012). A crucial aspect in the learning process is when students are given the opportunity in the classroom to discuss their solutions and pose new problems (Bakker et al., 2003).

Tasks form an important aspect of meaningful learning. The execution of tasks should guide learners to acquire the concepts that they are required to master. When too few tasks are given, this might hinder the process of acquiring knowledge, while too many tasks can result in learners that are bored or exhausted (Widjaja & Heck, 2003). Tasks should be designed in such a way that they start by investigating problem situations that can be systematised and solved by the Mathematics that needs to be learned (Boon, 2006). The purpose of investigation tasks is to give students opportunities to improve their general competencies, deepen existing mathematical knowledge and become more adept in applying their knowledge and skills in practice (Heck, 2009).

Assessment should be in line with learners' activities with technology, and should not be removed from the use of digital technology (Drijvers, 2013). Assessment can take on different forms such as writing an essay, doing an experiment, collecting data and drawing conclusions, designing exercises that can be used in a test, or designing a test for other learners in the classroom (Zulkardi, 2000).

3.2.5 Teaching Methods and Strategies

Learners' attitudes have been noted to improve as a result of RME-based courses (Fauzan et al., 2013). The use of real world situations in school Mathematics is necessary to nurture a positive attitude towards the subject (Mousoulides et al., 2007).

Modelling activities that take place within real contexts can promote motivation and self-regulation (Mousoulides et al., 2007; Widjaja & Heck, 2003). Practical work can be done in groups and creates the opportunity for interaction between learners with each other and the teacher, where discussion and reflection about Mathematics and mathematical thinking is stimulated (Widjaja & Heck, 2003).

Dolk, den Hertog, and Gravemeijer (2002) describe reflection as a prerequisite for learning and constructing meaning and knowledge, specifically when dealing with learning from one's own activities. This is important to remember in teacher education: beginner teachers need to be encouraged to reflect on their actions and experiences in the classroom (Dolk et al., 2002). Reflection and discussion can serve as encouragement to learners to do observation. When discussing what they have observed, they reflect on the strategies that they used to report and observe—this encourages better and deeper observations (Dolk et al., 2002).

3.2.5.1 Models

The term model refers to situation models and mathematical models that are generated by learners themselves (Zulkardi, 2000). Models are more than a visual representation of a piece of abstract Mathematics. They can be used to bridge the gap between abstract, informal strategies and real, formal Mathematics (Boon, 2006; Doorman, Drijvers, Gravemeijer, Boon, & Reed, 2013; Gravemeijer, 1999; Widjaja & Heck, 2003). Although modelling also necessitates computation and deduction processes, it is predominantly about focused description, explanation or conceptualisation (Mousoulides et al., 2007).

Gravemeijer (1999) explores a discussion about two types of models: a "model of" where reality is diminished into the form of a model (created after a concept is deliberated) and a "model for" where the same model can be utilised in other situations and in new realities. This implies that the "model of" informal mathematical thinking becomes a "model for" more formal mathematical reasoning (Doorman et al., 2013; Gravemeijer, 1999). The shift in the role of the model takes place alongside a shift in the learners' thinking.

Activities that involve modelling are intrinsically social experiences since students often work together in small groups to develop a product that can be shared with others in the classroom (Mousoulides et al., 2007). Activities that require the production of models, can lead to significant forms of learning because they involve mathematizing which includes activities such as quantifying, coordinating, categorizing and systematizing (Mousoulides et al., 2007). Activities such as these are intended to disclose the way in which students think about real life situations that can be modelled through Mathematics (Mousoulides et al., 2007). The creation of a model is often a cyclical process (Mousoulides et al., 2007).

The roles of context problems and modelling are closely intertwined (Gravemeijer & Doorman, 1999). When modelling activities are set within realistic contexts, this allows for learners to make use of multiple interpretations and approaches, thereby promoting intrinsic motivation and self-regulation (Mousoulides et al., 2007). It is important to work with and study modelling of intricate systems that occur in real life situations, even from the early grades, because such models are essential aspects of knowledge that need to be emphasised in teaching and learning. This is especially important for learners preparing to work in fields such as Mathematics, Science and Technology (Mousoulides et al., 2007). By using modelling, learners are able to reason with a model of the problem, but also think about how they are to act in the real life situation (Andresen, 2007). Eventually, learners will not need the support of a model for more formal mathematical reasoning (Andresen, 2007).

Models emerge from learners' activities. As learners reason, models are generated while discussions and activities take place in the classroom (Doorman et al., 2008). Learner sense-making can be enhanced when using realistic modelling problems in Mathematics. This also helps to nurture a positive attitude towards Mathematics (Mousoulides et al., 2007). The descriptions, explanations and justifications that learners make use of form an integral part of the models that they produce (Mousoulides et al., 2007).

Models clearly play a different role in RME than in the more conventional teaching approaches (Gravemeijer, 1999). In the traditional teaching approaches, models are most often used as didactic embodiments of the formal Mathematics that is taught. This means that the formal Mathematics is concretized in order to be made more tangible for the students (Gravemeijer, 1999). The RME philosophy advises that instruction should be designed to use models and diagrams to build learners' reasoning gradually from the concrete to the abstract, thereby reinforcing learners' reasoning (Fitzallen & Watson, 2014). For RME to work, learners need to know how to model new situations (Boon, 2006). Models are able to support mathematization of the intended concepts (Doorman et al., 2008). The models should be generalised to develop into entities of their own, which then can be used as models for mathematical reasoning (Doorman et al., 2008; Widjaja & Heck, 2003).

Virtual manipulations which are facilitated by computer software are similar to physical manipulations which means that ICT can effectively support the learning process, especially in Mathematics (Zaranis et al., 2013). Technology can successfully enhance the meaning of symbolic information by making it more visual and more easily manipulated, which makes the content more accessible (Gravemeijer, 2012).

3.2.5.2 Strategies

RME focuses on the development of abstract thinking (Fitzallen & Watson, 2014) by using context problems to encourage students to develop situation-specific representations and strategies (Doorman et al., 2008). The RME approach can assist in creating a positive classroom climate which

allows for interaction and collaboration (Fauzan et al., 2013; Wijers et al., 2010). Learners should adopt the necessary classroom social norms to suit an inquiry-oriented classroom culture (Gravemeijer, 2012). Learners enjoy performing experiments during lessons rather than just listening to the teacher and doing written exercises (Widjaja & Heck, 2003). This tends to create a livelier, noisier and messier classroom, but does provide a more enjoyable atmosphere for teachers and learners to work in, and learners tend to be more enthusiastic about the work (Widjaja & Heck, 2003; Wijers et al., 2010).

An inquiry-oriented classroom creates the opportunity for learners to explain and justify their solutions, to try and understand other learners' reasoning and to ask questions if they do not understand (Gravemeijer, 2012). Apart from these inquiry-based norms, learners should also be prepared to solve mathematical problems, discuss solutions and deliberate about the core concepts (Gravemeijer, 2012). An interactive classroom allows for learners to discover things for themselves, talk actively with one another and with the teacher, and to be more aware of their own mathematical thinking (Widjaja & Heck, 2003).

It is important that teachers are willing to adapt their role in the classroom by moving towards more learner-centred learning (Widjaja & Heck, 2003). Teachers often are required to improve their skills in conducting class discussions, addressing questions that challenge learners and encourage them to think critically (Widjaja & Heck, 2003). The shift from the more traditional teaching approach to a more inquiry-driven approach means that cooperation, problem solving and metacognition are promoted (Gordon et al., 2012; Mousoulides et al., 2007).

3.2.6 Mathematical Content

According to Gravemeijer (1999), one of the reasons that learning Mathematics has been branded as difficult is that the gap between everyday life and formal Mathematics is vast. Formal Mathematics should grow out of learners' activities and should not be seen as something abstract and removed from reality (Gravemeijer, 1999). Within the RME approach, learners are expected to develop formal Mathematics by mathematizing their informal mathematical activities (Gravemeijer, 1999).

The RME approach distinguishes itself from other approaches in that it surpasses the contrast between informal and formal knowledge. The design of a hypothetical learning trajectory (HLT) can assist students in reinventing formal Mathematics (Gravemeijer & Doorman, 1999). Ideally the learning trajectory develops in such a way that the formal Mathematics surfaces in the activities that the students do (Gravemeijer & Doorman, 1999; Heck et al., 2008). In the RME philosophy, different Mathematics topics should be integrated in one curriculum. This promotes the idea of an integrated view of Mathematics, and sanctions flexibility to connect sub-divisions of the curriculum with each other and also to connect abstract Mathematics to meaningful problems in the real world (Widjaja & Heck, 2003).

The intention of the RME approach is that students should experience formal Mathematics and informal Mathematics in the same way (Gravemeijer, 1999). What students ultimately understand of formal Mathematics should remain associated with their understanding of the everyday phenomena that they experience (Gravemeijer & Doorman, 1999).

In the RME approach, it is essential that formal Mathematics can be developed as an instrument for solving real problems for the students (Boon, 2006). Real contexts that are meaningful to learners should be used as a starting point for their learning. Situations in which concepts appear in reality should be used as a starting point for concept formation and should lead to more formal Mathematics (Doorman et al., 2013; Widjaja & Heck, 2003). Technology can also assist in bridging the gap between formal and informal Mathematics. Mathematical applets are able to visualize mathematical concepts and explore context situations (Heck et al., 2008).

It is important in the RME approach that Mathematics teaching is a process in which students develop and apply mathematical concepts in real life problem situations (Domazet et al., 2013). The development of algebraic understanding and skills is an important topic in Mathematics education; however it is an obstacle for many students (Heck et al., 2007). One of the reasons for this is that algebraic manipulations are often carried out in a superficial way where rules are used but are not meaningfully connected to the underlying concept (Heck et al., 2007). Various programmes have been designed and developed to help learners practice algebraic skills in ways that make sense (Heck et al., 2007).

Geometry is often the most difficult topic in school Mathematics for learners and teachers (Fauzan et al., 2013; Stols, 2012). Learners' poor performance in Geometry, as well as their negative attitude to Geometry is a challenge in many classrooms (Fauzan et al., 2013). Making use of real contexts and data that students can relate to is essential in statistics education (Fitzallen & Watson, 2014). Technology can provide many options for representing graphical data which can help improve student learning in statistics (Fitzallen & Watson, 2014). The appropriate use of technology can help students to understand mathematical concepts more effectively (Zaranis, 2014b). According to the principles of RME, learners should mathematize everyday subject matter as well as their own mathematical activity (Gravemeijer & Doorman, 1999).

3.2.7 Learner Aspects

The theory of RME is predominantly about knowledge construction (Gravemeijer, 1999). Activities based on the RME approach allow for learners to build their own mathematical knowledge (Gravemeijer, 1999). When designing activities, teachers should be sensitive about where their learners are in terms of their anticipated learning so that activities can be based on ideas that are less sophisticated than the Mathematics being taught (Kizito, 2012a). Through interaction with each

other, students can enhance the understanding of mathematical concepts and their application in real life, which is an important characteristic of RME (Cahyono, 2012).

Social interaction, one of the five tenets or characteristics of RME, is an essential part of RME (Cahyono, 2012; Widjaja & Heck, 2003; Zaranis, 2014a, 2014c; Zulkardi, 2000). The aim of RME is to allow learners to consider the knowledge that they acquire as knowledge for which they are responsible. For this to happen, certain social norms should be in place, such as "you should not guess the answers," and "you need to work things out yourself" (Gravemeijer & Doorman, 1999). The learning process is enhanced by social interaction in the form of discussions, between learners and learners and learners and teachers (Cahyono, 2012; Widjaja & Heck, 2003). Interaction can promote the understanding of mathematical concepts and the way in which those are applied in real life (Cahyono, 2012). Modelling activities are essentially social experiences because learners work together in groups to produce something that can be shared (Mousoulides et al., 2007; Zaranis, 2014a).

Digital learning activities can inspire learners to work collaboratively (Zaranis et al., 2013). A learning environment that includes a mobile device has the potential to encourage collaborative work in learners (Kizito, 2012a; Zaranis et al., 2013). A virtual learning environment (VLE) provides an opportunity for learners to interact with one another and with the teacher (Cahyono, 2012)

3.2.7.1 Learner Understanding

By allowing learners to use informal strategies to solve problems, and allowing for discussion with fellow pupils and the teacher, the process of understanding is stimulated (Widjaja & Heck, 2003). When learners apply their mathematical knowledge in a tangible context and in a meaningful way, it leads to a deepening of their knowledge and consolidation of the concepts involved (Heck, 2009).

In RME, the holistic view of learning is emphasised where students' needs are addressed and the realisation of educational goals and purposes are facilitated (Fitzallen & Watson, 2014). RME focuses on the development of abstract thinking which assists in relating ideas in the practical context of a situation (Fitzallen & Watson, 2014). The use of the RME approach has the potential to improve learners' understanding of Mathematics (Cahyono, 2012). A benefit of using the RME approach is that learners can use the new knowledge and skills that they acquired from one lesson in the lessons that follow (Fauzan et al., 2013).

Educational technologies provide alternatives for presenting data through different representations, thereby improving student learning (Fitzallen & Watson, 2014). Computer-assisted learning can augment the development of mathematical skills and can encourage a deeper perceptual aptitude for learners (Zaranis et al., 2013). Tools influence the way in which students make sense in Mathematics (Doorman et al., 2008)

3.2.7.2 Learner Reasoning

Poor performance of learners, especially in international testing, can possibly be attributed to the instructional setting (Widjaja & Heck, 2003). Learners' own constructions are an important part of the learning process because they form the basis of classroom discussions and interactive reflection (Wijers et al., 2010). Learner achievement improves as a result of the intervention of an RME course (Fauzan et al., 2013). Learners' reasoning can be reinforced by using models, diagrams and other imagery (Fitzallen & Watson, 2014).

The interactive classroom encourages learners to explore things for themselves, talk more actively and become more conscious of their own mathematical thinking (Widjaja & Heck, 2003). When working with symbols, it is important for teachers to remember that students do not always have the mathematical background to interpret those symbols correctly. The teacher should explain to students what can be seen, how it can be interpreted and how they need to reason with those symbolic representations (Bakker et al., 2003).

3.3 Realistic Mathematics Education (RME)

Figure 3.4 represents the theme of RME with its sub-themes as categorised in the systematic literature review.

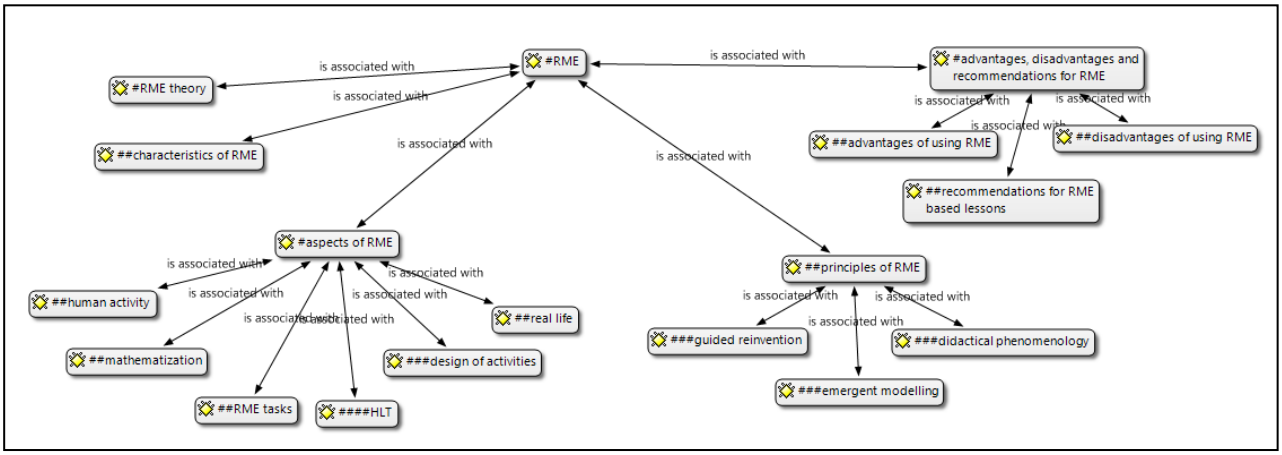

Figure 3.4: Realistic Mathematics Education (RME) as Theme from the Systematic Literature Review

According to Freudenthal (1991), students should be given the opportunity to reinvent Mathematics through a process of mathematization (Cobb et al., 2008; Doorman et al., 2008; Doorman et al., 2013; Gravemeijer, 1999), where they formalize their informal understandings and intuitions (Cobb et al., 2008) and are supported in re-creating or reinventing Mathematics (Doorman et al., 2013). The

central idea of Realistic Mathematics Education (RME) is that instruction is designed in which everyday situations and mathematical activities are mathematized. This allows for learners to reinvent Mathematics and thereby realise a better understanding of the subject (Kizito, 2012a). One of the aims of RME is to provide learners with the opportunity to consider the knowledge that they acquire as their own (Boon, 2006).

3.3.1 Realistic Mathematics Education Theory

RME, a teaching and learning theory in Mathematics education (Zulkardi, 2000), was based and developed on Freudenthal's view of Mathematics as a human activity (Cahyono, 2012; Cobb et al., 2008; Dolk et al., 2002; Domazet et al., 2013; Doorman et al., 2008; Doorman et al., 2013; Freudenthal, 1991; Kizito, 2012a; Perez, 2012; Widjaja & Heck, 2003; Zaranis, 2014c; Zulkardi, 2000). Various studies in Mathematics education have made use of the theoretical framework based on the RME approach (Andresen, 2007; Heck et al., 2007; Kizito, 2012a; Zaranis, 2014a).

RME is a foremost view on the learning of Mathematics in The Netherlands (Doorman et al., 2007). The main aim of the Freudenthal Institute is to do research and curriculum development so as to promote innovation and improve Mathematics education (Boon, 2006). The RME principles of discovering learning in a real context, where Mathematics is seen as a human activity, and where students make sense through participation in mathematical representation, is greatly treasured (Heck, 2009). The RME theory is a vision or philosophy of Mathematics that is being developed in an on-going process (Gravemeijer, 1999; Zaranis, 2014a). It is not fixed, but involves a process of experimentation, analysing and reflecting and is constantly under construction (Gravemeijer, 1999). RME develops in an iterative process of expansion, adjustment and refinement (Gravemeijer, 1999) and relates to the work of Van Hiele (Gravemeijer, 1999).

RME is more than simply situating Mathematics in a real world situation; instead the instructional tasks should draw on realistic situations as a foundation for students' mathematization. The activities should be designed in such a way that students can systematise their activity within the realistic context to reinvent significant Mathematics (Stephan & Akyuz, 2014).

3.3.2 Characteristics of Realistic Mathematics Education

Various researchers highlight the five tenets or characteristics of RME (Cahyono, 2012; Dolk et al., 2002; Drijvers & Doorman, 1996; Widjaja & Heck, 2003; Zulkardi, 2000), namely:

i) the use of contextual problems
ii) the use of models
iii) the use of student contribution
iv) interactivity (among pupils and between pupils and teacher)
v) intertwining of learning strands.

Real contexts that are meaningful and natural to pupils are important to use as a starting point for learners' learning (Boon, 2006; Dolk et al., 2002; Widjaja & Heck, 2003; Zulkardi, 2000). These contexts can be concrete or abstract and should be explored to develop intuitive notions that form the foundation of concept formation (Stols, 2012). This allows them to engage with the situation immediately. It is imperative that the instruction should not start with the formal Mathematics and end with the application in a real context, but rather that the contexts should be used as anchors for the formation of concepts (Widjaja & Heck, 2003). When using personalised contexts, where the meaningfulness of the context increases, students' solution of word problems improve and student motivation increases (Gravemeijer & Doorman, 1999).

Using models or bridging by vertical instrumentation is an important aspect in RME. Learners should develop and use models when solving problems as a bridge between what is abstract and what is real. Initially the model is a representation of what is familiar to learners, later by generalization and formalization, it becomes an object on its own that is used for mathematical reasoning and can assist in developing sophisticated mathematical concepts (Dolk et al., 2002; Widjaja & Heck, 2003). Learners should be given the opportunity to create concrete objects which assists in informal problem solving strategies. Teachers should design activities and instructional material in such a way that learners are guided through a bottom-up reinvention process (Widjaja & Heck, 2003).

Interaction in the classroom is an important aspect in RME since it encourages discussion and collaboration, both important aspects when reflecting on the work. The kind of interaction that takes place is explaining, justifying, agreeing and disagreeing, questioning alternatives, and reflecting (Widjaja & Heck, 2003). The integration of different topics in Mathematics into one curriculum is imperative in the RME philosophy. Learners should have a cohesive view of Mathematics as well as the flexibility to associate content with other disciplines or domains and also to problems in the real world (Widjaja & Heck, 2003).

With the introduction of RME principles in the classroom, interactivity can be promoted as learners take more responsibility for their learning (Widjaja & Heck, 2003). The classroom is inclined to become more energetic as learners do experimental work and are involved in discussions and debates (Widjaja & Heck, 2003). The open computer learning environment can assist with interactivity as learners explore on their own, and tend to be more aware of their own mathematical thinking (Widjaja & Heck, 2003).

A high quality RME-based course requires three quality criteria, namely: validity (content validity where the intervention includes new knowledge, and construct validity where interventions are linked to each other); practicality which means that teachers and learners consider the interventions to be engaging in normal conditions; and effectiveness which refers to the experiences and outcomes that are consistent with the proposed aims (Cahyono, 2012; Fauzan et al., 2013).

In a study that investigated the teaching of triangles and circles, with and without technology, teaching intervention was based on the characteristics of the theory of RME and the van Hiele model. These characteristics include: the introduction of a problem using a realistic context; the main objects of the problem are identified; social interaction and teacher intervention to refine the models of the problem; encouraging the process of reinvention; and focusing on the connections and aspects of Mathematics in general (Zaranis, 2014a).

3.3.3 Aspects of Realistic Mathematics Education

3.3.3.1 Mathematics as a Human Activity

Various researchers refer to Freudenthal's work (Freudenthal, 1971) when discussing his view of Mathematics as a human activity (Cahyono, 2012; Cobb et al., 2008; Dolk et al., 2002; Domazet et al., 2013; Doorman et al., 2008; Freudenthal, 1971; Kizito, 2012a; Perez, 2012; Widjaja & Heck, 2003; Zaranis, 2014c; Zulkardi, 2000), rather than a man-made system (Kizito, 2012a). Mathematics must be connected to reality (Cahyono, 2012; Widjaja & Heck, 2003; Zulkardi, 2000), where learning is viewed as a process within a social context (Perez, 2012) that can be used as a source for mathematization (Widjaja & Heck, 2003). Students should be supported (Doorman et al., 2013) and encouraged to reinvent Mathematics (Cobb et al., 2008; Dolk et al., 2002; Doorman et al., 2008).

According to Freudenthal (1968), in order for Mathematics to be of human value, it should be taught so as to be useful. This means that it should be closely related to reality, close to children and relevant to society (Zaranis, 2014a). Students should be able to understand the concepts of Mathematics and its application in the real world (Cahyono, 2012),

3.3.3.2 Mathematization

Freudenthal's view of Mathematics as a human activity (Freudenthal, 1968) suggests that Mathematics can be used as a source for mathematization (Widjaja & Heck, 2003), which means organising matter from a mathematical perspective (Gravemeijer & Doorman, 1999). The process of developing mathematical concepts and ideas that originate in a concrete situation in the real world is known as mathematization (Cahyono, 2012; Freudenthal, 1968; Zulkardi, 2000). The process forces students to explore the situation, find and identify relevant Mathematics, schematize and visualize, in order to develop a model which leads to the Mathematics concept. They can then apply mathematical concepts to new areas of the real world, and so reinforce the concept (Zulkardi, 2000).

Students should learn Mathematics by mathematizing subject matter from reality and their own mathematical activity (Freudenthal, 1968; Gravemeijer, 1999). Freudenthal highlights the importance of mathematical activities that are taken from reality, that consist largely of organizing, mathematizing

subject matter (Cahyono, 2012; Freudenthal, 1968). He believes that mathematizing can comprise the mathematizing of both subject matter from real life situations as well as mathematical subject matter (Freudenthal, 1968; Gravemeijer & Doorman, 1999).

Treffers (1978) differentiates between two kinds of mathematization, namely horizontal and vertical mathematization (Freudenthal, 1991; Treffers, 1978; Widjaja & Heck, 2003; Zulkardi, 2000). Horizontal mathematization refers to the modelling of experientially real situations into Mathematics and vice versa (Freudenthal, 1991; Treffers, 1978; Widjaja & Heck, 2003). This is the process in which learners convert problem situations that they perceive as real into some form of Mathematics. They use and create mathematical tools to organise and solve mathematical problems located in real life situations (Freudenthal, 1991; Treffers, 1978; Widjaja & Heck, 2003; Zulkardi, 2000). Vertical mathematization refers to the process of accomplishing a higher level of abstraction within Mathematics (Widjaja & Heck, 2003). This refers to reorganization within the mathematical system, such as finding short cuts, generalizing methods, and making connections between concepts (Freudenthal, 1991; Treffers, 1978; Widjaja & Heck, 2003). Freudenthal (1991) describes the two as follows: horizontal mathematization moves from the world of life to the world of symbols, while vertical mathematization means moving within the world of symbols (Widjaja & Heck, 2003). Progressive mathematization, also known as vertical and horizontal mathematization, allows learners to rediscover the knowledge, insight and mathematical procedures (Cahyono, 2012).

With regard to mathematization, Treffers (1978) divides Mathematics education into four types, namely the mechanistic, empiristic, structuralist and realistic approach. Firstly, in the mechanistic or traditional approach, horizontal and vertical mathematization are seldom or never used. Secondly in the empiristic approach, students are faced with situations in which they have to do horizontal mathematization, but do not need to produce a model or formula. Thirdly, in the structuralist approach, which is based on set theory, flowchart and games, the approach relates to horizontal mathematization in a created world, and is not linked to the real world. Finally, in the realistic approach, a real world situation is taken as the starting point for learning Mathematics (it is explored using horizontal mathematization), students then organize the problem, identify regularities and relations and by using vertical mathematization, they develop concepts (Freudenthal, 1991; Treffers, 1978; Zulkardi, 2000).

Zulkardi (2000) distinguishes between conceptual mathematization and applied mathematization. Conceptual mathematization is the process of extracting the applicable concept from a real situation. The process compels students to explore the situation, identify the relevant Mathematics, systematise and visualise to develop a model resulting in a mathematical concept. Applied mathematization occurs when the concept is applied to new areas of real life in which the concept is supported and reinforced (Zulkardi, 2000).

In the RME approach, learners are given the opportunity to create concrete objects that can be used as a point of departure for mathematization and the subsequent formalization of the informal strategies (Gravemeijer, 1999; Widjaja & Heck, 2003). Activities that stimulate the generation of a model can lead to imperative forms of learning because they involve mathematization (Mousoulides et al., 2007). The mathematization occurs by counting, dimensioning, classifying, algebraising, and organising different objects, associations, actions, arrangements and regularities (Mousoulides et al., 2007).

The process of solving contextual problems starts with the real world problem which the learner then will mathematize, reflect on the problem, do abstraction and formalisation and then return to the real world at the end of the process (Cahyono, 2012). The real world should be truly authentic for mathematization to be most effective (Doorman et al., 2007). Educational designs should be based on carefully chosen real world situations that can easily be mathematized (Boon, 2006). Software is an ideal means to stimulate such situations to recall familiarities and extend them with new ones (Boon, 2006).

3.3.3.3 The Use of Tasks in Realistic Mathematics Education

Tasks are defined as problematic situations that are experientially real for students. This means that they can experience the problem that they encounter, as real (Stephan & Akyuz, 2014). They need to be appropriate for mathematization (Stephan & Akyuz, 2014) and should be designed in such a way that students are encouraged to reinvent key mathematical concepts (Stephan & Akyuz, 2014).

Teachers involved in the design of instructional material participate in various ways: anticipating supportive mathematical imagery; creating challenging formative assessment; making use of their mathematical knowledge to change and improve the instructional sequence; and working and revising tasks that were already created (Stephan & Akyuz, 2014). Apart from the instructional sequence itself, which is considered the most important aspect by teachers in guiding their actions, lesson imaging is also an important aspect. Lesson imaging allows teachers to envision how students will solve problems, and how this can be exploited to result in powerful mathematical discussions, where objectives can be met (Stephan & Akyuz, 2014). Collaboration plays a crucial role in teachers' practices in their own success in the classroom (Stephan & Akyuz, 2014).

3.3.3.4 Hypothetical Learning Trajectory (HLT)

The hypothetical learning trajectory (HLT) refers to the consideration of the learning goal, the tools they will use, if technology is involved (Perez, 2012; Simon, 1995), the learning activities, and the thinking and learning in which students might engage (Perez, 2012; Simon, 1995). Originally, HLTs were designed for short teaching cycles of one or two lessons, but later were extended to sequences

of lessons varying from eight to twenty lessons (Bakker et al., 2003). The concept of HLT is a highly flexible instrument suitable when discussing different aspects of teaching and learning (Perez, 2012).

The development of an HLT involves the design of instructional activities that relate to the assessment of the initial level of understanding, the formulation of the end result and the envisaged mental activities of the students (Bakker et al., 2003). HLTs allow for students to reinvent formal Mathematics (Gravemeijer, 2012). They are designed in such a way that the formal Mathematics emerges from the mathematical activity that the students are involved in (Gravemeijer, 2012). The HLT should not have a rigid structure and should not expect students all to follow the same learning trajectory at the same speed; the HLT should represent a broader learning route (Bakker et al., 2003). The development of the HLT and the design of instructional activities are closely related.

The HLT guides the design of the instructional activities, however within the design process, the HLT may be reconsidered and adapted (Bakker et al., 2003). The HLT will normally be improved after a teaching experiment, based on classroom experiences. Thereafter, a new teaching cycle is started, and within design-based research, a new research cycle is also started (Bakker et al., 2003). An aspect of HLT that challenges designers is that each tool, although seemingly similar, can have varying effects on how students interact in the activity (Perez, 2012). What is important is that students' investigations, reasoning and solutions are shared, discussed and generalised to other problem situations (Boon, 2006).

The HLT deals with a small number of instructional activities and is tailored to the teacher's own classroom at any given moment (Gravemeijer, 1999). The HLT is important to teachers at the start of a project to help in orientating them (Stephan & Akyuz, 2014). The hypothetical nature of these learning trajectories implies that teachers need to examine students' reactions to determine whether the actual learning trajectory corresponds with what was intended (Bakker et al., 2003; Gravemeijer, 2012). As a result, teachers should interpret and create new instructional activities (Gravemeijer, 2012), depending on whether the conjectures can be verified or should be rejected (Bakker et al., 2003).

The HLT is a suitable research instrument in observing the development of instructional design activities and the associated hypotheses within design-based research (Bakker et al., 2003). As students' mental activities are emphasised, the expected results are motivated (Bakker et al., 2003). If an HLT is designed where technology is integrated, the designer ought to be knowledgeable about the tool and also how teachers and students perceive the use of technology in a learning activity (Perez, 2012).

3.3.3.5 Design of Activities

When designing learning activities, it is important to remember that the activity should encourage the students' work with Mathematics (Andresen, 2007). Designers should make use of their domain specific knowledge, teaching experience and their view on the teaching and learning of the topic when designing activities for the students (Bakker et al., 2003). The design of instructional activities is an essential part of executing a teaching experiment (Bakker et al., 2003). Instructional tasks should be designed so that students are given the opportunity to reinvent important mathematical concepts (Stephan & Akyuz, 2014). The development of an HLT is related to designing instructional activities (Bakker et al., 2003). Unlike with HLT's which are hypothetical, when instructional activities are performed, the teacher should look for evidence of whether the conjectures can be verified or not (Bakker et al., 2003).

3.3.3.6 Real Life Contexts

Context problems are defined as problems in which the problem situation is experientially real to the student (Gravemeijer & Doorman, 1999; Widjaja & Heck, 2003). Solving problems in realistic contexts, which students recognise as relevant and real, and which offer opportunities to develop situation-specific reasoning and tentative representations for organizing repeated calculations, plays a crucial role in the RME approach from the start (Boon, 2006; Doorman et al., 2008; Gravemeijer & Doorman, 1999; Stephan & Akyuz, 2014). In RME learners have the opportunity to learn Mathematics based on activities they experience in their everyday lives (Fauzan et al., 2013).

The students' understanding of the formal Mathematics should be entrenched in their understanding of the everyday-life occurrences (Gravemeijer & Doorman, 1999). Authentic contexts and real data that students can relate to are especially important in statistics (Fitzallen & Watson, 2014). This allows for optimal learning opportunities (Fitzallen & Watson, 2014). Students' solutions to word problems improve when personalized contexts are used. This enhances the meaningfulness of the context and can increase motivation (Gravemeijer & Doorman, 1999). Didactical phenomenology presents students with phenomena that need to be organised by mathematical structures. These phenomena can best be generated by meaningful contexts from real life which should occur naturally and with meaning (Bakker et al., 2003).

Even a pure Mathematics problem can be considered a context problem, if the Mathematics involved is experientially real for the student (Gravemeijer & Doorman, 1999). Context problems can act as anchoring points for students to learn and reinvent Mathematics (Gravemeijer & Doorman, 1999; Stephan & Akyuz, 2014; Widjaja & Heck, 2003), and should be selected so that they provide students with the opportunity to develop situation specific strategies (Bakker et al., 2003; Doorman et al., 2008). Well selected context problems provide opportunities for students to develop informal, context-specific solution strategies (Gravemeijer & Doorman, 1999; Widjaja & Heck, 2003).

Context problems form the foundation for progressive mathematization (Gravemeijer & Doorman, 1999) and should be observed as natural and meaningful in order to offer a foundation for the mathematization (Bakker et al., 2003). Solving contextual problems starts from real life problems that students mathematize and reflect on, form abstractions and formalise, then return to the real world at the end of the process (Cahyono, 2012).

Context problems are rooted in students' reality, yet by solving these context problems students are able to expand their own reality (Gravemeijer & Doorman, 1999). They allow for students to develop informal, context-specific models and strategies for solving the problems, which can later be formalized and generalized to establish a process of progressive mathematization (Doorman et al., 2008) and give students the opportunity to develop representations and strategies that relate to the situation (Doorman et al., 2008).

In the RME approach, models should be grounded in the contextual problems that students should solve (Gravemeijer, 1999). Context problems that offer students opportunities to develop situation-specific strategies should be chosen. The models that develop from these contexts emerge from the students' activities (Gravemeijer & Doorman, 1999). Modelling activities should take place in a situation that is experientially real for the students (Andresen, 2007; Doorman et al., 2008). Mathematical ideas should be fixed in meaningful real world contexts and are developed by students as they work on problems (Mousoulides et al., 2007). These ideas should be close to children's reality and should be relevant to everyday situations in life (Zulkardi, 2000).

Context problems are designed to support the reinvention process that gives students an opportunity to come to terms with formal Mathematics (Gravemeijer & Doorman, 1999). Activity sheets are one way in which students can be guided to advance from informal to more formal activities (Heck et al., 2008). RME not only uses contexts in the teaching and learning of Mathematics, but attaches substantial significance to Mathematics teaching as a process in which students develop and apply mathematical concepts and tools in realistic contexts (Domazet et al., 2013). The RME approach uses real world contexts in problem-solving to encourage motivation in students because the Mathematics is linked to the real world (Fauzan et al., 2013; Risnawati et al., 2014).

Realistic contexts are vital in not only developing sophisticated symbols, but also in developing meaning within the symbol (Bakker et al., 2003). Lessons should be designed to allow learners to use their knowledge of the context to support their thinking (Fitzallen & Watson, 2014). Instruction that is designed where everyday situations and mathematical activities are mathematized, assists students in reinventing Mathematics, and therefore achieving a better understanding of the subject (Kizito, 2012a). Many learners dislike Mathematics because they do not learn something useful and significant to them (Fauzan et al., 2013).

Digital technology should be entrenched in a context that is comprehensible and in which the technology is integrated in a natural way (Drijvers, 2013). It should be simple, attractive, easily accessible and close to the student's life (Risnawati et al., 2014). Real world situations should be chosen in such a way that software can simulate the situations which allow for mathematization to take place (Boon, 2006). ICT tools allow learners to utilise new learning platforms and also assist them in realising new knowledge through activities related to real life scenarios (Zaranis et al., 2013). ICT can assist in realising realistic analysis by allowing for the following: collecting good quality real-time data; analysing and visualising the data; doing otherwise complex calculations; building and using computer models; comparing results and producing reports (Heck, 2009). The graphics calculator can stimulate the use of realistic contexts (Drijvers & Doorman, 1996) and the mobile phone has the potential to allow students to engage in real, authentic tasks (Kizito, 2012a). Over and above the use of contexts in Mathematics teaching and learning, it is imperative in the RME approach that Mathematics is taught as a process in which students develop and apply Mathematical concepts and tools in problem situations with a realistic context (Domazet et al., 2013).

3.3.4 Principles of Realistic Mathematics Education

The three principles or key heuristics of RME that inform the design of instructional sequences are: guided reinvention or progressive mathematization, didactical phenomenology and emergent modelling (Andreasen, 2006; Bakker et al., 2003; Cahyono, 2012; Dolk et al., 2002; Drijvers et al., 2013; Stephan & Akyuz, 2014; Widjaja & Heck, 2003). These three principles should guide the design process to ensure that meaningful problems are used to foster students' cognitive development (Bakker et al., 2003). The instructional designer requires knowledge of the suitable design principles as well as their application in different context-specific situations (Doorman et al., 2013).

3.3.4.1 Guided Reinvention

The principle of guided reinvention (or progressive mathematization (Andreasen, 2006)), the first instructional design principle in RME (Gravemeijer, 1999), implies that learners should be given the opportunity to develop their own Mathematics (Bakker et al., 2003; Drijvers et al., 2013; Gravemeijer, 1999; Gravemeijer & Doorman, 1999). They should be allowed to experience a process which is similar to that by which a given mathematical topic was invented (Drijvers et al., 2013). In guided reinvention, learners will devise informal strategies to solve problems that may be formalized and generalized to establish a process of further abstraction (Doorman et al., 2008). The process requires guidance from the teacher who can help to direct the progression in a sensible manner (Drijvers et al., 2013).

In guided reinvention, Freudenthal (1991) believes that the emphasis should be on the character of the learning process, rather than on the invention itself (Gravemeijer & Doorman, 1999). Learners

should consider the knowledge that they acquire as their own, and should take responsibility for that knowledge (Gravemeijer & Doorman, 1999).

Guided reinvention encompasses reconstructing the expected way of developing a mathematical concept from a given problem situation (Bakker et al., 2003). The process begins with the mathematizing of real life subject matter, and leads to reinvention where students mathematize their own mathematical activities (Gravemeijer, 1999; Gravemeijer & Doorman, 1999). Formal Mathematics develops from students' activities (Gravemeijer, 1999). Guided reinvention can involve the development of new problem solving strategies which are necessary to solve tasks which cannot be solved with the existing strategies (Drijvers et al., 2013). Guided reinvention provides a manner in which to bridge the gap between formal and informal Mathematics (Gravemeijer & Doorman, 1999). This process, which provides students with the opportunity to reinvent Mathematics, surpasses the contrast between Mathematics as an activity and Mathematics as a body of knowledge (Gravemeijer, 1999).

Context problems play a key role in the reinvention process. Well-selected context problems provide students with opportunities to develop informal solution strategies that are relevant for that specific context (Gravemeijer & Doorman, 1999). Students are not expected to reinvent everything themselves (Gravemeijer & Doorman, 1999). The teacher's role is to facilitate learners through the process of guided reinvention, and provide students with the opportunity to reflect on the strategies they invented (Widjaja & Heck, 2003). It is important in teacher training, when learning about the reinvention process, that student teachers experience mathematization and reinvention first hand (Dolk et al., 2002). This can be extended to include activities such as anticipating learners' solutions and analysing their work (Dolk et al., 2002).

Guided reinvention is also applicable in digital design. ICT provides opportunities for exploration and investigation which is well suited to reinvention (Drijvers et al., 2013); however in some cases, technology may constrain students' opportunity for exploration as a result of pre-designed tools that provide too much guidance (Drijvers et al., 2013). There can also be tension between the reinvention process, which is considered to be bottom-up, and the nature of ICT, which tends to be top-down (Bakker et al., 2003).

3.3.4.2 Emergent Modelling

The term emergent modelling refers to the notion that models emerge from the activity of the students, and furthermore the required formal Mathematics emerges in the process (Gravemeijer, 1999; Gravemeijer & Doorman, 1999). The principle of emergent modelling focuses on the use of models during different phases of activities. A model is initially context-specific (Doorman et al., 2008; Doorman et al., 2013; Drijvers et al., 2013). This refers to a model which represents a meaningful, experientially real problem situation (Doorman et al., 2013; Drijvers et al., 2013; Kizito, 2012a). The

second phase continues as the learner works with the model where it gradually acquires a more generic character and progresses into a model for mathematical reasoning. This is possible because the model starts to refer to new mathematical objects in a more abstract framework of mathematical relations (Drijvers et al., 2013).

In the instructional design theory for RME, models are used to promote a process in which formal Mathematics is reinvented by the students themselves (Gravemeijer, 1999). It can be challenging for the designer of the tasks to find appropriate problem situations that are suited to the development of such models (Bakker et al., 2003; Drijvers et al., 2013; Gravemeijer, 1999). Instructional activities should be designed in such a way that students are able to shift from reasoning with models of informal activities to actual modelling of formal mathematical objects, relations and activities (Bakker et al., 2003; Doorman et al., 2013; Gravemeijer, 1999; Heck et al., 2007; Stephan & Akyuz, 2014). Thereby the formal Mathematics is made more accessible for the students (Gravemeijer, 1999). The task designer should support students in this transition from informal to formal by using tools that students have created, to explain their mathematical reasoning (Stephan & Akyuz, 2014).

Modelling and symbolising is an integral part of activities that aim to deal with problem situations (Gravemeijer & Doorman, 1999). The development of the model and the symbolization thereof complement the development of mathematical conceptualization of the problem situation (Gravemeijer & Doorman, 1999). Models are not derived from the intended Mathematics, but rather are grounded in the contextual problems that the students need to solve (Gravemeijer, 1999). The principle that underpins this notion is that students who work with the models will be motivated to reinvent the formal Mathematics (Gravemeijer, 1999). The purpose of using models is to bridge the phenomenological appearances of Mathematics in reality with formal Mathematics (Gravemeijer, 1999).

When analysing the design principle of emergent modelling, Gravemeijer (1999) refers to three interrelated processes. Firstly the process of the overall transition whereby the model emerges from informal mathematical activity, but gradually progresses into a model for more formal mathematical reasoning. The second process comprises the establishment of a new mathematical reality. Finally, the third process involves the emergence of a sequence of signification which serves as a concrete demonstration of the model in a sequence of signs, where each new sign can signify an activity with a previous sign (Gravemeijer, 1999). Emergent modelling can be a useful principle in digital design (Drijvers et al., 2013). When dealing with paper and pencil design, the models need to be suitable for further development in moving towards complexity and mathematical abstraction. In digital design, the emerging models must be supported by the digital tools that are available (Drijvers et al., 2013).

3.3.4.3 Didactical Phenomenology

The principle of didactic phenomenology is concerned with the relation between the thought object and the phenomenon itself (Drijvers et al., 2013). It deals with the concept of how mathematical structures can assist in organising and structuring phenomena in real life (Bakker et al., 2003; Drijvers et al., 2013; Zulkardi, 2000). Students are invited to develop mathematical concepts in this process (Bakker et al., 2003). The designer of the tasks is required to find meaningful phenomena that need to be structured and organised by the Mathematics (Drijvers et al., 2013).

The three RME principles can be well-utilised in digital design, although some adjustments may be necessary as compared to paper and pencil design (Drijvers et al., 2013). These principles however, are essential for digital design, despite the constraints of the digital tool (Drijvers et al., 2013). When dealing with digital design, the principle of didactical phenomenology is also valuable, however the phenomena that are dominant in the tasks do not necessarily come from real life (Drijvers et al., 2013). The student must contend with not only the world of Mathematics, but also ICT as a separate entity. Drijvers et al. (2013) are of the opinion that making use of a real life context together with these two domains can cause a cognitive overload.

3.3.5 Advantages, Disadvantages and Recommendations for Realistic Mathematics Education

3.3.5.1 Advantages

RME-based courses can help to improve learners' motivation, their understanding of Mathematics (Cahyono, 2012; Fauzan et al., 2013), their attitude towards Mathematics, their reasoning, activity and creativity and can assist in improving the classroom climate (Fauzan et al., 2013). RME is able to promote interactivity and collaboration in the classroom (Widjaja & Heck, 2003).

By following the RME approach, learners are able to make noteworthy progress in their performance in Mathematics, and both teachers' and learners' opinions about the teaching and learning activities are inclined to be positive (Widjaja & Heck, 2003). Learners tend to be more involved in the lessons and are more willing to try new and different things in classwork, and are less easily bored (Widjaja & Heck, 2003). Where technology is involved, learners become accustomed to new technologies (Widjaja & Heck, 2003). RME allows learners the opportunity to be actively involved in the learning process and promotes learning experiences that start with rich contexts (Fitzallen & Watson, 2014). Different classroom arrangements promote social interaction, stimulate the use of tools and improve reflection and generalisation (Doorman et al., 2013).

RME can be considered to be versatile, since an RME course designed for primary school Mathematics, which uses context problems and modelling, has proved to be suitable for an advanced

topic such as Calculus (Gravemeijer & Doorman, 1999). The use of the RME approach to teaching Mathematics allows for students to actively participate in the learning process. It sanctions the development of learning experiences that start with a rich and meaningful context that illustrates Mathematics in real life (Fitzallen & Watson, 2014).

3.3.5.2 Disadvantages

By following the RME approach, the classroom can become noisy and messy, but the positive effect of the approach outweighs this (Widjaja & Heck, 2003). Fauzan et al. (2013) report on some issues that emerged in classroom experiments when developing an RME-based course. They report that learners could not finish the contextual problems for reasons such as a negative attitude, dependence on the teacher, and they were not used to group work. They also report that with certain context problems, learners do not use the context to solve the problem because the statement did not guide them to do so (Fauzan et al., 2013).

3.3.5.3 Recommendations for Realistic Mathematics Education Based Lessons

The research of Widjaja and Heck (2003) has revealed recommendations for teachers who might want to introduce RME-based lessons that are supported by technology. Firstly, teachers should be willing to adapt their role in the classroom to more learner-centred and should refine their skills with regard to classroom discussions and dealing with challenging questions. Secondly, activities and tasks need to be carefully selected—there should not be too few activities, and also not too many, since either way, this could hamper the process of learning. They also point out that the logistical matters need to be attended to in advance for example preparing laboratories and making arrangement for group work (Widjaja & Heck, 2003).

3.4 Information and Communication Technology

Figure 3.5 illustrates ICT as one of the major themes that emerged from the systematic literature review.

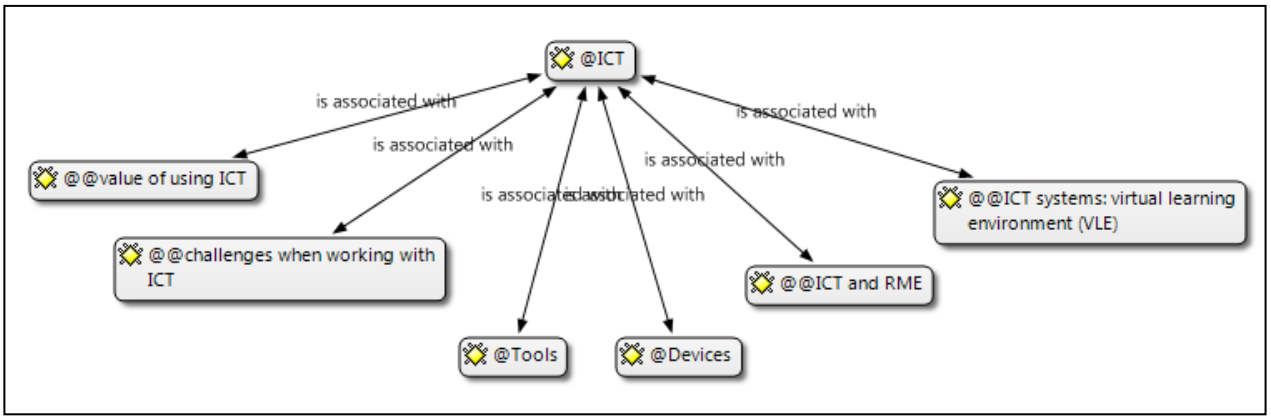

Figure 3.5: Information and Communication Technology as Theme from the Systematic Literature Review

3.4.1 The Value of Using Information and Communication Technology

There are numerous advantages discussed in the literature that highlight the value of using ICT in education. The use of ICT can promote student learning (Andresen, 2007) and promote mathematical reasoning (Widjaja & Heck, 2003; Zaranis, 2013, 2014b). Student learning can improve because educational technologies have various options to display data with different representations such as tables, graphs and formulas, which is particularly helpful when dealing with statistical concepts (Doorman et al., 2013; Fitzallen & Watson, 2014; Perez, 2012) and also to overcome the difficulty of integrating the operational and structural aspects of the function concept (Doorman et al., 2013).

The role of the teacher is described as both critical and problematic when it comes to integrating technology in teaching (Drijvers et al., 2010a). It is critical because the way in which teachers approach the use of technology has far-reaching consequences on the effects thereof in the classroom, and problematic because teachers find it difficult to adapt their teaching techniques when technology is incorporated, and can even avoid using technology when they do not perceive it to be useful (Drijvers et al., 2010a).

ICT has an imperative role to play in gathering information, acquiring data, processing and analysing data, solving problems, reporting and communication (Heck, 2009). It provides affordances for simulations, manipulation of data and is able to convert representations (Perez, 2012). Where possible, existing technologies should be extended and converted into concepts that work for school Mathematics (Heck et al., 2007) because technological developments encourage innovation in the teaching and learning of Mathematics by adjusting to conditions (Cahyono, 2012).

Not only have various research projects confirmed that the implementation of ICT in education can have positive effects on numerous subjects, but ideally, information technologies should be treated as

tools for teaching and learning (Zaranis, 2014b). ICT is a good facilitator to realise alternative approaches such as an activity-based approach or a realistic approach to Mathematics and Science instruction (Widjaja & Heck, 2003). Teaching and learning through ICT has a positive effect on the teaching of rectangles, circles, triangles and squares, particularly when using the RME approach (Zaranis, 2013, 2014c).

Computer tools provide opportunities for thinking and learning as they facilitate the learning activities that students engage with (Doorman et al., 2013). Computer aided learning is often a more enjoyable way of practising subjects that are otherwise seen as boring (Heck et al., 2008) and have shown to have a positive effect on the teaching of geometric shapes (Zaranis, 2014b). Educational software is found to be valuable in education, specifically Mathematics (Zaranis, 2013). Computer-assisted learning can significantly help in developing mathematical skills, and can promote deeper conceptual thinking than the traditional Mathematics teaching approach (Zaranis, 2014b, 2014c). When ICTs are treated as tools for teaching and learning, students can use these tools to become more familiar with new technology and can integrate investigation, communication and understanding across the curriculum (Zaranis, 2014c).

Technology also proves to be valuable for teachers (Dolk et al., 2002; Zulkardi, 2000). They can use web technology to store information like lessons or problems, can access information from anywhere in the world and discuss and share experiences after using the material in the classroom with colleagues or experts (Zulkardi, 2000). When using ICT in education, teachers that have less experience can be supported by experienced teachers, where shared experiences can be used to improve practice (Heck et al., 2007).

Learners' appropriate use of computers can be related to their ability to more efficiently understand the different mathematical concepts as well as develop mathematical thinking in school (Zaranis, 2014b). Heck et al. (2007) have found that learners who practice Mathematics using mathematical tools on computers are better prepared for writing exams than for doing written assignments. Technology provides social interaction and additional opportunities for a rich learning environment(Zaranis, 2014b), and has a positive effect on children's cognitive and sensory development (Zaranis, 2014c). The use of ICT can enhance students' comprehensiveness in learning Mathematics and engage students in the learning process (Domazet et al., 2013). According to Kizito (2012a), the partnership that needs to exist between a student and teacher in a distance learning environment cannot take place without some form of technological intervention or mediation.

The Internet can provide students with access to the same resources that professionals make use of. It allows for students to gather information and make contact with experts in their field of study. It also enables students to not only gather subject information, but also to collect good quality real-time data, do computations that are otherwise impossible, build models using dynamic software and report results (Heck, 2009).

With the aid of technology, a learning environment can be designed in which students investigate and acquire practical knowledge which can be generalised to the broader teaching context (Dolk et al., 2002). An integrated learning environment can provide students with the following benefits: students can practice Mathematics anywhere and anytime; assignments can be generated randomly which means that exercise material can almost be considered to be unlimited; student work (activities and assessment) can be stored for future reference; and quality feedback can be given to students automatically (Heck et al., 2007; Risnawati et al., 2014). Direct feedback that gives students hints and suggestions, and allows for a trial and error approach, makes it possible for students to explore different strategies for solving problems (Heck et al., 2007).

Learners who work in a computer-learning environment are more actively involved in discussions and debates relating to their experimental work. They tend to talk more actively and are more aware of their own mathematical thinking (Widjaja & Heck, 2003). Virtual learning environments are able to integrate a variety of tools that function in the following ways: provision of information, communication tool, means for collaboration, learning and management (Cahyono, 2012). Discussion in a technological environment can be a great advantage because as the discussions reveal issues, different representations and techniques can be tested with fast and dynamic feedback (Drijvers et al., 2010a).

Digital activities can contribute in the field of education in that they allow children to participate in a world in which they learn to speak, think and act in new and different ways (Zaranis et al., 2013). These activities can benefit learners in the following fields: learning (well-designed activities provide motivation and encourage learning), cognitive skills (through repetition, spatial ability, visual attention) and social interaction (cooperative interaction) (Zaranis et al., 2013). Digital media can introduce learners to abstract concepts that were previously considered too advanced for their age, and encourage learners to work together (Zaranis et al., 2013). Digital assessment adds to the motivation and performance of learners in Mathematics education (Heck et al., 2007).

When learning activities are designed using ICT, it is important that they are done in such a way that learners actively engage with the Mathematics (Andresen, 2007). Digital technology should be embedded in an educational context in such a way that the technology is integrated in a natural way (Drijvers, 2013). It is therefore not only important that teachers need to be knowledgeable about Mathematics, but they also need to be prepared in basic technological literacy (Widjaja & Heck, 2003).

For teachers to benefit from using technology in everyday Mathematics teaching, it is important that they are adequately equipped with not only basic knowledge, but knowledge about new teaching techniques that are necessary in a technology-rich classroom (Drijvers et al., 2010a). The teachers' knowledge of Mathematics as well as their beliefs and views about Mathematics education and the

role of technology in that, is an important aspect to consider when introducing technology into the classroom (Drijvers et al., 2010a). This will include aspects such as the teachers' knowledge and skills on how to incorporate technology in the classroom and their concerns about time constraints and behavioural control (Drijvers et al., 2010a).

3.4.2 Information and Communication Technology Tools

Information technology offers invaluable possibilities for creating educational tools that can help students come to grips with various ideas (Gravemeijer, 2012). Different technology tools makes it possible for teachers to track students' progress and diagnose problem areas (Heck et al., 2007), and create new possibilities for problem solving in Mathematics by opening new horizons that lend themselves for exploration and problem solving activities (Doorman et al., 2007). By providing direct feedback and giving students hints and tips, teachers create a trial and error approach which makes it more possible for students to explore different strategies in order to solve the problem (Heck et al., 2008). Technology tools also influence the process of students' sense making in Mathematics (Doorman et al., 2008), allow for students to review their mistakes and can store feedback which enhances the already positive effects of direct, instantaneous feedback (Heck et al., 2007).

Heck et al. (2007) distinguish between two types of applets, namely model applets, which aid in developing the mathematical understanding of concepts, and exercise applets, which can support the development of mathematical skills. Applets offer many benefits for learners: they are fun and motivate learners; they allow students to work at their own level, therefore addressing individual differences between learners; applets help to make the Mathematics easier to understand because of the visual, interactive and dynamic features they have; and their ability to do complex calculations allows learners to focus on the mathematical concepts and models. Students are more creative when using applets, have a more positive self-esteem and the practice and feedback features provide more benefits than pencil-and-paper exercises (Heck et al., 2007). Exercises on the applets help learners develop mathematical understanding and skills more thoroughly than with pencil and paper (Heck et al., 2008).

An important aspect to remember is that applets should be integrated in the daily classroom routine to gain their full benefits (Heck et al., 2007). Applets are able to provide feedback in cases of error as well as success. The feedback is both visual and audible, which makes it easy for learners to understand (Zaranis et al., 2013). For teachers, the benefits of using applets include being able to review what students actually did after a computer aided lesson: what progress they made, which problems arose and what areas need attention in future lessons (Heck et al., 2008).

GeoGebra is an open-source dynamic software for Mathematics that combines arithmetic, geometry, algebra, statistics and calculus (Stols, 2012). GeoGebra can be useful to provide competence development for teachers in terms of mathematical representations (Perez, 2012). Technology can

help create an active learning environment where students scan discover, explore and visualise (Stols, 2012). According to Stols (2012), in a study that investigated the geometric cognitive growth of pre-service Mathematics teachers in terms of the Van Hiele levels, it was found that dynamic geometry software could enhance students teachers' geometric visualisation, analysis and deduction, but did not extend to the next Van Hiele levels of reasoning, informal justification and formal deduction.

When students are exposed to new technology, their skills and abilities are expanded in the computer-learning environment and they have the opportunity to improve their presentation skills (Widjaja & Heck, 2003). Interactive computer tools are able to present symbolic information such as graphs, models or numerical measures, which allow these tools to be employed successfully in enhancing the meanings of the symbolic information by making them more visible, accessible and more easily manipulated (Gravemeijer, 2012). A technology-enriched environment can improve the conceptual geometric growth of learners (Stols, 2012).

3.4.3 Devices

mLearning is defined as learning that takes place in learning environments and areas which make use of the mobility of technology, learners and learning (Zaranis et al., 2013). The term mobile learning (mLearning) is used in different contexts and involves a number of mobile devices such as mobile phones, personal digital assistants, handheld devices and notebooks (Kizito, 2012a). mLearning is an emerging and rapidly expanding field that provides new opportunities for education (Kizito, 2012a). In the past, mLearning was hampered by slow networks, limited services and hesitancy to invest in devices with a relatively short shelf life. Device attributes such as the screen size, battery life, security, and limited resources also delayed the adoption of mLearning (Kizito, 2012a); however mLearning is becoming a popular component of education. An added advantage of mLearning is in the distance education environment; where the majority of students cannot afford access to web-based learning, mLearning is a more viable alternative to provide instructional support (Kizito, 2012a).

Drijvers (2013) differentiates between three didactical functionalities for digital technology: the tool function for doing Mathematics; the function of providing the learning environment for practising skills; and the function of providing a learning environment for promoting the development of conceptual understanding. When designing digital technology, the guidelines and design heuristic should be guided by pedagogy and didactical considerations rather than the limitations or properties of technology (Drijvers, 2013). Digital activities are considered to be most effective when they are aimed at examining a specific problem or teaching a specific skill such as Mathematics, where detailed objectives can be determined (Zaranis et al., 2013). Digital educational activities are appealing to students' interests as well as a pleasurable pastime and an attractive learning environment for them to work in (Zaranis et al., 2013).

Mobile devices offer many advantages in the learning process including stimulation, motivation, ease of use and availability. Mobile devices are becoming more valuable in education because they are attractive, portable, and more affordable in relation to desktop computers. They offer the opportunity for learning with wireless technology which allows for easy access to information, promotes digital literacy, and provides opportunities for independent learning (Zaranis et al., 2013).

Mobile devices fit better into the lifestyle of young children than desktop computers because they do not need to sit at a desk or in an office to use the device. The touchscreen is also irresistible for children (Zaranis et al., 2013). By introducing mobile technology in education, there is a positive correlation between the learners' everyday life and their school life. Mobile devices can be used for various activities such as comparing, sorting, matching and counting (Zaranis et al., 2013). Educators should be sure to design the technological integration in such a way that learners are equipped with the necessary knowledge and skills they need in life (Zaranis et al., 2013).

The use of handheld technology in Mathematics education traditionally focused on content such as algebra and graphing, and took place in regular teaching sessions. It is now more common that these devices offer options for other topics such as geometry, and can be used outside the classroom due to the wireless options available (Wijers et al., 2010). The wireless option allows for opportunities for situated learning outside of school and encourages characteristics such as situated authentic learning, peer collaboration and motivational power (Wijers et al., 2010).

One of the many devices that can be used in the Mathematics classroom is the graphics calculator. The graphics calculator has the potential to stimulate learners to engage in informative exploratory activities, and can kindle the use of realistic contexts (Drijvers & Doorman, 1996). The realistic quality of a problem can be enhanced when using a graphics calculator, since the device takes care of the time-consuming technical work, allowing learners freedom to concentrate on the process of mathematization (Drijvers & Doorman, 1996).

Mobile phones have the potential to open opportunities for learners due to their mobility, accessibility and flexibility. They also enable students to engage in real, authentic tasks (Kizito, 2012a). Their benefits range from a means of communication and social networking to being handy as a learning medium (Risnawati et al., 2014). The mobile phone offers the feature of working collaboratively (sharing graphs and solving problems collectively), which assists in establishing a community of Mathematics learners (Kizito, 2012a). In South Africa, a mobile tutoring system known as *Doctor Maths*, is a very popular instant-messaging service that caters to over three million school-aged subscribers to support the teaching and learning of Mathematics (Kizito, 2012a).

The term smartphone describes mobile phones which have similar features and characteristics of tablets on a smaller screen, as well as the usefulness of voice data over cellular networks (Zaranis et al., 2013). Smartphones with multimedia facilities, which allow for data collection, the recording of

video images or audio clips and short message services, can potentially be useful for teaching and learning in many subjects. These features can assist students in building new knowledge (Kizito, 2012a). Smart mobile devices can be used to present digital activities such as exercises relating to comparing, sorting, matching, counting and the general knowledge of numbers (Zaranis et al., 2013).

An advantage of using tablets in education is that most tablets do not have phone features, which means there is less opportunity for disruption by incoming calls or text messages than with mobile phones. Tablets offer the benefit of mobile apps in a broader context, at all levels of education, and provide a rich tool which can be used inside and outside the classroom (Zaranis et al., 2013). Students can store educational materials in a digital portfolio (Zaranis et al., 2013). In a study that compared the outcomes that students were able to achieve through the traditional teaching approach as opposed to tablet aided learning, it was revealed that the tablet aided approach produced better learning outcomes for the students (Zaranis et al., 2013). The portability of tablets allows teachers and learners to use various locations in the classroom which allows for collaboration and creativity (Zaranis et al., 2013).

Various governments, worldwide, of both developing and developed countries, have in the last few years paid special attention to the development and implementation of mLearning in teaching and learning (Zaranis et al., 2013). However, affordability and ease of use of mobile devices are issues which can hinder effective delivery and acceptance by users (Kizito, 2012a).

Multimedia studies can act as a mediating tool in surpassing the contrast between theory and practice. It can also be instrumental in helping teachers develop situated practical knowledge about teaching (Dolk et al., 2002).

3.4.4 Information Communication Technology Systems: Virtual Learning Environment

A Virtual Learning Environment (VLE) is a collection of integrated tools that facilitates the management of online learning, provides a means of delivery, allows for student tracking, assessment, and provides access to resources (Heck et al., 2007). A VLE offers various functions, such as providing information, sanctioning communication, collaboration, learning and management (Heck et al., 2007).

An advantage of using an existing VLE that students and teachers are familiar with, is that users know how to log on to the system, how to send e-mails, how to work with the built-in communication tools, and how to export results to the administrative system (Heck et al., 2007). VLEs can promote anytime communication and interaction with the teacher and with fellow students which can take the form of text-based, audio or video communication. The VLE can also stimulate the students to do homework (Heck et al., 2007). Students tend to like the fact that teachers have insight into their work

through the VLE. Teachers are able to assist with common mistakes and therefore can address problems more effectively (Heck et al., 2007).

Since virtual manipulations are similar to physical manipulations, using ICT could effectively support the learning process especially in Mathematics (Zaranis et al., 2013). Virtual worlds provide a promising structure for learners since they are allowed to play many different roles (Zaranis et al., 2013).

3.4.5 Information Communication Technology and Realistic Mathematics Education

Although there are challenges in the integration of ICT with the principles of RME (Drijvers et al., 2013), various studies have shown that technology can act as a catalyst in the RME approach to teaching Mathematics (Widjaja & Heck, 2003). Teaching by the principles of RME with the aid of educational software for tablets produces better outcomes than traditional teaching (Zaranis et al., 2013). Instruction involving technology should equip learners with the necessary skills and knowledge for later life (Zaranis et al., 2013).

When dealing with RME theory, where real world situations form the foundation of mathematical activities, software should be carefully chosen in order to stimulate these situations, recall old experiences and extend these to new ones by introducing purposeful interactions (Boon, 2006). The mobile phone is useful in quickly determining a student's starting point before designing instruction in the RME perspective (Kizito, 2012a). An important aspect when using the RME approach in designing applets is that the problems that are presented should be real and meaningful to the learners and worth solving (Heck et al., 2008).

3.4.6 Challenges when Working with Information Communication Technology

Teachers and learners alike can benefit from ICT in the form of different computer programs, lesson material and communication available on the Internet, and much more. However, not all stakeholders share the optimism about the effective use of ICT in teaching and learning (Drijvers et al., 2010a; Heck et al., 2007).

The use of technology in Mathematics education should not be seen as an instant remedy that reduces the importance of the teacher (Drijvers, 2013). When computers and technological tools are used continuously in the classroom, students can develop a dependency on these tools (Zaranis, 2014b). An added challenge for teachers is that students can be at different levels of computer literacy, which the teacher will have to deal with in order to progress (Zaranis, 2014b), and where online activities are prescribed for homework, a teacher needs to keep in mind that not all students have an Internet connection (Risnawati et al., 2014). The use of technology challenges the stability of teaching practices, and the way teachers coordinate student learning (Drijvers et al., 2010a).

Techniques that have always been used are often not suitable when technology is available. Teachers need to develop new teaching techniques that are applicable with the available tools (Drijvers et al., 2010a).

With regard to mobile technology, although there have been studies about the use of mobile phones in Mathematics education, Kizito (2012a) suggests that interviews should be used in future studies to explore the in-depth perceptions of students' experiences of mobile phone technology. One of the limitations of the mobile phone in teaching Mathematics is the difficulty in manipulating symbols and equations; most mobile phones and smart phones have limited features to deal with this effectively (Kizito, 2012a). With the rapid advancement of technology, it might be possible in the near future to have affordable systems which allow easy manipulation of symbols (Kizito, 2012a). Kizito (2012a) is of the opinion that more focused research is required to investigate the use of the mobile phone in distance education.

3.5 Methodology: Design-based Research

Design-based research is cyclical in nature where thought experiments and teaching experiments alternate, following the process of analysis, design, development, implementation, evaluation and reflection (Bakker et al., 2003; Dolk et al., 2002; Doorman et al., 2013; Fauzan et al., 2013). Bakker et al. (2003) distinguish between micro cycles (at the level of the lessons) and macro cycles (at the global level of the teaching experiment). Design-based research is a means for the researcher to understand teaching, learning and educational systems (Bakker et al., 2003). Design-based research comprises articulating, testing and refining conjectures, designing instructional activities, and teaching experiments (Doorman et al., 2008).

Design-based research consists of three phases, namely the preliminary design phase, the teaching experiment phase, and the phase of retrospective analysis (Bakker et al., 2003; Perez, 2012). In the preliminary design phase, an HLT is developed and instructional activities are designed, and usually adapted as a result of the teaching experiment (Bakker et al., 2003). Fauzan et al. (2013, p. 166) use the following terms to refer to the three main phases of design-based research, namely: front-end analysis, the prototype phase, and the assessment phase. The purpose of front-end analysis is to get "a picture of the starting point and the potential end points of the course". This normally involves needs analysis, literature reviews and the analysis of examples that are available (Fauzan et al., 2013). In the second phase, the instructional activities as well as the prior expectations rooted in the HLT are confronted with the reality of the classroom (Bakker et al., 2003). The third phase of design-based research involves data analysis and reflecting on the findings (Bakker et al., 2003).

Design based research has the following two purposes: to develop a prototypical product, with evidence of its quality, and to produce guidelines to design and evaluate that product (Fauzan et al.,

2013). The development methodology needs to be systematically reflected on in order to produce design principles (Fauzan et al., 2013). Fauzan et al. (2013) summarise two different types of design-based research as presented by various other authors, namely validation studies and development studies. Validation studies focus on the design of learning environments to validate theories about the learning process; they aim to promote learning and instruction theories like RME. Development studies focus on design principles for developing innovative interventions that are significant for educational practice, which is done through a process of systematic reflection on the development methodology (Fauzan et al., 2013). It can happen that a study can be both a validation study and a developmental study (Fauzan et al., 2013).

Some reasons offered as to why design-based research is used include the following: design-based research affords a perspective to develop theory, the results are useful in the sense that educators can use the relevant research products and it gives researchers the opportunity to improve education by creating innovative designs (Dolk et al., 2002). Design based research within RME would reflect the three key principles of RME, namely guided reinvention, didactical phenomenology and emergent modelling (Fauzan et al., 2013). A detailed description of the methodology of design-based research was done in Chapter Two.

3.6 Role players

Traditionally, the role of learners was to listen, write and perform tasks provided by the teacher (Widjaja & Heck, 2003); however understanding is stimulated when learners are given an opportunity to be active, investigative learners, where they solve problems using their own strategies, as is required in RME (Dolk et al., 2002; Widjaja & Heck, 2003). In RME, learners need to be given space for exploration and constructing their own products and strategies (Dolk et al., 2002; Widjaja & Heck, 2003; Wijers et al., 2010).

The role of the teacher is also important in implementing RME principles (Doorman et al., 2008; Drijvers, 2013): he or she needs to guide discussions (Doorman et al., 2008; Gravemeijer, 2012), facilitate learners' learning, and address challenging questions from learners; encourage them to think critically (Widjaja & Heck, 2003); allow learners space to do construction; ensure that open exploratory activities are used; give learners the opportunity to share and discuss their work, and contemplate relationships between different approaches (Dolk et al., 2002). For teachers to profit from technology in the Mathematics classroom, they need to have knowledge about emerging teaching techniques in technology-rich classrooms (Drijvers et al., 2010a).

Widjaja and Heck (2003) and Zulkardi (2000) testify to the changing role of learners and teachers in RME towards more learner-centred learning. Interactivity in the classroom increases and learners become more responsible for their own learning. This changing role requires the support of school

management to achieve success (Widjaja & Heck, 2003). In-service courses for teacher education should address teachers' concerns and improve their knowledge and experience (Dolk et al., 2002). Teacher training, both in-service and pre-service, is essential since teachers are key figures in educational change (Zulkardi, 2000).

3.7 Chapter Summary

The chapter presented the review of the current literature with regard to the implementation of RME principles, aided by the use of ICT in Mathematics education. The themes of Mathematics, RME, ICT, methodology and role players were discussed. Table 3.1 lists the role of ICT in the RME approach to enhance teaching and learning.

		development of functions. The final test data did not reveal whether all students improved with regard to the understanding of functions.		creating tables, graphs and formulae. The applet is used to provide tasks which the teacher can monitor.		
(Doorman et al., 2008)	Tool use and the development of the function concept: from repeated calculations to functional thinking	The study focuses on activities with computer tools that help students to construct mathematical representations and actions. They are given the opportunity to explore the representations. The concept of functions is explored. The transition from function machines to actual objects is represented in different ways.	One aspect that forms part of the theoretical framework is emergent modelling, which has its foundation in the theory of RME.	The study reports on a project where the following activities are combined: paper and pencil and computer tools as well as the careful guidance of the teacher. The tool that is used is an applet called AlgebraArrows. This which permits the construction and use of chains of operations and provides options for creating tables, graphs, and formulae.	The study makes use of design-based research. This involves the formulating, testing and filtering of conjectures, and designing instructional activities. The assumptions create a connection between the teaching experiments and the manner in which students can be supported in the development of the topic.	An initial small-scale pilot study took place. Thereafter the learning arrangement was tested and improved in two successive teaching experiments in Grade 8, with mid- and high-achieving 13–14-year-old learners.
(Doorman et al., 2007)	Problem solving as a challenge for Mathematics education in The Netherlands	The focus was on the implementation of a problem based curriculum, centred on the principles of RME and incorporated the use of technology.	The study was based on the principles of RME.	No ICT	The aim of the study was to investigate how Dutch high-achieving Grade four learners did problem-solving tasks. These tasks were specifically developed for the World Class Tests.	A total of 152 high-achieving fourth grade learners (9 – 10 year olds).
(Doorman et al., 2008)	Tool use supporting the learning and teaching of the Function concept	The focus is on the use of computer tools for grade 8 (13-14 years) students' acquisition of the concept of functions. The aim is to identify the relationship between the use of technological tools and	The study is based on the philosophy of RME	Computer tools	The research process involves a cyclical process of instructional design, teaching experiments and data analysis.	Grade 8 learners

		the learning of Mathematics.				
(Drijvers, 2013)	Digital technology in mathematics education: Why it works (or doesn't)	The study shows that the success or failure of the integration of technology in Mathematics education relies on three factors: the design, the role of the teacher, and the educational context. The study identified factors that promote or hinder the successful integration of digital technology in Mathematics education.	RME is one of the theoretical perspectives that is investigated in this study.	The paper looks at the contribution of technology in Mathematics education from a more realistic perspective.	Six different cases from leading studies in the field were studied.	The role of the teacher is extremely important in the incorporation of technology in Mathematics education
(Drijvers et al., 2013)	Digital design: RME principles for designing online tasks	The design of tasks is important—this paper explores how the RME principles which are usually used for paper-and-pencil tasks can be used in a digital environment. Examples of tasks relating to Algebra, Calculus and Geometry are designed and presented in the Digital Mathematics Environment.	The paper investigates how the principles of RME can be used to design online tasks. They concluded that the principles of guided reinvention, didactical phenomenology, and emergent modelling can inform and guide digital design.	A Digital Mathematics Environment (DME) is used. The DME integrates a content management system, a learning management system and an authoring environment.	This is a theoretical paper in which different digital designs of tasks for Algebra, Calculus and Geometry are studied.	Grade 8 learners
(Drijvers & Doorman, 1996)	The graphics calculator in mathematics education	This study supports the notion that the graphics calculator can encourage the use of realistic contexts. The graphics calculator is used to integrate Algebra and Geometry and encourages the learner to create links	The theory of RME was used as point of departure for the study.	Graphics calculator	Developmental research.	Prevocational secondary education (16 year olds).

		students and to make wise choices when constructing a lesson.				
(Kizito, 2012a)	Pretesting mathematical concepts with the mobile phone: Implications for curriculum design	This paper describes the characteristics of a diagnostic test which was used to determine initial student understanding of the basic Calculus concepts of the derivative and the integral before the start of their course. The aim of the project was to try to find out what the didactic functionalities of a mobile phone were and how these could be used to support the learning of Mathematics through distance education.	RME was used as the theoretical framework for this project. This testing was part of a larger project that examined what was required to adapt the instructional design viewpoint of Realistic Mathematics Education (RME) to the teaching and learning of Calculus via distance education.	The mobile phone was used as mode of delivery for the diagnostic test. The speed and ease of following the students' results was a positive aspect of the mobile phone, while issues of availability like cost and ease of use was an imitation.	Pilot study	The students were UNISA students who had completed their first semester in a first-year calculus course.
(Mousoulides et al., 2007)	From problem solving to modelling	In this paper, the concept of emergent modelling is explored from the field of problem solving. The importance of modelling is discussed from the existing literature.	The use of modelling problems can enhance student sense-making within a real context. It can bring real world situations into school Mathematics, which aids in fostering a positive attitude towards Mathematics.	No ICT	In essence, this study followed the structure of design-based research. The modelling approach involves a number of iterative cycles, in which students refine their results and improve their solutions.	The paper is a literature review that explores the emergence of modelling within the genre of problem solving research
(Perez, 2012)	Scaffolding Teachers' Construction of a Learning Trajectory for Mathematics Supported by ICT	The teachers indicated content areas that their learners found challenging—the first theme that was identified was Algebra, in particular the	The instructional theory of RME is used to develop a hypothetical learning trajectory (HLT) to develop class activities that reflect the notion that	This project explores how technology can be used to improve teachers' teaching practices and their students' learning of Mathematics. 		teachers' geometric visualisation, analysis and deduction, but not their ability to informally justify their reasoning and to understand the formal aspects of deduction.				
(van Loon-Hillen, van Gog, & Brand-Gruwel, 2012)	Effects of worked examples in a primary school mathematics curriculum.	For a three week period, the study tested the effects of relying more heavily on worked examples, as analogies for problem solving. The curriculum was used to teach both the control group and the experimental group. Although the results showed no significant di ffer performance or cognitive load; the experimental group achieved this level with significantly less acquisition time.	The existing curriculum was taught using a RME teaching approach.	No ICT.	The study made use of a quasi-experimental design.	Primary school Mathematics class, using the existing curriculum.
(Widjaja & Heck, 2003)	How a realistic mathematics education approach and microcomputer-based laboratory worked in lessons on graphing at an Indonesian junior high school	The project investigated the expectations, performance, and opinions of the pupils and the teacher with respect to graphing activities using a computer tool. The content that was used in this project was graphs with emphasis on interpretation and application.	The RME approach was used. The results of the project indicated that the pupils made remarkable progress in their performances that can be attributed to the approach that was used.	The project made use of Microcomputer-Based Laboratory (MBL). Computer tools were used for measuring data in practical work.	The research experiment was set in a classroom situation where the pupils made use of the designed classroom activities. Pre- and post-tests were used to investigate the effect of the ICT-rich RME-based instructions on the pupils' graphing skills.	One class with 13 – 14 year old pupils (Junior High School) used the materials and activities that were designed. This was done in an Indonesian classroom context.

Author(s)	Title	Mathematics	RME	ICT	Methodology	Role players
(Zaranis, 2013)	The use of Information and Communication Technologies in the first grade of primary school for teaching rectangles based in Realistic Mathematics Education	The purpose of the study was to investigate the impact of the intervention of Primary Shape Model (PSM) on the Geometry competence of the first grade learners, This model was based on the Van Hiele levels and also on the RME principles.	The educational software was designed following the principles of RME.	The first level of the Primary Shape Model (PSM) started with the educational software which was designed using Flash CS3 Professional Edition. Various computer activities were included in the following levels.	An experimental group, were taught rectangles with computers and a control group received only the traditional instruction relating to rectangles. Students in both groups were pre-tested and post-tested for their performance in Geometry.	First grade learners from ten primary schools in Athens and Crete.
(Zaranis, 2014c)	The use of ICT in the first grade of primary school for teaching circles, triangles, rectangles and squares	This study investigated whether ICT helps to improve first grade students' basic Geometry achievement regarding circles, triangles, rectangles and squares or not. The study examined and compared the effects of a new model which made use of both computer and non-computer activities for teaching circles, triangles, rectangles and squares separately.	Rather than following a traditional teaching method, the RME approach was used to present the material.	A story called 'The Family of Shapes' was presented to the students. Various geometrical shapes were presented in a fictional family setting where each member of the family represented a particular shape. The story was designed using Flash CS3 Professional Edition and presented with a video projector in the classroom.	There was an experimental and control group. The experimental group were taught about circles, triangles, rectangles and squares with the support of computers. The students in the control group were not exposed to the computer oriented curriculum. Students in both groups were given pre-tests and post-tests to establish their Geometry performance.	First grade learners from ten public primary schools in Athens and Crete.
(Zaranis, 2014a)	Geometry Teaching Through ICT in Primary School	Using computer based mathematical teaching to teach learners can significantly help in developing proper mathematical skills and cultivate deeper conceptual thinking than in traditional teaching. The Van Hiele model formed	The software that was designed and the students' activities that were developed for this study were inspired by the framework of RME.	Technology was used to create a rich learning environment, consistent with the modern era.	Experimental research	First grade pupils

		part of the framework for the study.				
(Zaranis, 2014b)	The use of ICT in kindergarten for teaching addition based on realistic mathematics education	The study investigated the effect of ICT on learners' achievement in addition and counting. The researcher and the teachers developed a model which combines the principles of RME and the use if ICT in kindergarten. The main purpose of the model was to foster learners' mathematical concepts and skills about addition and to involve them in self-regulated learning. Some activities were computer activities and others not.	A comparison is made between learners who are taught by the traditional approach as opposed to those being taught by the principles of RME.	The learners were given software that consisted of a story and several activities, some with the use of computers and others without. The results showed that the use of computers had a positive effect on the learning of addition.	The learners were divided into two groups—the experimental group who were taught with computers and the control group who were not exposed to the computer oriented curriculum.	The participants were kindergarten learners in Crete.
(Zaranis et al., 2013)	Using mobile devices for teaching realistic mathematics in kindergarten education	The activities are based on the fundamental Mathematical concepts of kindergarten. These include counting and simple addition and subtraction. The paper investigated the use of ICT in preschool education, as well as the learners' knowledge	The project revealed that the teaching of RME with the use of educational software for tablets produces better learning outcomes than traditional teaching methods.	The purpose of the paper was to provide a better understanding of the characteristics and the effect of ICT and mLearning in preschool education. The results showed that the use of the tablet supported learning compared to the traditional teaching method without technology.	An instructional intervention.	The initial pre-tests were done with a small sample of kindergarten learners in a specific region in Greece.

Chapter Four

Participants' Needs and Perceptions with regard to Real Life Mathematics

4.1 Introduction

In this chapter I report on the data set that I obtained when doing the needs analysis individual interviews with the participants. Two factors were the driving force behind the necessity to do a needs analysis with the participants. Firstly, the systematic literature review exposed various aspects that should be further explored within the context of this study. Secondly, the needs analysis was driven by the research sub-question: *What support needs do teachers have in order to successfully implement the RME approach in their teaching practice?*

A closer analysis of the research sub-question revealed that there were various areas that had to be investigated in order to sufficiently answer the question that this study proposed. It was therefore necessary to meet with the participants in order to ascertain their perceptions and experiences relating to a number of aspects. These aspects include the following: which content areas they found problematic to teach; which content areas their learners found challenging; and the facets of the curriculum they had difficulty in relating to real life situations. I also obtained information about their perceptions and ideas about teaching Mathematics in a realistic way as well as their observations about the use of technology in Mathematics teaching and learning. These aspects would inform the design process of the mobile app (Chapter 5).

The way in which I obtained this information was by conducting individual interviews with four teacher-students. I designed an interview schedule (Addendum 2.6) based on the findings of the systematic literature review as well as the requirements needed to answer the research sub-question. I made use of purposive sampling to select the participants. These students all attended contact sessions at the Potchefstroom Campus of the NWU and agreed to meet with me and participate in this research. They also all complied with the criteria for selection, which were discussed in § 2.8.1. The individual meetings took place at a location and at a time convenient for the students and did not interfere with their teaching schedule in any way. Two meetings took place at my office at the Potchefstroom Campus of the NWU. The third meeting took place at one participant's school in Potchefstroom in the HOD's office and the fourth meeting took place at a coffee shop in Ventersdorp. I paid for the transport costs of the participants that needed to travel to Potchefstroom, and I provided all participants with refreshments to ensure that they were comfortable and not inconvenienced in any way.

I transcribed each interview and coded these interviews with the aid of ATLAS.ti™, a Computer Assisted Qualitative Data Analysis Software (CAQDAS) (ATLAS.ti, 2014). Data were coded in the same HU as the systematic literature review in ATLAS.ti™. I therefore used the existing codes and created additional codes where necessary in order to code and categorise the interviews as part of an integrated HU. The detailed codebook was discussed in Table 2.6 (§ 2.6.5). In order to ensure the trustworthiness of the coding, two peers who are experts in the fields of Mathematics education peer-coded one interview (§ 2.8.3.2) Cohen's Kappa was calculated as 0.99 which therefore validated this process. This calculation can be seen at Addendum 2.7. The systematic literature review revealed five main themes; four of these five themes were used to structure the analysis of the interview data. The four main themes used in this chapter were: Mathematics, RME, ICT and role players. In order to analyse the interviews, these themes were further refined as: participants' needs in term of Mathematics; the facets of RME that arose in the interviews; their thoughts and ideas about ICT; and finally the role players that played a part in the given context (Figure 4.1). Each of the said main themes has various sub-themes that will be further explored in this chapter.

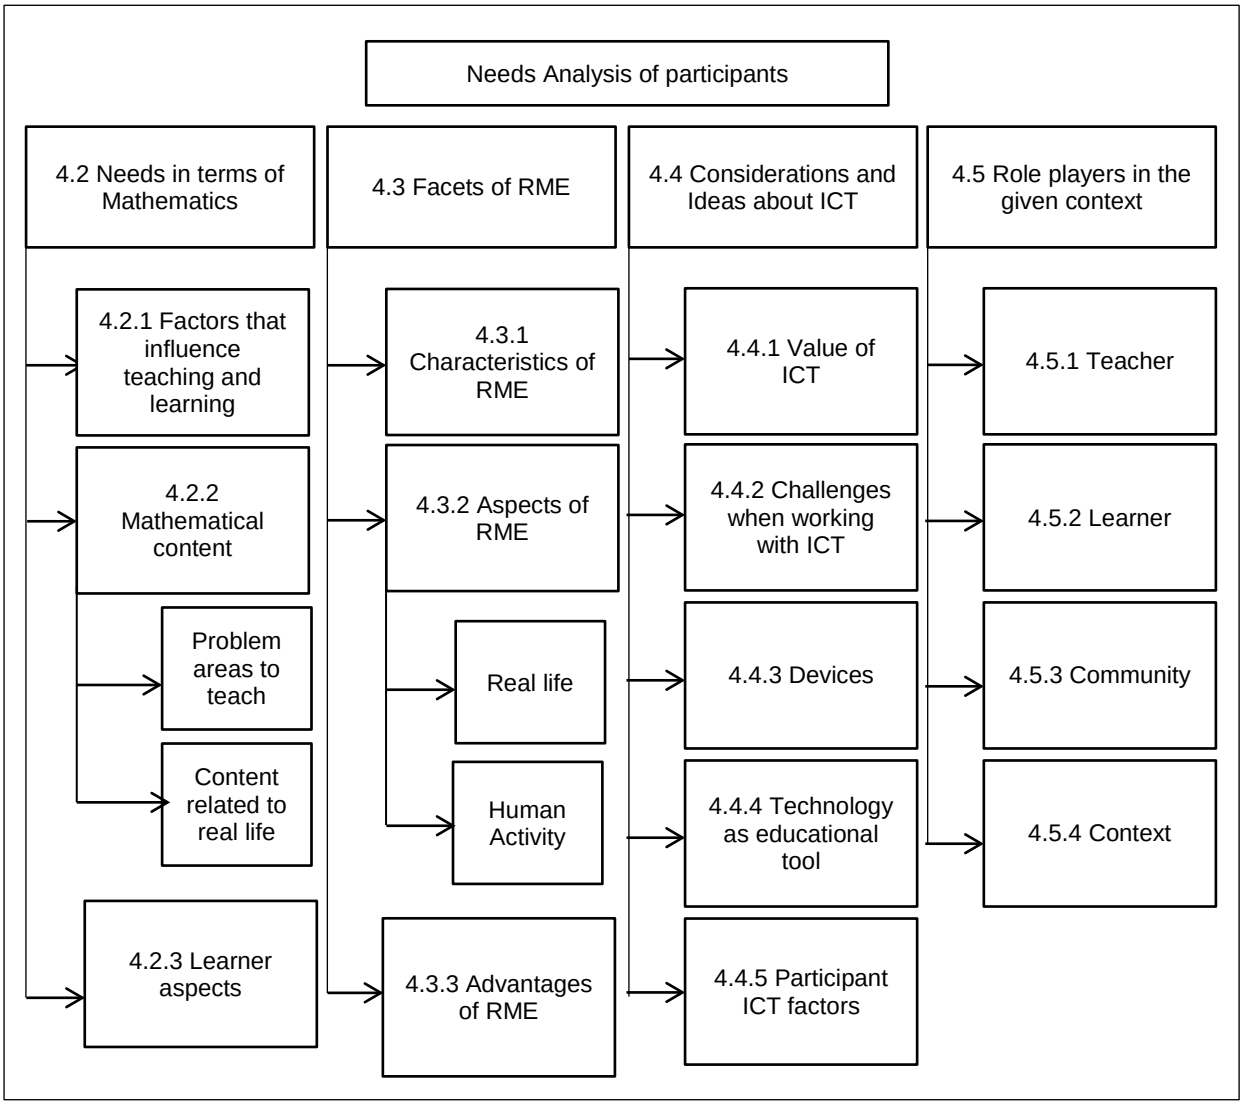

Figure 4.1: Advance Organiser of the Main Themes for the Analysis

Figure 4.2 illustrates the network view of the coding structure and themes that arose from this set of data, the four main themes being: Mathematics; RME; ICT; and finally role players. As discussed above, when analysing the data, these themes were made more specific in order to zoom in on the interview data. Due to the fact that the participants were asked to share their perceptions and experiences of aspects relating to these themes, I focused the discussion on their perceptions of these critical themes. This chapter reveals those support needs as well as other insights that the student-teachers had in terms of realising the RME approach in their classrooms.

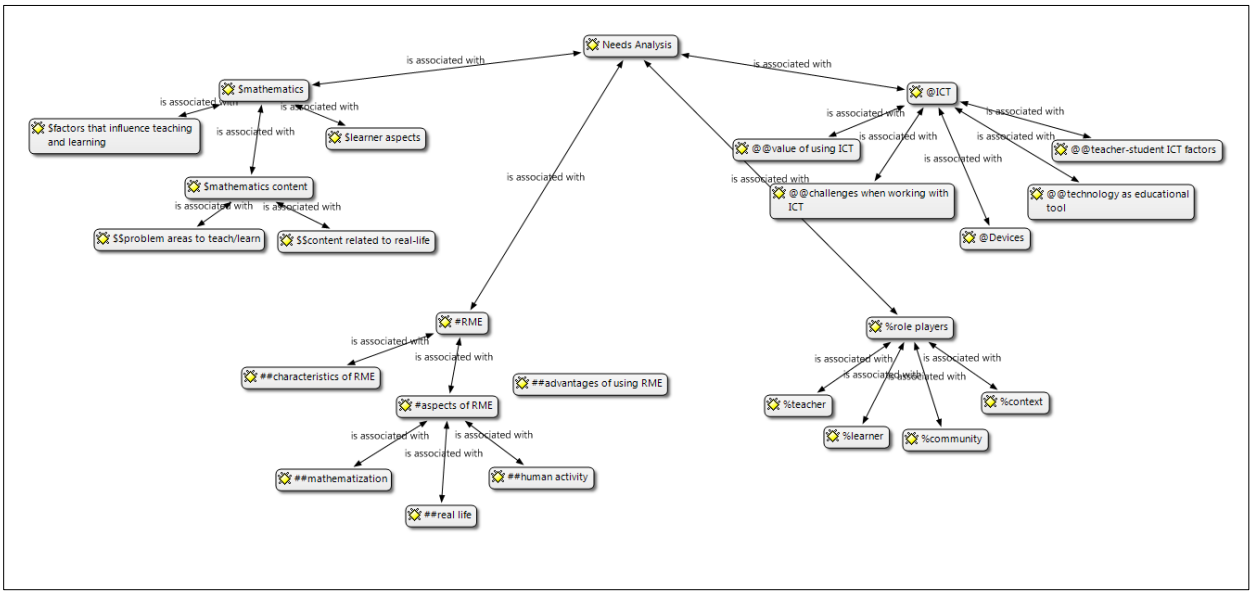

Figure 4.2: Coding Structure for the Needs Analysis Individual Interviews

4.2 Needs and Perceptions in Terms of Mathematics

The three sub-themes that emerged within this main theme are: factors that influence teaching and learning; Mathematics content—with the specific focus on areas that the participants found problematic to teach as well as content that can be related to real life; and learner aspects. Figure 4.3 indicates the participants' needs with regard to the Mathematics that they are teaching.

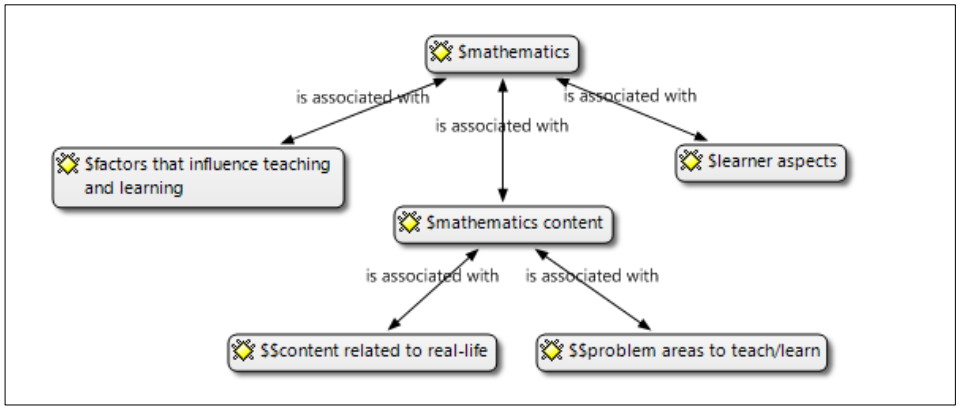

Figure 4.3: Coding Structure for the Participants' Needs in terms of Mathematics

4.2.1 Factors that Influence Teaching and Learning

One of the factors that clearly stood out in the interviews was the participants' aspirations to move forward. Not only are they currently studying to improve their qualifications, although they are employed full-time, but they expressed their desire to develop in other ways as well which could improve teaching and learning:

> *Then if they are not doing well, I used to think that maybe I need some sort of development (P59:23).*
>
> *So, I'm learning again (P49:3).*
>
> *If I'm given a chance everything is okay (P49:37).*
>
> *Yes, I am eager I am eager you know (P60:72).*

Another aspect that influences the teaching and learning of Mathematics is establishing good foundations of Mathematics from the Foundation Phase already:

> *I think it's because they lack a proper foundation, the problem starts at the foundation phase (P59:7).*

Not only does what takes place in the classroom impact on students' learning (Samuelsson, 2010, p. 61), but early Mathematics knowledge and skills are said to be the most important predictors for later achievement in Mathematics, and also for achievement in other content areas (Claessens & Engel, 2013, p. 1).

Immediate feedback to learners is an essential aspect of effective teaching and learning (Sancho-Vinuesa, Escudero-Viladoms, & Masla, 2013, p. 1). The participants also reported that immediate feedback to the learners was important:

> *It will help the learners, even with speed. Uh, marking, even that immediate feedback, because if you are given feedback immediately, you can try it again (P59:67).*

4.2.2 Mathematical Content

In this section, the data revealed two sub-themes relating to Mathematics content, namely: problem areas to teach and learn, and content related to real life. The first sub-theme revealed the following information about areas the learners found challenging and also facets of the curriculum that teachers found to be problematic. The areas of the curriculum that were most problematic for the participants to teach were: Financial Mathematics; Geometry; Probability; Algebra; Integers; Counting techniques; Graphs; Functions; the application of Calculus and Trigonometry. In some cases the content was problematic for the learners as well:

> *Learners do have a problem with algebra and integers in fact. If they do have a problem with integers, it is going to give them a problem when dealing with algebra (P59:4).*

In some cases the teachers found the content challenging as well:

> *Then, recently we have Euclidean geometry which has been introduced. Uhm, it's also a major problem, but I think the problem is not the learners but maybe the majority of teachers who are teaching that. They did not even do it during their times at school. It's something that was brought in as a crash program for teachers to be taught as well (P61:3).*

One of the key characteristics in RME is that learning strands should be intertwined (Drijvers & Doorman, 1996, p. 429). Learners ought to have a cohesive view of Mathematics and the way different topics are associated with each other and fit into one curriculum (Widjaja & Heck, 2003, p. 5). One participant expressed his desire to also learn progressively across grades and across the curriculum:

> *The thing is I started learning probability when I was teaching grade 12. After xxx left, then I took over. So I wanted to do it from grade 10. So this is how now I'm learning, right from grade 12. Because if you're teaching it at grade 12, there are some of the concepts that you don't know at the grade 11 and grade 10 level (P49:8-9).*

The content they found the easiest to relate to real life was Calculus, Probability, Integers, Data Handling, Measurement and Financial Mathematics:

> *Because we are working with money every day (P49:16).*
>
> *Through and through it every day life situations where you talk of borrowing, investments and other areas of activities (P61:8).*

A reason offered for poor learner performance in Mathematics was that learners dislike Mathematics because they are not learning relevant and significant content (Fauzan et al., 2013, p. 162). The study aims to make participants more aware of the need to relate the content that they teach in Mathematics to real life situations. I therefore asked them which areas they needed help with to relate the content to real life. The content areas where they needed help to relate the content to real life were: the application of Calculus; exponents, algebra, functions; integers; counting principles. Although the participants considered Financial Mathematics and probability as topics that can easily be related to real life situations, they also felt that they needed help to relate those two areas to real life situations.

4.2.3 Learner Aspects

One of the participants likes to use peer teaching in her classroom. She pointed out the benefits that her learners experienced:

> *Yes, the learners present and they present it so well, they present it so well. In the meantime they are also learning, you understand? They are also learning. So, I also tell some other learners they must also do it, because you gain more knowledge by just standing there and going home to prepare the topic to do it. They come prepared and then they do it so nicely (P60:85).*

Cahyono (2012) indicated that by interacting with each other, learners can enhance their understanding of mathematical concepts and the way in which they relate to real life (§ 3.2.7).

4.3 The Facets of Realistic Mathematics Education

Participants discussed various aspects that highlighted the facets of RME that are present in their teaching. This section includes a discussion on the characteristics of RME; certain aspects of RME; and the advantages of RME. Figure 4.4 indicates the coding structure that represents the framework for this discussion.

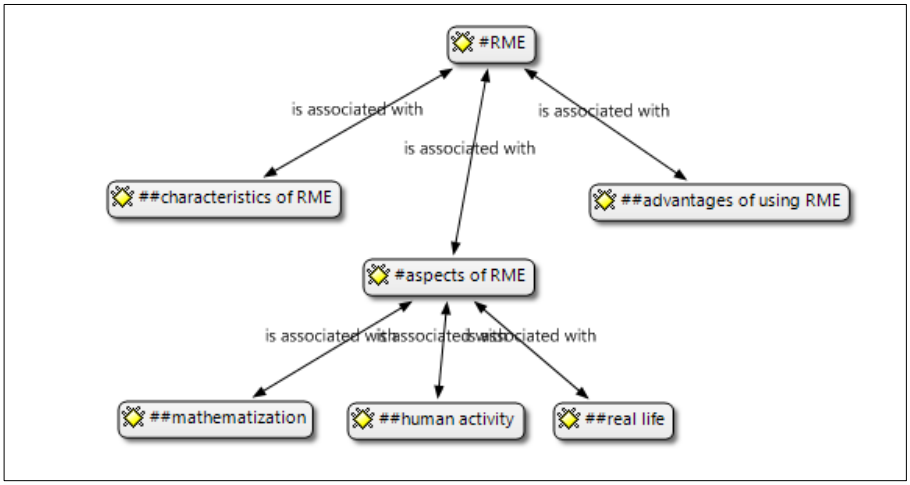

Figure 4.4: Coding Structure for the Facets of Realistic Mathematics Education as Highlighted by the Participants

4.3.1 Characteristics of Realistic Mathematics Education

Participants raised a number of factors that related to the characteristics of RME. As discussed in Chapter Three, the systematic literature review revealed various authors that have discussed the characteristics of RME. These characteristics include: the use of contextual problems; the use of models; student contributions are encouraged; interactivity; and the intertwining of learning strands (Drijvers & Doorman, 1996).

A crucial aspect of RME is when students are able to solve problems in realistic contexts which they deem as relevant (Boon, 2006). The participants expressed their views about the importance of referring to real life situations when teaching Mathematics:

> *Definitely, it is more important to relate it to more real life situations (P49:24).*
>
> *Because if you relate it to real life situations, it becomes easier for them to understand and they can also relate other things to the topic that you are teaching (P59:29).*

Context problems should be the mooring points for students to learn and reinvent Mathematics (Stephan & Akyuz, 2014). The value of using real life situations should therefore not be underestimated. Participants expressed their views about the importance of relating Mathematics to real life:

> *Because then we are linking the new work to something that they are familiar with (P60:26).*
>
> *Like, I said, some of the learners they don't know, when you're playing football or any other sports, Maths is applicable everywhere (P49:25).*
>
> *When they are sleeping, when they get up, Maths is applicable to them, every way, they don't know that, so they take it as something that is very special, they put it aside (P49:27).*

When designing learning activities, teachers should remember that the activity should encourage the students' work with Mathematics (Andresen, 2007). The teachers' role in the design of instructional material is crucial: they need to anticipate supportive mathematical imagery; create challenging assessment; use their mathematical knowledge to improve on the instructional sequence; and rework existing tasks (Stephan & Akyuz, 2014). Participants indicated a few examples of how real life situations can link with mathematical content:

> *In most cases that had to do with gradient. The gradient of that particular road is not evenly balanced. In mathematical terms that has to do with gradient (P61:7).*
>
> *It appears as if there is no link but calculus it also talks about gradient and so forth. That is real life situations (P61:11).*
>
> *Uhm, in Financial Mathematics as well. Through and through it every day life situation where you talk of borrowing, investments and other areas of activities (P61:8).*

Modelling activities should come about in situations and contexts that are experientially real to the students (Doorman et al., 2008). The problem situation should set models in motion that initially represent the problem situation, but have the potential to develop into a more general model (Bakker et al., 2003). One participant clearly emphasized this aspect of RME:

> *So, you cannot do Mathematics without modelling. And, once you talk about modelling, you are now talking about real life situations (P61:12).*

The starting point for learners' learning should be real contexts that are meaningful to them. These situations should be used as the basis for concept formation which leads to more formal Mathematics (Widjaja & Heck, 2003). One participant acknowledged the importance of choosing a context that is experientially real for those particular learners:

> *So it is difficult to relate this to somebody who doesn't know about the situation (P49:21).*

Interactivity is promoted when learners are more accountable for their own learning (Widjaja & Heck, 2003):

And especially sharing those ideas of Mathematics, it will help a lot (P59:57).

As was mentioned in § 3.3.2, the intertwining or integration of different strands or topics is an essential part of RME (Widjaja & Heck, 2003). Participants encourage this integration.

Because then we are linking the new work to something that they are familiar with (P60:26).

Another participant diagnosed a challenge that learners had with integration and also acknowledged the misconceptions that can develop due to a lack of integration:

We have a problem in functions, but the problem emanates from the fact that they don't understand for example exponential function—if learners don't understand how to solve exponential equations then when you go to functions it becomes very difficult (P61:1).

4.3.2 Aspects of Realistic Mathematics Education

The two aspects of RME that were evident in the discussion with the participants were that Mathematics is considered to be a human activity (Freudenthal, 1971); and that problem solving should be done in realistic contexts (Gravemeijer & Doorman, 1999). Freudenthal (1971) advocated that for Mathematics to be of human value, it needs to be useful, i.e. closely linked to reality. One participant used the example of children playing football, and how that could link to Mathematics:

Like, I said, some of the learners they don't know, when you're playing football or any other sports, Maths is applicable everywhere (P49:25).

As mentioned in § 4.3.1, it is important when implementing the principles of RME that we pose problems in realistic contexts, that learners recognise as relevant and real (Boon, 2006). One participant indicated that by following that teaching approach, finding relevant contexts could be challenging. He indicated that what might be familiar to learners in urban areas, might not be relevant to learners in rural areas. In the example that he used, he pointed out that not all learners were familiar with the Kentucky™ fast food franchise, and that teachers should be cautious when deciding on an appropriate context for the learners that were in their classrooms:

You see, most of our learners they are not, how can I say it, they are not familiar with the situations. Like for instance you cannot just ask somebody from the farms about Kentucky, you see? So it is difficult to relate this to somebody who doesn't know about the situation (P49:17-21).

One of the participants expressed his opinion that certain content areas were well-suited to real life situations:

Some of the topics, they come clear to real life situations (P49:13).

He as well as another participant also pointed out that not all areas were easy to connect to realistic contexts:

It's difficult to relate (P49:14).

Hmm, there are topics that we can relate to real life situations, the others they are a little bit more confusing or difficult to relate (P59:17).

A third participant pointed out examples of a realistic context that could be used to relate the content

area of Financial Mathematics to reality:

> *Uhm, in Financial Mathematics as well. Through and through it is an everyday life situation where you talk of borrowing, investments and other areas of activities (P61:8).*

The participants also expressed their ideas about which content areas they found easy to relate to real life. These were Calculus, Financial Maths, Probability, Integers, Data handling, and Functions.

4.3.3 Advantages of Realistic Mathematics Education

In Chapter Three, I pointed out various advantages that are expressed in the literature regarding the use of RME principles (§ 3.3.5.1). These include: improvement of learner motivation (Cahyono, 2012); a more positive attitude towards Mathematics (Fauzan et al., 2013); and interactivity and collaboration are promoted (Widjaja & Heck, 2003). A participant also suggested that by using real life examples, learner understanding could possibly be improved:

> *Because if you relate it to real life situations, it becomes easier for them to understand and they can also relate other things to the topic that you are teaching (P59:29).*

4.4 Ideas and Considerations about Information and Communication Technology

In this section I will discuss the considerations and ideas of the participants relating to ICT that were revealed in the individual interviews. I discuss this section as five main themes, namely the value of using ICT; challenges when working with ICT; various technology devices; the manner in which technology can function as an educational tool; and ICT factors that relate specifically to the participants. Figure 4.5 illustrates the network view of the coding structure for the participants' considerations and ideas about ICT.

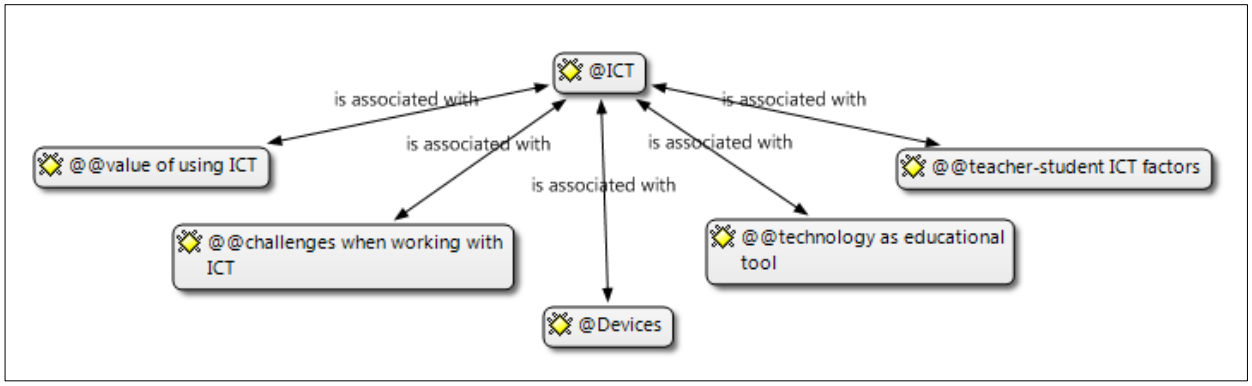

Figure 4.5: Coding Structure for the Participants' Considerations and Ideas about Information and Communication Technology

4.4.1 The Value of Using Information and Communication Technology

In relation to the integration of technology in teaching, Drijvers et al. (2010a) describe the role of the teacher as both critical and problematic (§ 3.4.1). The teacher's role is critical because the teacher's

approach to using technology has far-reaching effects in the classroom. It is problematic because teachers have difficulty in adapting their teaching strategies when working with technology. The participants pointed out positive aspects of using technology in their experience. This is a promising aspect since the teacher's role is so crucial in implementing the use of technology in the classroom. With reference to the Interactive Whiteboard (IWB), the participants said:

> *Because if you are prepared, it could save time. You don't have to write again. As long as you prepare in time, then you just put your preparation there and you go on, so a lot of time will be saved (P59:64).*
>
> *It would be much beneficial for example if I use the interactive whiteboard, almost all learners like it at our school. The whole generation of today, they can all use computers (P61:37).*

With reference to the overhead projector, they said the following:

> *It was easy to use them, rather than making use of the chalk. We could prepare in advance (P49:33-34).*
>
> *But all in all it's too beneficial to use technology. It also saves time, instead of you writing notes on the board for one hour, it's easier using the technology (P61:40).*

4.4.2 Challenges while Working with Information and Communication Technology

Participants expressed their concerns and challenges concerning the use and integration of ICT in their teaching of Mathematics. We should keep in mind that the literature review revealed that using technology in Mathematics education does not provide instant improvement (Drijvers, 2013). Challenges will therefore always exist. One of the participants expressed his concerns about the use of calculators in the lower grades:

> *What about these calculators? Because with the grade eight, let me say grade six, seven and eight, I think that using calculators is not good. Because they tend to...how can I put it—to lose those skills, calculating skills or basic skills of Mathematics. Even a simple problem, they want to use a calculator instead of doing it themselves (P59:68).*

When I asked him about using calculators in higher grades, the same participant said:

> *No, no, calculators at least with them, it saves time. Because there, they are doing more complicated things. For example with financial Maths, they have to use a calculator (P59:70).*

Another challenging area that the participants discussed related to proper training on the use of technology in the Mathematics classroom:

> *There was training, and then the department sent someone from them to come. But, it was not only for Maths (P60:33).*
>
> *Yes, they have the tablet. We have the interactive whiteboard, but we the teachers are still struggling to use the interactive whiteboard. Most especially for Maths. They say that somebody from the department will come and help us (P60:8).*

Further challenges that concerned the participants related to poor infrastructures and facilities:

> *At present we don't have technology devices at our school, but I think those devices if we can have those devices they are going to help us...because it will ease the burden (P59:31).*
>
> *Ja, last time when we were using the overhead projectors, but now the state of our school we cannot, we have so many projectors here, but they are not functioning (P49:34).*

General concerns that they expressed had to do with their experiences and perceptions of technology:

Yes, and my experience as well is that learners might be fascinated with the use of the computer and the overhead for one or two days, then they will lose interest. That is my experience (P61:26).

You can say cell phones are not designed for teaching and learning, it's just for communication purposes, so if you use them for teaching and learning, I don't think it's a good idea, unless if you want to communicate with them, send them homework, maybe the results, something like that (P59:37).

4.4.3 Devices

Two participants pointed out the benefit of working with an Interactive White Board (IWB):

Yes and I can also save my lessons. I can even use it next year for the other groups (P60:54).

It would be much beneficial for example if I use the interactive whiteboard, almost all learners like it at our school. The whole generation of today, they can all use computers (P61:37).

Because in our interactive whiteboards there are pre-recorded lesson (P60:58).

For me, to be able to create a suitable intervention tool, that all participants would have access to, it was necessary to establish which devices the student-teachers would be willing to use. They indicated that they were happy to use the following devices: IWBs, mobile phones, tablets, laptops and desktop computers. Since mLearning is a rapidly expanding field that provides new opportunities for education (Kizito, 2012a), and as the participants indicated their willingness to work with mobile devices, I therefore decided to design a mobile app as an intervention tool. Some of the advantages that mobile devices offer were discussed in § 3.4.3. These include the following: mobile devices offer the potential for stimulation, motivation, availability as well as ease of use (Zaranis et al., 2013). A detailed description of the mobile app is presented in Chapter Five.

4.4.4 Technology as an Educational Tool

The use of WhatsApp™ for groups of learners is said to have various advantages in the educational arena (Barhoumi, 2015, p. 223). The technical advantages of WhatsApp™ include: simple operation; low cost; availability; and immediacy (Bouhnik & Deshan, 2014, p. 217). One participant makes use of WhatsApp™ groups with her Mathematics classes and relies on the immediacy that it offers:

So, I usually take the answers, then I sometimes take a camera, and then I send it to them (P60:41).

The educational advantages include creating a pleasant environment and in-depth acquaintance with fellow students (Bouhnik & Deshan, 2014, p. 217). The academic advantages are accessibility of learning materials; teacher availability; and the extension of learning after class hours (Bouhnik & Deshan, 2014, p. 217). The participant confirms these aspects of teacher availability and extended learning:

We've got a group WhatsApp™. If there is maybe something that they don't understand, we chat (P60:36).

Yes, like I give them homework, somebody's stuck along the way they don't have any, you know they don't have many resources even to refer to. I will give them one or two tips on how to continue with the problems (P61:29).

Participants referred to other forms of technology that are used as educational tools. The participants

referred specifically to the use of web-based interactives and GeoGebra:

> *With a computer, I think there are other programmes which might help. When I was doing ACE in Potchefstroom, there are those programmes where you will be tested on a certain topic. Then the computer will immediately correct you and show you how to do this problem if you are doing it wrongly (P59:66).*
>
> *If you want to show a learner that the angle at the centre is double the angle at the circumference attended by the same chord for example, you can do it by technology (P61:16).*

Tablets are another form of mobile technology that is becoming a popular educational tool. The benefits of using tablets include: ease of use; anywhere, anytime learning; a variety of educational apps are available for use; teachers' workload can be reduced with digital collection and marking of tasks; and greater autonomy of learning (Churchill, Fox, & King, 2012, p. 252). Participants also referred to the use of tablets in the classroom:

> *Some of the questions, previous question papers are there with memos, and they can research, they can do whatever they want there. It's off-line at night, but during the day it's on-line (P60:14-15).*

4.4.5 Participants' Information and Communication Technology Factors

The participants in general are positive about and can benefit from the use of technology in various ways:

> *Yes, I am eager I am eager you know, to let them come and use that (60:72).*
>
> *I'd be willing to use it with other colleagues to discuss tasks related to Maths (P59:42).*
>
> *I'm using a computer at my home (P60:45).*

However, a number of challenges remain:

> *I don't have time for social media (P49:44).*
>
> *My email is not working, but I will try to fix it (P49:65).*

4.5 Role players

In this section I discuss four role players that emerged in both the literature and in the interview data. These are teachers, learners, the community and the context. Figure 4.6 illustrates the coding structure that I used for this data analysis.

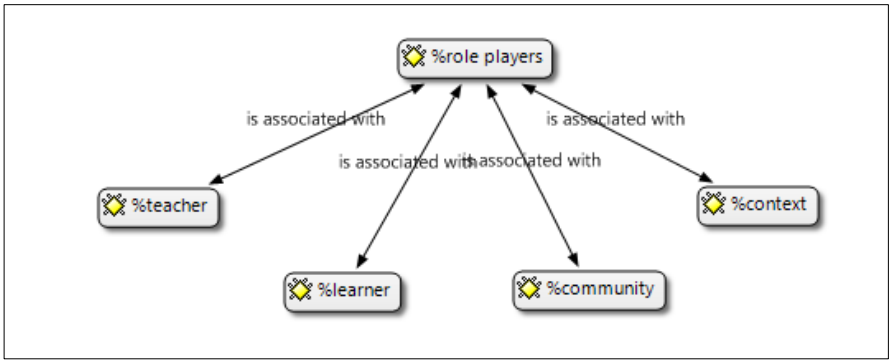

Figure 4.6: Coding Structure for the Role of Various Role players in this Study

Although teachers and learners could benefit from the use of technology, not all stakeholders share the optimism about how ICT can effectively be used in teaching and learning (Drijvers et al., 2010a; Heck et al., 2007). Widjaja and Heck (2003) and Zulkardi (2000) affirm the changing role of teachers and learners in the RME classroom. These issues can account for the increased pressure on the various role players in education. The participants expressed their opinions on the topic.

4.5.1 The Role of the Teacher

Various issues were raised that related to the role of the teacher. Firstly, the challenging task of a Mathematics teacher was emphasized:

> *Ja, so it's difficult to teach Maths, very difficult (P49:31).*

Yet the participants' enthusiasm was tangible:

> *I'm excited (P60:28).*

A common belief exists that teachers teach the way they were taught. Dunn and Dunn (1979, p. 241) rather believe that teachers teach the way they learned, and that their teaching style is directed by learning styles. One participant also raised this issue:

> *But how I think is also influenced by the way I was taught myself although I have changed a bit (P61:13).*

The participants also raised challenges that they experience in terms of time and professional development:

> *Time is a problem, because now I'm having extra classes with the grade elevens on Wednesdays and also on Saturdays. I don't have time for social media (P49:43-33).*
> *I feel that maybe if I can maybe have more knowledge (P60:31).*

4.5.2 The Role of the Learner

Since the study was more focused on the perceptions of the teachers, few aspects relating to learners were revealed despite social and contextual circumstances that can negatively influence learners' learning (Considine & Zappala, 2002, p. 130). One participant testified to the poor socio-economic status of their learners:

> *But, maybe only, let me say ten percent of our children have got a good background, they have got a satellite dish. So mostly they are from shacks, where they do not have electricity, you know... (P60:77).*

4.5.3 The Role of the Community

The role of the community should not be underestimated. Community demographics affect how students perform in Mathematics (Sackey, 2014, p. i). The participants shared their experiences of the community:

> *Yes, because I once asked them to watch that learning channel. Then I realized that most of our learners, 90% of them don't have that. Some they have the TV, but they don't have the*

dish, they can't afford to pay the dish every month (P60:78).

If learners have supportive relationships with their parents, it positively influences learner motivation (Wentzel, 1998, p. 206) and academic performance (Makgato & Mji, 2006, p. 261). Despite often being aware of this, parents are rarely involved in their children's schooling (Makgato & Mji, 2006, p. 261). The participants touched on this aspect in the discussion:

> *It goes back to what I said; there are so many factors within the community which are inherent on how this will work. I did not think that I had enough support from their parents. Because learners in their own, they have a lot of things they need to do (P61:30).*
>
> *Even their parents, they are worse than these learners (P49:29).*

4.5.4 The Role of the Context

There is a definite link between the quality of school facilities and student achievement (Uline & Tschannen-Moran, 2008, p. 55). Participants point out the challenges they experience with regard to the school facilities:

> *And some of the classes do not have electricity. That's another problem (P49:35).*
>
> *You have a situation here where there is no electricity in the community, electricity is gone. But, for me I think through my experience, I have tried both electronic and the traditional. I think they should all be used concurrently in such a way that for example after using the traditional one, you can move onto technology so that the learners can understand it better (P61:38).*
>
> *Unfortunately at the moment, because we have only one interactive whiteboard in one of the computer labs. So, any specific teacher who wants to use it will have to discuss it with other teachers when and so on. So, I have not agreed to having a class with them because of the congestion of the program of the curriculum. Because for example in grade 10 we have nine classes, grade 11 around seven, grade 12 we have close to two hundred learners. It has not been easy (P61:35).*

Howie (2003, p. 2) suggests various factors for the poor performance of learners in Mathematics in South Africa in particular. In relation to institutional issues these include "the lack of professional leadership; heavy teaching loads; overcrowded classrooms; poor communication between policy-makers and practitioners; and a lack of professional staff in the ministry of education." So too did the participants highlight aspects relating to the higher structures that they found problematic in their teaching practice:

> *For example with Euclidean geometry, the curriculum statement does not give the teacher the opportunity for learners to discover where these theorems are coming from (P61:15).*
>
> *Since the department said that every grade 12 teacher must have a laptop, but we are still waiting for them to give that to us, the laptop (P60:44).*
>
> *We even went to the workshop, but you know those workshops are only for three days. And we were doing so many things—we were doing geometry because they also introduced geometry. But we did it in our times—those theorems. Yes, all of us feel that it was not enough training, really it was not enough (P60:3-5).*

4.6 Chapter Summary

In this chapter I presented a detailed analysis of the interview data that were generated to establish

what needs the participants had in terms of teaching Mathematics in a more realistic way. I firstly explored the participants' needs in terms of Mathematics itself, and started by focusing on factors that influenced teaching and learning. An aspect that emerged that was very reassuring was the desire of the participants to move forward and improve as teachers. Their aspirations were evident not only in that they are currently improving their qualifications, but they also expressed the desire to be involved in professional development and training. Other aspects that they raised regarding factors that influence teaching and learning were twofold. They discussed the importance of establishing good Mathematical foundations when teaching and also mentioned the significance of providing learners with immediate feedback.

This chapter also presented a discussion on the problem areas that learners had, as well as challenges that teachers faced regarding the content of the Mathematics curriculum. Literature has pointed out that a possible reason for learners' poor performance in Mathematics is that the content is not presented as relevant and significant. I therefore explored areas that the participants had difficulty in making the content realistic, relevant and significant for their learners. This would help me in designing a relevant and appropriate intervention tool.

Since this study is deeply entrenched in the theory of RME, it was essential to touch on the characteristics of RME in this discussion of the data. All five characteristics of RME emerged in the data as participants discussed the importance of interactivity, modelling, integration between strands, the use of realistic contexts and learner participation. These characteristics all featured strongly in the discussion with the participants. Apart from the characteristics of RME, I further explored two aspects related to RME, namely that Mathematics is considered to be a human activity and the importance of real life examples in Mathematics teaching. This led to a discussion on the advantages of using real contexts to improve learner understanding, which literature has shown us.

Apart from Mathematics and RME specifically, the other main theme that underpins this study is the use of ICT in teaching and learning. This chapter also detailed the teacher-students' considerations and ideas about ICT. I discussed their ideas regarding the value of ICT and the critical role that teachers play in the integration of technology in teaching. I further explored the challenges raised by the participants. These included concerns about using calculators in the lower grades; the lack of technological training that the participants experienced; the poor infrastructures and facilities that they had to deal with which impacted on their use of ICT; and general experiences and perceptions that the participants shared about ICT. They also discussed their ideas and experiences about different technological devices such as the Interactive Whiteboard. In order to successfully incorporate technology in the intervention stage of this study, it was important for me to establish which technology they were most comfortable with. The participants shared their ideas on this topic and clearly indicated their preference for mobile technology. This informed my choice of technology for the design phase of the study. I also explored their ideas on technology as an educational tool. They shared their experiences of working with WhatsApp™ groups, GeoGebra, web-based interactives and tablets.

The final stage of this chapter dealt with the four role players that featured in the discussion with the participants, namely the teacher, learner, community and context. In the interviews, the participants reinforced the notion that teaching Mathematics was a challenging task, yet their enthusiasm to be Mathematics teachers was evident. They expressed their opinions on challenges they experienced in terms of teaching styles; time and professional development. The most dominant aspect relating to learners that featured was the effect of a poor socio-economic status on their learning. The role of the community and the context was also discussed and participants shared their views on aspects such as the crucial role that parents play in the children's education; the effect of poor school and home facilities on learner achievement and the influence that decisions by authorities had on teaching and learning.

Chapter Five presents the design of the intervention tool. In this chapter I discuss in detail the purpose of the mobile tool; and the design process. When discussing the purpose, I explored the theory of mLearning, the connection between technology and RME and also the context for which the tool was designed. In the discussion on the design process, I expanded on the theoretical aspects of the design process and also the technical facets of the design process.

As was discussed in § 2.4, upon completion of each stage of a design-based research project, researchers will perform systematic reflection and documentation to produce the required scientific yield in the form of theories or design principles (Plomp, 2007, p. 15). As is illustrated in Figure 2.6, upon completion of the needs and content analysis phase, I have produced a number of design principles relating to that phase. The design process led to the realisation of a number of principles that were established in the needs analysis phase. These principles are presented in Table 4.1.

Table 4.1 Design Principles for the Design of a Mobile App Based on the Principles of Realistic Mathematics Education Derived from Individual Interviews with Participants

Aspect	Implications
Determine participants' needs in terms of teaching Mathematics	• Establish what needs the participants have with regard to content areas (both teachers and learners) • Establish participants' needs in terms of making Mathematics realistic for the learners
Establish the participants' eagerness for being mentored	• Participants should indicate a desire to be involved in professional development • Participants must aspire to move forward
Adhere to the characteristics and principles of RME	• Meaningful, realistic contexts should be the foundation for students to reinvent the Mathematics • Student contributions should be encouraged • Incorporate the use of modelling • Make use of interactivity • Ensure the intertwining of content areas and concepts
Establish participants' views about ICT	• Participants should see the value of ICT • The challenges that participants experience with regard to ICT should be addressed as far as possible • Establish which devices the participants find most suitable

Aspect	Implications
	• Determine in what manner participants use technology as an educational tool
Determine which role players feature most prominently within the context	• Teachers are the key role players in integrating ICT in teaching and learning • Learners' learning is influenced by their socio-economic circumstances • Parents play an essential role in learners' academic performance • Facilities and higher authorities can be important within the given context

Chapter Five

The Design and Development of the Mobile Intervention Tool

5.1 Introduction

A purpose of this phase of the investigation was to establish the support needs of teachers in order to effectively implement the RME approach in their teaching practice. After doing individual interviews with students (Chapter Four), I established the areas in which they needed assistance, not only with their teaching, but also in making Mathematics more realistic for their learners. To address these areas of need, it was necessary to design an intervention tool for the teacher-students to use, based on the principles and characteristics of RME. Figure 5.1 illustrates the structure that will be followed in this chapter.

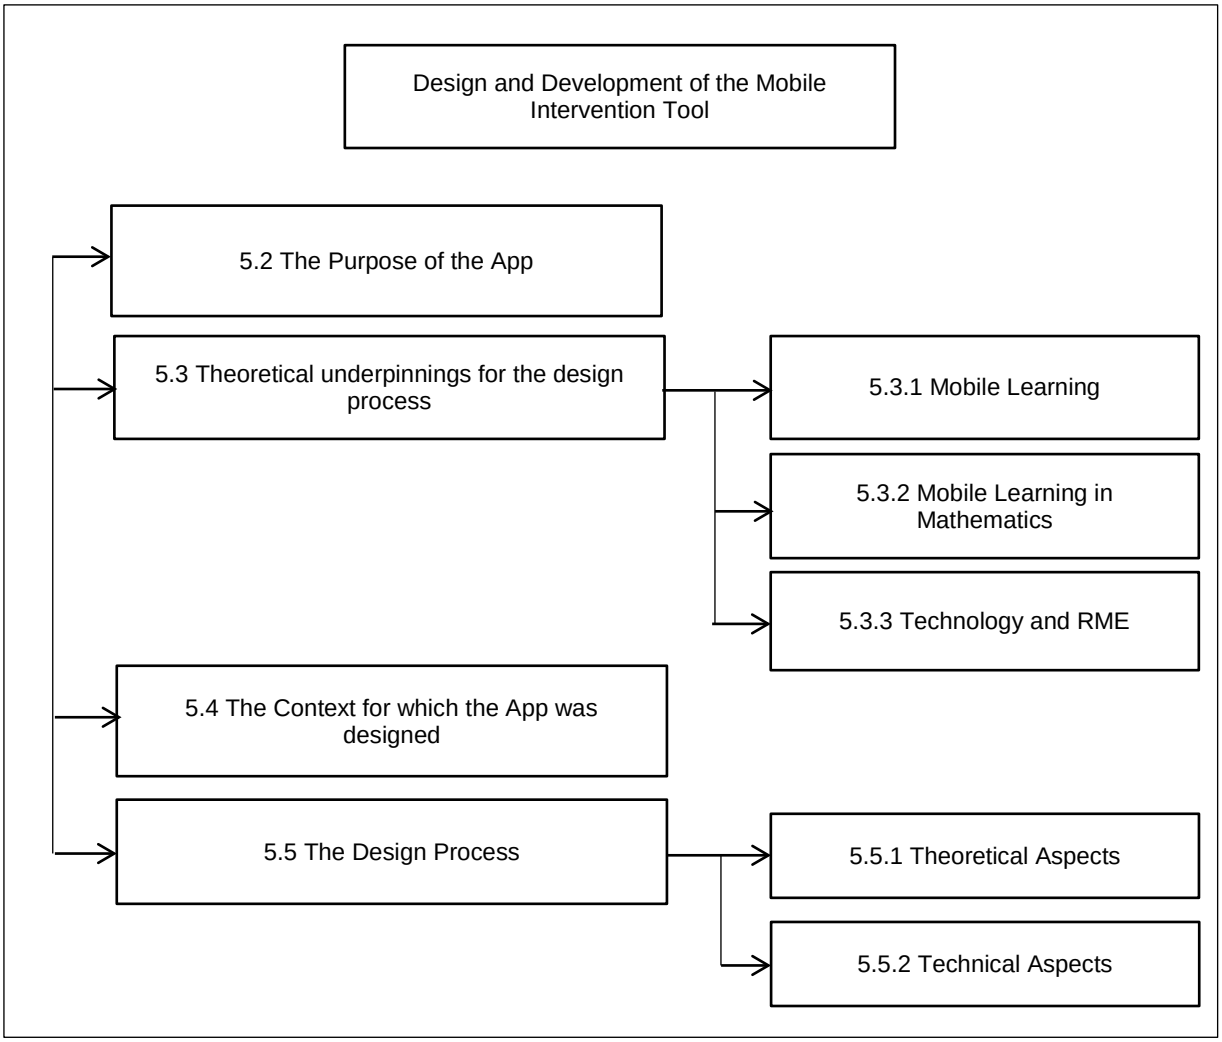

Figure 5.1: Advance Organiser for the Design and Development Process of the Intervention Tool

5.2 The Purpose of the Mobile Tool

MLearning has made a valuable contribution to the educational environment in recent years (Alzaza & Yaakub, 2010, p. 95). Mobile devices are stimulating platforms for learning due to their computing ability, their affordability and their ubiquitous nature (White & Martin, 2014, p. 95). The teacher-students in this study shared their perceptions, experiences and needs regarding the academic content and the effective implementation of the RME approach in their teaching practice (Chapter Four). They confirmed inter alia that they were excited about the use of mLearning to address the issues and needs that they faced in their teaching, specifically relating to content and linking school Mathematics to real life situations. I therefore deemed a mobile tool, in the form of an app, to be suitable for the teacher-students in order to present the mathematical content and principles of RME to them.

5.3 Theoretical Underpinnings for the Design Process

In this section I discussed some of the theoretical underpinnings that drove the design of the app. I investigated relevant literature relating to mLearning in general and probed aspects relating specifically to the design and use of mLearning in Mathematics. I also briefly mentioned the link between technology and RME. A detailed discussion of this literature concerned with ICT and RME was done in the systematic literature review in § 3.4.5.

5.3.1 Mobile Learning (mLearning)

Literature offers various definitions for mobile learning. MLearning is learning realised with the aid of a small, portable computing device, which typically involves the viewing of content or lessons in manageable chunks (McConatha, Praul, & Lynch, 2008, p. 15) as a specific type of learning model for using mobile technology (Cheon, Lee, Crooks, & Song, 2012, p. 1054). Sharples (2013, p. 2) provides various definitions for mobile learning. He highlights one definition that encompasses both perspectives of learners' mobility as well as learning with portable technology as that of O'Malley et al. (2003, p. 7), which states: "Any sort of learning that happens when the learner is not at a fixed, predetermined location, or learning that happens when the learner takes advantage of the learning opportunities offered by mobile technologies."

Mobile technology offers a new generation of learning to people of all ages without being bound by place and time (Alzaza & Yaakub, 2010, p. 95). mLearning is becoming more popular within formal education as its benefits are widely publicised as being cost effective and flexible in terms of time and location; it is a ubiquitous form of communication, and can serve as a study aid (Cheon et al., 2012, p. 1054). Cheon et al. (2012, p. 1054) summarise the characteristics of mobile devices into three aspects: the portability; instant connectivity; and context sensitivity.

Al-Emran, Elsherif, and Shaalan (2016, p. 94) list the benefits of mLearning for students: it enhances collaboration between learners with each other as well as with their educators; it facilitates team collaboration; the sharing of knowledge; and raising of technological awareness. MLearning assists students to create social interaction; it promotes collaborative learning, interactivity and instant feedback as well as collaboration between peers; it improves their knowledge structure; their learning achievements (Domingo & Garganté, 2016, p. 22; Mouza & Barrett-Greenly, 2015, p. 3) and motivation (Mouza & Barrett-Greenly, 2015, p. 3). Domingo and Garganté (2016, p. 22) further point out that students are more willing to engage when learning with mobile technology; their desire to accomplish educational tasks also increases with the use of mobile technology; and it helps learners to be more self-directed in their learning. Mobile communication in education is a solution with a selection of prospects and challenges (Kommers & Hooreman, 2009, p. 88).

mLearning applications have various educational benefits: they can be used as study aids; can be accessed from almost anywhere; and with the aid of location capabilities, students can use location-based information (Cheon et al., 2012, p. 1054). Mobile technology apps enrich higher education by extending traditional educational platforms and encouraging distance learning or settings outside of the classroom (Al-Emran et al., 2016, p. 94). Content applications that make use of personalized instruction can facilitate academic growth and self-efficacy among students (Mouza & Barrett-Greenly, 2015, p. 12). In their paper on the professional development of teachers, Mouza and Barrett-Greenly (2015, p. 13) note that professional development that is grounded in recognised best practices is essential in assisting teachers to obtain the knowledge and skills they need to fully benefit from mLearning.

The use of mLearning has become essential for higher education due to its numerous benefits (Al-Emran et al., 2016, p. 94). Increased affordability and functionality has made mLearning more attractive in education (Domingo & Garganté, 2016, p. 21). Jantjies and Joy (2015, p. 308) are of the opinion that mLearning apps used in subjects such as Physical Science and Mathematics require appropriate content that considers the users' challenges and needs.

In recent years, there has been a tremendous increase in the use of tablets and smartphones in the educational arena (Calder, 2015, p. 233). Tablet computers provide new potential for Mathematics learning, (Zhang, Trussell, Gallegos, & Asam, 2015, p. 32). Tablets offer the following benefits: they are light; they are portable; most tablets have a long battery life; and they offer a positive sensory experience to children. They also allow learners to do Mathematics tasks at their own pace; and provide immediate feedback (Zhang et al., 2015, p. 33). Immediate feedback is one of the aspects that teacher-students in this study identified as an essential aspect of teaching and learning in the individual interviews (§ 4.2.1).

5.3.2 Mobile Learning (mLearning) in Mathematics

The use of digital technology in Mathematics education allows for improved engagement with mathematical processes and concepts (Calder, 2015, p. 233). Specifically, mLearning affords new learning opportunities in Mathematics (Graven, 2011, p. 45). Mathematics apps are an effective way in which learners who struggle can be provided with instructional support (Zhang et al., 2015, p. 38). They allow students to solve more problems than when using paper and pencils; they are easy to use; and are generally able to actively engage students (Zhang et al., 2015, p. 38). Students' experiences with mobile devices are often more rewarding than teachers may realise (Lee & Kautz, 2015, p. 575). When learning Mathematics, students have the opportunity to explore and take risks with digital technology, which is not always otherwise possible (Calder, 2015, p. 238).

Cayton-Hodges, Feng, and Pan (2015, p. 3) report on a survey of Mathematics apps available in the Apple App Store. The intention of the survey was to learn what should and should not be done in the development of Mathematics assessment in the apps. They mention various aspects that should be considered in the design of Mathematics apps. There should be a rich and accurate representation of the mathematical content; the interactions around the mathematical content should be lavish and engaging; there should be an opportunity for users to reflect on tasks they have done; and hints, scaffolds and other tools are important and are typically presented on a need to know basis (Cayton-Hodges et al., 2015, p. 16).

Lee and Kautz (2015, pp. 576-577) present a framework for the design and implementation of mathematical tasks with the aid of mLearning. The framework consists of six steps, which do not have to take place chronologically. The purpose of the framework is to provide structure, specify components and indicate the relationships between technology-based task design and implementation. The steps are as follows: define the lesson objective; define the technological environment; define the types of investigations; design and develop the tasks; implementation; and enactment (Lee & Kautz, 2015, p. 577). Figure 5.2 illustrates the framework suggested by Lee and Kautz (2015) which focuses on the aspects that need to be considered and the actions that need to be taken when incorporating mobile technology into Mathematics teaching and learning.

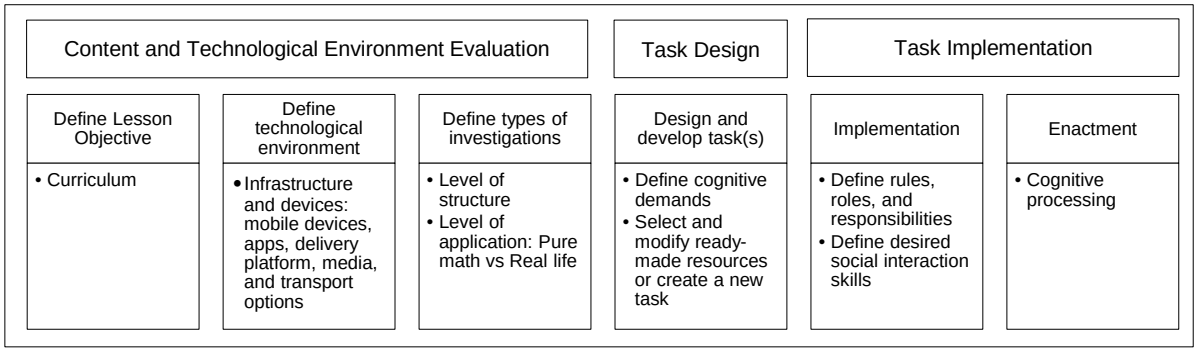

Figure 5.2: Framework for mLearning task design and implementation (Lee & Kautz, 2015, p. 577)

Students and teachers alike generally find apps engaging and motivating, and promote their inclusion in programmes. This might partly be due to the fact that learners today are captivated by digital media, and are able to use these to communicate, investigate and process ideas very effectively (Calder, 2015, p. 246).

5.3.3 The Relationship between Technology and Realistic Mathematics Education

Drijvers et al. (2010b, p. 89) describe the integration of technology into the teaching and learning of Mathematics as urgent. The fundamentals of how Mathematics should be taught are challenged by the incorporation of technology in Mathematics education (Olive et al., 2010, p. 138). Digital technology in Mathematics education has the capability to allow students to construct and engage with mathematical knowledge which allows for the subject to be entrenched in authentic contexts and sanctions the creation of meaning for the students (Bray, Oldham, & Tangney, 2015, p. 2489). Technology can be used as an effective facilitator in the implementation of the RME approach (Widjaja & Heck, 2003), and using technology in the RME approach produces better results than traditional teaching (Zaranis, 2013). As discussed in Chapter Three, it is essential that digital technology be incorporated in different contexts in a natural way (Drijvers, 2013) (§ 3.3.3.6). So too should the context be chosen in such a way that the technology can aid the process of mathematization (Boon, 2006). Technological environments have the prospect of reconnecting the learners with authentic contexts in which they can create meaning (Olive et al., 2010, p. 138). The use of technology also places the emphasis on the "practice and applications of mathematics through visualisation, manipulation, modelling, and the use of mathematics in complex situations" (Olive et al., 2010, p. 139).

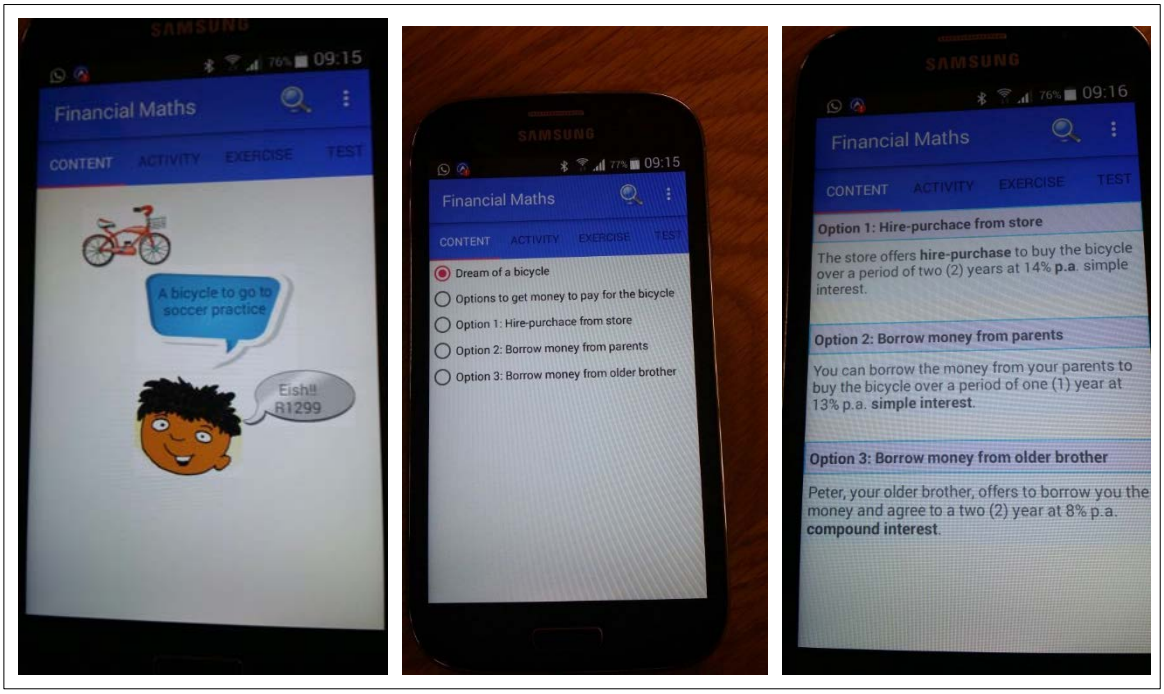
5.4 The Context for which the App was designed

The app was designed to assist teacher-students with the challenge of making the mathematical content more realistic for their learners. The teacher-students are in-service teachers from both rural and urban environments. They are enrolled for the BEdHons programme in Mathematics education which implies that they either have a first degree or a certificate such as the Advanced Certificate in Education (ACE) with Mathematics as specialisation area. They all share the common desire to improve their qualifications. The teacher-students are older than the average student since they already have a prior qualification and are required to be employed full-time as teachers. They often have family commitments along with the commitments of full-time teaching and part-time studying. The majority of the students teach at disadvantaged schools and are women (Kok, 2009). The participants in this study agreed that they were willing to use technology to take part in the project, and all agreed that mobile technology was a suitable method of communicating and delivering material within the context of this study (§ 4.4.3). It was therefore appropriate within the context of this study to design an app as an intervention tool.

In the 2016 ECAR Educause survey performed at the North-West University, 68% of students were found to have android devices, 21% to have iOS, 8% to have a windows device and 3% to have other devices (Dahlstrom, Brooks, Pomerantz, & Reeves, 2016). It was therefore fitting to design the app for Android devices since the majority of students own an Android device.

5.5 The Design Process

The process of designing the app required a team effort. The team consisted of an experienced programmer that designed the app; myself, who featured as the content specialist and also the creator of the design documents; my promoter, an expert in the field of using technology in teaching and learning, and who also oversaw the design process; and my assistant promoter, an expert in the discipline of Mathematics as well as Mathematics education, with a keen interest in the use of technology in Mathematics education. Various theoretical and conceptual aspects as well as specific technical aspects guided the process. The app consists of two main sections: a content section and an activity section. In the content section the mathematical content is presented in a systematic way. The progression of the topic is done methodically to assist those users who are not completely au fait with the content. The second component in the app is an activity section, where the concepts that were presented in the content section are reinforced and also extended to new and challenging situations.



5.5.1 The Theoretical Aspects of Creating the App

McKenney and Reeves (2012, p. 78) state that the process of design-based research starts with an analysis of the existing problem in educational practice and is often supplemented by literature to establish a proper understanding of the problem. In Chapter Two, Figure 2.6 illustrates the design process specific to this study. A detailed discussion of the research design methodology is presented in Chapter Two. After the completion of the systematic literature review and the needs analysis interviews with the teacher-students, the first phase of the design process for this study was completed.

After the needs analysis interviews with the teacher-students had been done, the data were coded, classified and analysed. The detailed analysis was described in Chapter Four. Teacher-students shared their perceptions and experiences relating to what support needs they had in terms of effectively implementing the RME approach in their teaching practice. The data analysis revealed the content areas that the teacher-students and/or their learners had difficulty in understanding. The topics which all four respondents experienced as problem areas were Financial Mathematics; Geometry; Probability; Algebra; Integers; Counting techniques; Graphs; Functions; Calculus and Trigonometry (§ 4.2.2). The participants shared that they needed help in relating the following content

areas to real life: Calculus; Exponents; Algebra; Functions; Integers; Financial Mathematics; Probability; and Counting principles (§ 4.2.2). I selected to design and develop a mobile app for the content area of Financial Mathematics because this topic featured in both categories discussed above. This process encompasses the needs and content analysis stage of the design process as presented in Figure 2.6.

The second phase of the process (Figure 2.6) relates to the design development and evaluation phase. Solutions informed by existing design principles and innovations in technology comprise the second step in the process (Amiel & Reeves, 2008, p. 34). To implement this phase, I approached a programmer who is experienced in mobile app development to design and construct the intervention app. An initial discussion took place between my promoter, the programmer and I where we discussed the possibilities and requirements for designing the app. I then proceeded to draw up a first draft of the app design document (Addendum 5.1). This document provided the programmer with a broad idea of the content of the app. It also outlined the tasks, hints and instructions in detail, as well as some notes to the programmer on how I wanted the app to work. The initial draft of the app design document was perused by my promoter and sent to the programmer before he developed a first prototype of the app. Figure 5.3 illustrates the screenshots of the first prototype of the app.

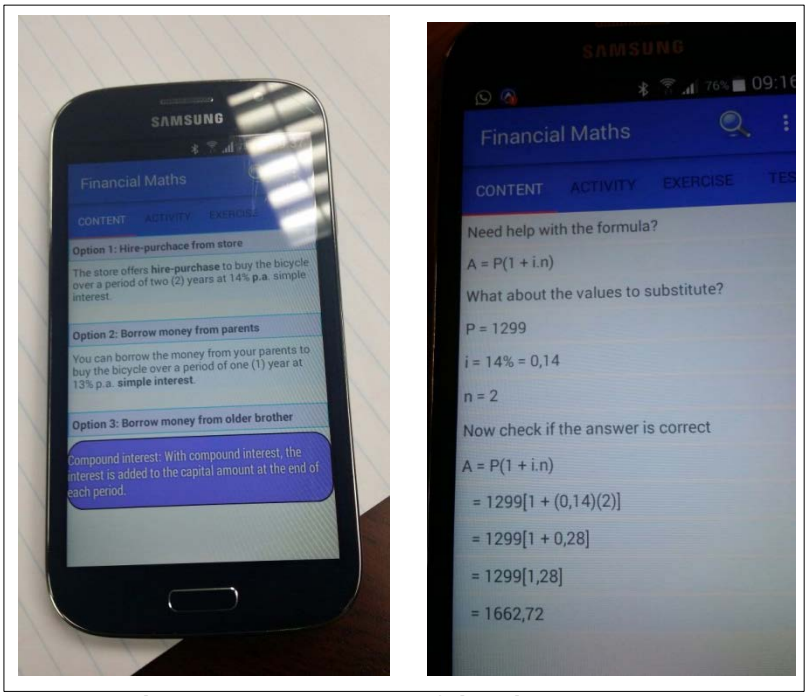


Figure 5.3: Images of the First Prototype

My promoter and I met with the programmer once the first prototype was designed. We discussed further expansion of the app and looked at possibilities that were viable within the parameters of the study. These factors were also discussed with the assistant promoter, who gave guidance particularly in the areas of the mathematical content and the principles and characteristics of the RME approach. After this discussion, I edited and extended the app design document for the further development of the app. A third meeting was arranged between the other three experts involved in the design of the app. At this meeting the second prototype was presented and discussed. The assistant promoter also provided input and feedback on the second prototype. Plomp (2007, p. 15) states that experts or users can be involved in the testing of the prototypes. In this case the first and second prototypes were tested by the promoters, me and the programmer.

The final evaluation and reflection stage forms the third step of the design-based research process (Figure 2.6). This involves iterative cycles of refinement of solutions that are implemented in practice (Amiel & Reeves, 2008, p. 34). To refine the app further, I asked an RME expert, who is extensively experienced and qualified in both Mathematics and Mathematics education to evaluate the third prototype of the app with the specific focus on the inclusion of the RME principles and characteristics. His evaluation revealed that the principles and characteristics were sufficiently included in the app. He further added that the app should achieve the purpose for which it was created, which is to assist teacher-students with making the teaching and learning of Mathematics more realistic for their learners. He suggested that the app be tested before being released for the teacher-students to use.

This suggestion was followed up and duly done—the app was further tested by two Mathematics education experts. Their main suggestion to improve the app was to expand on the initial problem situation, and make it more understandable to the user:

Put something in that sets the scenario more clearly. The start of the app is too vague.

Their evaluation also reinforced the need to create the app and confirmed its suitability for teacher-students:

> *It works very well because all the steps are clearly shown. It will help the teachers to teach their learners to follow logical steps in their calculations.*

The app included an activity that clearly showed the intertwining of the concepts of compound and simple interest, a key characteristic of RME (Widjaja & Heck, 2003). The Mathematics education experts found this appropriate and necessary:

> *I like this very much. By including this comparison of concepts you can see wow, it's quicker to use the compound interest formula, and yet you still get the same answer as when repeating the simple interest formula.*

The experts also suggested that the app be extended to other content areas and that it be made available to a wider range of teachers.

When designing the app, the principles and characteristics of RME played an essential role. As was discussed in detail in Chapter Three, the five characteristics of RME are: i) the use of contextual problems; ii) the use of models; iii) the use of student contribution; iv) interactivity (between pupil and between pupils and teacher); and v) intertwining of learning strands.

The context was selected so that it was meaningful and natural to the students. As is illustrated in Figure 5.4, in the app in the section on the content, the scenario of a school girl or boy who wants to buy a bicycle to attend sport practice was used as it is a common and natural phenomenon to school children.

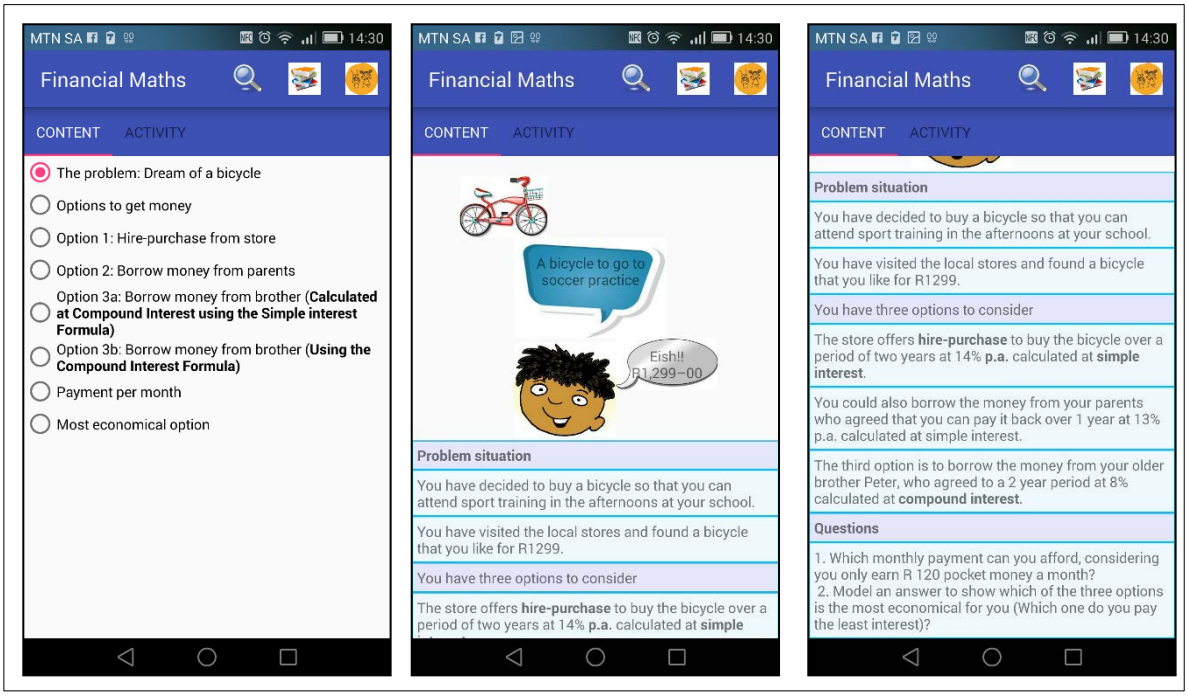

Figure 5.4: A Meaningful and Natural Context is Created

The context should allow students to develop intuitive notions that form the foundation of the concept (Stols, 2012). The authentic purchase option for the bicycle allows the students to establish and expand on the concept of Financial Mathematics. As Widjaja and Heck (2003) state (§ 3.3.2), the context should be the anchor for the formation and development of concepts. As Figure 5.5 illustrates, from the given context, the concepts of simple interest and compound interest develop in a natural manner.

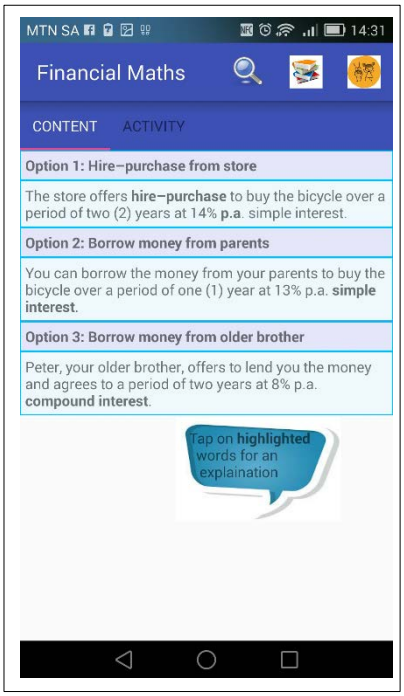

Figure 5.5: Simple Interest and Compound Interest Develop in a Natural Manner

The use of models is encouraged in RME (§ 3.3.2). Models in the form of equations (Figure 5.6) are used in this task and students are also asked to model an answer when comparing the three options for the loan. They are encouraged to use any type of model and are then given information to establish if their model contains the correct information.

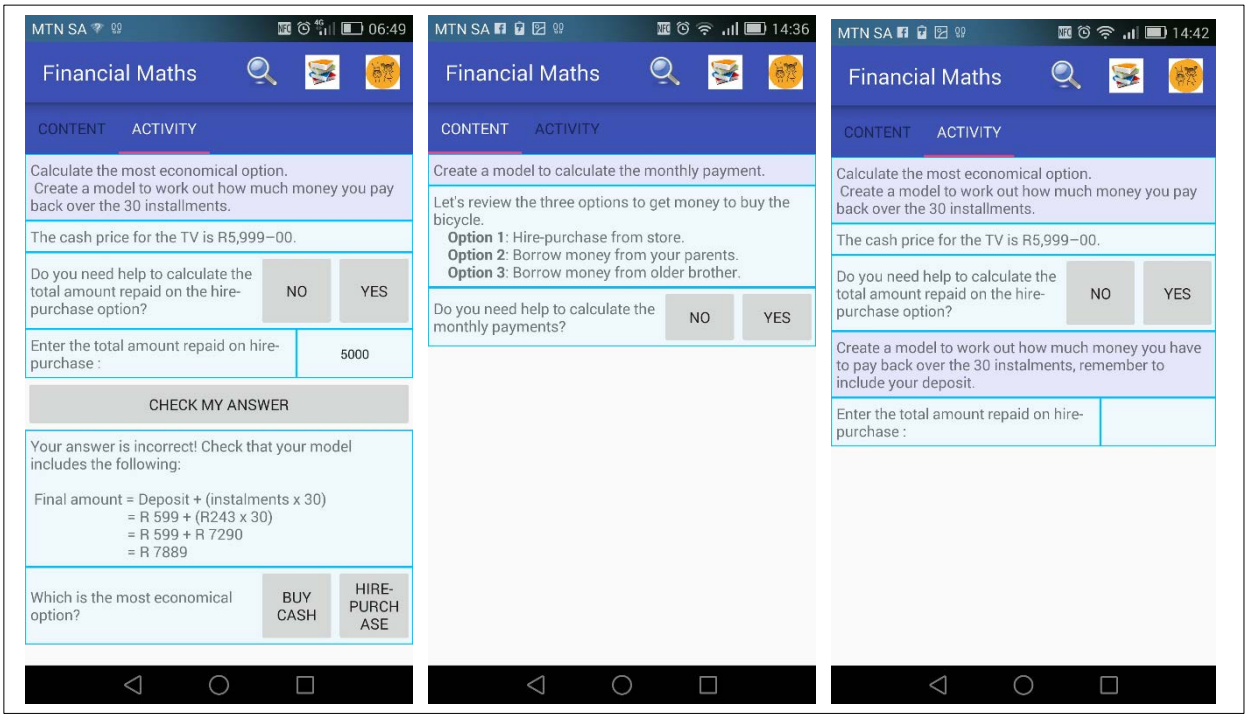

Figure 5.6: The Use of Models is Encouraged

The third characteristic of RME is that student contributions are encouraged. Technology assists in creating an environment in which learners can be actively involved, where they can discover, explore and visualise (Stols, 2012) (§ 3.4.2).

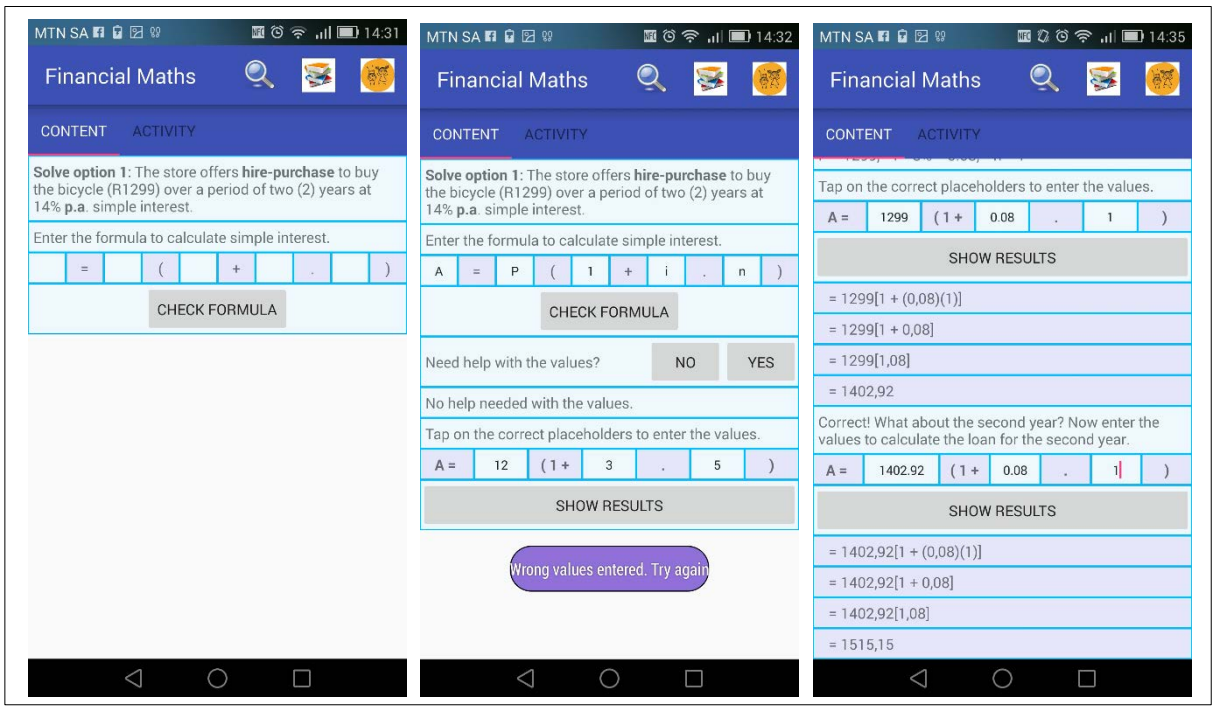

Figure 5.7: Student Contribution is Emphasised

Figure 5.7 illustrates that the app is designed with a strong emphasis on student contribution. Students are expected to enter their own values, do their own calculations and are then evaluated on

whether the solutions are correct or not. Figure 5.8 illustrates that guidance is given to redirect them if their solutions are incorrect, but otherwise they have the freedom to work on their own.

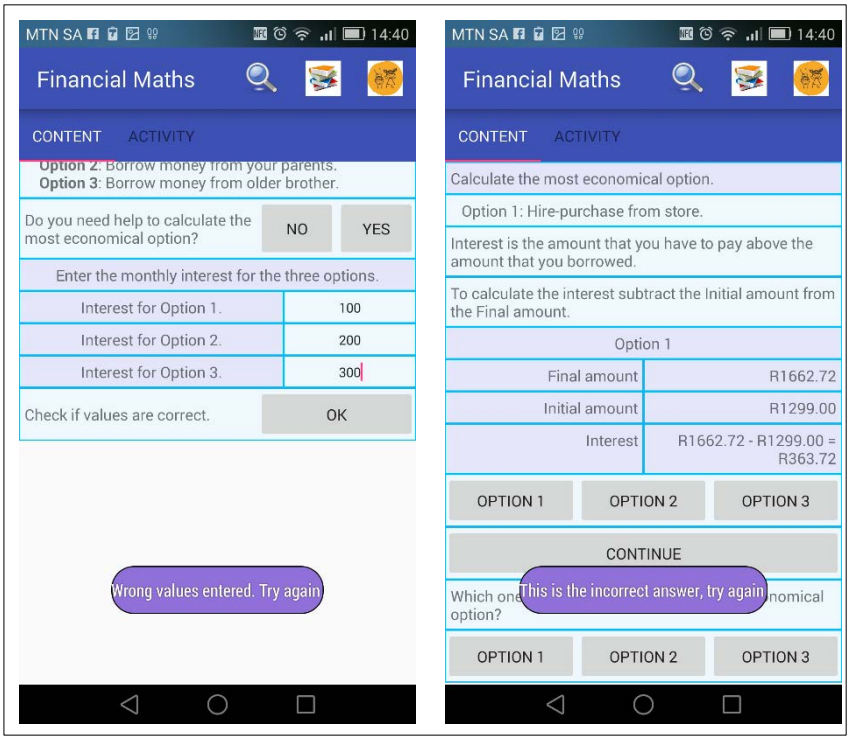

Figure 5.8: An Example of an Incorrect Entry

Since this app is used by teacher-students who are situated at various rural and urban areas in South Africa, interactivity is a challenging aspect to incorporate. During the activity in the app, teacher-students are given a task that requires of them to give advice as to the most economical option between buying a television for cash or on hire-purchase. After having an opportunity to model a solution and offer the most economical option, if their answer is incorrect, they are recommended to discuss these mathematical issues with a colleague. The screenshot on the left in Figure 5.9 illustrates this example. The screenshot on the right of Figure 5.9 indicates a situation where the answer was correctly calculated, but the teacher-students are given an opportunity to discuss possible reasons as to why that answer was correct.

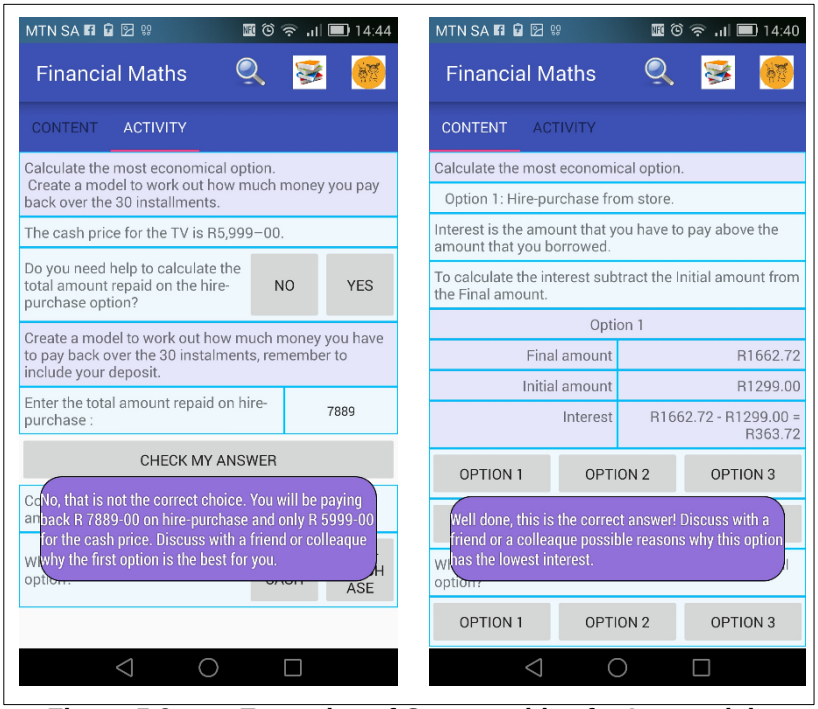

Figure 5.9: Examples of Opportunities for Interactivity

These examples allow for communication and collaboration with peers about the content presented in the app and activity. By discussing problem areas, it forces the teacher-students to reflect on the content, also a key principle of RME discussed by Widjaja and Heck (2003) in § 3.3.2. The aim of the app is to guide teacher-students on the implementation of the RME approach in their teaching. In a classroom situation the teacher-students will more easily be able to implement interactivity between themselves and the learners as well as between learners themselves.

The intertwining of learning strands is an essential part of RME. In this app, two types of integration have taken place. Firstly the content is integrated with a problem in the real world (Widjaja & Heck, 2003). Secondly the integration of the two concepts presented in the app is done by asking the teacher-students to calculate the compound interest option using the familiar formula for simple interest. This is illustrated in Figure 5.10. In so doing, the concepts are then presented alongside each other and the links and similarities, as well as the differences are highlighted.

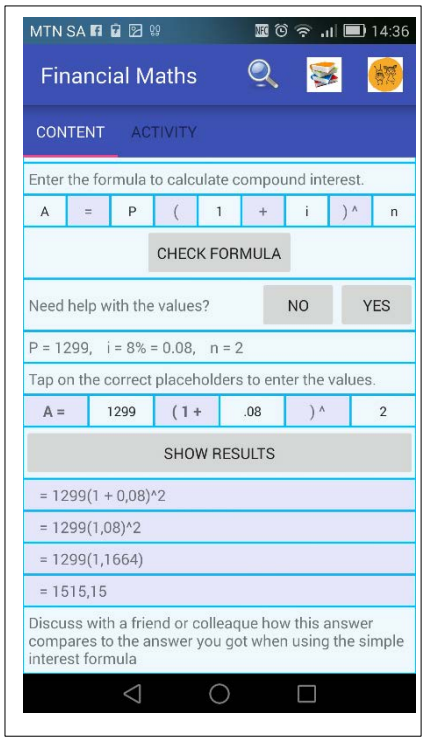

Figure 5.10: An Example of how Intertwining of Strands is Incorporated

A further area of connectivity is the link between the Financial Mathematics concepts and basic order in which operations are dealt with in Mathematics. In order to do correct calculations with the formulas, operations must be performed in the correct order to achieve the correct results.

Horizontal and vertical mathematization play an essential role in RME as is presented in § 3.3.3.2 with reference to the work of Treffers (1978) and Freudenthal (1991). In horizontal mathematization the student converts the problem situation into some form of Mathematics (Freudenthal, 1991). In the app, when teacher-students think about what formula to use, and what values to substitute, this conversion takes place. Vertical mathematization involves a higher level of abstraction within Mathematics, e.g. finding shortcuts and making connections between concepts (Freudenthal, 1991). Both these aspects are encouraged when teacher-students are asked to initially calculate the compound interest using repetition of the simple interest formula, and then compare that answer to the calculation done with the compound interest formula.

The process as suggested by Cahyono (2012) (§ 3.3.3.6) starts with a problem in the real world (the child wants to buy a bicycle to attend sport practice in the afternoons). The student will mathematize, reflect on the problem, do formalization (by using formulas and making comparisons) and then return to the real world (by solving the problem of which is the most economical option).

The principles of RME are discussed in detail in § 3.3.4 and include the following aspects: guided reinvention (otherwise known as progressive mathematization); emergent modelling and didactical phenomenology. These principles should be used in the design of tasks within the RME approach.

As suggested above, teacher-students are given the opportunity to develop their own Mathematics by inventing their own strategies to solve the problem. Should their strategy be incorrect, the app is designed in such a way that there is help if they require it, as can be seen in Figure 5.11. If they do not need help, they have freedom to solve the problem in their own way (Figure 5.11).

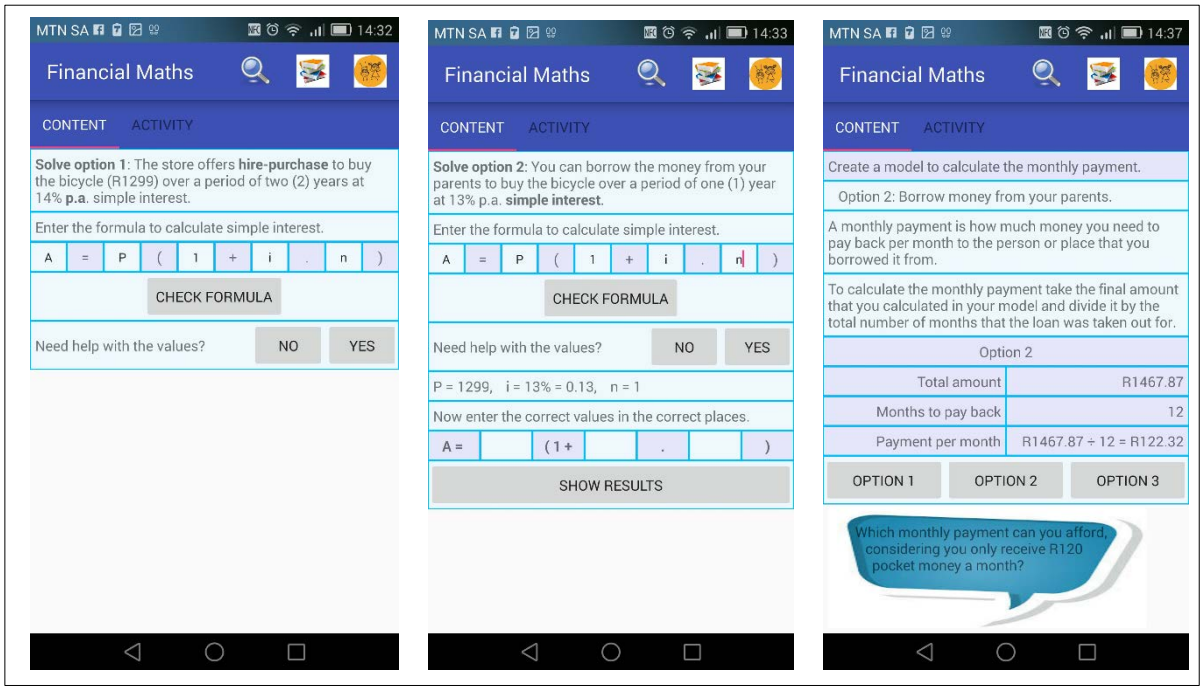

Figure 5.11: Assistance is Available Should Students Require It

This assistance is in line with the work of Drijvers et al. (2013) (§ 3.3.4.1) who suggests that the process requires guidance from the teacher to help direct the progression in a sensible manner.

Guided reinvention was touched upon in the discussion above about vertical and horizontal mathematization. Formal Mathematics develops out of the students' activities (Gravemeijer, 1999). The context plays an important role in the reinvention process. Students are not expected to reinvent everything themselves (Gravemeijer & Doorman, 1999) and it is essential that the teacher facilitates the teacher-students through the process. The hints and guidance in the app act as a means for me as the "teacher" to facilitate their progress. In Figure 5.12, I have illustrated two different hints that are available. The first screen indicates that certain terminology has been highlighted in the app. When teacher-students click on the bold words or terms, a definition or explanation of what the term means appears on the screen. The second screen illustrates a hint that appears when an incorrect calculation is made. The teacher-students are given guidance as to how the correct value can be calculated. As I mentioned in § 3.4.2, by providing hints and tips, teachers construct a trial and error approach which allows students to use different strategies to solve problems (Heck et al., 2008).

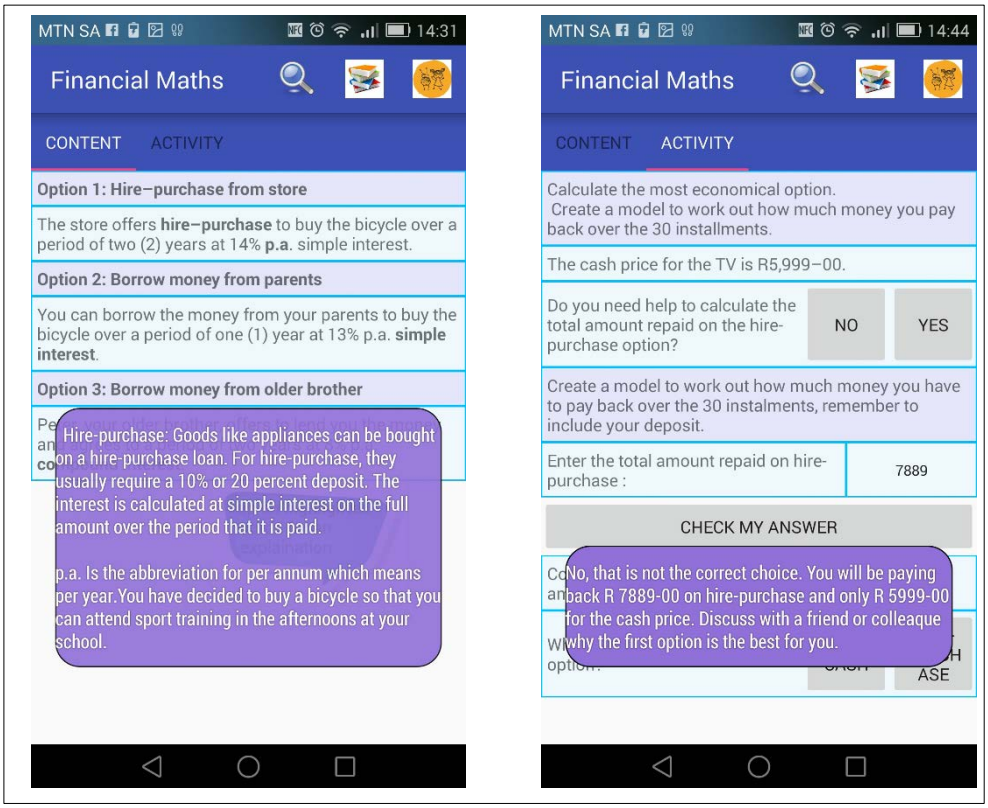

Figure 5.12: Hints relating to the Terminology and Calculations can be Accessed

In certain instances like in Figure 5.13 they are given three opportunities to make their own attempt at a problem, and only after three attempts, will there be any intervention in the form of a hint. This allows the teacher-students the opportunity to develop and try their own strategies first, before any intervention is offered, which is a key principle in RME.

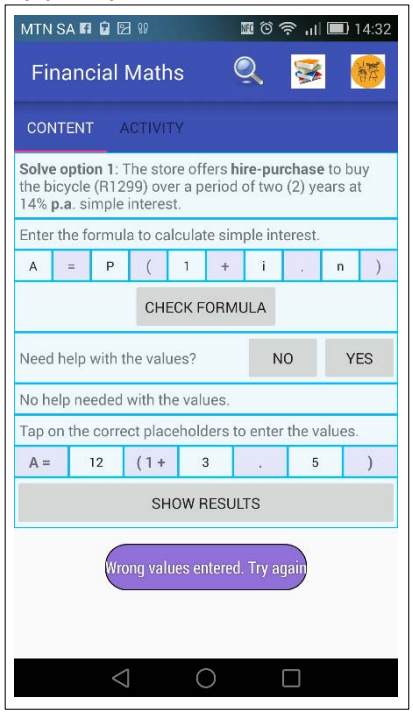

Figure 5.13: Three Opportunities are offered for Students' own Strategies

As Dolk et al. (2002) suggests, when training teachers, it is important that they experience mathematization and reinvention first handed when learning about the reinvention process. This was an important motivation for designing the app for teacher-students to use in order for them to learn about the RME approach and implement it in their classrooms.

In the discussion on guided reinvention in § 3.3.4.1, Drijvers (2013) points out that although ICT provides opportunities for reinvention, it may constrain students' prospects for exploration as a result of too much pre-planned guidance. I kept this in mind when designing the app and hence incorporated the prompts that first ask if the student needs help, rather than just offering the help, also allowing them three opportunities to offer a solution before any remediation or hints are given.

The second principle of RME is emergent modelling, which refers to the idea that models emerge from the activity of the students (Gravemeijer, 1999). The use of models is also discussed above as one of the characteristics of RME. An important aspect is that activities should be designed in such a way that students can shift from reasoning with models of informal activities to modelling of formal Mathematics (Bakker et al., 2003). I have tried to incorporate the modelling of informal activities through the use of the simple and compound interest formulas. In the activity, when teacher-students are asked to model an answer that would be the most economical purchase of a television, they have the opportunity to model the formal Mathematics. As discussed in § 3.3.4.2, models should be grounded in the context problems and not in intended Mathematics (Gravemeijer, 1999). In the app, the purpose of creating the model is to solve the problem in the given context, for example to give advice on which of the three options is the most economical when buying the bicycle, and also which option is the best when buying a television. The context demands the creation of the model, not the Mathematics.

The third principle of RME as was discussed in § 3.3.4.3 is didactical phenomenology. Meaningful phenomena that need to be structured and organised are presented to students and should be organised by the Mathematics (Drijvers, 2013). The phenomena of a person's personal finances, is the focus of the app. The scenario of buying a bicycle, and the choices offered when buying a television needs to be organised and structured with the aid of the mathematical content.

With reference to the aspects that should be considered in the design of Mathematics apps as suggested by Cayton-Hodges et al. (2015, p. 16) in § 5.3.2, I incorporated the following four aspects in the design process. Firstly, a rich and accurate representation of the mathematical content should be done. In the app I provided users with definitions of terms such as hire-purchase, simple interest, compound interest, the meaning of p.a.; I gave assistance with necessary simple and compound interest formulas and also made connections between different strands to reinforce the content. The second aspect discussed in § 5.3.2 was that the interactions around the content should be lavish and engaging. I provided numerous opportunities for the user to interact with the content at various levels.

I ensured that the user is constantly engaged by providing cues and links between screens and activities. When calculating the compound interest using the simple interest formula, I involve the users by saying the following: *Correct! What about the second year? Now enter the values to calculate the loan for the second year.* This is illustrated in Figure 5.14.

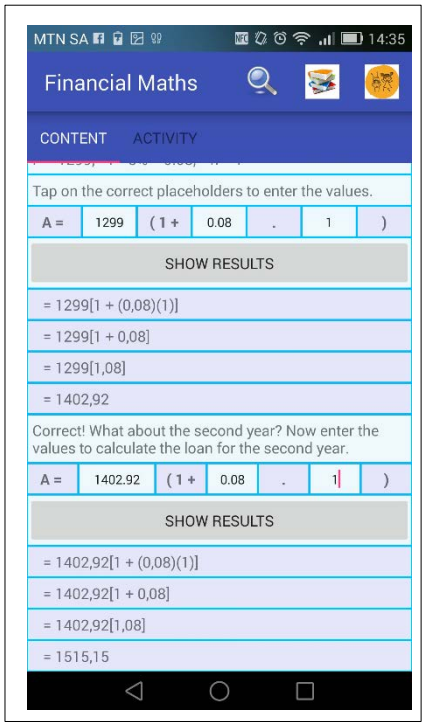

Figure 5.14: An Illustration of How Users are Encouraged to Engage with the Content

The third aspect discussed by Cayton-Hodges et al. (2015, p. 16) is that users should be given the opportunity to reflect on tasks. This aspect has also been incorporated in the Financial Mathematics app. In Figure 5.10, I encourage users to reflect on why two answers are the same and recommend that they discuss possibilities with a friend or colleague. Another example of this can be seen in the screenshot on the right of Figure 5.12, where users are again encouraged to reflect on a particular answer. The fourth aspect discussed in § 5.3.2 is that hints, scaffolds and other tools are important in the design of apps and that these should be presented on a need to know basis. Figure 5.11 and 5.12 both illustrate examples of hints and assistance that are available to the user, should they require these. The manner in which the app was structured and designed is evident of a process of scaffolding. Small portions of information and tasks are given one step at a time so that users can be guided through the process of learning the content and doing the activities.

5.5.2 The Technical Aspects of Creating the App

When creating the app, the design team followed nine distinct steps. Firstly, a clearly defined purpose of the mobile app was defined. This entailed a detailed exploration of what the app should be able to do; what its primary appeal would be; which concrete problem it would address; what aspect of life it

aimed to improve. I designed, re-evaluated and refined the design documents which sketched the standards, planning design, development and on-going evaluation of the project (Alessi & Trollip, 2001). The second step set the basis for the user interface. This entailed a visual conceptualisation of the main features as well as a rough layout and structure of the app. The designer created sketches of the proposed layout and structure of the app. Step three involved a search to establish if there were other similar apps available. This was necessary because there are over one million apps for Android and iOS already available. This search also assisted the designer with design inspiration for the Financial Mathematics app, and provided him with information on the technical requirements for the app. The designer downloaded three free analogous apps from the Google Play Store and studied their look and feel, and where applicable noted aspects that could be appropriate for the Financial Mathematics app.

In the fourth step, all the ideas and features came together as a clear picture of the prototype of the app. This process is known as wire framing (Lloyd & Dykes, 2011, p. 2501) and also entails the creation of a storyboard for the project. The storyboard provided a road map which illustrated the connections between the different screens and also how the user could navigate through the app. The result of the fourth step, the prototype and the storyboard, became the basis of the back-end structure for the fifth step. This step involved the sketching of the servers, app programming interface (APIs), and data diagrams as helpful references to the designer. These sketches provided self-explanatory diagrams that all could follow during the project. Step five also included modifications to the prototype and storyboard according to technical limitations. Because of the limited size of the app, no additional modifications to the prototype and storyboard were necessary.

The sixth step was an essential one. Friends, family, colleagues and experts were approached to review the prototype. They were requested to test the app and give feedback and identify flaws and dead-end links. Based on this feedback, the app was modified. This review step was done to finally specify the app concept before going into the design process. At this point I tested the app with the RME expert and two colleagues, who are Mathematics education experts (§ 5.5.1).

In step seven, individual screens were designed. The task was to create high-resolution versions of the prototype. Here, the designer included all comments from the prototype testers, so that the optimal user interface could be designed. Upon completion and implementation of the individual screens, the actual app concept was complete. All the graphics were inserted and I signed off on all text. The actual design was now implemented and made clickable. Step eight was to test the full design again and collect as much feedback from a variety of users. These new ideas and suggestions were used to refine the app. The designer effected the last changes to the layout.

The final step ensured that there was a consistent look and feel to the layout, and that it would perform reliably on different devices. The Financial Mathematics app was installed on various android devices

and was tested for functionality in a live environment. The final completed product was uploaded to Google Play Store and made available for the teacher-students to utilise and examine further.

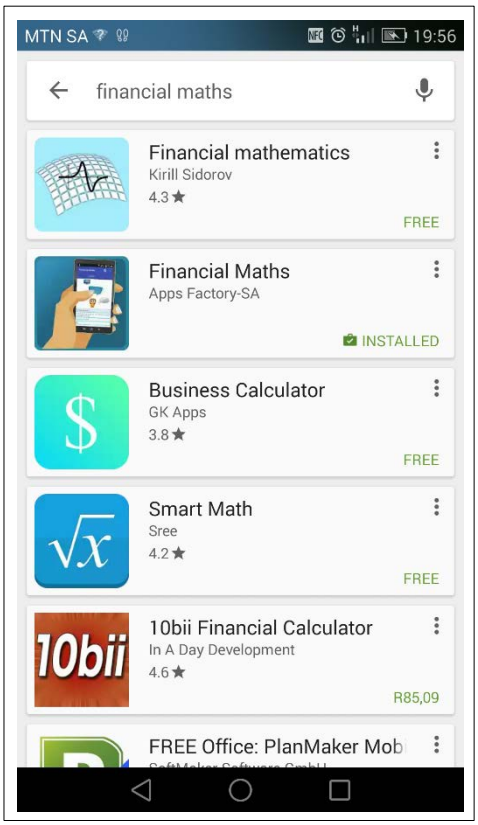

Figure 5.15: Illustration of the App in Google Play Store

Figure 5.15 illustrates the app which is available for free in Google Play Store. The app in question is the second from the top in the illustration. The next phase of this process was to present the completed app to the teacher-students in order to establish their experiences, perceptions and feedback regarding the app.

The nine steps that the design team followed in designing the Financial Mathematics app are loosely based on the framework that Lee and Kautz (2015, p. 577) suggest for the design and implementation of mathematical tasks in mLearning environments (§ 5.3.2).

Table 5.1: Comparison of the steps used in designing the Financial Mathematics app with the Design Framework of Lee and Kautz (2015, p. 577)

Design and implementation framework as suggested by Lee and Kautz (2015, p. 577)	Design and implementation steps of the Financial Mathematics app
Define Lesson Objective	1. A clearly defined purpose for the app was designed.
Define technological environment	2. A visual conceptualisation of the main features as well as a rough layout and structure of the app was designed. 3. A search was done to establish if there were other similar apps available.
Define types of investigations	4. Wire framing and the creation of a storyboard for the project.
Design and develop task(s)	5. The servers, app programming interface (APIs), and data diagrams were sketched. Modifications to the prototype and storyboard were done.

Design and implementation framework as suggested by Lee and Kautz (2015, p. 577)	Design and implementation steps of the Financial Mathematics app
	6. The review of the prototype by various parties. 7. Individual screens were designed.
Implementation	8. Testing of the full design again. As much feedback as possible from a variety of users was collected. 9. Ensuring a consistent look and feel of the layout, and that the app would perform reliably on different devices.
Enactment	The app was presented to the teacher-students for their feedback and perceptions.

Table 5.1 illustrates how the steps that were followed in the design process for this study was based on the design framework of (Lee & Kautz, 2015, p. 577).

The paper entitled *Design of a prototype Mobile Application to make mathematics education more realistic* written by the programmer, myself and my promoter underwent a peer review process and has been accepted for the proceedings of the 13th International Conference of Mobile Learning in Budapest from 10 -12 April 2017. The paper is available at Addendum 5.2.

5.6 Chapter Summary

This chapter presented a discussion of why a mobile app was suitable for this study and went on to sketch the background of what mLearning is. The associations between the use of technology and the RME approach were also presented. The chapter further explored the context of the teacher-students for which the app was designed. A detailed discussion of the process that was employed to design and test the app followed. In this discussion the theoretical aspects of the design were discussed: the various phases of design were discussed; the creation of the different prototypes was explored as well as the testing of the app; how the design of the app was related to the principles and characteristics of RME; as well as the technical aspects that were followed to design the app. In Chapter Six, the data generated from the focus group interviews were analysed. Teacher-students were introduced to the app and their evaluation and perceptions of the app were analysed in the following chapter.

As was discussed in § 2.4, throughout each stage of a design-based research project, researchers will reflect and document aspects to produce scientific output in the form of theories or design principles (Plomp, 2007, p. 15). As is illustrated in Figure 2.6, upon completion of the design, development and formative evaluation phase, I have produced a number of design principles relating to that design phase. The design process led to the awareness of a number of principles that were followed in the design process. These principles are presented in Table 5.2.

Table 5.2 Design Principles for the Design of a Mobile App Based on the Principles of RME Derived from the Design Process

Aspect	Implications
Thorough planning of the app	• A detailed design document should be created • The problem situation should be clearly sketched • The purpose of the app must be clearly defined from the start
Rigorous testing of the app throughout the design process	• The different prototypes should be rigorously tested by a range of parties (novices and experts)
The principles and characteristics of RME should be included	• The intertwining of concepts and strands should be incorporated • Relevant contextual problems must be used • The use of models ought to be encouraged • User interaction with the app and contributions should be encouraged • Users ought to be given the opportunity to invent their own strategies to solve problems
Pedagogical Aspects	• Mathematics content should be rich and accurately presented • Interactions with the content should be engaging • Users must be given the opportunity to reflect on tasks • Hints and scaffolds should be incorporated and used on request

Chapter Six

Participants' Observations and Experiences of the Mobile App

6.1 Introduction

In this chapter I report on the analysis of the data obtained from the focus group interviews. Ultimately I aim to produce guidelines for the effective use of technology in implementing the principles of RME in teaching practice. In order to create these guidelines, I need to establish how the participants' experienced using the app and what observations they made about the app. After having gained insight into the existing literature regarding the use of the RME approach assisted by technology in Mathematics education in the systematic literature review (Chapter Three) as well as by establishing the needs expressed by the participants in terms of applying the principles of this approach in their teaching (Chapter Four), I, together with a design team, designed a mobile app for the topic of Financial Mathematics. In the design of this app I took into account all aspects previously explored in the existing literature and needs analysis of the participants to create a suitable and rewarding intervention tool that could aid the participants of this study as well as other teacher-students in future to make their teaching of Mathematics more realistic.

The next stage of this study was to effectively produce the required guidelines that would answer the third research question: *What are the guidelines for the effective use of technology in implementing the RME approach in teaching practice*? In order to proceed to this stage, it was necessary for me to again meet with participants and present them with the completed app. Then I had to establish how they experienced that app, determine their observations about the app and take note of any critique they had to offer about the app. The plan to gain this information was to arrange a focus group interview with all four participants. However, it was not possible for one of the participants to meet with the other participants due to logistical reasons. I therefore decided to divide the group in two and have two focus group interviews. In each focus group interview, there were two participants and myself, who acted as the interviewer. I designed an interview schedule (Addendum 2.8) which was loosely based on the main themes of the systematic literature review. The focus group interviews took place in my office at the Potchefstroom Campus of the North-West University. I paid for the travel expenses of each student and provided them with refreshments to ensure that they were comfortable and that I did not cause them any inconvenience. These meetings took place outside of school hours, and did not disrupt the participants' teaching programme in any way.

I transcribed the recordings of the focus group interviews with the aid of ATLAS.ti™ (ATLAS.ti, 2014). As with the individual interviews, data were again coded in the same HU as the systematic literature review in ATLAS.ti™. I therefore used the existing codes and created three additional codes in order to code and categorise the focus group interviews as part of an integrated HU. The detailed

codebook was discussed in Table 2.6 (§ 2.6.5). I extended the codebook with three additional codes, which are presented in Table 6.1.

Table 6.1 Extension of the Codebook Table

Code	Description	Example
Usability of the app	Any comments made by the participants regarding the usefulness and ease of use of the app.	"The app helps to make the lesson more interesting" (P62:51).
Positive aspects of app	Any positive aspect that the participants raised in relation to the design, implementation or usability of the app.	"It is also going to motivate the ones who didn't get the correct solution" (P65:7).
Suggestions to improve app	Any suggestions that the participants had with regard to improving the app in relation to content or technical aspects.	"Maybe you consider specific topics for the slower learners, for those who are willing to learn you can give them more advanced content" (P65:22).

As with the individual interview data, the five themes that the systematic literature review revealed also formed the foundation of the structure for the analysis of the focus group interviews. As in Chapter Four, the four main themes used in this chapter were: Mathematics, RME, ICT and role players. I refined the themes further to suit the focus group interview data as: observations of the app in terms of Mathematics; the facets of RME observed in the app; considerations and ideas about ICT; and role players in the given context. Since the focus group interviews also focused on the evaluation of the app, I added the following theme: suggestions relating to the app. Figure 6.1 depicts the network view of the coding structure and themes that were used in the data set.

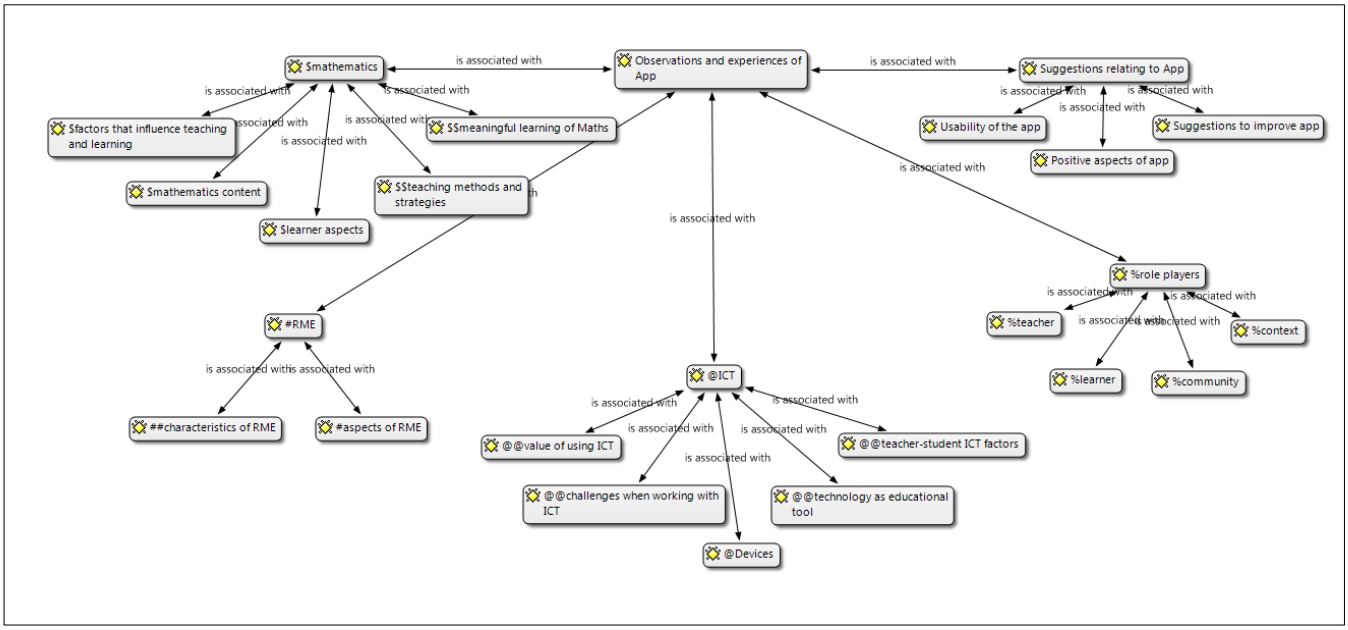

Figure 6.1: The Coding Structure for the Needs Analysis Individual Interviews

The themes as discussed above and a more refined structure for the analysis that follows in this chapter are presented in Figure 6.2.

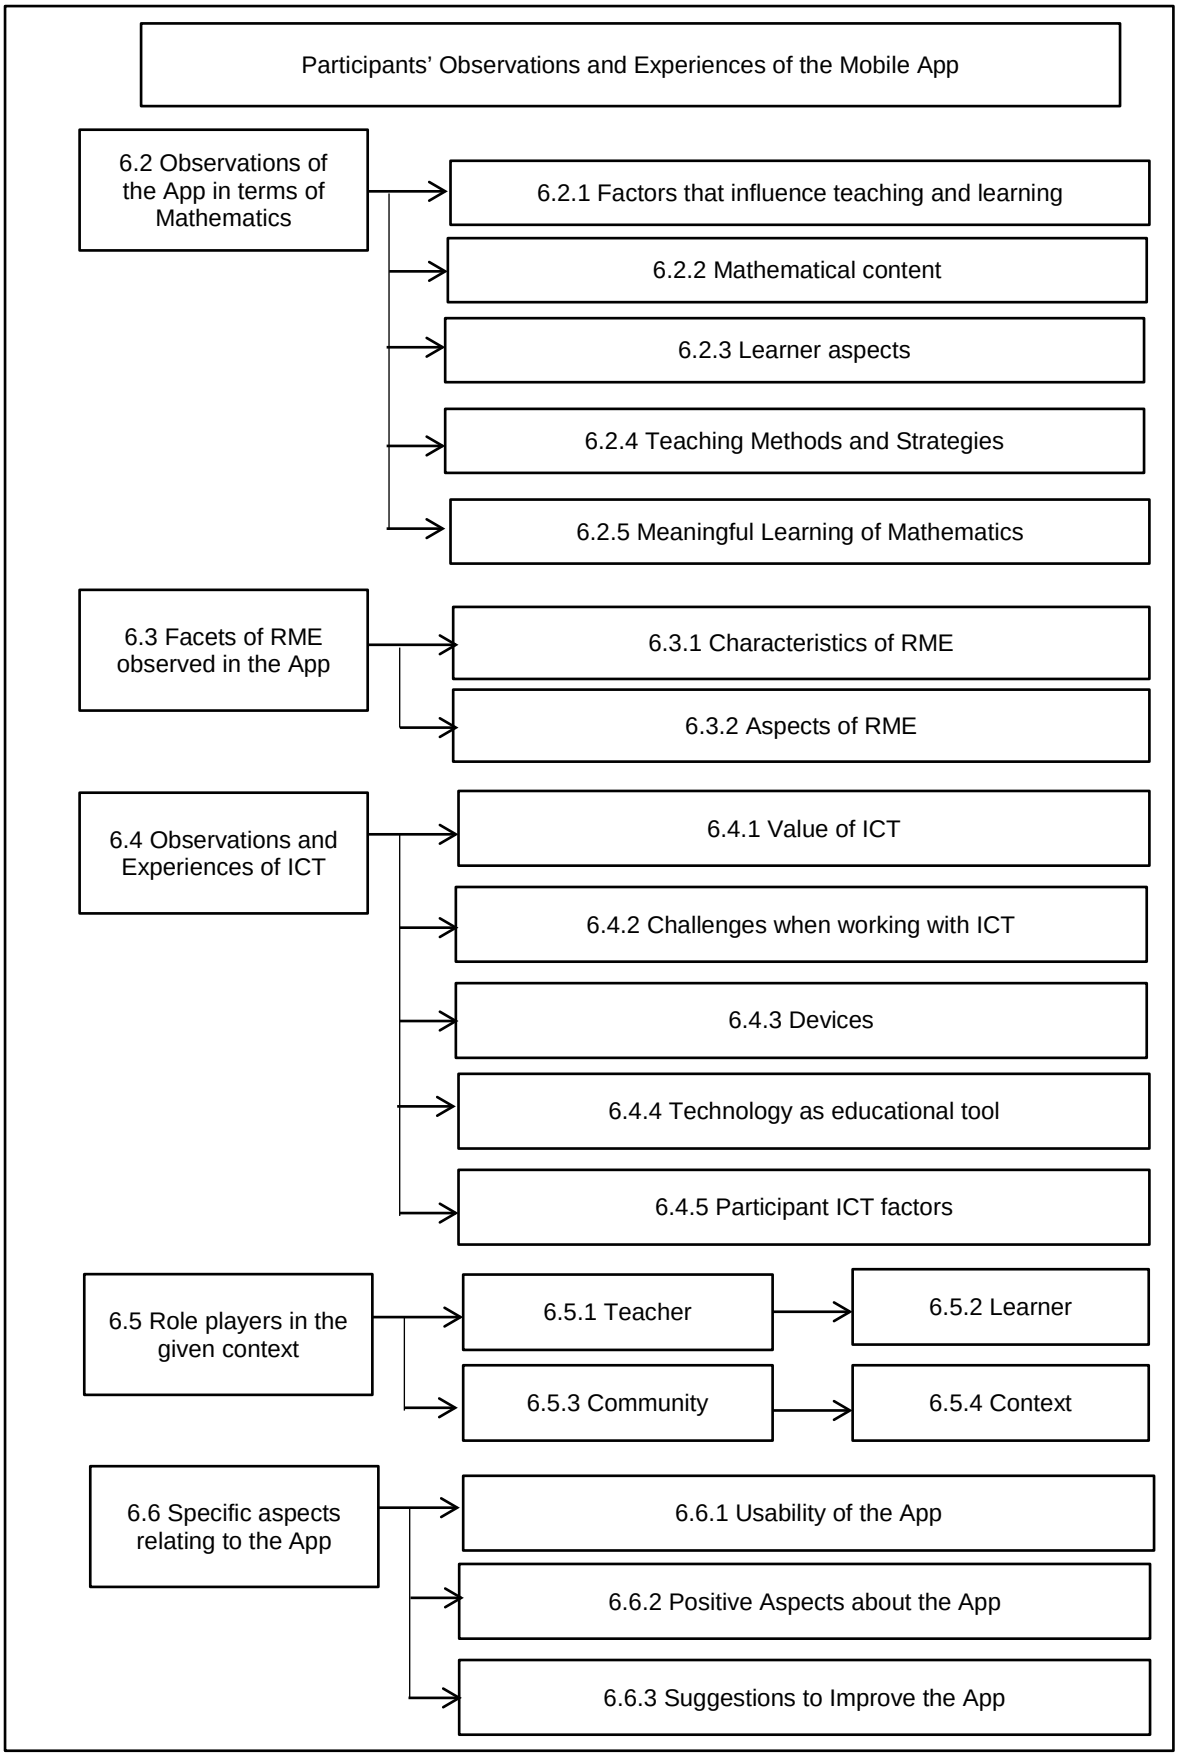

Figure 6.2: Advance Organiser of the Main Themes for the Analysis

6.2 Observations of the App in terms of Mathematics

There were five sub-themes that materialized within this theme, namely factors that influence teaching and learning; Mathematics content; learner aspects; teaching methods and strategies; and meaningful learning of Mathematics. Figure 6.3 displays the categories for the observations that the participants made in terms of Mathematics.

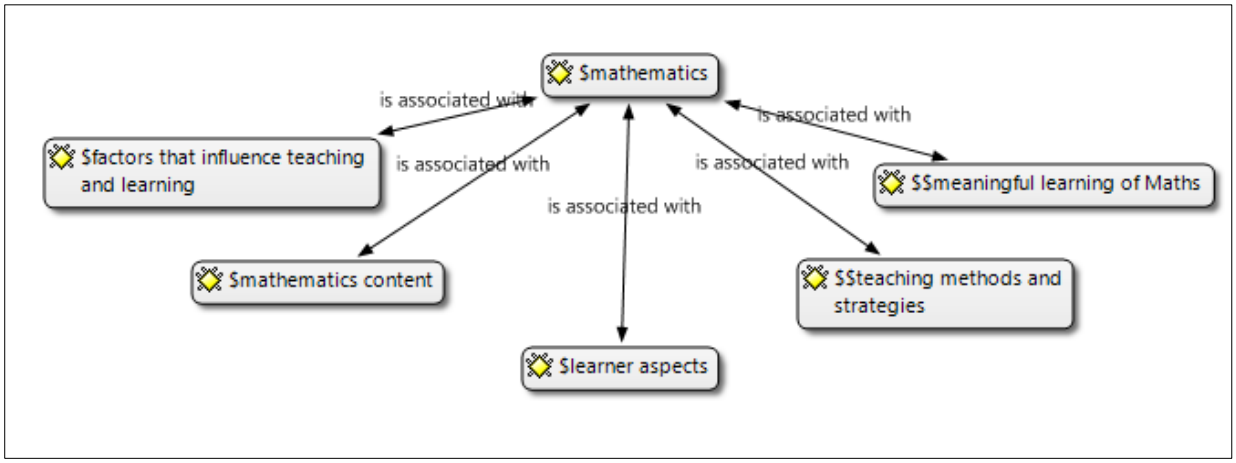

Figure 6.3: Coding Structure for the Participants' Observations of the App in terms of Mathematics

6.2.1 Factors that Influence Teaching and Learning

As discussed in § 4.2.1, immediate feedback is not only an essential aspect of effective teaching and learning, but was also an aspect that the participants found to be important for their learners. The participants reported that the app provided immediate feedback to the user:

> *And also the feedback—they will get immediate feedback. In the end it will help them to correct their sums. If they are getting it wrong, it will tell them— this is wrong. This is going to help the teacher in the class—getting feedback immediately. Even time is not going to be wasted (P65:19-20).*

> *I think it is good. I also think that it is going to challenge the users. Especially the part where they can choose if they want help or not. Most of them will choose the no[2]—they do not ask for help, but if they get it wrong, they will get feedback immediately from the app. Those slower ones will go for the yes. As time goes on, they will improve and will opt for the no. And then they will keep on improving (P65:2).*

In the systematic literature review (§ 3.2.1), it was also established that motivation can increase due to three factors: digital assignments; diagnostic testing; and the use of real life contexts. This was confirmed by the participants who said that:

> *The teachers and learners will be motivated to use this app (P62:22).*

> *There will be those that are so motivated by the app that they will just improve (P62:54).*

> *The first ones who have done a solution and find the solution to be correct, they will boast to the others who did not find a solution (P65:6).*

[2] "No" refers to clickable icons in the app where users are given the option to get help with formulas, values and methods or not. When users click on "No" it indicates that they do not need help. When they click on "Yes" it indicates that they do want help. In this case help is provided.

It will help them (P62:38).

They will love it! (P62:23).

When asked how they would use the app to improve teaching practice, the response was:

At any time when they feel like using it, while revising they can just use it (P62:37).

Those who are lazy to write and those whose handwriting is horrible—the app can help—it cuts all of that out (P62:52).

Those brighter ones will go for the no, they will want to do it for themselves. The slower learners will go for the yes, for the help. As time goes on they will also want to go for the no. So you are catering for both (P65:4).

It will also help those who battle to read. It will also improve their reading skills if they can hear and see at the same time (P65:41).

As discussed in § 3.2.1, technology allows learners to work creatively (Zaranis et al., 2013) and, when used correctly, improves problem solving skills and promotes critical thinking (Stols, 2012).

6.2.2 Mathematical Content

One of the participants raised an important issue in Mathematics education and that is mathematical content knowledge:

Based on the needs for the content, we must acquaint ourselves first with the content before we can use it here (P62:18).

Content knowledge is an essential component of what Ball et al. (2008, p. 395) refer to as mathematical knowledge for teaching (MKT). They define this as the "mathematical knowledge needed to carry out the work of teaching mathematics." Of relevance in this study as well is the incorporation of the teacher-students' knowledge of technology, as described by Mishra and Koehler (2006) in the TPACK framework (§ 1.3.1).

Further to the discussion on mathematical content, I asked the participants which sections of the curriculum they thought might benefit the most from an app such as this one. Their responses were: Calculus, Financial Maths, Probability, Geometry (specific mention was made of the theorem of Pythagoras), data handling, and graphs. The participants summarised it as follows:

The only one that will suffer will be Algebra. But the rest, even number patterns will be fine (P62:39).

Any section would be suitable (P65:35).

6.2.3 Learner Aspects

The theory of RME revolves around the construction of knowledge (Gravemeijer, 1999). Teachers should be sensitive to where their learners are (§ 3.2.7) and should design activities accordingly to provide them with the opportunity of constructing knowledge (Kizito, 2012a). Participants shared their ideas on how the app can meet the varying needs of different learners in the Mathematics classroom:

The weaker learners can be able to do it. If they can't then they click on the icon for help. It helps the weaker learners (P62:13).

There are learners who are so shy when they are in class they can work comfortably when they are alone. I think this will be so helpful especially for the weaker learners (P62:14).

A more advanced learner can do even more work. A slow learner you can give them more time (P65:21).

In this way you can attend to individual learners (P62:2).

The demotivated learners will also be motivated (P62:25).

It is also going to motivate the ones who didn't get the correct solution and even improve the pace at which they work (P65:7).

6.2.4 Teaching Methods and Strategies

Models come in many forms and are more than a visual representation of abstract Mathematics (Boon, 2006) (§ 3.2.5.1). Modelling ideas can be done in the form of words, diagrams and formulas (Muthen & Khoo, 1998). Participants discussed challenges they experienced with their learners with regard to the use of formulas:

So, you can even ask for the formula. Because sometimes they struggle to know which formula they should use (P62:3).

6.2.5 Meaningful Learning of Mathematics

As discussed in § 3.2.5.2, the RME approach can contribute towards a positive classroom climate (Fauzan et al., 2013). Participants mentioned the possibility of healthy competition between users when working with the app:

In fact there will be a competition (P65:5).

This endorses what was discussed in § 3.2.4 which says that one way in which meaningful learning can be encouraged is through playing games (Zaranis et al., 2013). Another participant said the following:

They like technology. They like to use cell phones. It's like playing games—they like playing games, wherever they are they play games. This is like playing a game (P62:25).

Participants suggested ways in which the app could contribute in their teaching:

My school has tablets and in my grade twelve Maths classes there are only twenty one learners, I am going to download the app to help them. What I like most is that the users can work on the Maths at home (P62:49).

This app can help with very large classes (P62:50).

When asked how this app can assist teachers to teach Mathematics in a meaningful way, the response was:

It can. It can. As a teacher...because each and every teacher wants their learners to be involved. You can get them involved if they have got this. You can communicate with them through this (P62:12).

6.3 Facets of Realistic Mathematics Education Observed in the Mobile App

The characteristics, principles and aspects of RME have featured strongly throughout this study. In the focus group interviews, participants also divulged their ideas on which facets of RME were apparent in the app. This theme was discussion with the sub-themes of characteristics and aspects of RME. Figure 6.4 illustrates the coding structure for this discussion.

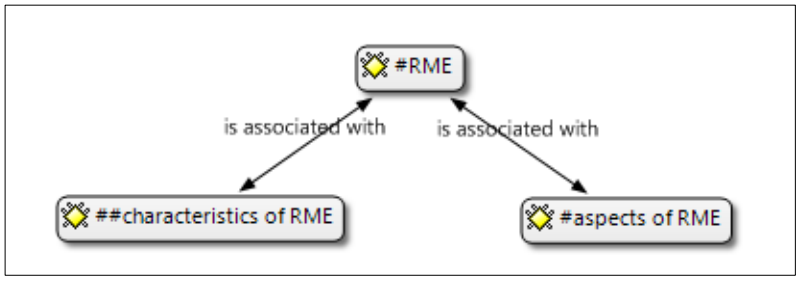

Figure 6.4: Coding Structure for the Facets of Realistic Mathematics Education Observed in the Mobile App

6.3.1 Characteristics of Realistic Mathematics Education

In § 3.3.2, I discussed the characteristics of RME in detail. These included: the use of contextual problems; the use of models; the use of student contribution; interactivity and intertwining of learning strands (Drijvers & Doorman, 1996). One of the questions in the focus group interview schedule was: *How does this app address the principles and characteristics of RME?* The participants shared their views of the characteristics of RME that they noticed in the app:

> *The topics are intertwined. They can bring topics together. They can see how this one is intertwined with the next topic (P62:11).*
>
> *And they are actively involved (P62:11).*
>
> *There will be collaboration, when they are together. They will ask each other: Who has done the sum first? (P65:17).*
>
> *I think all the characteristics of RME are there. There is collaboration; users will be actively involved for sure—they are doing it themselves. Intertwining of strands is there: like with simple and compound interest—showing that you can use simple interest to get to the compound interest formula (P65:18).*

6.3.2 Aspects of Realistic Mathematics Education

The emphasis on real life situations has been discussed throughout this study (Gravemeijer & Doorman, 1999). When evaluating the app, the participants also noted the link to real life:

> *You can do Maths with something that they know—make it real life (P65:46).*

The second aspect of RME that forms one of the cornerstones of the approach is that Mathematics is a human activity (Freudenthal, 1971). This aspect was discussed in detail in § 3.3.3.1. Participants shared their ideas on this aspect:

> *Anywhere, in a taxi, in a bus—wherever they are, they can do Maths (P65:10).*

6.4 Participants' Observations and Experiences of Information and Communication Technology in the Mobile App

In this section I will discuss the participants' observations and experiences of ICT in the mobile app. The five main themes are the same as those discussed in Chapter Four. These include: the value of ICT; challenges when working with ICT; the use of various devices; technology used as an educational tool; and factors of ICT that relate to the participants. Figure 6.5 illustrates the network view of the coding structure for the participants' observations and experiences of ICT in the app.

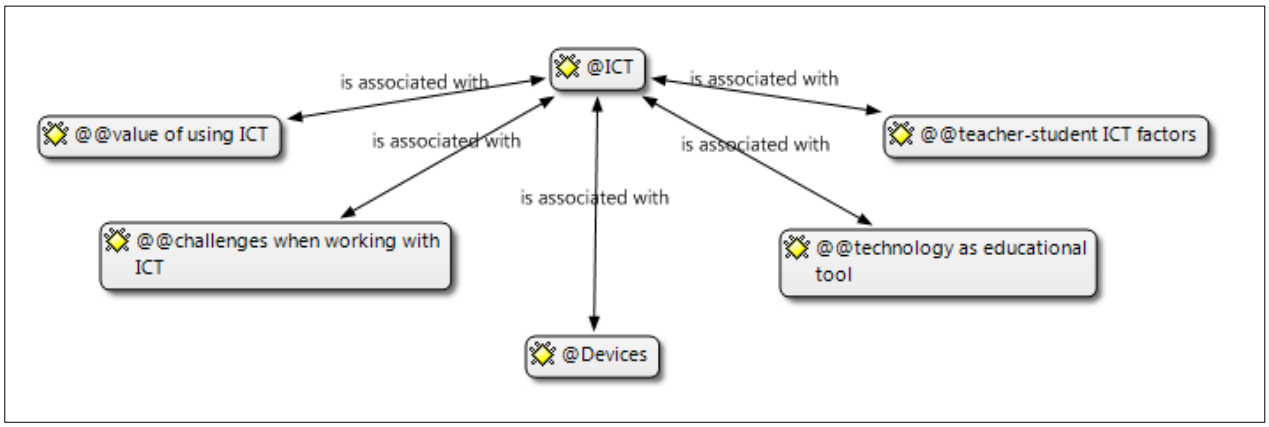

Figure 6.5: Coding Structure for the Participants' Observations and Experiences of Information and Communication Technology in the Mobile App

6.4.1 The Value of Using Information and Communication Technology

The systematic literature review detailed the value of using ICT in education (§ 3.4.1). More specifically, the benefits of mobile technology were discussed in § 5.3.1. Progressively more educators are using mobile technology for increased learner engagement; interaction and collaboration among peers; and as an extended time and place for learning (Kiger, Herro, & Prunty, 2012, p. 62). Participants also identified the value of using the app on a mobile device:

> *Because it gives the user a chance to do Mathematics anywhere, anytime. They will get immediate feedback (P65:9).*
>
> *Rather than going home, having to take out books and then learning—it can be done anywhere at any time (P65:10).*
>
> *They can afford to buy cell phones rather than computers. Even though that can't afford to buy computers they can buy cell phones (P62:8).*
>
> *It's more accessible to them and it's easy to carry, where they are and while they are relaxing they can learn while you are sitting outside (P62:9).*

6.4.2 Challenges while Working with Information and Communication Technology

Technology has proved to be a suitable way to facilitate RME in teaching Mathematics (§ 3.4.5), however, there are challenges when integrating ICT with the principles of RME (Drijvers et al., 2013). One of the recommendation in the work of Kizito (2012a) was that future studies should make use of

interviews to explore students' perceptions of mobile technology (§ 3.4.6). Participants in the current study were given the opportunity to express their views on mobile technology in two separate interviews. They discussed challenges they perceived when working with the mobile app:

> *It's a challenge for some teachers. The teachers must know how to download it. Without downloading it, I will be stuck (P62:16-17).*
>
> *To manage time can be a problem. If the users are used to doing Maths on the technology and they now have to write it out they will not know how much time they should spend on each question (P62:53).*
>
> *I think it would limit their basic skills—those learners will not have the basic Mathematics skill like calculating. When it comes to exam time, they will not be able to use this. They will use paper-and-pencil. If they are used to the technology—it can be a problem for them to write exams with paper-and-pencil (P65:48).*
>
> *I don't think they should only use this—in the end they should also write something. So, one should create opportunities for them to answer questions on paper-and-pencil as well—after learning the content, maybe use worksheets where they get to do the sums on paper (P65:49).*

In the last quotation above, participants expressed the concern of becoming too reliant on the app, and that written activities should also be incorporated into a lesson. This issue was also raised in § 3.4.6 where Zaranis (2014b) warns against tool dependency.

6.4.3 Devices

Various aspects of mLearning in Mathematics were discussed in § 5.3.2. One important aspect is that mLearning creates new opportunities for learning in Mathematics (Graven, 2011, p. 45). Participants mentioned their observations about various devices, particularly mobile devices in their contexts:

> *This generation like using these devices. They are interested in using cell phone, tablets. It will capture their minds. So they are focused, they will be focused (P65:34).*
>
> *Cell phones, there are many. Let's say more than 90% of them they have cell phones (P62:7).*

6.4.4 Technology as an Educational Tool

Mobile technologies such as the mobile phone and tablet computer have the potential to profoundly change how teaching and learning is conducted (Petocz & Manuguerra, 2011, p. 61). Mobile technology serves as an ideal means in which to facilitate change with regard to a new generation of students and their new ways of learning, yet offering the same content in new formats (Petocz & Manuguerra, 2011, p. 65). The participants in this study also saw the potential of mobile technology in teaching Mathematics:

> *They can teach themselves with this, while they are revising and doing this, they can check on themselves. Because the learners will be directly involved. They won't sit back and just listen to you saying everything. They will just type it in, rectify themselves. They are actively involved, and they can interact with others (P62:5-6).*

6.4.5 Participants' Information and Communication Technology factors

In the individual interviews, participants in general expressed their positive attitude towards working with technology in the Mathematics classroom. This stance was extended to the focus group interviews as well. Here it was also apparent that they felt that the Financial Mathematics app could aid the teaching process, and that users of the app would not have difficulty in navigating and using the technology:

> *I don't think the technology will hinder them. Let's take for example, all the Maths educators can use a calculator—so I don't think it will give them a problem. They will get used to smart phones. As long as they get used to using a calculator, they will get used to using the smart phone. Those educators that are not Maths educators, they struggle to work with a calculator (P65:24).*
>
> *If they can be showed how that is working, it won't be a problem. Even the calculators—how to use the calculator—we were never taught how to use a calculator, but in the end we know how to use the calculator. There are topics that we have to use a calculator, so we were never taught how to use a calculator (P65:25).*
>
> *It wasn't a problem to navigate. The fact is we own cell phones and we have been fiddling with the app. To work on this technology, is easy. But for a person who has got this for the first time it will be a challenge. Based on what we know about learners, most of them do have cell phones. I think they can use it (P62:15).*

The participants did mention possible challenges relating to technology use, especially for the older generation of teachers:

> *It will be easier for the new teachers because they know technology. The older teachers they might struggle a bit (P62:51).*

Despite the challenges, their aspiration to move forward is again evident (§ 4.2.1):

> *With the cell phone, nowadays we all have cell phones, we use cell phones and we are also encouraged to align ourselves with the current technology. So it shouldn't be a problem (P65:26).*

In the individual interview, one participant in particular expressed his views about mobile phones, where it was apparent that he did not see them as a tool for teaching Mathematics. He said the following:

> *About the cell phones, I don't think it's good...you can say cell phones are not designed for teaching and learning, it's just for communication purposes, so if you use them for teaching and learning, I don't think it's a good idea, unless if you want to communicate with them, send them homework, maybe the results, something like that (P59:36-37).*

When I presented the app to him and we proceeded to discuss its use in the Mathematics classroom, he said the following:

> *It will work. It is interesting...This is a new method of doing those things which are giving learners a problem. Nowadays people like this sort of things—they like using technology...This generation like using these devices. They are interested in using cell phone, tablets. It will capture their minds. So they are focused, they will be focused (P65:44-49).*

It was encouraging to notice a change of heart in this participant with regard to using mobile technology in the classroom. Another participant summarised his impression of the app in the following manner:

> *I am very impressed. In fact we are tired of chalkboards—it will be nice to use something new (P65:50).*

6.5 Role Players

One question in the focus group interview was: *Which role players will influence the use of an app such as this in the school situation?* One of the participants responded in the following way:

> *I think all of them play a role (P65:28).*

Figure 6.6 portrays the coding structure for the different role players in this study.

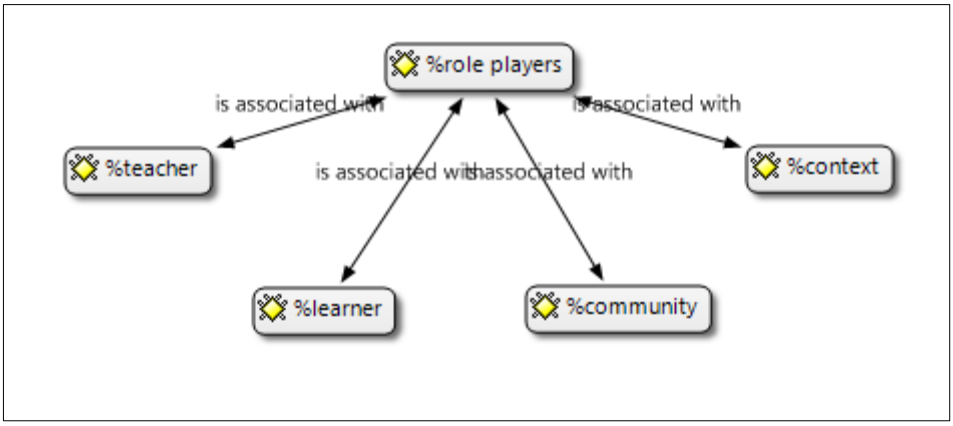

Figure 6.6: Coding Structure for Various Role players in the given Context

6.5.1 The Role of the Teacher

In the systematic literature review (§ 4.5), it was noted that not all stakeholders share the same optimism about using ICT in teaching and learning (Heck et al., 2007). The participants all suggested that the Mathematics teacher would be the greatest influence on the successful use of the app:

> *The Mathematics teacher is directly involved with this app. They must convince the parents; they must convince the Department that they need this app. The Mathematics teacher will influence its use (P62:26-27).*

> *The Mathematics teacher must encourage all the stakeholders to be involved in using the app. By showing them how possible, how easy and how economical it is to use it. But if you have no facts to support your statement then you will fail, the Department will fail to deliver this. But if there is a need and it can be shown to the stakeholders that if we apply this app—we save time, all learners are involved, all learners are interested. Maybe we should have one class where we use the traditional method and one classroom, use this technology and show the difference between them (P62:29).*

> *On the part of the educator—the educator, the Mathematic educators should take the initiative to show that this really works (P65:28).*

A participant also emphasised the key role that the teacher should play in the implementation of the mobile app in the classroom:

> *But, a teacher is a leader—they must always be in front of the learners. Teachers must learn more. They must be able to know it first before they can take it to the learners (P62:20).*

6.5.2 The Role of the Learner

A participant expressed her optimism that the learners would positively influence their parents with regard to the learners' use of the mobile app in the Mathematics classroom:

> *You just show the learners first. Then we call a parents' meeting. The learners would already have told their parents about the app. We will just show them how easy it will be (P62:28).*

6.5.3 The Role of the Community

When discussing the role of the community after having done the individual interviews, various factors relating to parents were raised (§ 4.5.3). An aspect that was evident was that parental support has a significant effect on learner motivation (Wentzel, 1998, p. 206) as well as academic performance (Makgato & Mji, 2006, p. 261). In the focus group interviews, parents also featured in the discussion:

> *Even their parents will be motivated to buy them cell phones and then even improve to buy more smartphones and install mathematical programs on the cell phones (P65:15).*
>
> *Because let's say for example parents—in terms of the cell phones—if we can tell the parents to buy cell phones for the learners, then parents can buy it. As long as they realise that it is effectively used and can benefit the learners, they are going to buy it (P65:28).*

6.5.4 The Role of the Context

School management and departmental issues featured in the focus group interviews, as they did in the individual interviews. Departmental characteristics have a definite impact on student learning (Vermunt, 2005, p. 205). Some of the aspects that are referred to as departmental characteristics include: course design and objectives, learning materials, and assessment procedures. The participants raised issues relating to departmental issues as well. Their concern was with role players such as the Heads of Department (HODs), Principals and the Department of Education:

> *In terms of the HODs and principals, they are the ones that should come up with the implementation and encourage the educators to implement this. So, if the Head of Department can encourage educators to implement and if the educator is prepared to implement—then from the Department to the parents—everything will run smoothly. Because the Department I think they should come up with programs where they design programs for the schools then the HOD's and the principals should check that those programs are implemented (P65:28).*

When asked if school principals would be happy for teachers to use an app such as this one, participants responded as follows:

> *Not at all. They like teachers to work. They think we are lazy (P62:30).*
>
> *Not at all. It involves money. This involves money. If for example you go to the principal and say that you want to use this app, you will work out the feasibility—how much will it cost—it will work out to be thousands. If the principal had never seen it being applied, it will not be easy to convince them. It was for the Maths teacher to convince. That's why I said if I bring*

the principal to class and show him how wonderful this app works, then maybe he can buy the story. Then we'll be fine (P62:30).

I think this is a question of whether the school has money to buy the technology. If the Department can provide the technology, then we can always use this technology. Just like textbooks—they provide textbooks, so they can provide mobile technology, then it will be simple (P65:27).

6.6 Specific Aspects Relating to the App

The codes that were added to the HU when coding the focus group interviews all fall into this category. Since the emphasis of the focus group interviews was on the evaluation of the app and to determine what observations and perceptions the participants had about the app, it was necessary to create codes that accounted for any suggestions the participants had with regard to the app. The sub-themes that fell into this category were: the usability of the app, positive aspects about the app and suggestions to improve the app. The coding structure for this section is illustrated by Figure 6.7.

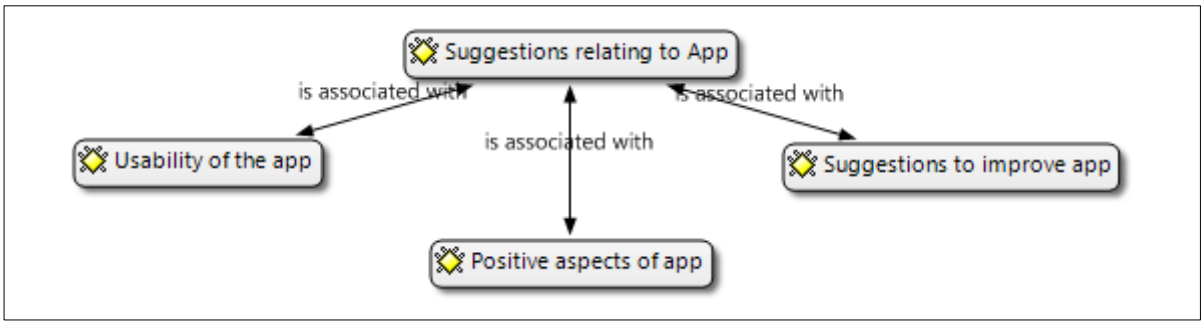

Figure 6.7: Coding Structure for Specific Suggestions relating to the App

6.6.1 Usability of the App

The usability of the app refers to the usefulness and ease of use of the app. Usability is often measured in terms of three aspects, namely: effectiveness, efficiency and satisfaction (Harrison, Flood, & Duce, 2013). These three aspects were all accounted for by the participants in this study. Effectiveness is illustrated by the following comments:

It will work. It is interesting (P65:30).

The app helps to make the lesson more interesting (P62:51).

Efficiency is illustrated by the comments that follow:

They can play with this and still arrive at the right answer (62:4).

They won't find it difficult to use this technology—they are hands on (P65:33).

Satisfaction is demonstrated by the following:

Ah, it's so easy! (P62:1).

This is excellent, excellent! (P65:31).

When asked if the app was easy to navigate, the participants replied:

> *It was for the first time, but it was not so difficult. But once used, I'm telling you it will come easy to them (P62:36).*

6.6.2 Positive aspects about the App

Two comments that the participants made related to design aspects:

> *The terminology helps them to differentiate between the two concepts (P65:1).*
>
> *It helps by giving them three chances to do sums (P65:3).*

The other observations were made concerning more general aspects:

> *This is a new method of doing those things which are giving learners a problem. Nowadays people like this sort of things—they like using technology (P65:32).*
>
> *I think this will help in other subject too—if teachers that teach other subjects can see this, they would also want to use such apps. This will help them too (P65:47).*

6.6.3 Suggestions to Improve the App

The suggestions offered by the participants in terms of improving the app can be divided into three categories. These categories are suggestions relating to pedagogical aspects; design aspects and general additional aspects to consider. Regarding pedagogical issues, participants suggested a greater variety of questions for two reasons: firstly to cater for slower learners and secondly to ensure the whole coverage of the curriculum.

> *Maybe you consider specific topics for the slower learners, for those who are willing to learn you can give them more advanced content (P65:22).*
>
> *I think putting all the questions that could be available—so that you can attempt each and every question that is possible. Otherwise if the question is not there and they are applying this—there will be a challenge, even if I don't know how to do it now. They will be a challenge; I can contact whoever to help me. So to improve it, let's have as many questions as possible, especially those in real life. Having all the questions will give an opportunity for interaction with other learners and with the teacher. Once they are loaded it will put a challenge to the user each and every time they open the phone. I think it can be improved in that way (P62:41).*

In § 5.5.1, I have illustrated how I made use of hints and scaffolds, which is encouraged by Cayton-Hodges et al. (2015) in the design of mobile Mathematics apps. Participants were reluctant to immediately offer such hints and would prefer that users have plenty of opportunity to try on their own before any such scaffolding takes place:

> *Like we already said, just to change where the learners have to choose between yes or no. They should be given more opportunity to do it on their own first. They should be forced to try the sums on their own first, and then the help can come. Twice or thrice is enough otherwise they might become demotivated (P65:36).*
>
> *Block it and then they can't access it anymore. Then they know they must try themselves. They must be able to think (P62:44).*

Concerning the issue of design, interactivity was an essential component that was taken into account in the app for two specific reasons. Firstly, interactivity is an essential characteristic of RME (Zulkardi,

2000) and secondly it is one the main attributes of mLearning (Domingo & Garganté, 2016, p. 22). Although some interactivity was built in to the app, the participants were keen to increase the levels of interactivity:

> *Secondly, I would say how can I show this to someone else—how can this be shown to a colleague, while I am working, so that other colleagues can help me (P62:41).*
>
> *They should be able to contact fellow users, like with WhatsApp™. I can say how do you do this? I couldn't get to the right answer, how do I tackle it? They can look into your steps and say no, you are using the wrong formula. Let's try this formula. By a friend, the learners feel so proud when they can help a fellow learner (P62:42).*

The final aspect to be discussed is the additional aspects that might be considered for inclusion in the app. Apps have the potential to offer affective engagement. This type of engagement is often influenced by the visual and interactive characteristics of the app (Calder, 2015, p. 245). This is a shortcoming that the design team also identified in the design of the Financial Mathematics app. Participants pointed out the following:

> *I think if you can make it to be audio-visual - that would be great (P65:37).*
>
> *There was also no sound. The sound can tell them what to do. Maybe make it an option for learners—those who want sound maybe have that option, those who don't want sound can switch it off (P65:38-39).*
>
> *I have seen that you have put some colourful pictures in there—even in the formula—maybe add some pictures but not too much. It should also depend on the grades—maybe in the senior and FET phases you can limit the images. In the lower grade you can include more pictures (P65:42-43).*
>
> *What about animation? It will be good especially for the grade fours, fives and sixes—because they like cartoons—you can add it there. If you can include animations that will be good for the lower grades (P65:44).*

A general comment which is encouraging for future development was:

> *It would be good if you could develop these apps for the whole curriculum—from foundation phase right through. Then they can get used to using it (P65:45).*

6.7 Chapter Summary

In this chapter, I presented a detailed analysis of the data that were generated at two focus group interviews with four participants in this study. The aim of the focus group interviews was to establish the participants' observations, opinions and experiences of the mobile app for Financial Mathematics. A number of familiar themes were apparent in this data. I firstly explored the participants' observations and experiences of the app in terms of Mathematics. I dealt with various factors that influenced the teaching and learning of Mathematics. The aspects that arose in this section were the importance of immediate feedback in the app; and the opportunity for increased motivation that mobile technology offers its users. Participants also offered various reasons as to why they felt that the mobile app could improve their teaching practice. In this category, I also explored the participants' ideas on mathematical content. Two important aspects transpired. Firstly participants discussed the importance of mathematical content knowledge, and secondly they revealed other sections of the curriculum that would possibly benefit from the design of similar apps. The third aspect of this section

addressed learner aspects. Participants discussed how the app met the varying needs of different learners. Concerning teaching methods and strategies, I discussed the modelling of formulas as an important teaching method. Finally, I discussed aspects relating to the meaningful learning of Mathematics. Features that were discussed included the notion of competition and games that the app evoked in the participants, and the importance thereof in contributing towards an environment in which meaningful learning could take place.

The second theme that I explored was that of RME. The facets of RME that the participants observed in the app were characterised into two components: characteristics of RME and aspects of RME. The participants were able to identify all the characteristics of RME, in particular collaboration and intertwining of strands. The other aspects of RME that were evident were the notion of Mathematics as a human activity, and that activities should be based on real life situations.

The third theme was the participants' considerations and ideas about ICT that they observed in the app. They were able to identify a number of positive aspects that the app offered in terms of ICT, and also pointed out some challenges. I explored the participants' opinions about different devices. The discussion centred on the use of mobile devices and the suitability thereof for the app. Participants also shared their thoughts on technology as an educational tool. I discussed factors that related specifically to the participants with regard to factors of ICT.

I discussed the data which related to the theme of role players, and considered the participants' views regarding the role of the teacher; the learner; the community and the context. They emphasised the importance of each of the role players and mentioned specific ways in which they could influence the use of the app. The final aspect that I discussed was suggestions that the participants made relating to the app. I discussed the usability of the app, where participants shared their ideas on the usefulness of the app. This was followed by a discussion of what they perceived to be positive about the app and also suggestions that they made to improve the app. I discussed these suggestions in three categories, namely: pedagogical issues, design aspects and as well as general suggestions.

By presenting the participants with the app and allowing them the opportunity the offer their observations and evaluation thereof, the first cycle of the final phase of the design-based research process had been completed. In figure 2.6 I illustrated this as the final evaluation cycle. I ended the preceding two chapters with design principles that were derived from the analysis of the interview data and the design process of the app. I will proceed to do the same in this chapter. Since this phase also completes a cycle (final evaluation) of the semi-summative evaluation phase (Figure 2.6), the outcome here too will be design principles, which this time will relate to the evaluation of the mobile app for Financial Mathematics.

Table 6.2 Design Principles for the Design of a Mobile App Based on the Principles of Realistic Mathematics Education Derived from Focus Group Interviews with Participants

Aspect	Design Principles
Participants' observations of the app in terms of Mathematics	• The immediate feedback that users are provided with is useful • Working with the app promotes motivation • The content knowledge of a teacher is essential in effectively implementing the app • All areas of the curriculum are suitable for such an app • A variety of learners with varying needs can be catered for by the app • The app can promote the classroom climate through the use of competitions and games
Facets of RME observed in the app	• The app is able to present content based on the characteristics and aspects of RME
Considerations concerning ICT in the app	• Mobile technology is a suitable means of presenting the app • Teachers should guard against using the app only, there should be written activities as well • Teachers are required to have basic technology skills such as being able to download the app from Goole App Store • The older generation of teachers may need more assistance with ICT than the younger generation
The effect of role players on the use of the app	• The Mathematics teacher is the most prominent role player in the implementation of the app • Parents play an important role in the successful use of the app • Institutional and departmental issues might hinder the implementation of the app in teaching practice
Suggestions form participants about the app	• The app should comply with the aspects that define usability of the app, namely effectiveness, efficiency and satisfaction • The app should be extended to other subject areas • The app should present a variety of questions to cater for slow learners and cover the full spectrum of the curriculum • Hints and scaffolds should be used wisely and on request, after allowing the user sufficient opportunities to make their own attempt on activities • More interactivity should be incorporated. Consider aspects that can aid interaction outside of the app such as WhatsApp™ • The app should be presented with sound and more visual aspects—less text should be used • Animation should be considered for future designs

Chapter Seven

Guidelines for the Effective use of Technology in Implementing the Realistic Mathematics Education Approach in Teaching Practice

7.1 Introduction

The study was underpinned by the main research question: *What are the guidelines for the effective use of technology in implementing the RME approach in teaching practice?* This chapter addresses this research question and presents a voluptuous overview of the research journey. I start with a detailed overview of the preceding chapters and also address the research questions. I also present the envisaged guidelines for the effective use of technology in implementing the RME approach in teaching practice. I discuss the contribution that this study has made to the field of Mathematics education and will also mention the limitations of the study. Future questions that arose from the study are presented and I also share my reflections of the research journey which I undertook.

7.2 Summary of Chapters

In this section a summary of the first six chapters will follow.

7.2.1 Chapter One: Orientation to the Research Journey

Chapter One provided an orientation for this research and presented a detailed plan of the research report that followed. It sketched the problem situation that needed to be investigated and provided a motivation for doing the research. I explored the existing literature and pointed out the gaps in that literature. A literature review concerning the main themes of the study was presented. The discussion of the literature revolved around three themes: RME; the use of technology in Mathematics education; and the relationship between RME and technology. I then presented the research questions and the purpose of doing this research. An overview of the research design and methodology was discussed and issues such as the population; participant selection; methods of data generation; and analysis were mentioned. I detailed a review of the methodology of a qualitative design-based research study and discussed the ethical implications thereof. This chapter also provided a list of terminology for clarification and mentioned the contribution that the study might make towards the field of Mathematics education.

7.2.2 Chapter Two: Research Design and Methodology

In Chapter Two the detailed research design and methodology was presented. Upon closer inspection of the research questions, the research approach and method was selected and presented in detail. This chapter provided the roadmap of the research process that was to follow. I discussed the theoretical underpinnings of a qualitative design-based research study from an interpretivist perspective. After exploring the literature concerned with design-based research, I discussed the various phases of this design-based research process applicable specifically to this study. The necessary ethical considerations were documented. In Chapter Two I presented a comprehensive documentation of the systematic literature review process that I followed. This discussion included a description of the document search process; the criteria according to which the documents were selected; the measures followed to assure quality assessment of the documents and a description of how the data were analysed with the aid of ATLAS.ti™. In this chapter I also presented the codebook relevant for this study. I indicated the manner in which validity and reliability issues were adhered to and discussed the limitations of the systematic literature review.

The chapter continued to explain the processes and methods followed in the first qualitative strand—the needs analysis. Here I discussed the criteria for the selection of the participants and the selection of the site. The data for the needs analysis were in the form of individual semi-structured interviews with the teacher-students. Data were analysed with the aid of ATLAS.ti™ in the same HU as the systematic literature review. The next phase of the research that I reported on in this chapter was the second qualitative strand in which I determined the teacher-students' perceptions of the intervention tool, which took the form of a mobile app. In this section I also discussed the participant and site selection. Data were collected through two focus group interviews and the analysis was also done with the aid of ATLAS.ti™ in the same HU. I finalised the chapter with an illustration of how validity and reliability were ensured in the qualitative inquiry and gave a description of the role that I played as researcher.

7.2.3 Chapter Three: Systematic Literature Review

Chapter Three provided a report of the systematic literature review of the current literature that pertained to the use of ICT in the implementation of the RME approach in Mathematics education. The systematic literature review revealed five themes: Mathematics; RME; ICT; methodology; and role players. The discussion on Mathematics revolved around seven aspects. These aspects were as follows: the factors that influence teaching and learning were discussed; the impact of RME and technology on Mathematics education; the influence of different teaching approaches on teaching practice; ways in which meaningful learning could be established and promoted; different teaching methods and strategies, which included the use of models; the effect of RME and technology on mathematical content; and various aspects that relate specifically to learners such as learner understanding and learner reasoning.

The second theme was that of RME. I first discussed the theory of RME, followed by the characteristics, aspects and principles of RME. The five characteristics of RME featured throughout the study as did the three principles of guided reinvention, emergent modelling and didactical phenomenology. Specific aspects that related to RME were also explored such as the implementation of tasks in RME; the use of HLTs; and the use of real life contexts. The chapter continued with a report on the advantages, disadvantages and recommendations for RME.

The third theme of this chapter was ICT. I explored the value of using ICT in Mathematics education as well as the challenges that go with its use and implementation. I also discussed different ICT tools and devices that were apparent in the systematic literature review. The discussion on devices concentrated mainly on mobile tools such as smartphones, tablets, and calculators. I extended this discussion on ICT by exploring virtual learning environments and the connection between ICT and the RME approach to teaching Mathematics.

The next theme that was discussed was methodology. The emphasis was on design-based research specifically since it featured as the chosen methodology for this study. The final theme that was explored in this chapter was role players. In this chapter I discussed only two sub-themes for role players, namely the role of teachers and the role of learners. In further thematic analyses in this study, I extended these to other relevant role players.

7.2.4 Chapter Four: Participants' Needs and Perceptions with regard to Real Life Mathematics

In Chapter Four I reported on the data that were gathered through the individual interviews with the teacher-students. The purpose of gathering this data was to assemble sufficient information to answer the research question: *What support needs do teachers have in order to successfully implement the RME approach in their teaching practice?* The data were coded in ATLAS.ti™ in the same HU as the systematic literature review, which meant that the same codes as well as some additional codes were used for this process. Four of the five main themes from the systematic literature review were addressed in the analysis and were discussed. These themes were Mathematics, RME, ICT and role players. I centred the discussion on the teacher-students' needs and perceptions in terms of Mathematics and divided the category into three sub-themes, namely factors that influence teaching and learning; mathematical content and learner aspects. The focus in the section on mathematical content was particularly on problem areas that the teacher-students had in terms of teaching the mathematical content and also areas of the content which in their opinions was related to real life.

The discussion continued to the theme of RME. Here, as with the systematic literature review, I looked at the characteristics, aspects and advantages of using RME as expressed by the teacher-

students in the interviews. In the section on characteristics, the analysis centred on student contributions; interactivity; the use of context problems; modelling; and the integration of different strands of the curriculum. The next theme that was discussed was ICT. Five sub-themes for ICT emerged in Chapter Four. These included the value of using ICT; challenges experienced when working with ICT; devices; technology as an educational tool; and teacher-student ICT factors. The latter two themes (and codes) were introduced at this point to cater for the data relating to the teacher-students' needs and perceptions of ICT in Mathematics education. In the section on technology as an educational tool, I explored factors such as the teacher-students' use of WhatsApp™ in their teaching as well as other educational tools such as web-based interactives and GeoGebra. The final theme that was discussed in this chapter was the various role players. In this chapter it was necessary to discuss the data under four sub-themes, namely the roles of the teacher; learner; community; and context. In the section on the role of the community, the role of parents featured strongly as a factor that influences learner motivation. Under the role of the context I explored the teacher-students' opinions about the importance of facilities at schools as well as departmental factors that play a role in effective education. The final stage of this chapter was a summary of the design principles relevant to the data obtained from the individual interviews.

7.2.5 Chapter Five: The Design and Development of the Mobile Intervention Tool

Chapter Five encompassed a report on the design phase of this study. The intervention tool, which was in the form of a mobile app on Financial Mathematics, was designed to assist teacher-students with incorporating the characteristics of RME into their teaching practice. This chapter detailed the process that was followed in the design of that app. Firstly I addressed the purpose of designing the app. I explored the theoretical underpinnings for the design process and reported on current literature relating to mLearning. I concentrated on mLearning in Mathematics specifically; and again considered the connection between technology and RME, in particular the role that technology played in this approach to teaching Mathematics. I briefly sketched the context for which the app was designed by reporting on the teacher-students' contexts. I then continued to explain the process that was followed with regard to the design of the app. A team consisting of myself, a programmer; my promoter, an expert in the field of using technology in teaching and learning; and my assistant promoter, an expert in Mathematics and Mathematics education, were involved in the design process. I discussed the theoretical aspects of designing the app and also explained how the design process proceeded according to the phases of a design-based research methodology. The various stages of prototyping were discussed, as well as how the app was designed based on the characteristics and principles of the RME approach. The final part of this chapter explored the technical aspects of creating the app. Here nine specific steps were followed and these were discussed in this section. I also drew the comparison of the nine steps that we followed with the five design steps suggested in literature. The chapter ended with a summary of the design principles that were relevant for this design process.

7.2.6 Chapter Six: Participants' Observations and Experiences of the Mobile App

In Chapter Six I reported on the data that were obtained from the focus group interviews in which teacher-students were introduced to the app. Their observations and experiences of the app were recorded and analysed. The data were analysed in ATLAS.ti™ as an integrated data set in the same HU unit as all the other data in this study. The chapter presented this data analysis under five themes. The first four themes were familiar themes that arose in the systematic literature review and were also used in the data analysis presented in Chapter Four. These themes were Mathematics, RME, ICT and role players. An additional theme was created for the discussion of the data which centred on specific aspects relating to the app. Additional codes were also created to code and analyse this data. The subsequent extension of the codebook was presented in this chapter.

In the first theme, the focus was on observations about Mathematics that the teacher-students made in the app. The discussion was presented in five sub-themes: factors that influence teaching and learning; mathematical content; learner aspects; teaching methods and strategies; and meaningful learning of Mathematics. Factors such as the importance of immediate feedback; the role of teachers' mathematical content knowledge; modelling; and the creation of a positive classroom climate were discussed. The second theme that was discussed was facets of RME that the teacher-students observed in the app. Here I discussed two aspects that arose from the data, namely the characteristics of RME and also aspects of RME. Teacher-students' observations and experiences of ICT in the app were discussed next. The same five sub-themes were discussed here that were discussed in Chapter Four. These were the value of ICT; challenges when working with ICT; devices; technology as an educational tool and teacher-student ICT factors. Of importance here was a discussion on the benefits of using mobile technology specifically and also the challenges involved with the older generation with regard to adopting new technology. An interesting comparison was drawn between opinions that one teacher-student had about ICT before using the app compared to after having used the app. The teacher-students' aspiration to move forward was also discussed in the section.

The same role players featured in the discussion of the focus group data as was discussed in Chapter Four. Issues relating to the roles of teachers, learners, the community and the context were discussed. Once again, the role of parents as well as departmental issues was presented in the discussion. The final theme of this chapter was that of specific aspects relating to the app. Three sub-themes were explored. Firstly, the usability of the app, where I mentioned how teacher-students experienced the ease of use of the app, was discussed. I continued the discussion by investigating positive aspects that they experienced when working with the app and also suggestions that they made to improve the app. The discussion on suggestions was categorised into three divisions, where I discussed their suggestions in terms of pedagogical aspects; design aspects and general aspect that need to be considered for future design. This chapter concluded with a summary of design principles that were gathered from the focus group interviews.

7.3 Addressing the Research Questions

In order to effectively answer the main research question of this study, two sub-questions were posed to gain insight on the main question. These sub-questions were:

1. How can the use of the RME approach, facilitated by technology, enhance teaching practice?
2. What support needs do teachers have in order to effectively implement the RME approach in their teaching practice?

The first sub-question of this study: *How can the use of the RME approach, facilitated by technology, enhance teaching practice?* was addressed in Chapter Three the culmination of the systematic literature review. This chapter presented the current literature that existed relating to the effect of the RME approach, facilitated by technology, on teaching practice. The three most dominant themes that were discussed in this chapter were Mathematics, RME and ICT. The discussion illustrated the interaction between these three themes and discussed what literature revealed about how the RME approach, assisted by technology, could enhance teaching practice

The second sub-question of the study: *What support needs do teachers have in order to effectively implement the RME approach in their teaching practice?* was addressed in Chapter Four, the analysis of the individual interviews with the teacher-students. This chapter presented the analysis of data that revolved around the needs analysis of the teacher-students. The data were analysed with ATLAS.ti™ and revealed the teacher-students' needs in terms of teaching Mathematics. The content areas that they found problematic to teach as well as the areas of the curriculum that their learners found challenging was revealed. They also disclosed which areas of the curriculum they found difficult to relate to real life. The discussion also divulged aspects relating to the theory of RME that were important to the teacher-students, and they shared their views about using ICT in their teaching of Mathematics.

In order to address the main research question which guided the research: *What are the guidelines for the effective use of technology in implementing the RME approach in teaching practice?* I created an inventory of all the design principles that have emerged from this study. These design principles have been re-categorised according to the five main themes that were prevalent throughout the study: Mathematics, RME, ICT, role players, and aspects relating to the app. Table 7.1 presents a summary of the guidelines.

Table 7.1 Guidelines for the Effective use of Technology in Implementing the Realistic Mathematics Education Approach in Teaching Practice

Prevalent themes of this study	Guidelines for the effective use of technology in implementing the RME approach in teaching practice
Mathematics	• Establish what needs the teacher-students have with regard to content areas (both teachers and learners) • Mathematics content should be rich and accurately presented

Prevalent themes of this study	Guidelines for the effective use of technology in implementing the RME approach in teaching practice
	• Interactions with the content should be engaging • Users must be given the opportunity to reflect on tasks • Hints and scaffolds should be used wisely and on request, after allowing the user sufficient opportunities to make their own attempt on activities • The immediate feedback that users are provided with is useful • Working with the app promotes motivation • The content knowledge of a teacher is essential in effectively implementing the app • All areas of the curriculum are suitable for such an app • A variety of learners with varying needs can be catered for by the app • The app can promote the classroom climate through the use of competitions and games
RME	• Meaningful, realistic contexts should be the foundation for students to reinvent the Mathematics • Establish teacher-students' needs in terms of making Mathematics realistic for the learners • User contributions should be encouraged • Incorporate the use of modelling • Make use of interactivity • Ensure the intertwining of content areas and concepts • Users ought to be given the opportunity to invent their own strategies to solve problems
ICT	• Teacher-students should see the value of ICT when using such an intervention tool • The challenges that teacher-students experience with regard to ICT should be addressed as far as possible • Establish which devices the teacher-students find most suitable • Determine in what manner teacher-students use technology as an educational tool • Mobile technology is a suitable means of presenting the app • Teachers should guard against only using the app, there should be written activities as well • Teachers are required to have basic technology skills such as being able to download the app from Goole App Store • The older generation of teachers may need more assistance with ICT than the younger generation
Role players	• Teachers are the key role players in integrating ICT in teaching and learning • Learners' learning is influenced by their socio-economic circumstances • Parents play an essential role in learners' academic performance • Facilities and higher authorities can be important within the given context • The Mathematics teacher is the most prominent role player in the implementation of the app • Parents play an important role in the successful use of the app • Institutional and departmental issues might hinder the implementation of the app in teaching practice • Participants should indicate a desire to be involved in professional development • Participants must aspire to move forward
Aspects relating to the app	• A detailed design document should be created • The problem situation should be clearly sketched • The purpose of the app must be clearly defined from the start • The different prototypes should be rigorously tested by a range of parties (novices and experts) • User interaction with the app should be encouraged • The app should comply with the aspects that define usability of the app, namely effectiveness, efficiency and satisfaction • The app should be extended to other subject areas • The app should present a variety of questions to cater for slow learners and cover the full spectrum of the curriculum • More interactivity should be incorporated. Consider aspects that can aid interaction outside of the app such as WhatsApp™ • The app should be presented with sound and more visual aspects—less text should be used • Animation should be considered for future designs

The guidelines relating to Mathematics centre around three main categories: mathematical content, teaching and learning strategies and classroom ethos. The majority of the guidelines refer to mathematical content with the focus on rich and accurate presentation of the content; content that is engaging; and the importance of teachers' mathematical content knowledge. With regard to strategies—factors such as scaffolding, hints and immediate feedback were found to be useful tools in this study. Classroom ethos also featured in the guidelines. This refers to factors such as motivation and classroom climate. The study revealed how these factors could be promoted by the app.

The guidelines that centred on the theme of RME focused on the characteristics of RME. The importance of incorporating realistic contexts to allow for students to reinvent Mathematics is an important guideline. The use of modelling; interactivity and ensuring the intertwining of strands was essential in this study. With regard to ICT, the guidelines were varied, yet an important characteristic of the ICT guidelines was: taking into account the teacher-students view of different aspects of ICT. These included what they saw as challenges with ICT; the value they perceived of ICT; the devices and tools they felt comfortable with as well as the skills they had and were required to have to effectively use the technology.

The guidelines concerned with role players again centred on teachers, learners and contexts. The focus was on guidelines relating to teachers since they featured as the key role players in this study. Guidelines relating to parents and institutional matters were important factors when considering the implementation of the app. The final set of guidelines related to aspects relating to the app. The guidelines here were categorised into four categories. Various guidelines dealt with the phases of design, which included defining a definite purpose, proper planning and rigorous testing of the app. Some guidelines concerned with pedagogical issues were raised such as using different questions for a variety of learners and also for full coverage of the curriculum. Various guidelines relating to the usability of the app were revealed, and finally a number of guidelines were suggested for future development, such as including sound and animation.

The involvement of the NWU in the effective use of technology in implementing the RME approach in teaching practice is at the level of expanding the app to a wider range of teacher-students with more apps that cover the entire curriculum. Another guideline that has implications for the NWU is to expand the project to other subject areas other than Mathematics. This has cost implications that the university would have to consider. Either way, the NWU has a responsibility to assist in improving the Mathematical content knowledge of the teacher-students.

At the level of the lecturer, her or his involvement would be quite extensive in effectively using technology to implement RME in teaching practice. Most of the guidelines related to Mathematics would be the lecturer's responsibility, such as establishing the teacher-students' needs; creating content that is rich and accurately presented; designing the app to provide immediate feedback; and incorporating aspects such as competitions and games in the app to promote a positive classroom

climate. In the guidelines relating to RME the responsibility rests on the lecturer and the teacher-students. It is the lecturer's responsibility to teach and implement the characteristics of RME in any intervention tool that is designed for the teacher-students, and it would be the teacher-students' responsibility to then implement those characteristics in their own classrooms for their learners.

In the guidelines relating to ICT, the responsibility is also shared mainly between the lecturer and the teacher-students. The lecturer needs to establish various aspects about the teacher-students in order to design the intervention such as establishing what device is most suitable, and in what manner the teacher-students are willing to use technology as an educational tool. The teacher-students on the other hand initially need to acquire certain skills, if they do not already have those, like being able to download an app. Thereafter, when implementing the technology in their teaching, they need to guard against relying too heavily on technology in the classroom and should be able to balance written activities and exercises with the use of technology.

Teachers feature most strongly in the guidelines about role players. They feature as the key role players in implementing the RME approach in their teaching practice. Concerning the aspects relating to the app, it is the lecturer's responsibility to plan, create and test a well-defined tool for intervention. The lecturer should also ensure sufficient and appropriate questioning to suit all learners.

With reference to Figure 2.6, the final phase of a design-based research project is the semi-summative evaluation phase. As discussed in § 6.7, the teacher-students' evaluation of the app (Chapter Six) accounted for the final evaluation stage. The final stage of the entire process is the generation of guidelines (Figure 2.6). The guidelines presented above constitute the completion of the design-based research process for this study.

In § 2.4 I discussed that design-based research should generate evidence-based claims about learning that addresses theoretical issues and generate theoretical knowledge in the field, rather than show that a particular design works (Barab & Squire, 2004, p. 6). In this study, the guidelines that have been produced are able to provide specific strategies that should be followed when using technology to implement the RME approach in teaching. The guidelines are related specifically to themes that were dominant throughout the study. I have also discussed where the responsibility to carry out these guidelines lie, namely with the NWU, the lecturer or the teacher-student. Therefore, these guidelines have contributed to the theoretical knowledge in the field, and certainly did address relevant theoretical issues.

7.4 Contribution of the Study

The study contributes to the subject area and discipline of Mathematics in the following manner:

- The systematic literature review proved to be an invaluable tool in providing clarity and insight into the RME approach, as facilitated by technology, in enhancing teaching practice.
- The study contributed towards the discipline of Mathematics by providing insight into the needs that teacher-students have with regard to making Mathematics more realistic for their learners.
- The initial evaluators of the app found it to be practical, suitable and meaningful in the area of Mathematics education. They also felt it could contribute to a wider range of students than those involved in the study and recognised the contribution it could make if designed for other content areas as well.
- Teacher-students were given the opportunity for a robust exchange of ideas that contributed to enhance and enrich the study.
- The teacher-students were exceptionally positive about the app and its potential for a wider range of Mathematics teachers as well as their learners.
- The teacher-students found their participation in the study rewarding and shared how much they had learned in the process.
- The guidelines that were produced are practical, hands-on and meaningful pointers that can be used for future developments in the area of enhancing Mathematics education with technology.
- The design principles that were produced in this study have the potential to inform lecturers, instructional designers and curriculum experts in the design and adaptation of course material for students.
- Teacher-students and their learners have benefitted from the app since the mathematical content was presented in a relevant and realistic way.
- The study has the potential to be the start of a larger project in the Faculty of Education Sciences at the NWU where student-teachers can be supported in their Mathematics teaching practice through mobile technology.
- This thesis will contribute to the research output of the Research Focus Area Self Directed Learning (SDL) at the NWU.

7.5 Limitations of the Study

The limitations of this study relate at two levels, a methodological level as well as a practical level. Firstly, methodologically this study was a qualitative study that was seated in the interpretivist paradigm. This meant that it accounted for one quadrant or perspective in Figure 2.2 by Burrell and Morgan (1994, p. 22) on paradigms for the analysis of social theory (§ 2.2.2). The study might have been richer if the perspectives of the teacher-students could have been quantified by including a quantitative component to the study. This was my first attempt at a qualitative study, which could have impeded on its success; however, issues of trustworthiness proved the validity of the study.

On a practical level, the second area that might have limited this study was the small number of respondents that were used. The possibility exists that if more participants had taken part in the study, the results might have been different. However, data saturation was achieved with the participants in this study, which implied that it was not necessary to extend the study to any more participants (§ 2.8.3.2).

7.6 Future Questions

The study revealed the following future research questions:

- What are the most important factors that hinder Mathematics teachers from implementing technology in their teaching of Mathematics?
- What effect does teachers' mathematical content knowledge have on the implementation of the RME approach in their teaching?
- What effect does teachers' technological content knowledge have on the implementation of the RME approach in their teaching?
- How can parental support enhance learners' experience of Mathematics?
- How should hints and scaffolds be used in the design of a mobile intervention tool to effectively guide users through mathematical content?
- How does the interaction between users of a mobile tool influence their academic achievement in Mathematics?
- How do teachers incorporate the use of a mobile tool in the teaching of Mathematics?

7.7 Reflections on my Research Journey

I am fervent about teaching, in particular teaching Mathematics. My journey began as a high school Mathematics teacher, where I gained invaluable experience on the teaching and learning of Mathematics. There I developed a desire to assist other teachers in their efforts to make Mathematics more meaningful for their learners. I advanced to a lecturing position at the NWU, and here have the privilege of training and assisting Mathematics teachers.

As a researcher, my first experience with research was with quantitative research. Because of my love for working with numbers and statistics, this was the obvious choice. I enjoyed doing quantitative research and found it fairly easy to do. However, being a person, who likes to be challenged, I decided that I wanted to learn more about qualitative research. The research question for my PhD study steered me in the direction of qualitative research and gave me the opportunity to explore my interest with this type of research. I found the process challenging but rewarding.

Firstly, doing a systematic literature review was a fascinating process. That which appeared to be cumbersome in the beginning, turned out to be a highly structured frame according to which I could analyse the rest of the data in the study. This structure that the systematic literature review provided was familiar and comforting to me, the mathematician. I found the idea of having to do interviews daunting since I had no experience in that field. Yet I quickly felt comfortable for two reasons: I was discussing issues of Mathematics education that are crucial to me, and I was discussing them with people that I care for, my Mathematics teacher-students. I quickly got the gist of acting as an interviewer and enjoyed hearing my students' ideas on and opinions of aspects important to all of us.

The design process of the app was also a completely new experience for me. Although I have been involved in creating and designing course material at secondary school and tertiary level, I had no experience in designing material to be implemented by a technological tool. Since my second passion after Mathematics is technology, this was an exciting and stimulating process. The excellent support that I received from my promoter and the programmer helped to make the design process smooth and enjoyable. So much so that I would love to extend this study to many more apps that cover the entire Mathematics curriculum.

Experiencing the feedback from the teacher-students after introducing them to the app was a fulfilling experience. Because I am fully aware of their circumstances and contexts, being able to provide them with a tool that can assist them in their jobs was gratifying. Their reaction to the app was so positive, and they too could see the potential thereof for their daunting task as Mathematics teachers as well as for the learners that they are responsible for. It was also satisfying to notice a positive change in one of the teacher-students' perception of technology use in the Mathematics classroom.

By doing a qualitative study, I was able to experience the human side of Mathematics and technology, which in my Master's dissertation was much more quantitated. Although I had the desire to learn more about qualitative research, I was apprehensive as to how I would cope with the process. The experience exceeded my greatest expectations; I found the journey of doing qualitative research fascinating, rewarding, enriching and enlightening. I would encourage any quantitative researcher to take the plunge and also give qualitative research a fair chance.

ETHICS APPROVAL CERTIFICATE OF STUDY

Based on approval by the **Ethics Committee of the Faculty of Education Sciences (ESREC)** on **15/11/2016** after being reviewed at the meeting held on **26/11/2015**, the North-West University Institutional Research Ethics Regulatory Committee (NWU-IRERC) hereby **approves** your study as indicated below. This implies that the NWU-IRERC grants its permission that, provided the special conditions specified below are met and pending any other authorisation that may be necessary, the study may be initiated, using the ethics number below.

Study title: Guidelines for effective technology facilitation of Realistic Mathematics Education to enhance teaching practice.

Study Leader/Supervisor: Prof AS Blignaut
Research team: DJ Laubsher & Prof HD Nieuwoudt

Ethics number:

N	W	U	-	HS	-	2	0	1	4	-	0	2	6	7
Institution				Study Number						Year				Status

Status: S = Submission; R = Re-Submission; P = Provisional Authorisation; A = Authorisation

Application Type: N/A

Commencement date: 2016-11-15 **Expiry date**: 2017-11-15 **Risk:** Minimal

Special conditions of the approval (if applicable):

- Translation of the informed consent document to the languages applicable to the study participants should be submitted to the ESREC (if applicable).
- Any research at governmental or private institutions, permission must still be obtained from relevant authorities and provided to the ESREC. Ethics approval is required BEFORE approval can be obtained from these authorities.

General conditions:

While this ethics approval is subject to all declarations, undertakings and agreements incorporated and signed in the application form, please note the following:

- *The study leader (principle investigator) must report in the prescribed format to the NWU-IRERC via ESREC:*
  - *annually (or as otherwise requested) on the progress of the study, and upon completion of the project*
  - *without any delay in case of any adverse event (or any matter that interrupts sound ethical principles) during the course of the project.*
  - *Annually a number of projects may be randomly selected for an external audit.*
- *The approval applies strictly to the proposal as stipulated in the application form. Would any changes to the proposal be deemed necessary during the course of the study, the study leader must apply for approval of these changes at the ESREC. Would there be deviated from the study proposal without the necessary approval of such changes, the ethics approval is immediately and automatically forfeited.*
- *The date of approval indicates the first date that the project may be started. Would the project have to continue after the expiry date, a new application must be made to the NWU-IRERC via ESREC and new approval received before or on the expiry date.*
- *In the interest of ethical responsibility the NWU-IRERC and ESREC retains the right to:*
  - *request access to any information or data at any time during the course or after completion of the study;*
  - *to ask further questions, seek additional information, require further modification or monitor the conduct of your research or the informed consent process.*
  - *withdraw or postpone approval if:*
    - *any unethical principles or practices of the project are revealed or suspected,*
    - *it becomes apparent that any relevant information was withheld from the ESREC or that information has been false or misrepresented,*
    - *the required annual report and reporting of adverse events was not done timely and accurately,*
    - *new institutional rules, national legislation or international conventions deem it necessary.*
- *ESREC can be contacted for further information or any report templates via Erna.Conradie@nwu.ac.za or 018 299 4656*

The IRERC would like to remain at your service as scientist and researcher, and wishes you well with your project. Please do not hesitate to contact the IRERC or ESREC for any further enquiries or requests for assistance.

Yours sincerely

Mathematics Education student
School for Natural Sciences and Technology Education
North West University
Potchefstroom
South Africa

Dear Sir / Madam

Permission to participate in research

I, Dorothy Laubscher, am enrolled for a PhD study at the Faculty of Education Sciences, Potchefstroom Campus of the North-West University. I am in the process of conducting research on the teaching and learning of Mathematics. The title of my thesis is: *Guidelines for effective technology facilitation of Realistic Mathematics Education to enhance teaching practice.*

You have been selected as part of a sample of participants to take part in the above-mentioned research project about the use of technology to make Mathematics teaching and learning more realistic. The project will involve an informal discussion with the researcher regarding your needs in the mathematics classroom in relation to making Mathematics content more realistic for the learners. Different technologies, like Facebook, WhatsApp™, Interactive Whiteboards etc. will be used to present content to you based on your teaching needs, as expressed in the informal discussion. Thereafter, interviews about your experience and opinions regarding the topic will be conducted. I hereby request your participation in this project.

I pledge to maintain the professional and research ethical codes. This signifies that:
- Your participation in this research remains voluntary and you may, at any time, withdraw from the research without any penalty
- Your personal information will at all times be treated as confidential
- No demands will be made on your academic teaching programme
- Should you be interested, the research findings will be made available to you and your school.

The Ethical clearance number for this study is NWU-HS-2014-0267.

Could you please provide me with your written consent by filling in the section on the next page. Your participation is voluntary. Your input and opinions are greatly appreciated!

Thank you for your willingness to complete this research.

Yours sincerely

Dorothy Laubscher
PhD Candidate, North-West University
Student number: 10218343

Informed Consent to participate in Research Project:

Guidelines for effective technology facilitation of Realistic Mathematics Education to enhance teaching practice

LETTER OF PERMISSION: RESEARCH PARTICIPANT

I, _____, (name and surname)

a student from the North West University hereby give my permission to participate in the above mentioned research project. I am aware that my participation in this study remains voluntary and that I, at any time, may withdraw from the research. I understand that if I do not wish to participate in this research, it will not be held against me, as participation is voluntary. I also understand that all personal information will be treated as confidential by the researchers.

Questions for the individual interview

1. What sections of the curriculum are most problematic for you to teach?
2. How often are you able to relate the content you are teaching to real-life situations?
3. Which sections of work do you think will be easiest to link to real-life situations?
4. In which sections of the curriculum do you need help to link the content to real-life situations?
5. Do you think it is important to relate your teaching to real-life situations? Explain your answer.
6. How do you feel about using technology in your teaching?
7. How do you feel about using mobile technology such as WhatsApp™ and SMS to discuss with me and other colleagues, possible ways of making the mathematics content more realistic for you learners?
8. How do you feel about being part of a WhatsApp™ group to discuss issues of making the mathematics more realistic?
9. What experience do you have with Facebook?
10. How do feel about using Facebook to discuss issues of making mathematics more realistic for your learners?
11. What experience do you have regarding interactive whiteboards?
12. How do you feel about using the interactive whiteboard to discuss issues of making mathematics more realistic for your learners?
13. What type of technology would you be most comfortable with for this project?

1. Watter afdelings van die kurrikulum is vir u die mees problematies om te behandel?
2. Hoe dikwels is dit moontlik vir u om die inhoud wat u onderrig te verbind aan alledaagse lewensituasies?
3. Watter dele van die werk dink u is die maklikste om te verbind aan alledaagse lewensituasies?
4. Met watter dele van die kurrikulum het u hulp nodig om die inhoud te verbind met alledaagse lewensituasies?
5. Dink u dit is belangrik om u onderrig te verbind aan werklike lewensituasies? Motiveer jou antwoord.
6. Hoe voel u daaroor om tegnologie te gebruik gedurende u onderrig?
7. Hoe voel u daaroor om mobiele tegnologie soos Whatsapp en SMS'e te gebruik om met my, en u ander kollegas, die moontlike wyses waarop wiskunde-inhoud meer realisties vir u leerders gemaak kan word, te bespreek?

8. Hoe voel u daaroor om deel te wees van ‘n Whatsapp-groep wat die kwessies rondom wyses waarop wiskunde-inhoud meer realisties vir u leerders gemaak kan word, te bespreek?

9. Watter tipe ondervinding het u met Facebook?

10. Hoe voel u daaroor om Facebook te gebruik om die kwessies rondom wyses waarop wiskunde-inhoud meer realisties vir u leerders gemaak kan word, te bespreek?

11. Watter tipe ondervinding het u m.b.t. die interaktiewe witborde?

12. Hoe voel u daaroor om die interaktiewe witborde te gebruik om kwessies rondom wyses waarop wiskunde-inhoud meer realisties vir u leerders gemaak kan word, te bespreek

13. Watter tipe tegnolgie sal u die mees gemaklikste mee wees om te gebruik tydens hierdie projek?

Cohen's Kappa for Individual Interviews

		Peers: Agree	Peers: Disagree

Focus Group Interview Schedule

1. Why is mobile technology suitable to present Mathematics content in a realistic way?

2. How does this app address the principles and characteristics of RME?

3. How can this app assist teachers to teach Mathematics in a meaningful way?

4. What knowledge of technology would a teacher need to effectively use the app?

5. Which role-players will influence the use of an app such as this in the school situation?

6. How did you experience using this app?

7. How would you use this app to improve your teaching practice?

8. Which sections of the curriculum would benefit most from an app such as this one?

9. What can be done to improve this app?

Addendum 5.1

App Design Document: Financial Maths

Content

Problem situation

Sipho has decided to to buy a bicycle so that he can attend soccer training in the afternoons at his school. Sipho visited the local stores and found a bicycle that he likes for R1299.

He has three options to consider. The store offers **hire-purchase** to buy the bicycle over a period of two years at 14% **p.a**. **simple interest**, (his dad will need to do the hire-purchase for him). He could also borrow the money from his dad who agreed that he can pay it back over 1 year at 13% p.a. simple interest. The third option is to borrow the money from his older brother Peter, who agreed to a 2 year period at 8% **compound interest**.

Questions:

1. Which is the best option for Sipho, considering he only earns R 150 pocket money a month? Motivate your answer.

2. Model an answer to show which of the three options is the most economical for Sipho (Which one does he pay the least interest)? Motivate.

Definitions: Click on the bold words in the problem to reveal their meanings

Interest	When money is loaned, interest is charged for being able to use the money. When you invest money with a bank, you will be paid interest.
p.a.	Is the abbreviation for per annum, it means per year.
Hire-purchase	Goods like appliances can be bought on a hire-purchase loan. For hire-purchase, they usually require a 10% or 20% deposit. The interest is calculated at simple interest on the full loan amount over the period that it is repaid.
Simple Interest	Simple interest is calculated on the original amount of a loan or investment.

Formula to calculate simple interest

Simple interest is calculated with the following formula:

$A = P(1 + i.n)$ where

A is the total or accumulated amount.

For investments, A is the amount invested plus the interest earned.

For a loan, A is the total amount you have to pay back, the amount you borrowed plus the interest

P is the amount borrowed or invested.

i is the simple interest rate per annum (per year) (p.a.)

Remember that if the interest rate is 10% p.a. then

i = 10%

$i = \frac{10}{100}$

$i = 0{,}1$

n is the number of years that the money has been invested or borrowed.

Compound Interest

With compound interest, the interest is added to the capital amount at the end of each period.

Compound interest is interest on interest.

Long-term loans such as home loans make use of compound interest.

Formula to calculate compound interest

Compound interest is calculated with the following formula:

$A = P(1 + i)^n$ where

A is the future value of the money invested or borrowed. It includes the principal amount and the interest earned.

P is the initial (principal) amount invested or borrowed

i is the interest rate per annum, compounded annually

n is the number of years for which the money has been invested or borrowed.

Hints to answer Question 1:

Do you know how what to do for the hire-purchase option?

Hint 1a: **Calculate the simple interest** for hire-purchase option

Need help with the formula?

Yes	**No**
$A = P(1 + i.n)$	If the formula is correct, go on to the next question. If something is incorrect, correct that as follows: If P is not correct, give the hint: P is the amount borrowed or invested If i is not correct, give the hint: i is the simple interest rate p.a. If n is not correct, give the following hint: n is the number of years that the money has been invested or borrowed.

Fill in the values you need for the formula

P = ☐	If incorrect then say: P = 1299 this is the amount you need to borrow
$i = \square\% = \square$	If incorrect, then say $i = 14\% = 0{,}14$ the interest rate is 14% per annum (per year)
n = □	If incorrect, they say n = 2 because you will pay back the money over a period of 2 years

Now fill these values into the formula

$$A = P(1 + i.n)$$

= □[□ + (□)(□)]

If the correct value (see below) is entered in the block ✓

= 1299[1 + (0,14)(2)]

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: P = 1299 this is the amount you need to borrow

$i = 14\% = 0{,}14$ the interest rate is 14% per annum (per year)

n = 2 because you will pay back the money over a period of 2 years

= □[1 +□]

If the correct value (see below) is entered in the block ✓

= 1299[1 + 0,28]

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: P = 1299 this is the amount you need to borrow

0,14 x 2 = 0,28

= □[□]

If the correct value (see below) is entered in the block ✓

= 1299[1,28]

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: P = 1299 this is the amount you need to borrow

1 + 0,28 = 1,28

= R □

If the correct value (see below) is entered in the block ✓

= R 1662,72

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: 1299 x 1,28 = 1662,72

Do you know how what to do for the loan from dad option?

Hint 2a: **Calculate the simple interest** for the loan from dad option

Need help with the formula?

Yes	**No**
$A = P(1 + i.n)$	If the formula is correct, go on to the next question. If something is incorrect, correct that as follows: If P is not correct, give the hint: P is the amount borrowed or invested If i is not correct, give the hint: i is the simple interest rate p.a. If n is not correct, give the following hint: n is the number of years that the money has been invested or borrowed.

What about the values to substitute?

P = □ If incorrect then say: P = 1299 this is the amount you need to borrow

$i = \square\% = \square$ If incorrect, then say $i = 13\% = 0{,}13$ the interest rate is 13% per annum (per year)

n = □ If incorrect, they say n = 1 because you will pay back the money over a period of 1 year

Now do the sum

$A = P(1 + i.n)$

= □[□ + (□)(□)]

If the correct value (see below) is entered in the block ✓

= 1299[1 + (0,13)(1)]

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: P = 1299 this is the amount you need to borrow

$i = 13\% = 0{,}13$ the interest rate is 13% per annum (per year)

n = 1 because you will pay back the money over a period of 1 year

= □[1 +□]

If the correct value (see below) is entered in the block ✓

= 1299[1 + 0,13]

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: P = 1299 this is the amount you need to borrow

0,13 x 1 = 0,13

= □[□]

If the correct value (see below) is entered in the block ✓

= 1299[1,13]

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: P = 1299 this is the amount you need to borrow

1 + 0,13 = 1,13

= R □

If the correct value (see below) is entered in the block ✓

= R 1467,87

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: 1299 x 1,13 = 1467,87

Did you know that compound interest means that the interest is added to the capital amount at the end of each year? Keep this in mind and work out the compound interest using the simple interest formula.

Hint 3a: Loan at the end of the first year:

$A = P(1 + i.n)$

= □[1 + (□)(□)]

If the correct value (see below) is entered in the block ✓

= 1299[1 + (0,08)(1)]

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: P = 1299 this is the amount you need to borrow

$i = 8\% = 0{,}08$ the interest rate is 8% per annum (per year)

n = 1 Because you are working out the simple interest one year at a time

= □[1 + □]

If the correct value (see below) is entered in the block ✓

= 1299[1 + 0,08]

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: P = 1299 this is the amount you need to borrow

0,08 x 1 = 0,08

= □[□]

If the correct value (see below) is entered in the block ✓

= 1299[1,08]

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: P = 1299 this is the amount you need to borrow

1 + 0,08 = 1,08

= R □

If the correct value (see below) is entered in the block ✓

= R 1402,92

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: 1299 x 1,08 = 1402,92

What about the second year?

$A = P(1 + i.n)$

= □[1 + (□)(□)]

If the correct value (see below) is entered in the block ✓

= 1402,92[1 + (0,08)(1)]

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: P = 1402,92 the interest from year one was added to the amount you borrowed.

$i = 8\% = 0{,}08$ the interest rate is 8% per annum (per year)

n = 1 Because you are working out the simple interest one year at a time

= □[1 + □]

If the correct value (see below) is entered in the block ✓

= 1402,92[1 + 0,08]

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: P = 1402,92 the interest from year one was added to the amount you borrowed.

0,08 x 1 = 0,08

= □[□]

If the correct value (see below) is entered in the block ✓

= 1402,92[1,08]

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: P = 1402,92 the interest from year one was added to the amount you borrowed.

1 + 0,08 = 1,08

= R □

If the correct value (see below) is entered in the block ✓

= R 1515,15

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: 1402,92 x 1,08 = 1515,15

Now do the calculation for the loan from Peter. Do you need help?

Hint 4a: **Calculate the compound interest** for loan option from older brother Peter

Need help with the formula?

Yes	**No**
$A = P(1 + i)^n$	If the formula is correct, go on to the next question. If something is incorrect, correct that as follows: If A is not correct, give the hint: A is the future value of the money invested or borrowed. It includes the principal amount and the interest earned. If P is not correct, give the hint:

	P is the initial (principal) amount invested or borrowed If i is not correct, give the hint: i is the interest rate per annum, compounded annually If n is not correct, give the following hint n is the number of years for which the money has been invested or borrowed.

What about the values to substitute?

P = ☐ If incorrect then say: P = 1299 this is the amount you need to borrow

$i = \square\% = \square$ If incorrect, then say $i = 8\% = 0{,}08$ the interest rate is 8% compounded annually

n = □ If incorrect, they say n = 2 because you will pay back the money over a period of 2 years

Now check if your answer is correct

$A = P(1 + i)^n$

$A = \square(1 + \square)^{\square}$

If the correct value (see below) is entered in the block ✓

$= 1299(1 + 0{,}08)^2$

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: P = 1299 this is the amount you need to borrow

$i = 8\% = 0{,}08$ the interest rate is 8% per annum (per year)

n = 2 because you will pay back the money over a period of 2 years

= □(□)$^{□}$

If the correct value (see below) is entered in the block ✓

= 1299$(1{,}08)^2$

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: P = 1299 is the amount you need to borrow.

1 + 0,08 = 1,08

= □(□)

If the correct value (see below) is entered in the block ✓

= 1299(1,1664)

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows: P = 1299 is the amount you need to borrow.

$(1{,}08)^2$ = 1,1664

= R □

If the correct value (see below) is entered in the block ✓

= R 1515,15

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows:

1299 x 1,1664 = 1515,15

Now compare the two answers you got for this option (using the simple interest formula and using the compound interest formula. What do you notice?

To answer Question 1: Payment per month:

Not sure how to work out which option is best?

Hint 5a: Calculate the monthly payment for each option

I don't know what a monthly payment is ....

Hint 5b: A monthly payment is how much money needs to be paid back per month to the person or place that it was borrowed from.

How do I calculate a monthly payment?

Hint 5c: Take the final amount from your calculation and divide it by the total number of months that the loan was taken out for.

Does your model have this information for the hire-purchase option?

Hire-purchase option

Payment per month = □

If the correct value (see below) is entered in the block ✓

= R 69,28 per month

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows:

Payment per month = R 1662,72 ÷ 24

= R 69,28 per month

Does your model have this information for the loan from dad option?

Loan from dad option

Payment per month = □

If the correct value (see below) is entered in the block ✓

= R 122,32 per month

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows:

Payment per month = R 1467,87 ÷ 12

= R 122,32 per month

Does your model have the following information for the loan from Peter option?

Loan from Peter

Payment per month = □

If the correct value (see below) is entered in the block ✓

= R 63,13 per month

If the incorrect value is entered x . If the answer is incorrect three times, then give the correct answer as follows:

Payment per month = R1515,15 ÷ 24

= R 63,13 per month

Which is the cheapest option in term of monthly payments? □

If answer is Peter ✓

If any other answer x . If the answer is incorrect three times, then give the correct answer as Peter.

To answer Question 2: The most economical option (the least interest paid):

Hire-purchase option: Interest = □

If answer is R353,72 ✓

If answer is incorrect then x

Interest = Final amount – Initial amount

Interest = R 1662,72 – R 1299

= R 353,72

Loan from dad option: Interest = □

If answer is R 168,87 ✓

If answer is incorrect then x

Interest = Final amount – Initial amount

Interest = R 1467,87 – R 1299

= R 168,87

Loan from Peter: Interest = □

If answer is R 216,15 ✓

If answer is incorrect then x

Interest = Final amount – Initial amount

Interest = R 1515, 15 – R 1299

= R 216, 15

Most economical option is □

If answer is loan from dad ✓

If answer is incorrect three times, then give the correct answer as loan from dad

Activity

TV for sale

Cash Price R 5 999

OR

Hire-purchase

Deposit R599 and only R 243 per month

(30 instalments)

1. Sarah needs to decide which option is the most economical for her. Create a model to give her advice and help her to decide.

2. What is the interest rate that they are charging for the hire-purchase?

Question1:

Do you need help to start? yes □ no □

If they say yes, then say: Create a model to work out how much money Sarah pays back over the 30 instalments, remember to include her deposit.

After that say:

Hire-purchase final amount = □

If they say no then: Hire-purchase final amount = □

If they say R 7889 then say – well done, that is correct

If they have a different answer, then say: Your answer is incorrect. Check that your model includes the following:

Final amount = Deposit + (monthly instalment x 30)

= R 599 + (R 243 x 30)

= 599 + 7290

= R 7889

What is your advice to Sarah? Choose the most economical option for her.

Cash Price of R 5999 □ OR Hire-purchase with deposit R 599 and R 243 monthly □

If they choose Cash Price then say – Well done, that is the correct choice

If they choose Hire-purchase then say: No that is not the correct choice. She will be paying back R 7889 on hire-purchase and only R 5 999 for the cash price. Discuss with a colleague why the first option is the best for Sarah.

Question 2

Do you need help to work out what the interest rate is?

yes □ no □

If yes, then say: remember that Hire-purchase means Simple Interest and then say: Which formula do I use?

□ = □(□ + □.□)

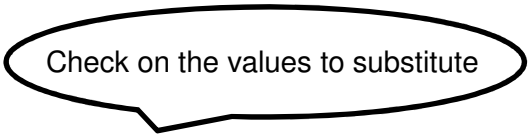
If no then say: Which formula do I use?

□ = □(□ + □. □)

The answer should be: $A = P(1 + i.n)$

If the formula is correct, go on to the next question. If something is incorrect, correct that as follows:

If P is not correct, give the hint:



P is the amount borrowed or invested

If i is not correct, give the hint:

i is the simple interest rate p.a.

If n is not correct, give the following hint:

n is the number of years that the money has been invested or borrowed.

P = □

A = □ x □

= □

n = □ years

The answers should be:

P = 5400

If P is incorrect three times, then say: Do you know why it is R 5400 and not R 5999? Because there was a deposit of R 599

$A = 243 \times 30$

= 7290

If anything above is incorrect three times, then display the correct answer

$$n = 2\frac{1}{2}$$

If n is incorrect three times, then say: What happened to 30 months? It was converted to years.

Now check your answer

$$A = P(1 + i.n)$$

$$= \square[\square + (\square)(\square)]$$

If the correct values (see below) are entered in the block then say ✓

$$7290 = 5400[1 + (i)(2\frac{1}{2})]$$

If the incorrect values are entered then say x . If the answer is incorrect three times, then give the correct answer as follows:

$$7290 = 5400[1 + 2{,}5i]$$

$$7290 = 5400 + 13500i$$

$$7290 - 5400 = 13500i$$

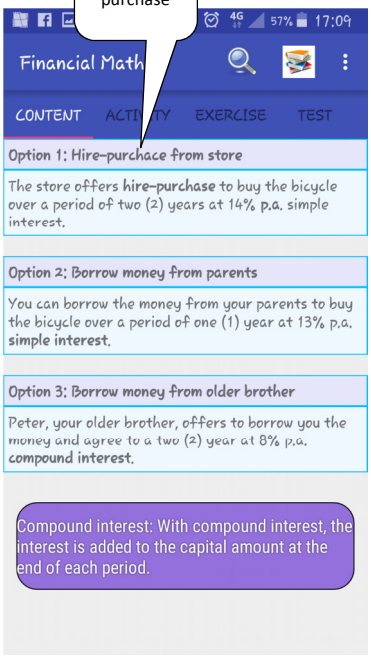
$$1890 = 13500i$$

$$i = \frac{1890}{13500}$$

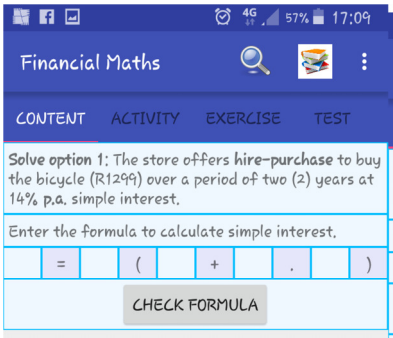
$$i = 0{,}14 = 14\%$$

What is the interest rate that they are charging for the hire-purchase?

$$i = \square\%$$



The answer should be 14%. If correct then say: Well done, that is correct.



If the answer is incorrect three times, then display the correct answer.

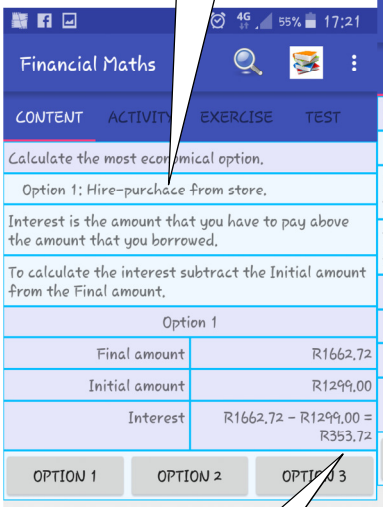
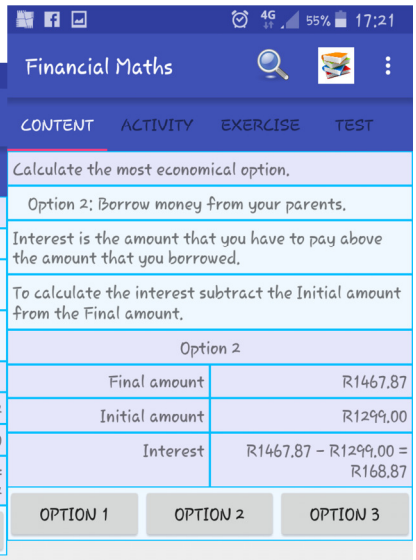
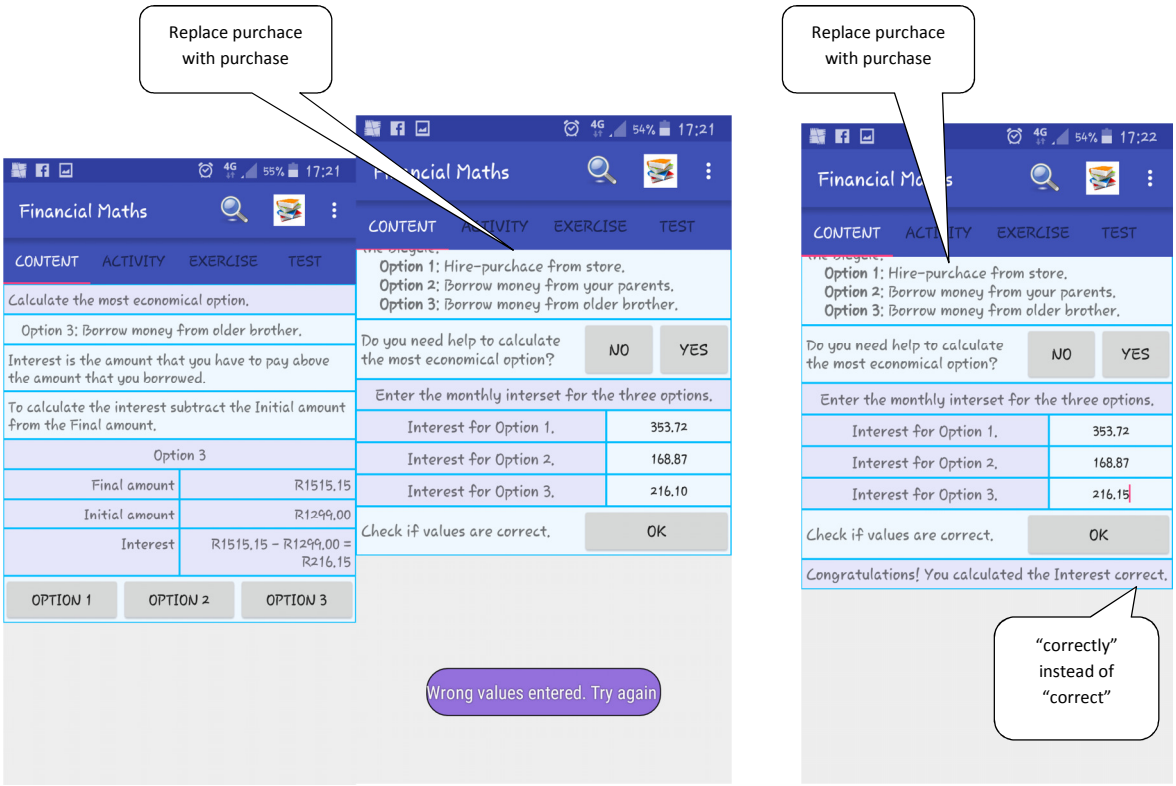
Calculate the monthly payment.
Let's review the three options to get money to buy the bicycle.
Option 1: Hire-purchase from store
Option 2: Borrow money from your parents
Option 3: Borrow money from old
Do you need help to calculate the monthly payments?
Option 1: Hire-purchase from store.
A monthly payment is how much money you need to pay back per month to the person or place that you borrowed it from.
To calculate the monthly payment take the final amount that you calculated in your model and divide it by the total number of months that the loan was taken out for.
Option 1
Total amount R1662.72
Months to pay back 24
Payment per month R1662.72 ÷ 24 = R69.28
Option 2
Total amount R1467.87
Months to pay back 12
Payment per month R1467.87 ÷ 12 = R122.32
OPTION 1 OPTION 2 OPTION 3
Enter the monthly payments
Monthly payment for Option
Check if values are correct. OK
Replace purchace with purchase
Please change the instruction to: Create a model to calculate the monthly payment.
Is it possible to put a ^ in the formula to indicate it's a power of n?
Please add a line: Discuss with a friend or colleague how this answer compares to the answer you got when using the simple interest formula.





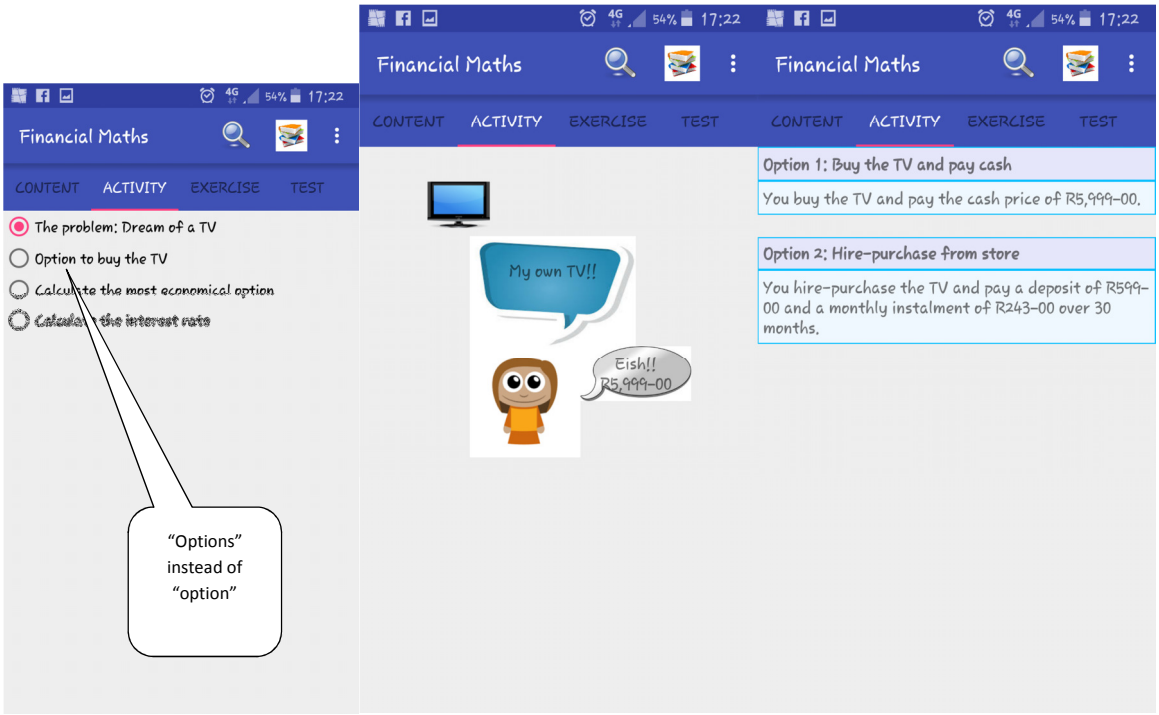
Replace purchace with purchase



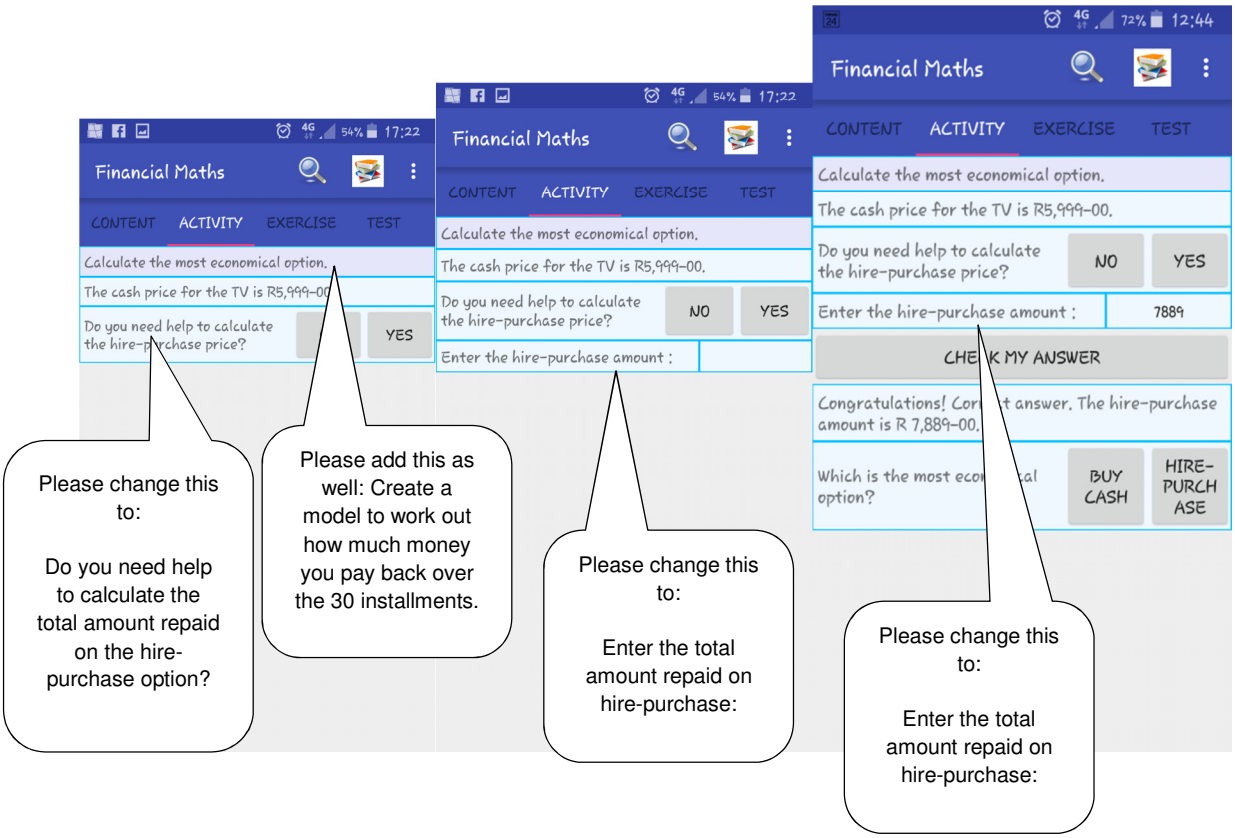
"interest" in the place of "interset"

Replace purchace with purchase

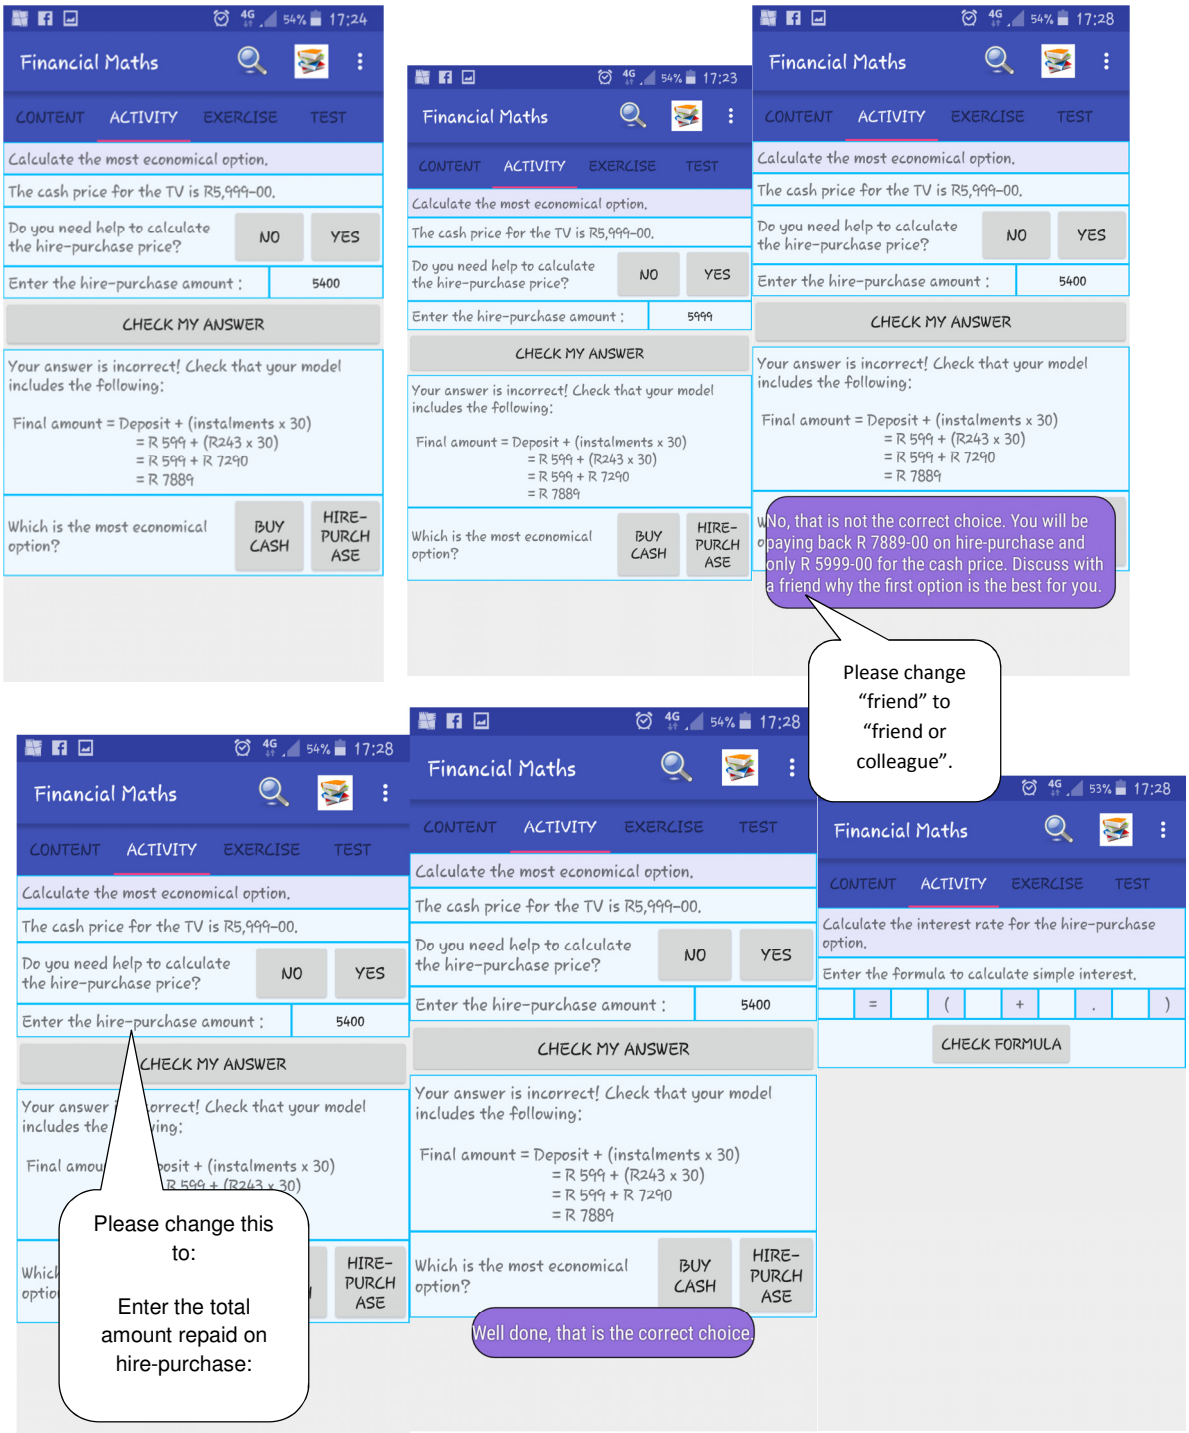
The answer should be R363,72



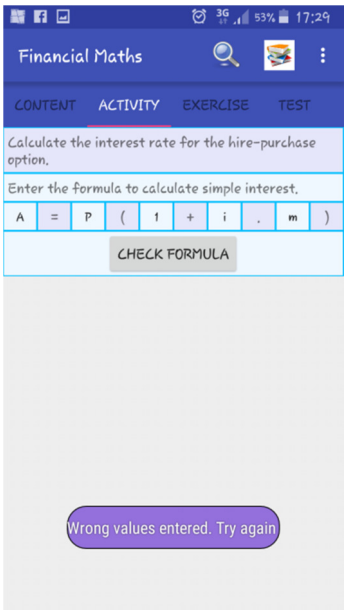
After this screen we need to answer the question:



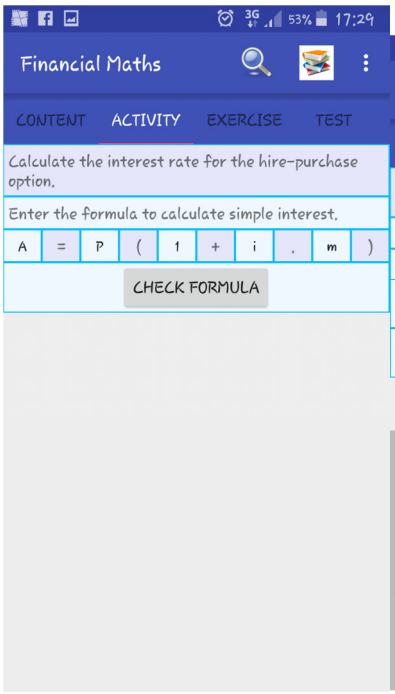
Which is the most economical option? Option 1 Option 2 Option 3



If the answer is Option 1 then say: This is the incorrect answer, try again.



If the answer is Option 2 then say: Well done, this is the correct answer! Discuss with a friend or colleague possible reasons why this option has the lowest interest.



If the answer is Option 3 then say: This is the incorrect answer, try again.

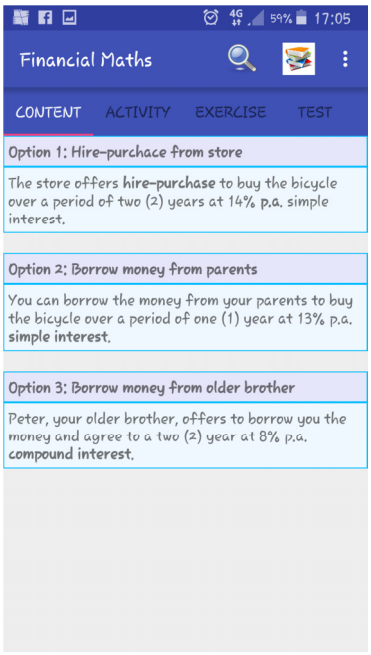
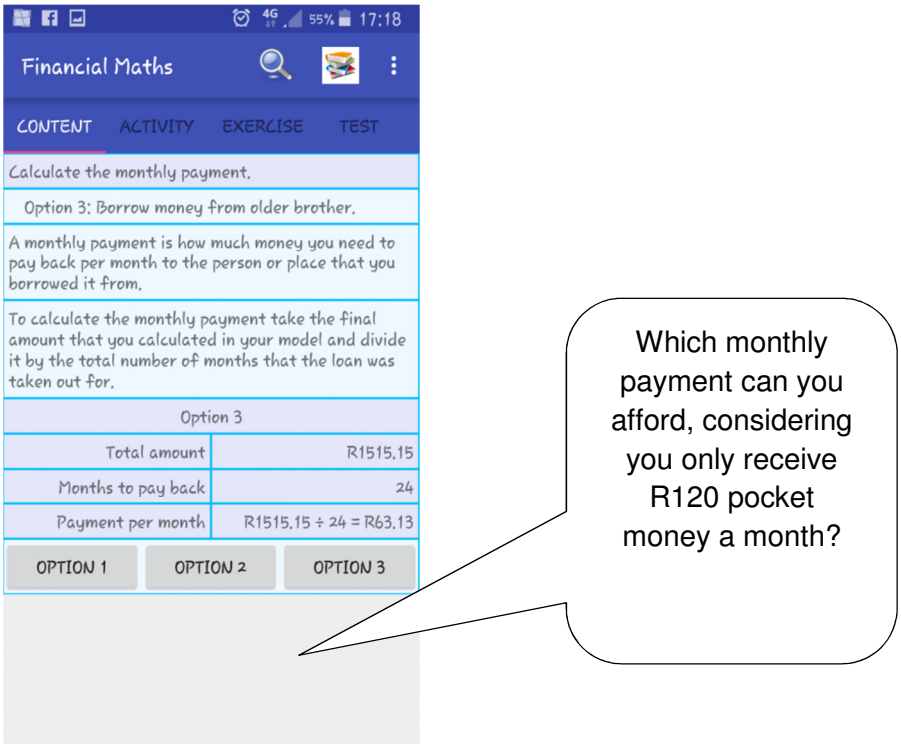
Changes to app 10-05-16

Can we introduce the content section with the detailed problem and questions that need to be solved? Perhaps have a screen that sets the problem situation and asks both questions before any other information is given.

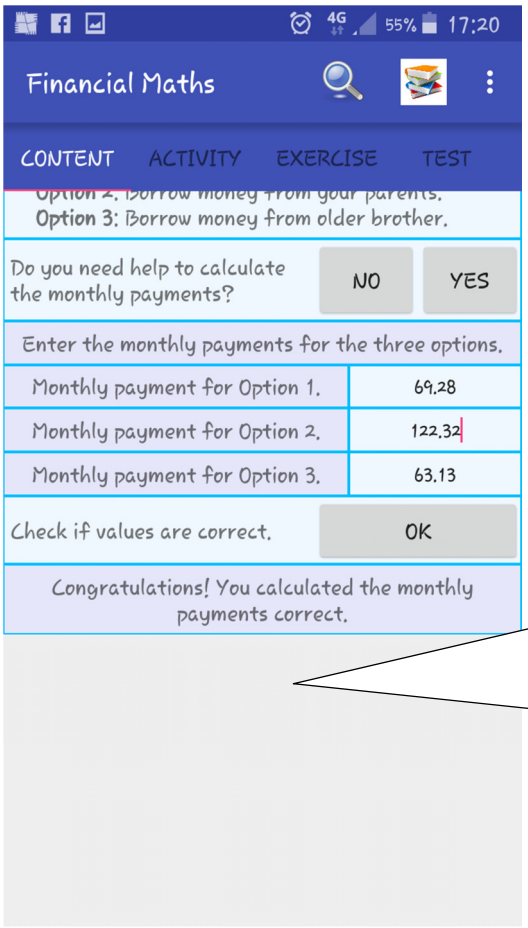


Problem situation
You have decided to buy a bicycle so that you can attend sport training in the afternoons at your school. You have visited the local stores and found a bicycle that you like for R1299. You have three options to consider. The store offers **hire-purchase** to buy the bicycle over a period of two years at 14% **p.a**. calculated at **simple interest**. You could also borrow the money from your parents who agreed that you can pay it back over 1 year at 13% p.a. calculated at simple interest. The third option is to borrow the money from your older brother Peter, who agreed to a 2 year period at 8% calculated at **compound interest**.

Questions:



1. Which monthly payment can you afford, considering you only earn R 120 pocket money a month?
2. Model an answer to show which of the three options is the most economical for you (Which one do you pay the least interest)?



They will not know that the highlighted words can be defined. Can we have a hint pop up or appear or something, so that they know to **tap** on the bold words.

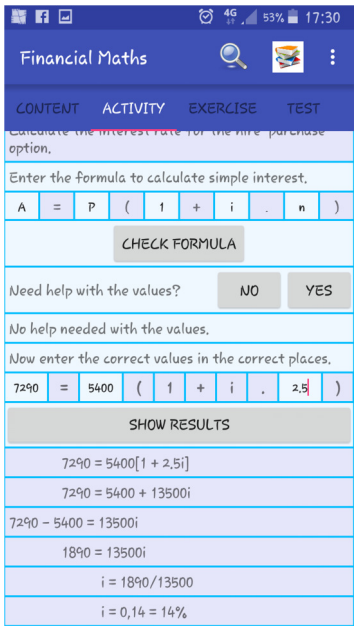
When they are asked to work out the monthly payment and if they say they need help to work out the monthly payment, then the three options' monthly payments can be seen. After the last one has been clicked, they must be asked the question again:

The question must also be asked if they entered the monthly payments themselves as well.

Which monthly payment can you afford, considering you only receive R120 pocket money a month?

Can we introduce the activity section with the detailed problem and questions that need to be solved? Perhaps have a screen that sets the problem situation and asks both questions.

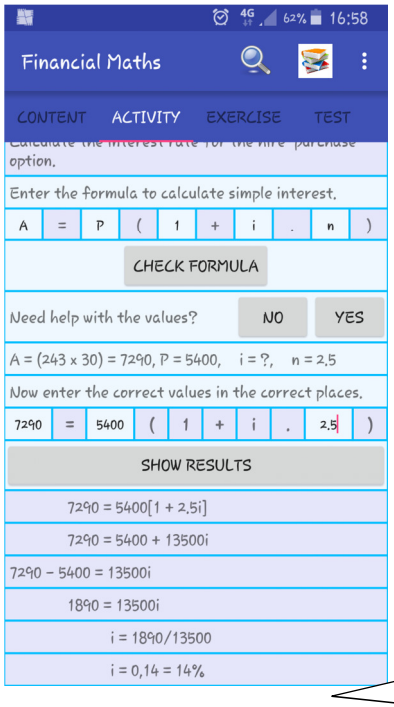
You want to buy a new TV. The following options are available for you:



Cash Price R 5 999

OR

Hire-purchase: Deposit R599 and only R 243 per month (30 installments)



1. You must decide which option is the most economical. Create a model to help make the decision.

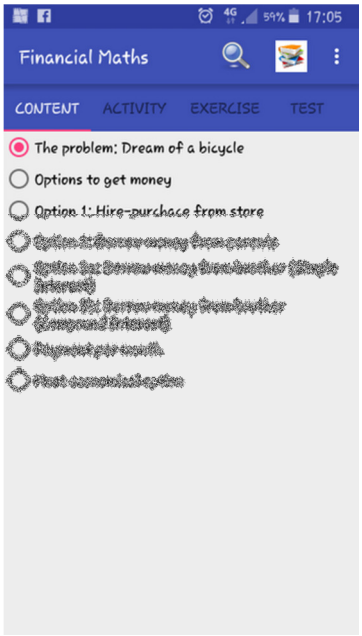
2. What is the interest rate that the store is charging for the hire-purchase?

When they calculate the interest rate correctly, can we include a final line that says:

Well done, you have correctly calculated the interest rate to be 14%

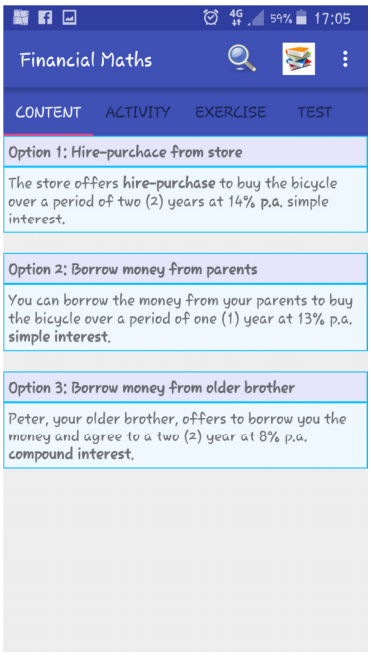
Also if they needed help with the values, and then correctly enter the values and calculate the interest rate, can we include a final line that says:

Well done, you have correctly calculated the interest rate to be 14%



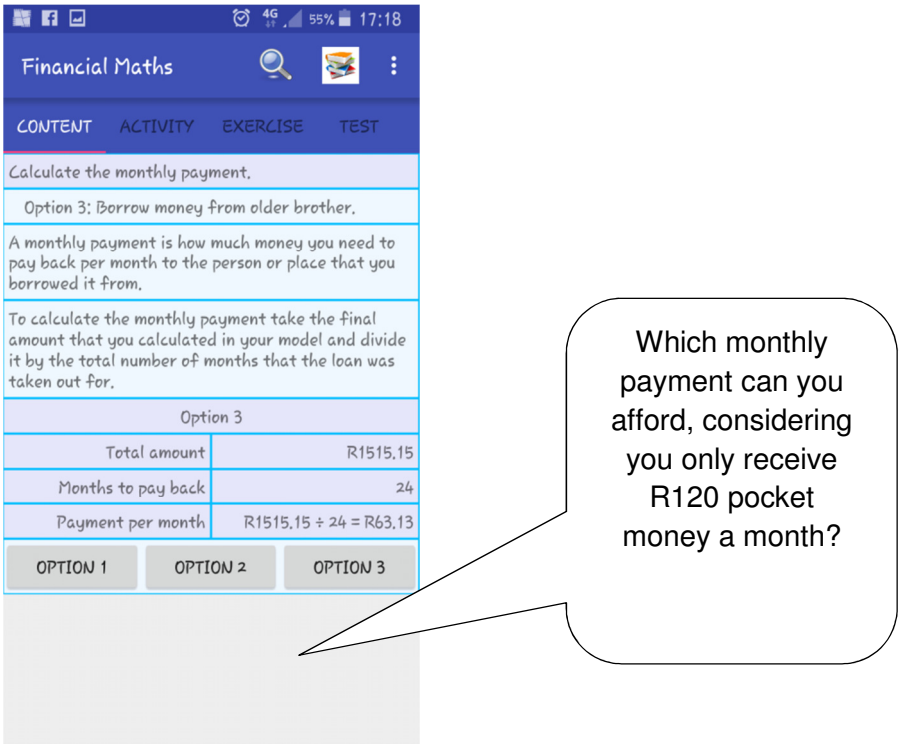
Changes to app 10-05-16

Can we introduce the content section with the detailed problem and questions that need to be solved? Perhaps have a screen that sets the problem situation and asks both questions before any other information is given.

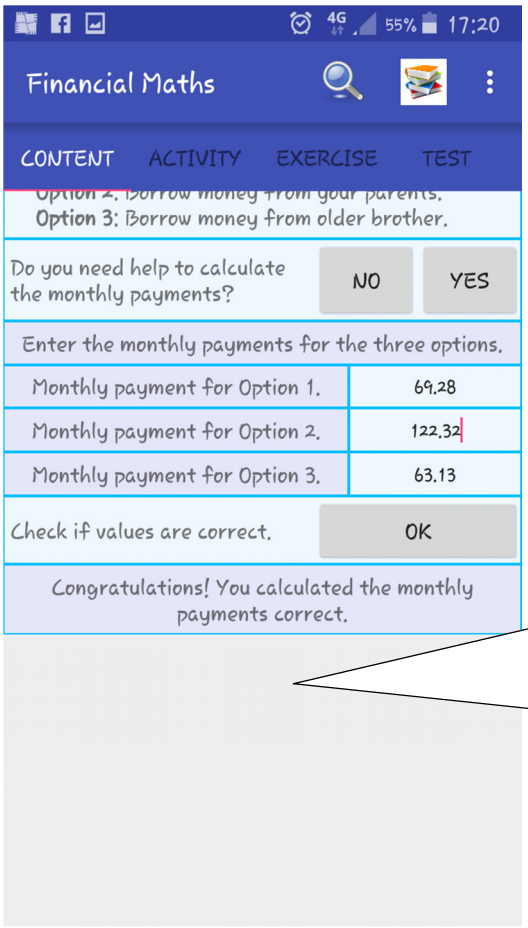


Problem situation
You have decided to buy a bicycle so that you can attend sport training in the afternoons at your school. You have visited the local stores and found a bicycle that you like for R1299. You have three options to consider. The store offers **hire-purchase** to buy the bicycle over a period of two years at 14% **p.a**. calculated at **simple interest**. You could also borrow the money from your parents who agreed that you can pay it back over 1 year at 13% p.a. calculated at simple interest. The third option is to borrow the money from your older brother Peter, who agreed to a 2 year period at 8% calculated at **compound interest**.

Questions:



1. Which monthly payment can you afford, considering you only earn R 120 pocket money a month?
2. Model an answer to show which of the three options is the most economical for you (Which one do you pay the least interest)?



They will not know that the highlighted words can be defined. Can we have a hint pop up or appear or something, so that they know to **tap** on the bold words.

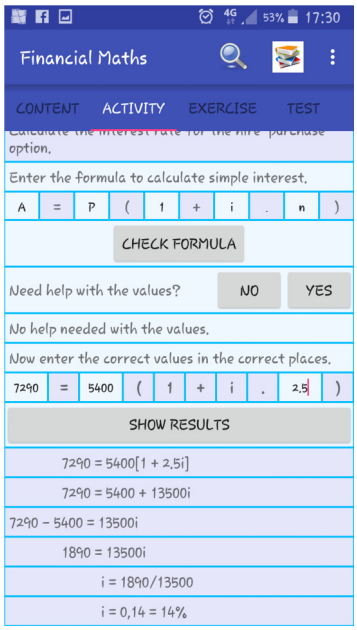
When they are asked to work out the monthly payment and if they say they need help to work out the monthly payment, then the three options' monthly payments can be seen. After the last one has been clicked, they must be asked the question again:

The question must also be asked if they entered the monthly payments themselves as well.

Which monthly payment can you afford, considering you only receive R120 pocket money a month?

Can we introduce the activity section with the detailed problem and questions that need to be solved? Perhaps have a screen that sets the problem situation and asks both questions.

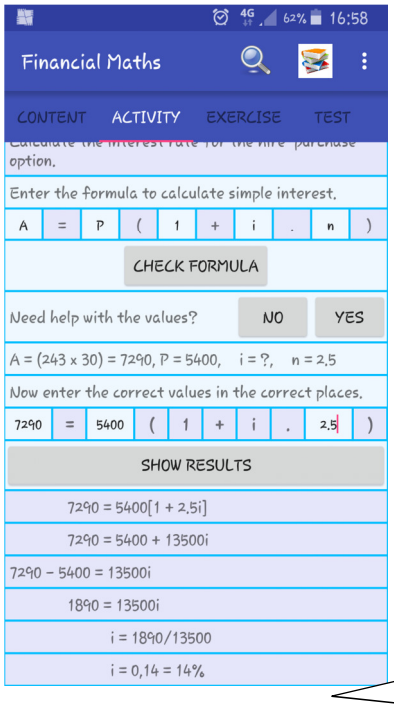
You want to buy a new TV. The following options are available for you:



Cash Price R 5 999

OR

Hire-purchase: Deposit R599 and only R 243 per month (30 installments)



1. You must decide which option is the most economical. Create a model to help make the decision.

2. What is the interest rate that the store is charging for the hire-purchase?

When they calculate the interest rate correctly, can we include a final line that says:

Well done, you have correctly calculated the interest rate to be 14%

Also if they needed help with the values, and then correctly enter the values and calculate the interest rate, can we include a final line that says:

Well done, you have correctly calculated the interest rate to be 14%

DESIGN OF A PROTOTYPE MOBILE APPLICATION TO MAKE MATHEMATICS EDUCATION MORE REALISTIC

Dawid B. Jordaan[1], Dorothy J. Laubscher[2] & A. Seugnet Blignaut[1]

[2]*SDL, North-West University, Potchefstroom Campus, South Africa*

ABSTRACT

To enter the world of work, students require skills which include flexibility, critical thinking, problem solving, collaboration and communication. The use of mobile technologies which are specifically created for a context could stimulate motivation in students to recognise the relevance of Mathematics in the real world. South Africa in particular is a suitable location to use mobile learning across distance due to its viability, affordability and availability as opposed to web-based technology. The design team developed an app for financial Mathematics based on the principles of realistic mathematics education (RME) for mathematics teachers to use with their students. The paper describes the design process and general usability aspects of the formative evaluation of the prototype app for financial Mathematics. The authors suggest that a graphic artist becomes part of the design team to enhance the visual attractiveness of the app.

KEYWORDS

Realistic Mathematics Education (RME); mobile applications; Distance Education (DE); Android; interactivity; user interface.

1. INTRODUCTION

The rapidly changing information society influences the roles of learners and teachers (Gravemeijer, 2012). Future jobs require what Gravemeijer (2012) refers to as 21st century skills, which include "flexibility, critical thinking, problem solving, collaboration, and communication." Gravemeijer (2012) emphasizes the importance of addressing these demands by investigating educational practices that may nurture these goals. Heck et al. (2007) are of the opinion that the use of mobile technology could increase motivation as well as performance in learners. Also, the use of real-life contexts stimulate motivation because the relevance of Mathematics can be seen in the real world (Risnawati et al., 2014).

Various reasons are offered for poor performance in Mathematics, which include: when topics are taught (Fauzan et al., 2013), inaccurate learning material, inadequate or outdated teaching methods, poor forms of assessment, students' anxiety about Mathematics (Widjaja and Heck, 2003); and students' negative attitudes towards Mathematics (Widjaja and Heck, 2003).

Mobile learning is a field that is rapidly expanding and it affords new possibilities to improve learning, especially in a distance education (DE) environment (Kizito, 2012). South Africa in particular is a suitable location to use mobile learning in distance education due to its viability and affordability as opposed to web-based technology (Kizito, 2012). The portability of mobile technology allows learners to work creatively and collaboratively (Zaranis et al., 2013). When used correctly, technology could promote critical thinking, improve problem solving skills and facilitate collaboration (Stols, 2012). Further research is required to determine how the mobile phone can effectively be used in testing in DE (Kizito, 2012).

This paper investigates the need for, and the design and development of, a mobile application which would assist Mathematics teachers in making their teaching and their students' learning more realistic in terms of the context in which the learning takes place.

2. LITERATURE REVIEW

2.1 Realistic Mathematics Education

Mathematics teachers are challenged to develop Mathematics education that is in line with the dynamic conceptions of symbolizing and the development of meaning (Bakker et al., 2003). The role of the teacher is essential to understand how to teach effectively with technology (Drijvers, 2012). Digital tasks should be designed in such a way that students are encouraged to develop their own Mathematics. The teacher should guide the process and should know when to further explore a topic or concept and when to cease to investigate a topic (Drijvers et al., 2013).

The traditional approach to teaching Mathematics still dominate in many classrooms today (Fauzan et al., 2013). This approach is characterized by teachers who actively explain material and provide examples and exercises, while learners listen, write and perform the tasks the teacher requires (Gravemeijer, 2012, Widjaja and Heck, 2003). The social norms of traditional classrooms dictate that the teachers' answers are always correct and that students should follow given procedures to reach correct answers, which are more important than reasoning (Gravemeijer, 2012). Learners seldom have the opportunity to understand the rationale behind algorithms that are taught to them (Risnawati et al., 2014). Such a traditional approach to teaching Mathematics is held responsible for the poor quality of Mathematics Education and students' negative attitude towards Mathematics (Fauzan et al., 2013, Widjaja and Heck, 2003). Another consequence of traditional teaching is that when students solve word problems, high level cognitive and metacognitive processes are often absent (Mousoulides et al., 2007).

Reform from the traditional approach demands that curricula, teaching materials and assessment need to be adapted (Zulkardi, 2000). Freudenthal (1968), often regarded as the father of Realistic Mathematics Education (RME), opposes the traditional idea that the end result of the work of mathematicians is the starting point for Mathematics Education (Gravemeijer and Doorman, 1999). RME is regarded as a domain-specific instruction theory for the teaching and learning of Mathematics (Drijvers et al., 2013). The RME-based teaching and learning process promotes learner-centred learning (Fauzan et al., 2013). Problem solving through modelling leads to the design of activities that allow for students to deal with non-routine problem situations that demand the development of important mathematical ideas which can be extended, explored and refined in other problem situations (Mousoulides et al., 2007). Technological tools create new prospects for problem solving in Mathematics (Doorman et al., 2007). A corner stone of RME is that students are encouraged to not only receive information, but also question and process information (Widjaja and Heck, 2003), actively participate in the educational process and develop mathematical tools and insights (Drijvers et al., 2013).

2.2 Mobile learning

Mobile technology offers a new generation of learning to students of all ages without being bound by place and time (Alzaza and Yaakub, 2010). Mobile learning (mLearning) is becoming more popular within formal education as its benefits offer cost-efficiency, portability; instant connectivity; and context sensitivity. Mobile learning assists students to create social interaction; it promotes collaborative learning, interactivity and instant feedback as well as collaboration between peers; it improves their knowledge structure; their learning achievements and motivation (Mouza and Barrett-Greenly, 2015). Domingo and Garganté (2016) further point out that students are more willing to engage when learning with mobile technology; their desire to accomplish educational tasks also increases with the use of mobile technology, and it helps learners to become more self-directed in their learning. Mobile communication in education is a solution with a selection of prospects and challenges (Kommers and Hooreman, 2009).

mLearning applications have various educational benefits: they can be used as study aids; can be accessed from almost anywhere; and with the aid of location capabilities, students can use location-based information (Cheon et al., 2012). Mobile technology applications supplement higher education by extending traditional educational platforms and encouraging distance learning or using settings outside of the classroom (Al-Emran et al., 2016). Content applications that make use of personalized instruction can facilitate academic growth and self-efficacy among students (Mouza and Barrett-Greenly, 2015).

3. METHOD

This research relates to the first phase of a four-phased qualitative design-based research process where four teacher-students in the Open Distance Education (ODL) program of the North-West University (NWU), Potchefstroom Campus participated in individual interviews. They shared their perceptions and experiences on support teachers' need in order to effectively implement the RME principles in their teaching practice. The teacher-students confirmed that their own students inter alia (i) had problems with certain areas of Mathematics, (ii) suffered challenges with the integration of the content across the curriculum, (iii) were excited about the affordances that mobile learning could bring to Mathematics education, and (iv) experienced challenges to link school Mathematics to real life problems, e.g. handling their own finances. The researchers decided to zoom in on the aspect of financial Mathematics for the content aspect of the mobile application (app) because all the participants mentioned this area as troublesome to their students.

The context in which the app will be used should form the anchor for the development of the content (Widjaja and Heck, 2003). The app was specifically designed for teacher-students enrolled in an open distance learning (ODL) teacher professional development programme through the Unit of Open Distance Learning (UoDL) at the North-West University at the Potchefstroom Campus. They were all established Mathematics teachers at semi-rural schools in the North-West Province, South Africa, and enrolled for a BEd Honours programme. The design of the application was based on RME principles: (i) guided reinvention (or progressive mathematisation); (ii) emergent modelling; and (iii) didactical phenomenology (Andresen, 2007). The process of guided reinvention began with a real-life problem which was then mathematised (Gravemeijer and Doorman, 1999). The aim with the app was to guide these teacher students to become comfortable with using technology in teaching and learning, as well as to enable them to interact with their learners on RME.

3.1 Creating the app

Software engineering (SWE) is the application of *engineering* to the design, development, implementation, testing and maintenance of *software* in a systematic method. The objective of software engineering is to produce software systems to customers in a cost effective way. Once installed these systems should display characteristics such as efficiency, reliability, maintainability, robustness, portability and so on (Sommerville, 2016). The software process is a set of activities and associate results which produce a software product. Software specification, development, validation and evolution are fundamental process activities common to all software processes.

Software development models are processes or methodologies used for the development of software projects. There are many development models that have been developed in order to achieve different objectives. The models specify the various stages of the process and the order in which they are carried out (Sommerville, 2016). Examples of software development models are: Evolutionary Prototyping Model; Spiral Method (SDM); Iterative and Incremental Method; Extreme programming (Agile development); Waterfall model; Prototype model; Rapid application development model (RAD) and so on (Whitten and Bentley, 2007). Choosing the right model for developing a software product or application is very important as the model determine where and when the development and testing processes are carried out.

For the development of our app, which we name *Financial Maths* App, we decided to use the Prototype Model because of the advantages that this model offer: Users are actively involved in the development; Since a working model of the system is provided, the users get a better understanding of the system being developed; Errors can be detected much earlier; Rapid user feedback is available leading to better solutions; Missing functionality can be identified easily; and Confusing or difficult functions can be identified (Mohammed et al., 2010). The basic idea is that instead of freezing the requirements (as required by many other models) before a design or coding can proceed, a prototype is built to understand the requirements based on the currently known requirements. By using this prototype, the client can get an "actual feel" of the system, since the interactions with the prototype can enable the client to better understand the requirements of the desired system. The prototype is usually not a complete system and many of the details are not built into the prototype. The goal is to provide a system with overall functionality. Figure 1 depicts the phases in the development of a prototype.

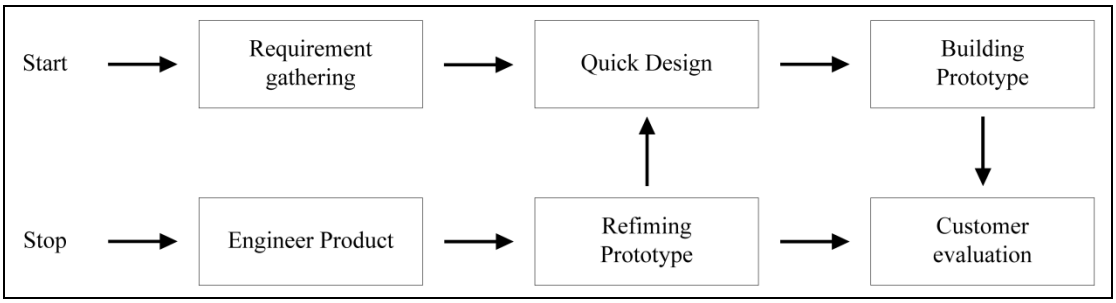

Figure 1. Prototyping model (Sommerville, 2016)

3.2 Creating the app

Background. While the first author of this paper was the designer of the app, the second author was the content specialist and also responsible for the various design documents, and the third author was the expert on the use of technology in teaching and learning. Together they formed a tight project team. They obtained ethics clearance for this research from the Ethics Committee of the North-West University (NWU-HS-2014-0267).

Requirement (Step 1). The first step in creating an app was to develop a clearly defined purpose for the mobile app: we had to determine what the app should be able to do; what its primary appeal would be; which concrete problem it was going to address; and what part of life it aimed to improve. Detail design documents were created which outlined the standards, planning design, development, and ongoing evaluation of the project (Fleisch and Schöer, 2014).

Quick Design (Step 2). Next the foundation of the user interface was laid. This step visually conceptualized the main features and a rough layout and structure of the app. Sketches for the proposed layout and structure of the app were drawn which assisted the team to understand the journey better Figure 2 is an example of such a sketch.

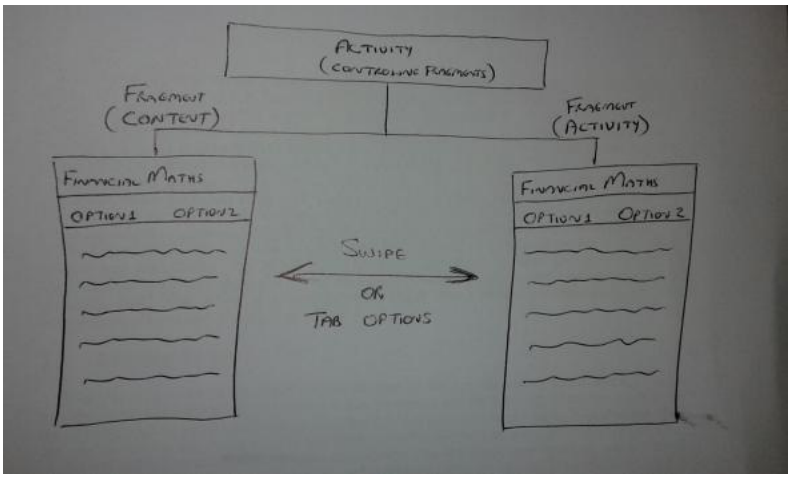

Figure 2. Example of layout sketch (own scetch)

Building Prototype (Step 3). At this stage all the ideas and features culminated as a clear picture of the structure and a storyboard for the project was created. The storyboard provided a road map which illustrated the connections between the different screens and how the user could navigate through the app. The storyboard formed the foundation for the first version of the prototype.

Customer Evaluation (Step 4). The next step involved the testing of the prototype. Friends, family, colleagues, and experts all helped to review the prototype. They were requested to test run the app and give sincere feedback and identify flaws and dead-end links. If possible to monitor how they used the app, one should take note of their actions as these would provide important feedback for user interface (UI) and user experience (UX) evaluation (Molich and Nielsen, 1990). Based on their feedback, the prototype was modified. The aim was to finally specify the app concept before going into the design process. For the

Financial Maths app, the content author tested the app with two of her Mathematics colleagues who are Mathematics lecturers, as well as with a RME expert.

Refining Prototype (Step 5). Next, individual screen content were designed. The task was to create high-resolution versions of the prototype. All comments from the prototype testers were included in order to design the most suitable user interface. With the screen designs completed and implemented, the actual app concept was complete, all the graphics were inserted, and all text was signed off—the actual design was now implemented and made clickable.

Repeat (Step 2 to 5). The next step was to test the full design once more and collect as much feedback as possible from a variety of users. The new ideas and comments were used to refine the app. A consistent look and feel of the layout was assured and we ensured that it would perform reliably on different devices.

Deployment (Step 6). As the vast majority of the intended students used Android devices (Dahlstrom et al., 2016), the brief was to develop the *Financial Maths app* for Android devices (smart phones and tablets). The *Financial Maths* app was consequently installed on Android devices and tested for functionality in a live environment.

4. USABILITY OF THE APP

4.1 The user interface

Figure 1 illustrates two scenarios that are realistic and relevant to students at school, from which the concepts of simple and compound interest could develop. Students are not expected to reinvent all the content themselves, and should be guided by the teacher who allows them the opportunity to reflect on their invented strategies (Gravemeijer and Doorman, 1999). Drijvers et al. (2013) suggest that guidance from the teacher will help the progression in a sensible manner, as is suggested in Figure 3.

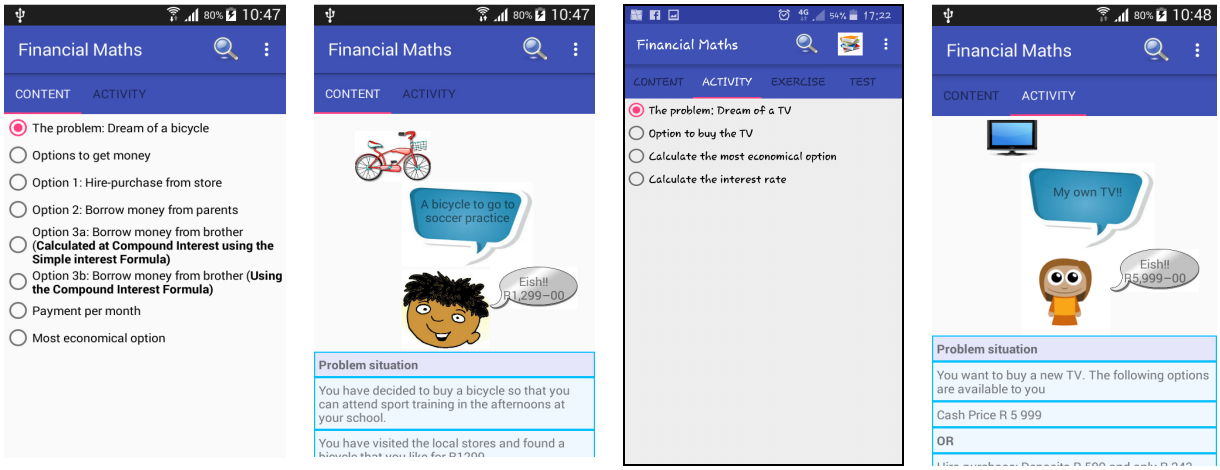

Figure 3. A context that is meaningful and natural is created

Emergent modelling refers to the development of models from the student's activity which leads to the emergence of formal Mathematics (Gravemeijer and Doorman, 1999). The use of models is encouraged as a bridge between what is abstract to students and what is real (Dolk et al., 2002). Figure 4 illustrates how the use of models has been encouraged in the app. The models too are grounded in the contextual problem and are not derived from the intended Mathematics (Gravemeijer, 1999). The last screenshot in Figure 4 illustrates that students are in various instances given three opportunities to attempt to develop their own strategies to solve a problem before a hint is given.

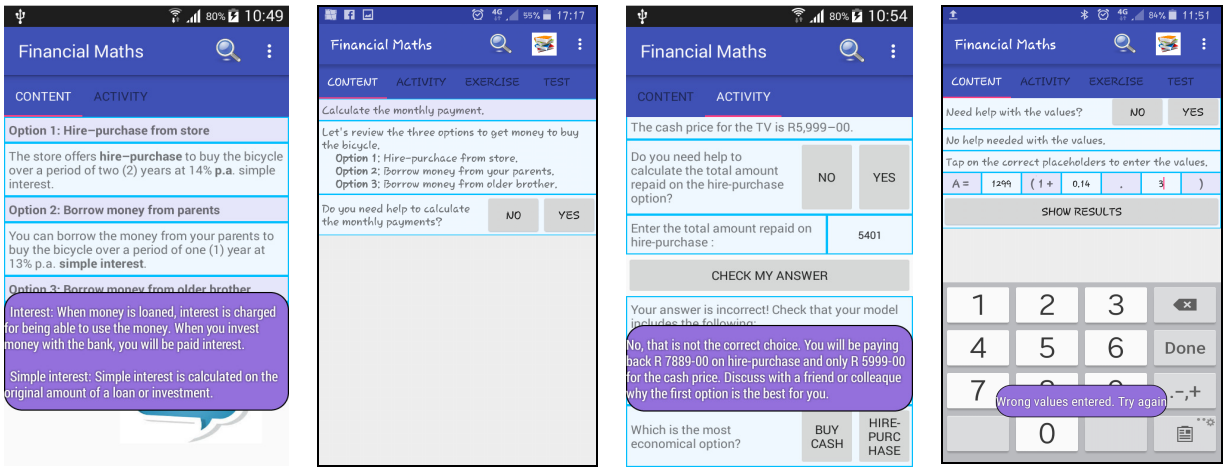

Figure 4. Hints and tips are provided should students require them

The third principle that was incorporated in the design of the app was didactical phenomenology, which deals with the idea of how mathematical structures can assist in organising phenomena in real life (Zulkardi, 2000). Students are confronted with situations that need to be organised, and in that way students can build concepts (Bakker et al., 2003). The phenomena of personal finances, hire-purchase and interest rates are relevant real-life notions that can be structured with mathematical content (Figure 5).

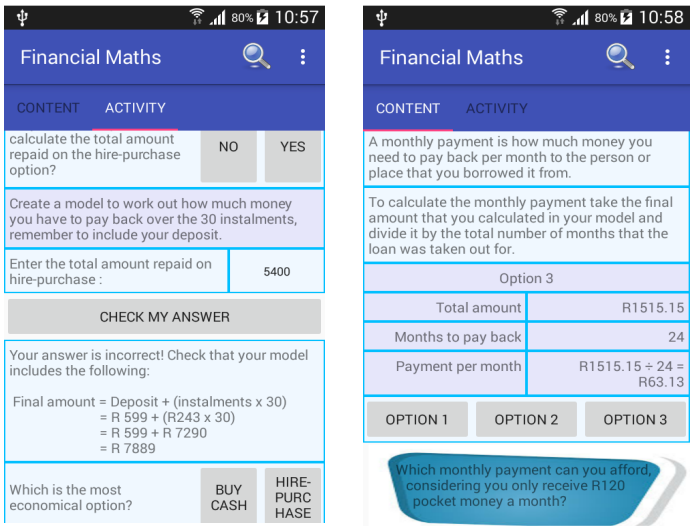

Figure 5. An illustration of the use of models

4.2 General usability of the app

The initial design document provided the design team with a broad idea of the content of the app. In the drafts to follow, more particulars are given with regard to the detail of when hints and tips should appear; how many attempts students can make on a solution before receiving help; and words of encouragement when the solutions are correctly worked out. Molich and Nielsen (1990) are of the opinion that general usability evaluations should comprise not more than ten members, and the design team followed this suggestion. The three team members perused and tested the first two prototypes and suggested changes in terms of usability. An RME expert evaluated the third prototype of the app and focused specifically on the inclusion of the RME principles. His evaluation revealed that all the principles of RME were sufficiently addressed in the app and that it should achieve the purpose for which it was designed, namely to make

teachers' teaching of Mathematics, and learners' learning experiences more realistic, relevant and experientially real. He suggested that the app be thoroughly tested before being released for student use.

Two more experts in the field of Mathematics education tested the app. Their main suggestion for improving the app was to make the problem situation more visible at the start of the app:

> *Put something in that sets the scenario more clearly. The start of the app is too vague.*

Their evaluation also included comments on why they felt the app was suited to the purpose for which it was created:

> *It works very well because all the steps are clearly shown. It will help the teachers to teach their learners to follow logical steps in their calculations.*

The app included an activity that clearly showed the intertwining of the concepts of compound and simple interest, a key characteristic of RME (Widjaja and Heck, 2003). The Mathematics education experts found this appropriate and necessary:

> *I like this very much. By including this comparison of concepts you can see wow, it's quicker to use the compound interest formula, and yet you still get the same answer as when repeating the simple interest formula.*

They also suggested that the app be extended to other content areas and that it be made available to a wider range of teachers.

5. CONCLUSIONS AND RECOMMENDATIONS

The design of this app has the potential to be extended into a larger project where a variety of problem content areas in Mathematics, at different grade levels, could be addressed. These apps could be made available to any Mathematics teacher who needs assistance with both content as well as the notion of incorporating relevant, real life contexts in their Mathematics teaching.

A comment made by a Mathematics education specialist relates to the need for the development of users of such apps in terms of the integration of technology into their every teaching and learning:

> *We had a bigger problem working the phone that doing the sums. Let's hope that the students that will be using this app are comfortable with the technology.*

Although one of the points of criticism from the subject experts was that the problem scenario was not well articulated, the design team is of the opinion that a more graphic approach would work better. The context and content should be presented with the aid of more graphics and less words.

ACKNOWLEDGEMENT

We would like to thank the National Research Foundation of South Africa for in part supporting this work. Any opinion, findings and conclusions or recommendations expressed in this material are those of the authors and therefore the NRF does not accept any liability in regard thereto.
Thank you also to the teacher-students who shared their needs for the app with us for their patience, dedication and willingness to participate in the study and learn with us.

Subject: [SPF:fail] ML 2017: paper accepted

Dear Author

We are pleased to inform you that your submission to the 13th International Conference on Mobile Learning (ML 2017) has been accepted as a "Full Paper".

Please, make the suggested corrections to your paper (see details below), use the correct format available at http://mlearning-conf.org/submissions/ (very important: if this format is not followed we cannot accept your contribution and it won't be published in the proceedings). Make sure that your final submission has the number of pages allowed for this category which is 8 pages (additional pages up to 4 will be charged as specified in the registration form). Also note that your final submission must be a WORD file since proceedings are produced in WORD,

Also, login to your author area available at http://www.conf-system.org/confman_ml2017/author_menu.asp with your login and password, and
1 - submit the final version - in word or rtf version please until 9 December 2016 (please submit from your author area link only),
2 - access the copyright form, fill it out and send it in order for your contribution to be published (until 9 December 2016),
3 - print an invitation letter (if required) for you or any of your co-authors,
4 - register for the conference (deadline for this procedure is also 9 December 2016 - if not registered the paper won't be published in the proceedings. This deadline also corresponds to the early registration rates for this call - select the early registration option from the rates part of the registration form),
5 - View hotel information and book hotel at http://mlearning-conf.org/venuehotel-info/ ,
6 - Check the guidelines for presenters available at http://mlearning-conf.org/guidelines/ .

Hope to see you in Budapest, Hungary, during 10 - 12 April 2017.

For any information please contact us. Thank you.

Best regards,

Inmaculada Arnedillo Sánchez, Trinity College Dublin, Ireland
Program Chair

Pedro Isaias, University of Queensland, Australia
Conference Chair

NOTE: This e-mail is being sent to all co-authors of this submission.

Introduction of a new construct: The conceptual tool "Flexibility"
Mette Andresen
1
Danish University of Education
Abstract
This paper presents a new construct: the conceptual tool 'Flexibility'. The construct was a result of an attempt to extract experiences of teaching and learning with the use of laptops. It was further developed and refined on the basis of four small-scale teaching experiments. The teaching experiments, being part of a development project in upper secondary school mathematics, investigated the use of laptops for teaching differential equations from a modeling point of view. The research was double-aimed: one objective was to conclude the project with some recommendations for the design of teaching, in the form of guidelines suitable for a wider dissemination amongst upper secondary mathematics teachers. The other main aim was to draw on the project's experiences for theory development within a framework based on Realistic Mathematics Education (RME) and related ideas. The construction of 'Flexibility' served both these aims.
Keywords: computer environments; flexibility; instrumental genesis; technology; teaching and learning; laptops; differential equations; Realistic mathematics education (RME)
1. Background
In Denmark, a recent reform of the structure and the curriculum in upper secondary school encompassed introducing the use of CAS in mathematics, chemistry and physics. Teaching with CAS was not required to follow authorized plans or materials: the design of teaching sequences, planning and preparation of extra teaching materials etc. were still the individual teacher's responsibilities. Thereby, the reform made new demands on the teachers' professional development: it was far from obvious how the use of CAS should be integrated in the individual teacher's repertoire of teaching instruments
2
. A metropolitan area six-year school development
project, titled 'World Class Math and Science'
3
. partly served as a precursor for the reform,

although the government did not sponsor the project. Part A of the development project
4
encompassed experiments with laptop classes in upper secondary school mathematics.
I was employed at the Danish University of Education to do the research in part A of the development project for my Ph.D. in mathematics education. Following the standpoint described in Wittmann (1998) and Lesh & Sriraman (2005), that mathematics education is a design science, I believe that research and development has to be linked to teaching and learning practice at crucial points. Improvement of teaching practice must be merged with the progress of the whole field of educational research and reversely, research progress linked to the development of teaching practice. So, the research for the Ph.D. project became double-aimed: one objective was to conclude the World Class project with some recommendations for the design of teaching, in the form of guidelines suitable for a wider dissemination amongst upper secondary mathematics teachers. The other main aim was to draw on the project's experiences for theory development within the theoretical framework based on Realistic Mathematics Education (RME) and related ideas. My construction of 'Flexibility' served both these aims.
1.1 Objectives of the construction
With this background, the initial goal of the research was to extract knowledge from the project's teaching experiments in a way that made this knowledge useful. More precisely, the aim was to identify, articulate and conceptualise the participants' shared experiences of improved learning and, subsequently, to turn these experiences into a form that would:
- Allow teachers to take them into account for improvement of their own teaching
- Serve as a contribution to math education theory
In yearly evaluation interviews, participants from the World Class A project repeatedly had expressed a shared experience of improved learning: in the interviews, a number of students and teachers described their feelings of getting "a better overview" and "a deeper understanding", apparently as a result of the use of laptops. These remarks were developed further with explanations like "because you can easily get series of graphs", "you do not get stuck in technical details", "it is easy to see examples" or "in stead of remembering a lot of techniques you are allowed to concentrate on the ideas". Such answers are in accordance with some expectations to CAS (and computer) use, widespread amongst math teachers. Teachers, like many researchers
5
, believe that besides to favour visualisations, the CAS routines can be
incorporated into the design of teaching as shortcuts, to facilitate students' focusing on ideas, structures and conceptions.
Hence, in the research project the challenge was to critically sort out examples of fruitful support of students' learning from the general feeling of "flow in the classroom". So the objective turned out to be pointing out important elements of learning activities, for teachers to aim at in their future design and preparation of teaching sequences and single lessons. These elements of learning activities are important, according to two criteria:
1. The activity should promote the student's actual work with mathematics in an observable way

4
See (Andresen 2006 chapter 3, p 21-39) for a detailed description
5
See for example (Drijvers, 2003, p 92). Hypothetically, the work with CAS may offer the students a shortcut to reification or a shortcut to working with "objects" as if the processes were reified. TMME, vol4, no.2, p.232
2. Arguments based on the theoretical framework should support the claim that the activity could promote the student's learning
The mental actions 'change of perspective' and 'change of representation' turned out to be a common denominator for the important elements in focus of my interest. They gave inspiration to my choice of the term 'flexibility' to denote the new construct in the following definition.
1.2 Definition: Flexibility of mathematical conceptions
Definition
The flexibility of a mathematical conception constructed by a person is the
designation of all the changes of perspective and all the changes between different representations the person can manage within this conception.
(Andresen, 2006, p. 136):
In this definition of the conceptual tool flexibility, the term 'change of perspective' means change between different facets of the mathematical conception in question, regarded as the student's construct
6
. My selection of a number of complementary pairs of perspectives intended
to make flexibility an operational tool. Two main considerations determined my choice of pairs, in accordance with (1.) and (2.) above:
- Changes within the pairs of perspective should be recognisable for the teacher (or any observer)
- The changes should be pivots for the students' learning process.
Within the notion of flexibility, the term 'representation' is used in the sense of the media of expression or communication. The objective of the construction was not to categorise all mental changes. The overall aim was to offer teachers a few building blocks in the form of simple design heuristics. My design of these building blocks should be appropriately based on the research to ensure that the use of them was likely to support the students' learning.
Neither did the construction aim to establish any one-to-one correspondence between every mathematical conception and its exposure within each perspective. Supposedly, it is clear that any mathematical conception can be expressed in each perspective in more than one way, and it may be exposed in more than one way in each representation. The perspectives and representations, referred to in the definition, are presented in a later paragraph in this paper. Before that, the next paragraph tells about the theoretical basis for the concept of flexibility.

6
According to L. P. Steffe and P. W. Thompson (Steffe & Thompson 2000 p 268-269), the experience of students' learning allows the researcher to inquire the students' mathematical realities. These realities are called students' mathematics and by (partly) knowing them, it is possible for the researchers to construct a model of students' mathematics, called mathematics of the students. Students' mathematics, which the students have constructed as a result of their interactions in their physical and sociocultural milieu, is indicated by what the students say and do when they engage in mathematical activity. In contrast, mathematics of the students is part of the shared knowledge in the classroom, compatible with the educational goals. TMME, vol4, no.2, p.233
2. Basic ideas beyond the concept of 'flexibility'
Literature studies played an important role for the development and refinement of my earliest idea of 'flexibility'. This paper only presents three main ideas from the framework that forms the basis for my definition of 'flexibility'
7
: i) a specific dynamical approach to concept formation
that combines main heuristics of Seymour Papert and Jean Piaget, introduced by Edith Ackermann, ii) vertical and horizontal mathematising in the RME sense realised in Koeno Gravemeijer's four level model and iii) the French theory of Instrumental Genesis.
2.1. A dynamical approach to concept formation
To facilitate cognitive growth, Edith Ackermann presents the idea of a bi-directional interplay between "diving in" and "stepping back" in (Ackermann 1990 p 6). Ackermann refers to both Jean Piaget and Seymour Papert
8
as constructivists who see children as the builders of their own
cognitive tools, as well as builders of their external realities. Both Piaget and Papert consider knowledge as a personal experience to be constructed. Further, they both acknowledge adaptation as
.. the ability to maintain a balance between stability and change, closure and
openness, continuity and diversity, or, in Piaget's words, between assimilation and accommodation. (...) The main difference is that Piaget's interest was mainly in the construction of internal stability whereas Papert is more interested in the dynamics of change. (Ackermann, 1990, p.4)
The main point in Ackermann's description of Papert's view is: diving into situations rather than looking at them from a distance, connectedness rather than separation are powerful means of gaining understanding: becoming one with the phenomenon under study is a key to learning.

Ackermann's description of Piaget's view can be summarised like this: the way children progressively become detached from the world of concrete objects and local contingencies is closely related to their gradually becoming able to mentally manipulate symbolic objects within the realm of hypothetical worlds, so that rules and invariants are means of interpreting and organizing the world, and abstract and formal thinking are the most powerful way to handle complex environments.
Ackermann states that her own perspective is
..an integration of the above views. Along with Piaget I view separateness through progressive decentration as a necessary step toward reaching a deeper understanding. I see constructing invariants as the flipside of generating variation. (..) I share Papert's idea that diving into unknown situations, at the cost of experiencing a momentary sense of loss, is a crucial part of learning. (..) My claim is, that both "diving in" and "stepping back" are equally important in getting such a cognitive dance going. (Ackermann 1990 p 6)

7
The complete theoretical framework is presented and discussed in (Andresen 2006, chapter 5)
8
In a footnote, Ackermann says: "Describing the difference between Piaget and Papert has been useful for me, and might be of general interest for the reasons mentioned in the text. It is through working directly with both thinkers (first, at the Piaget Institute, and currently at MIT) that I became progressively convinced of the need for integrating structural and differential approaches in describing human development." (Ackermann 1990 p 27) *TMME*, vol4, no.2, p.234
Ackermann's idea of a 'cognitive dance' gave me the inspiration to construct 'flexibility' as a means to capture the dynamics of concept formation rather than static descriptions of cognitive structures. My method was to identify and group changes of perspective and changes between representations.
2.2. Vertical and horizontal mathematising in RME
Within the paradigm of RME, guided reinvention (or progressive mathematising), didactical phenomenology and emergent models are the three key heuristics for the design of teaching. In contrast to the cognitive theories of concept formation, 'modelling' was acknowledged to be an issue of interest in the World Class project's teaching culture. Moreover, a 'guided reinvention' design is to a great extend in accordance with the prevailing norms for good teaching. So it seemed reasonable to include RME into the framework in the following way. The four-levelmodel of activity intends to capture the way students' thinking evolves (Gravemeijer & Stephan 2002 pp 159-160):
Fig 1. Levels of activity (Gravemeijer and Stephan, 2002, p. 159)
In the model, the activities at the level of task setting take place in a situation that is experientially real for the students. This enables the students to reason with a model of the problem but still think about acting in the situation. For experienced students an experientially real situation may also be mathematical. At the next, referential, level the students act with a model that is meaningful because it signifies an experientially real activity for them. At the general level the type of activity has changed since the students' attention has shifted from the contextual meaning to the mathematical relations involved. The students' activities are no longer dependent on situation-specific imagery. Finally, the students will no longer need the support of a model for their more formal mathematical reasoning, which constitutes the fourth level of activity.
So, progressive mathematising implies the students' raising up through the four levels. The levelraising does not happen as a total, one-directional movement: the student may in one context of content be at one level and in another context at another level. Besides, the raising from one level to another happens over time, where the student switches between two levels in both directions several times. The levels, further, have different character. It follows that in terms of RME, *TMME*, vol4, no.2, p.235
concept formation by modelling can be expressed as changes between levels: horisontal mathematising happens as changes from situational, task setting level to referential level when models emerge, and vertical mathematising happens as changes from the level of model of (referential) - to the level of model for (general) and to further up to the formal level. In the description below, the first three levels in the four-level-model are considered as perspectives on the mathematical conceptions in question. Level-raising is considered as the result of bidirectional changes between these perspectives, which are included in 'flexibility'.
2.3. The French theory of Instrumental Genesis
The French theory of instrumental genesis is based on the idea that an artefact, for example a CAS calculator, does not in itself serve as a tool. It becomes useful, and then denoted an 'instrument', only after the user's formation of (one or more) mental utilisation scheme(s). Such utilisation schemes connect the artefact with conceptual knowledge and understanding of the way it may be used to solve a given task. The utilisation schemes contribute to the formation of instrumented action schemes. So, an instrument consists of the tool, for example a laptop with the CAS software Derive, the student's mental utilisation schemes and the task or problem to be solved. (Drijvers, 2003, pp. 96-97).
The process in which the artefact becomes an instrument is called 'instrumental genesis'. The process proceeds through activities in
The two-sided relationship between tool and learner as a process in which the tool in a manner of speaking shapes the thinking of the learner, but also is shaped by his thinking. (Drijvers & Gravemeijer, 2005, p. 190).
The two directions of the process can be linked to the construction of epistemic and pragmatic knowledge, respectively. The distinction between construction of epistemic and pragmatic knowledge is reflected in the definition of flexibility, which discerns between pairs of perspectives with relation to the construction of epistemic knowledge and, partly corresponding, pairs with relation to pragmatic knowledge.
This outline of the theory of instrumental genesis reveals the underlying French framework: the scheme concept, encompassing utilisation schemes and instrumented action schemes, was introduced by Vergnaud (Trouche, 2005, p.149). Since the mental utilisation schemes are not directly accessible for study and analysis, the concept of 'instrumented techniques' is of special interest: instrumented techniques are the external, visible and manifest parts of the instrumented action scheme. Still, an instrumented technique involves conceptual elements, since the technique reflects the schemes. This leads me to the following two crucial conclusions:
- The study of a student's development and use of instrumented techniques is useful to enlighten the student's development of those instrumented action schemes, to which the techniques relate
- Development of mathematical conceptions cannot be studied if use of technology is considered separate from the student's other activities *TMME*, vol4, no.2, p.236
The first point stresses the importance of empirical studies of students' work. The second point opposes my research to the standpoint, that teaching may be performed independently of what tools the students have at their disposal. It is also in contrast to the view, that the influence of for example computer use can be overlooked as if it were just a matter of 'digitising the pencil case'. This is in line with what Jean-Baptiste Lagrange stresses in (Lagrange, 2005, pp. 131-132):
The traditional opposition of concepts and skills should be tempered by recognising a technical dimension in mathematical activity, which is not reducible to skills. A cause of misunderstanding is that, at certain moments, a technique can take the form of a skill.
Besides the very grouping of the pairs of perspectives, the construction of the 'tool - object' pair was another result of the impact of the theory of instrumental genesis. The pair composed by a 'tool' perspective on a mathematical conception and an 'object' perspective on the same conception is realised for example in problem-solving settings. The tool - object pair corresponds to Anna Sfard's process - object duality (Sfard 1991). The tool perspective on mathematical conceptions is opposed to the 'pure skill' viewpoint and it implies the technical dimension that Lagrange refers to in the above quotation. So, within the notion of perspectives, the term tool denotes mathematical processes, carried out by the student with his instrument to serve a concrete purpose. It should be remarked that the purpose of the activity makes the difference between the tool perspective and Sfard's process perspective, not the instrument. Activities that aim at construction of pragmatic knowledge, involves the tool perspective on the mathematical conception in question. If the purpose is construction of epistemic knowledge, the process perspective is involved. This tool perspective on mathematical conceptions is in accordance with Régine Douady's definition of concept as a tool:
We say that a concept is a tool when the interest is focused on its use for solving a problem. A tool is involved in a specific context, by somebody, at a given time. A given tool may be adapted to several problems, several tools may be adapted to a given problem. (Douady, 1991, p. 115)
Mathematical activities, then, must be considered from a tool perspective when they are considered as parts or elements of a technique in the above mentioned sense. To take the corresponding object perspective, genesis of the instrument is requested. Therefore, the instrumental genesis is in a crucial way linked to and maybe a prerequisite for the change to object perspective.
2.4. Perspectives and representations, referred to in the definition of flexibility
The pairs of perspectives form three groups: perspectives intrinsic to mathematics, and perspectives relevant for construction of epistemic- and pragmatic knowledge respectively. As it was mentioned above, the distinction between epistemic and pragmatic knowledge intended to take into account that the conceptual tool flexibility should resonate with the theory of instrumental genesis. All the changes between perspectives and between representations are bidirectional. Each pair of perspectives can be developed reflexively during the bi-directional changes. *TMME*, vol4, no.2, p.237
In the notion of flexibility the term representation means representation system or communication media in a functional sense. So, the representations function partly as the media for externalisations of internal conceptual systems (Lesh and Doerr, 2000, p. 364; Mousoulides, Sriraman & Christou, 2007) and resembling the use of the term in the KOM-report (Niss, 2002). There is no sharp distinction between the four representations. Especially, the technical representation in many cases widely overlaps with the others.
2.4.1. Perspectives intrinsic to mathematics
Local and global position
Local position and global position are intrinsic mathematical perspectives. For example, changes between them occur when a single member of a group of objects is picked out for closer examination or if a single object is incorporated into a collection or family of objects. Using CAS, this change is easily realised for example by the use of facilities as substitution and copy - paste.
General - specific
General status and specific status are intrinsic mathematical perspectives, which concern the domain of validity. Inductive reasoning is linked to changes from specific to general perspective, whereas deductive reasoning is linked to changes from general to specific perspective. The use of CAS allows a quick and easy generating of specific objects from general expressions or formulas.
Analytic- constructive
The analytic and constructive perspectives are well-known phases in working with geometry. Examples are measuring a given thing and construction of a figure with a given measure, respectively. Especially, changes between these two perspectives are of relevance in sequences of modelling at a functional level.
2.4.2. Perspectives linked to construction of epistemic knowledge
The process - object duality.
The process perspective is operational and the object perspective is structural. The distinction and the connection between these two perspectives are encompassed by the reification theory. In contrast with the viewpoint of reification theory, the students' mental activities captured in the notion of flexibility, though, may go in both directions and thereby support the development of both perspectives.
Situated - decontextualised
The situated perspective is used to capture concrete aspects of problems, and of handling actual problems and challenges. The decontextualised perspective is the result of extracting rules, aiming at internal stability, which can occur through abstraction. Changes between situated and decontextualised perspective are linked to reflections, but not necessarily to modelling at the functional level. Therefore, this pair of perspectives relates to formation of epistemic rather than pragmatic knowledge. Changes from situated to decontextualised perspective correspond to the raising from referential to general level in the four-level model described above. *TMME*, vol4, no.2, p.238
2.4.3. Perspectives linked to construction of pragmatic knowledge
The tool - object duality
The tool perspective
9
focuses on the use of a mathematical conception for solving a problem in a specific context, with some specific aids. The corresponding object perspective means the distant overview-perspective on the tool. Flexibility in this case encompasses the student's distant overview over a collection of mathematical tools, besides his capability to change from the distant over-view perspective into a tool perspective in the actual context.
Model - reality
The changes between reality and model perspective result in level-raising from the first to the second level in Gravemeijer's four-level model. In a number of cases, reality is expressed in natural language, and changes from reality to model then happens in connection with a change of representation from natural- to formal language.
Model of - model for
The changes between model of and model for perspective result in raising from the referential to the general level in Gravemeijer's four-level model. The change is exemplified in the case of calculus by K. Gravemeijer and M. Doorman (Gravemeijer & Doorman, 1999, p.111).
2.5. Representations
The term representation is used in a very broad sense. Consequently, changes between the four representations may occur in different contexts, and happen at a variety of levels. As part of the students' modelling and problem solving activities, the communication media may for example change at a functional level. In contrast, in other cases a single change to natural language may involve cognitive challenges like interpretation of a graph or ascribing meaning to a symbol.
The four representations do not intend to form any classification of media for expression of mathematical conceptions. In line with this, computer language is included as a representation on its own although it overlaps with the other representations, because changes to and from computer language is one part of the instrumental genesis.
Analytic representation (formal language)
Analytic representation includes formal expressions and formulas, algebraic expressions and symbols. Changes to analytic representation are related with symbolising whereas changes from analytic representation are connected with interpretation of symbols and the ascribing of meaning to symbols. The changes may cover more or less complex actions: For example, a shift to formal language may imply a routine translation from the graph of a linear function into the corresponding formal expression. Or it may describe the level raise from situated to formal level or from referential to general level. During modelling processes, the changes to formal language often happens stepwise, passing stages of partly formalised in-between-expressions.

9
Here, the term tool is used in a broad meaning, not synonymous with artifact in contrast to instrument like in the theory of instrumental genesis *TMME*, vol4, no.2, p.239
Graphical representation
Graphic representation includes graphs, curves, diagrams and tables, drawings etc. and explanatory gesticulation. Changes to and from graphic representation may be the result of for example the student's construction of a spatial conception of a curve that corresponds to the formal expression of a mathematical conception. Though, the curved line in the calculator's window, created by one press on the button is regarded as a graphic representation of the

conception in question as well.
Natural language
The representation natural language encompasses spoken as well as written expressions and includes talk, explanations and negotiations, some texts written by the students or the by teacher, and some textbook texts.
The teacher's assessment has an impact on the communication in the classroom: depending on the social norms in the classroom, the students' can learn standard phrases of explanation by rote. The teacher's assessment of the student's understandings often relies on the student's capability to handle the content "in his or her own words". Standard phrases resembling own words, of course, can still be learned by root. Nevertheless, in the notion of flexibility such standard phrases are considered natural language. Natural language can overlap with formal language when technical terms are used, for example in group discussions.
The changes to natural language in many cases cover complex processes of interpretation and construction of meaning.
Technical representation (computer language)
Changes to technical representation encompass the translation from other representations into the version, adapted to the computer or calculator in question. Changes to computer language span from simple routines where students choose a well known instrument, to complex processes of instrumental genesis. Expressions in the other representations and changes between them are mediated in computer language: graphs, formal expressions and natural language can all be expressed in technical language too. In some cases, further, the software allows simultaneously use of formal language and graphic representation.
3. Methods and modes of the research
The initial construction of flexibility was based on teaching experiences, a preparatory classroom study and literature studies
10
. The teaching experiences were partly my personal ones; partly
from the World Class A project referred to in the evaluation interviews, and partly second-hand ones, collected over years in informal talk and discussions with teacher-friends and colleagues.
Subsequently, I carried out an empirical study which aimed to
- Identify signs which could indicate flexibility in the students' mathematical conceptions
- Inquire how the teaching, the task, the teacher's questions etc. provoked the students to demonstrate flexibility
- Interpret the role of flexibility for the students' further working with mathematics
-
10
The research design, the empirical studies and inquiries and their relations and roles in the design are presented and discussed in (Andresen, 2006, chapter 6) *TMME*, vol4, no.2, p.240
The outcome of the study appeared at different levels. For example, one of the overall conclusions was that flexibility of the students' conceptions in general was prerequisite for acting with competence in the KOM sense (Niss, 2002). In several concrete cases I concluded that the use of certain software commands enhanced the flexibility of the students' mathematical conceptions. Finally, at the level of analysis I concluded that the conceptual tool flexibility was useful to throw light on the students' process of getting used to computer use.
Four small-scale teaching experiments served as cases for the empirical study. The participating teachers designed teaching sequences on differential equations for the experiments based on shared written materials in the form of a booklet, prepared by a group of teachers from the development project (Hjersing, N., Hammershøj, P. and Jørgensen, B. 2004). For the teachers, the aim of the teaching experiments was to develop good practices of teaching differential equations from a dynamical systems point of view. The booklet focused on modeling with a problem solving approach.
Data from the teaching experiments had the form of field notes and film recordings from classroom observations, students written reports, group interviews with teachers and students, and teaching materials. I observed fifty lessons spread over the four classes with 22, 12, 10 and 6 lessons during the winter 2003-2004. The lessons were chosen, restricted by practical circumstances. The four teachers who had voluntarily agreed were very helpful and obliging supportive. Thanks to them, the students were also helpful and open-minded.
I observed almost all lessons on the subject differential equations, taught by one of the booklet's teacher-authors. The goals were: i) to study the authors' overall intensions with the modelling approach to the subject, ii) to qualify my reactions on the booklet to the authors and iii) to inquire the use of laptops in class room teaching. In one other class, my observations focused on the modelling aspect. In the last two classes, I observed students' group work on project tasks. It was my hope that the dialogue and negotiations between the students in the groups would reveal signs of their learning process at a closer and more personal level, compared to the classroom observations.
Data were studied during interpretative analysis, taking social and psychological perspectives into account. The analysis followed the approach, designed by Paul Cobb et al. to meet the following three criteria (Cobb, Stephan, McClain & Gravemeijer 2001 p 116):
- Enable documentation of the collective mathematical development of the classroom community over the extended periods of time covered by instructional sequences
- Enable documentation of the developing mathematical reasoning of individual students as they participate in the practices of the classroom community
- Result in analyses that feed back to inform the improvement of the instructional designs.
4. Episode from a case study
The rest of this paper presents an excerpt from one of the Ph.D. project's nine cases. The objective of this part of the research was to inquire into the hypothesis: the construct 'flexibility' may capture important elements of learning activities, like they were described in the first parts of this paper. The excerpt is the larger part of one (the second) of the case's three episodes. It intends to illustrate the analyses of data following the three main aims, listed above. *My* analysis *TMME*, vol4, no.2, p.241
of the episode mostly concentrates on the changes between model of perspective and model for perspective and on the inquiry of the model for perspective as it appears in two groups of students' work. Obviously, other perspectives and representations are involved and might have been chosen as the object of analysis as well. In the thesis, other cases concentrate on other perspectives and representations
11
.
4.1. Case 8, chemical reactions
The theme of case 8 was changes between model of perspective and model for perspective. This case encompassed episodes 8.1 to 8.3. The main aim of the analyses of the case was to inquire the model for perspective as it appeared in some of the students work. Two groups of students (group 9 and group 11) in two different schools worked with the same project task. The project task concerned with exploration of differential equations' models of the rate of chemical reactions of order zero, one and two. The episodes in case 8 were based on the project task, the written reports from the two groups of students, a transcription of film recordings of one of the group's (group 9) work with the project task during one lesson, and my field notes from the same lesson. The project task took the model of chemical reactions as its starting point
12
. After a few
introductory statements concerning the technical handling of the amounts and concentrations of the compounds, for example in the case of precipitation of a compound, the model of the reaction rate was introduced in the task:
Fig 2. Excerpt from page 51 in (Hjersing et al. 2004), (author's translation)
The task's design intended to encourage the student's explorations of this model, aiming to see special cases and recognise them as models of certain reactions of order zero, one and two. The students in the two groups were taught these topics in chemistry in advance. In their study program, they all combined high-level chemistry and high-level mathematics. In the textbook the special cases of the model were deduced from the general expression and then treated mathematically. In that sense, the project task dealt with changes between model of perspective with reference to the chemical setting and model for perspective with reference to the more general model in the mathematical setting. In the following, only episode 8.2 is considered.

11
See the overview over Cases and episodes p. 202-204 in (Andresen 2006)
12
For an introduction to the rates of chemical reactions and equilibrium see H. F. Holtzclaw, W.R. Robinson and W.H. Nebergall (1984): General chemistry, D.C. Heath and Company, USA pp 407-449 or P.W. Atkins (1990): Physical Chemistry. Oxford University Press pp775-810
Theoretically, the rate of chemical reactions in general is expressed as:
The rate of combination of two or more chemical compounds is proportional to the product of their concentrations
The relation is expressed like this:

[ ] [ ] [ ]
dc x y z
Rate k A B C
dt
= = ∓
(1.1)
That is, the rate of production/consumption of C is proportional to the concentration of the reactants ([A], [B], [C]) raised to the power of x, y and z respectively. The degree of the exponent denotes the order of the reaction. *TMME*, vol4, no.2, p.242
4.2. Episode 8.2: group 9 answering question 3
When the episode took place, two students from group 9 worked with the chemical reactions project whereas the third member of the group was absent. At this time the students had passed the first one and a half page of the task's text, where the reaction rate was modelled for reactions of the different orders. The two students worked with page 53 in the booklet:
Fig3. Page 53 from the booklet (Hjersing et al. 2004), author's translation
Irreversible second order reactions
Consider the irreversible reaction A+ B X Y → + .
One molecule A and one molecule B combine to one molecule of each of the compounds X and Y. The rate of consumption of A and B equals the production rate of X and Y.
We have inquired second order reactions in the simple cases, where the initial concentrations of the reactants were equal. But what happens, if [A] does not equal [B] from the beginning, or if some X or Y is already produced?
This time, we will model the production of X. The differential equation, mentioned earlier, now changes into:

dx
kab
dt
=
(1.6)
We now want an expression on the right side, which only depends on the immediate [X], and on some initial values of [A] and [B]. So the goal is to express a and b as functions of x.
The immediate concentration of a equals: The initial concentration of a (a0) minus the 'new' x. The 'new' x equals the actual concentration of x minus the initial concentration of x (x0).
Similar to [B], so all in all gives (1.6) the equation:

0 0 0 0
(( ))(( ))
dx
k a x x b x x
dt
= − − − −
(1.7)

0 0 0 0
( )( )
dx
k a x x b x x
dt
= + − + −
(1.8)
Example
2 mol silver nitrate AgNO3 is mixed with 3 mol hydrochloric acid HCl. White silver chloride precipitates and the reaction runs completely. In this case there is ½ mol silver chloride when the reaction starts. The rate constant k is 1.
$AgNO_3 + HCl \rightarrow AgCl + HNO_3$

Based on the text we state the following:
k = 1
a0 = 2
b0 = 3
x0 = ½
Then, the differential equation is:
1 1
1(2)(3)
2 2
dx
x x
dt
= + − + −
(1.9)
Task3
Find the equilibrium points, where the rate equals zero for the differential equation in (1.8) and explain, what this means in practice *TMME*, vol4, no.2, p.243
In terms of flexibility, (1.1) gives a model for perspective since the level of the equation is general, whereas the perspective of (1.9) is model of because the level is referential – it refers to the actual experiment in the task.
Therefore, (1.8) can give both perspectives on the equation, depending on which of the two others it relates to:
(1.8) in model of perspective with regard to (1.1)
The model (1.8) is a general application of (1.1) to the case of a second order irreversible reaction with two reactants.
Fig 4. Explanation of (1.8)
So, with regard to (1.1) (1.8) serves as a model at referential level, referring to second order reactions. The perspective of (1.8), then, is model of whereas the perspective of (1.1) is model for.
(1.8) in model for perspective with regard to (1.9)
The model (1.9) is an application of (1.8) to the case of the reaction between Ag
+
and Cl

.
where
a stands for the concentration of Ag
+
(or AgNO3) and b stands for the concentration of Cl
-
(or
HCl). x stands for the concentration of AgCl and dx/dt is the formation rate of AgCl. Since (1.9)
is concerning with the actual formation of silver chloride, (1.9) is even more concrete than (1.8).
So, (1.8) is a more general and decontextualised equation than (1.9). Consequently, in this case
(1.8) serves to give the model for perspective and (1.9) serves to give the model of perspective
on the equation.
The example and task 3 (in fig 3.) both aim to make the students change in both directions
between the general mathematical model (1.8.) and the model of the actual reaction (1.9).
Therefore, in terms of flexibility, they encourage to changes between model for and model of
perspective. These changes happened stepwise in the actual case.
In the written report, the answer from group 9 to task 3 (fig 3.) was:
In (1.8),
[X] = x
equals the concentration of the product,
[ ] 0 0
A a a x x = = + − ( )
equals the concentration of one of the reactants, and
[ ] 0 0
B = = + − b b x x ( )
equals the concentration of the other reactant. 0
a
is the
initial concentration of the compound a, similar for b and x. TMME, vol4, no.2, p.244
Fig 5. The students' answer
Apparently, the students linked the notion of equilibrium points with the roots of the polynomial.
In their text, they interpreted the term equilibrium point in natural language in three (slightly)
different ways, namely as
1) Points of the reaction where the reaction rate equals zero
2) Points of the reaction where the concentration is unchanged
3) A point where the reaction stops

In all three interpretations the equilibrium points were seen in a model of perspective. The
students made a change to formal language when they turned to the equation #35 (fig 5.) and
simultaneously to graphic representation, which was used in parallel (mixed in between to
analytic expressions) with the formal language.
- Where does the rate for the differential equation equal 0? Where the rate equals zero are
the equilibrium points.
To make the differential equation equal zero, one of the 3 factors in the differential equation
has to equal zero.

It is seen from the graph, that the equilibrium points are 2,5 and 3,5.
This means that the concentrations are unchanged in these points. From a mathematical
point of view, both these points are useful, but in practice only 2,5 is of relevance because
the reaction will stop here. TMME, vol4, no.2, p.245
The students explicitly interpreted the actual values of the roots as concentrations. This
interpretation revealed that they could handle the changes between equilibrium points in the
model perspective (referential level) to the concentrations in the reality perspective. Later on, the
students changed to a model for perspective on the equilibrium points, where they interpreted the
equilibriums as the roots of the polynomial. They referred to the distinction between referential
level (that is, model of perspective) and general level (that is, model for perspective) with the
remark "From a mathematical point of view" in contrast to practice, which was understood to be
at the referential level, that is, in a model of perspective.
By the students interpretation of the equilibrium point as a point where the reaction stops and
where the rate equals zero, they linked the conception of equilibrium closely to the conception of
rate. From the excerpt of text from the report (fig 5.), it is uncertain to say whether the students'
chemical conception of equilibrium was a dynamic or a static one. The third point, (3), above
and the following excerpts from the recordings of the students' work with task 3 may suggest
that the students perceived the conception of chemical equilibrium in a static way even if the
conception of rate was well described in their report's introduction (mentioned in the previous
episode
13
). The students tended to confuse the rate and the rate constant:
S2: We look for the equilibrium point. Rate and rate constant is not the same, isn't it?
S1: The rate…
S1: Let us just…
S2: The rate, is it k or is that simply the rate constant
S1: It is the rate constant
S2: Then I guess we have to isolate k
In this way, then, the students were tempted to completely reduce the complexity of the problem.
The dialogue revealed that they might doubt whether the equations (1.1) (fig 2.) , (1.8) and (1.9)
(both fig 3.) modelled the reaction rate mathematically (general level) as well as chemically
(referential level). According to my interpretation, hence, what confused them was the
combination of mathematical and chemical models. Combining them is the very issue of
changing between model for perspective and model of perspective in this case.
The dialog continued:
S1: No, because the rate is zero
S2: Then we simply have to write it…
S1: I do not understand what we are supposed to do. (reads) "The equilibrium points where the
rate is zero"
S2: Where equal amounts are being produced. Where the amount left is the same as what is
produced, isn't it?

Here, S2 referred to the chemical conception of dynamical equilibrium. In the next remark, S1
interpreted this involvement of a chemical conception as a change from (mathematical) model
perspective to (chemical) reality perspective, but S2 maintained the model perspective by
referring to theory:

13
Episode 8.1 page 251-252 in (Andresen 2006) TMME, vol4, no.2, p.246
S1: This is explaining what it means in real world, isn't it?
S2: But didn't we learn theory about this in chemistry?
S1: I do not understand what they… when the rate is zero, is it simply the rate constant?
The students called the teacher who referred to page 16-17 in the booklet, where the equilibrium
solutions were considered:
Fig 6. Excerpt from (Hjersing et al. 2004, p.16), author's translation
S1: (reads) the right hand side of the equation is a polynomial of second degree, find the roots,..
T: So what is this?
S1: I am reading… Equilibrium solutions – that is what we are looking for
T: Equilibrium solutions, what is it then?
S2: It was negative and positive second degree
The problem had now been transformed to the simpler one of finding the roots of a polynomial
of second degree. This problem was expressed in graphic representation, natural and formal
language simultaneously. The problem was seen in a model for perspective
14
as far as it had to be
solved in a purely technical context with no connection with the chemical model.
When the dialogue continued, the teacher tried to establish the connection between the simpler
problem and the question of equilibrium solutions to the differential equation. In terms of
flexibility, the teacher insisted on keeping the changes between model for perspective and model
of perspective in focus of interest. Shortly after, the episode was concluded with the teacher
having accomplished the guidance of the students. The students went to the computer room for
doing some graphs.
4.3. Conclusion of case 8
The changes between model of and model for perspective were in this case realised as changes
between a mathematically formalised chemical model and a more general mathematical model. It
was understood in the project task's text that the students knew the formalised chemical models
in advance. So, the students were supposed in advance to manage changes between the chemical
reality, in the form of proceedings of the actual reactions, and the formalised chemical models. In
the episodes, the changes between the two perspectives went in both directions: the report from
group 11 for the major part took the model for perspective (illustrated in episode 8.1), but the

14
This situation illustrates a tool perspective on the solving of quadratic equation

The right side of the equation is a polynomial of second degree in P with the roots
P t( ) 0 =

P t N ( ) =

It is positive between the roots and negative outside. TMME, vol4, no.2, p.247
task's questions provoked changes to and fro a model of perspective and further interchanges
between model and reality perspective (it was demonstrated in episode 8.3). The report from
group 9 divided into parts that took the model of perspective and other parts that took a model
for perspective. The links between the two perspectives, though, were not always clearly
revealed (it was shown in episode 8.3).
Episode 8.2 demonstrated how the teacher guided the students to change between model of and
model for perspective. The episode pointed to the important role of the guidance from the
teacher, as well as from the task's questions.
During the complete case, changes between reality and model perspectives and between model
of and model for perspectives were realised on the relation, modelled by the differential
equations (1.1), (1.8) and (1.9). The same relation was expressed in all the four different
representations. According to the definition of flexibility, the individual student's flexibility of
the conception of this mathematical relation (e.g. the differential equations model), in this
context, was developed to the extent that he or she was able to manage these changes. Working
with the tasks in the case seemed to support this flexibility since the individual student was more
likely to manage the changes after the teaching sequence.
5. Conclusion
To conclude this paper three questions are discussed: what contribution does the construction of
flexibility add to the field, are the promises, criteria and requests from the first part of the paper
kept, and what questions does this paper not answer?
5.1. What is new?
The introduction of a new construct like flexibility with its definition and technical notion to the
field of math education, which may seem almost overloaded with a diversity of notions and
terms already, has to be justified. One important argument is that the introduction of flexibility
summarises, connects and simplifies key elements of well established and acknowledged theory.
The issue of visualisation, for example, is included in flexibility in terms of change to graphic
representation. The relation between the levels in Gravemeijer's model is another example. The
novel idea beyond the construction of flexibility is to focus on the dynamics as a common
denominator, which leads to consider all these key elements in a new light and in a new
combination.
The case illustrates how flexibility intends to serve as a tool for clarification: The case's task
presented a rich and complex structure of models at different levels, and links between them. The
task was suitable for the students' exploration of the relation, modelled by the differential
equations, exactly because it was sufficiently complex to offer possibilities of open ended
inquiries. During the case, one of the students' main difficulties concerned the changes between
the levels of the model, represented in the three equations. Another main difficulty was the
transformation of the problem to the simpler one of finding the roots of a second degree
polynomial, followed by interpretation of the result. These main difficulties are closely related to
the main learning potentials of the task, so attempts to avoid them by omitting parts of them for
simplification would be of little use. The analysis of the case demonstrates how these main issues
of the task can be interpreted in terms of flexibility. My claim is that the teacher could strengthen TMME, vol4, no.2, p.248
the guidance of the students and make it more explicit without giving the answers, if he or she
had such an interpretation in mind.
The case also illustrates that the apparent conflict of having the equation (1.8) at two different
levels is cancelled when focus, in terms of flexibility, is on the dynamics of changing between
levels rather than on placing conceptions at the levels.

5.2. Does flexibility keep the promises?
According to the initial goal of the research mentioned in this paper, flexibility should serve as a
tool for teachers to take the project's experiences into account for improvement of their own
teaching. The case gives an example of flexibility's potentials for improved guidance, according
to my interpretation. To meet the goal, though, more focused teaching experiments, based on an
elaborated description of the single elements of flexibility would be the next step.
The second request, which concerns the contribution to math education theory, was already
discussed in a previous paragraph. The objectives of the construction set two demands on
flexibility: signs of flexibility should be observable, and claims of its relevance should be
theoretically founded. The construction of flexibility intended to capture important learning
activities which promote the student's actual work with mathematics in an observable way. The
case demonstrates that the changes of perspective and changes between different representations
are observable. The presentation in this paper of three basic ideas beyond the concept of
flexibility serves to justify
15
the claim, that the changes promote the student's learning.
5.3. What is left?
It follows from the research design that the effect was not tested on teaching designs, which aim
at development of flexibility of the mathematical conceptions in question. A number of
guidelines are presented to conclude the Ph.D. thesis. The guidelines are meant for teachers who
want to aim at flexibility in the design of their teaching. A large scale inquiry of the effect could
include teaching materials and teaching designs based on these guidelines, pre- and after tests
and qualitative evaluation. The guidelines are (Andresen, 2006, pp. 294-295):

Teaching that aims to support flexibility in the mathematical conceptions with and without the use of CAS should be based on the following principles:
- The design of tasks and problems ensures that changes of perspective go in both directions in all the pairs of perspectives that form "flexibility":
1. Local – global
2. General – specific
3. Analytic- constructive
4. Process – object
5. Situated – decontextualised
6. Tool – object
7. Model – reality
8. Model of – model for
- The design of tasks and problems ensures that changes between representations go in both directions between graphic representation, analytic representation (or formal language), natural language and technical representation (or computer language)

15
Further justification builds on the discussions all through chapters 5 and 7 in (Andresen, 2006). TMME, vol4, no.2, p.249
- Expressive work and explorative work with mathematical models are both important. The teaching is designed to ensure that the students over time are encouraged to model a number of key conceptions including all the four levels situated, referential, general and formal.
- A diversity of strategies is not only accepted, but appreciated in the classroom. The students are encouraged to try out ideas and techniques. Results, ideas and strategies are discussed and negotiated with open minds in the classroom.
The relations between flexibility and the shortcuts mentioned in the first part of this paper, and the role of flexibility in the instrumental genesis, apparently, are issues in focus of interest for the continued work with development and refinement of the construct flexibility. It should be remarked that although the project took the use of laptops as its starting point, flexibility is not restricted to mathematical conceptions within a computer environment.

1. Introduction
Tool use is indispensable both in daily life as well as in doing and learning mathematics. Research suggests a close relationship between tool use, cognitive development and social practice. The TOOlUse-project at the Freudenthal Institute focuses on the use of computer tools for grade 8 (13-14 years) students' acquisition of the mathematical concept of function, in an effort to identify the relationship between the use of technological tools and the learning of mathematics
1
. The main research question aims at understanding how computer tools can be integrated in an instructional sequence on the function concept, so that their use fosters learning. This is studied in terms of the notion of instrumental genesis (Kieran & Drijvers, 2006, Trouche, 2004) and domainspecific theories on the teaching and learning of mathematics within the philosophy of realistic mathematics education (Freudenthal, 1991). The research setup includes a cyclic process of instructional design, teaching experiments and data-analysis (Gravemeijer, 2004).
2. Theoretical framework
We investigated an instructional approach for the function concept that aims at a learning process in which the mathematics is build upon everyday intuitions. This is also in line with the objective of realistic mathematics education (RME), where instructional design is aimed at creating optimal opportunities for the emergence of formal mathematical knowledge from situation specific reasoning. In order to achieve this, contextual problems are cast into situations that are experientially real for the students. During the process of teaching and learning students can preserve the connection between the mathematical concepts and what is described by these concepts. Students' final understanding of the formal mathematics should stay connected with their understanding of these experientially real, everyday-life phenomena (Freudenthal, 1991).
Well-chosen context problems offer students opportunities to develop informal, highly context-specific models and solving strategies (Doorman et al., 2007). These informal solving procedures then may become subject of formalization and generalization to constitute a process of further abstraction, in RME dubbed as: progressive mathematization. The instructional designer tries to construct a set of problems that can

1
The project is supported by the Netherlands Organisation for Scientific Research (NWO) with grant number 4121-04-123. The project's website is http://www.fi.uu.nl/tooluse.
'lead to a series of processes that together result in the reinvention of the mathematics aimed at.
Research on the design of primary-school RME sequences has shown that the concept of emergent models can function as a powerful design heuristic (Gravemeijer, 1999). Context problems are selected, offering the students the opportunity to develop situation-specific representations and strategies. Students' reasoning gives rise to (informal) models during classroom discussions and subsequent activities. In this sense, the models emerge from the activity of the students. Even if the models are not actually invented by the students, great care is taken to approximate students' inventions as closely as possible by choosing models that link up with their learning history and with their contributions. Another important criterion is in the potential of the models to support mathematization towards the intended concepts. The idea is to look for models that can be generalized and formalized to develop into entities of their own, which then can become models for mathematical reasoning (e.g. Doorman, 2007; Gravemeijer, 2004; Rasmussen & Blumenfeld, 2007).
An additional theoretical foundation of the research we discuss here is the use of computer minitools in mathematics education. In general, tools influence the process of students' mathematical sense making. Cobb (1999) illustrated this by describing the interplay between students' ways of symbolizing and mathematical reasoning. In relation to this he referred to the notion of affordances (Cobb, ibid). The computer minitools afforded the students' reasoning on statistical problems. Affordances are not properties of tools that exist independently of users, but are achievements of users in activity. As a consequence, instructional designers should take into account how students might act and reason with the tools as they participate in a sequence of mathematical practices.
We adopted these ideas for integrating a computer tool in the instructional materials for the teaching and learning of the function concept. The tool was meant to create opportunities for students to develop understanding of the input-output relationship and the related dynamics in graphs and tables.
The instructional design: AlgebraArrows
In the design phase of the project, teaching materials and a computer tool were developed. The computer, AlgebraArrows (AA), primarily supports the construction of input-output chains of operations (Boon, 2008). These chains can be applied to single numerical values as well as to variables. In the latter case, tables, formulas and (dot) graphs can be shown. The chains can be extended, linked, compared and compressed. The applet is embedded in an electronic learning environment, allowing students to save final situations of each activity and to continue working in any location with internet access. The researchers, as well as the teacher, are able to monitor the answers of the students with all-class result overviews.
We expected the starting function image for most of the students to be the local calculation procedure. This could be applied to one single input number at the time and then result in an output number. The instructional design aimed at the transition from these calculations to reasoning with a formula and its graphs and tables. The goal of the learning arrangement with the computer tool was to keep the chaining of calculations connected with formulas during the whole instructional sequence. The sequence started 2with three open-ended activities (mobile phone offers, a quadrilateral and breaking distance) to reveal the students' thinking and to provide for strategies that could be used by the teacher to introduce the computer tool AlgebraArrows. Both the purpose of and the representations in the tool were object of discussion (see Figure 1).

Figure 1 Poster of students' calculations and a ´living operation chain´

The chain of operations in the AA applet, applied to a single numerical value, signifies the function as an input-output assignment signifying a list of calculations. This is an important step for the function concept, because it supports the importance of identifying the relevant variables and their dependencies. The step is certainly not trivial for the students. During a pilot experiment we noticed that, even after a few activities with AA, many students wanted to translate a formula like 2·x + 100 into a chain starting with input 2.
In Figure 2, two chains concerning different mobile phone offers invite a global investigation of properties. The technique of putting numerical values in the input window allows for comparison of function values. A variable input allows for a more global comparison, in which graphs, tables and formulas can be involved.

3Figure 2 An input – output assignment
The applet allows not only a change of input value, but also the study of the covariation by means of tables and graphs. The chain in Figure 3 represents the cost of one particular mobile phone offer. The dynamics of the co-variation can be investigated by techniques of substituting different values, scrolling through the table, tracing the graph and studying the formula. The task for the students is to find the change of cost per minute change of the input variable – the number of minutes of phone calls.
Figure 3
4The computer tool AA was supposed to support students' investigations of many cases. The investigations by pairs of students were expected to foster a trial-and-improveprocess and negotiation of meaning. During the investigations they could find patterns and develop strategies in dealing with dynamic input-output dependencies. Consequently, AA was expected to afford a means to structure inquiry about these relationships through the construction and modification of arrow chains, graphs and tables, and the generation and comparison of argumentations.
The conjectures concerning the role of AA in the instructional sequence were investigated with a design research method of iterative phases of instructional design, teaching experiments and data analyses.
Results
The teaching experiments took place in three classes at three different schools. Video recordings were made of classroom teaching and group work (17 hours), and screen videos of three pairs of students working with the computer were captured (6 hours). Students' final answers on the activities with AA were saved on a central server (41 pairs). We collected written work of the students as well as the results of a written assessment at the end of the experiment. Data analysis was carried out by qualitative analyses and coding of the data using the video analysis tool ATLAS.ti.
We started the analysis by watching and annotating the work of a pair of students (Lisa and Romy). We had screen videos (with audio) of the three lessons with the computer tool. These screen videos were imported in ATLAS.ti. Initially, the clipping was guided by exercises as units of analysis. We described each exercise-clip with the comment-tool and added analytical notes. With these notes we wrote down a storyline of Lisa and Romy and their learning process with respect to the learning environment and our prior expectations. The clips were coded with the number of the activity as well as with their names. These codes could be used to browse through the data and to combine it with other data sources. We also imported and coded photocopies of written work and of screenshots of the computer activities of all the students which were saved on the central server.
We expected the two students to initially use the calculation chains in their reasoning about input-output-dependencies, and that this reasoning would change to using tables and graphs as basic structuring elements. These expectations were based upon the idea of emergent modeling, which is a characteristic of realistic mathematics education. One of the key aspects of emergent modeling is the development of a model and the ways of reasoning with the model through a sequence of manifestations (Gravemeijer, 2004)
In the teaching experiment we provided the students with one tool for a sequence of ten lessons. The manifestation of the chain itself did not change, but the function of the representation changed. As a result, we didn't see a clear development through a number of manifestations of a model, whereas the focus of reasoning with the model shifted from individual calculations to dependency relationships. Consequently, we noted in the work of Lisa and Romy that they reasoned with calculation chains during all the activities. Moreover, their reasoning changed from referring to individual calculations to characterizing dynamic processes. This storyline was discussed among the project 5members to try to understand these findings and the relation to the instructional sequence. During the discussions we successively clarified and assessed possible conjectures with the storyline and the references to the clips.
As a result of this analysis the idea arose that we could better use the principle of a form-function-shift (Saxe, 2002) for describing what happened in the learning process of Lisa and Romy. The arrow chain initially built on the notion of recording the structure of a series of calculations. The form-function-shift took place when the two students started using this record of calculations as a tool for investigating dependencyrelationships. Simultaneously, as the investigations with arrow chains built on the imagery of calculations with successive operations, constructing and modifying an arrow chain signified organizing a dependency-relationship. Calculation-routines turned into explorations, during which new narratives about relationships were constructed. The articulation of this shift seemed helpful in labeling different phases in the learning process with codes.
We conjectured that in this form-function-shift the goal of the activities for the students shifted from calculating a specific value to reasoning about relationships, and the chain is used as a means for scaffolding and communicating ways of reasoning (emerging mathematical goals: Saxe, 2002). Next, based upon the analysis of the work of Lisa and Romy, we identified two illustrative and rather similar open-ended activities, one in the beginning of the sequence and one in the end. For these activities we characterized different solution strategies with the notion of the form-function-shift and constructed four codes for these characterizations (from "a record for calculations" to "as a tool for reasoning"). All the screenshots of the students were coded in order to try to get quantitative support for the emerging conjecture. During the coding process we discussed a few cases for fine-tuning the code-definitions and the interpretations of the codes.
The result of this second analysis offered evidence for the conjecture of a formfunction-shift in the students' reasoning with chains of calculations in the computer tool. We found that with the activity in the beginning 25 (out of 41) pairs of students used the chain as a record for calculating a specific value, while the activity at the end of the sequence showed that 24 (out of 34) pairs used the chain as a tool for reasoning. However, during the coding we also observed that with the first activity students sometimes tried to use AA as a tool for reasoning, but were not able to really operate it sufficiently. This observation brought us back to a prior notion of the theoretical framework that tool-use development is closely related to a process of instrumental genesis.
Further research is needed to merge the notions of emergent modeling and formfunction-shift with the notion of instrumental genesis to be able to better understand the interplay between tool use and mathematics learning.
Moreover, in the classroom learning processes, we noticed that students initially reasoned and wrote about mathematical and kinematical notions with a tentative language and inscriptions that were not as precise as the notions aimed at. This seems similar to Goldin's description of three main stages in the development of representational systems: (i) an inventive and semiotic stage, (ii) structural development and establishment of relationships, and (iii) an autonomous stage (Goldin, 2003). During the inventive stage, students tentatively used inscriptions and language to communicate their developing ideas. In the autonomous stage the system can function flexibly in new contexts. We observed that the teacher played an important role during this process. The teacher guided 6whole class discussions and alternated between evoking students to present their solutions and focusing to the mathematics needed for what is to come (Doorman, 2007; Sherin, 2002).
Redesign and further research should also reveal the criteria by which the teacher can make decisions during this balancing act of guiding students through a process for developing the function concept.

DIGITAL TECHNOLOGY IN MATHEMATICS EDUCATION: WHY IT WORKS (OR DOESN'T)
Paul Drijvers
The integration of digital technology confronts teachers, educators and researchers with many questions. What is the potential of ICT for learning and teaching, and which factors are decisive in making it work in the mathematics classroom? To investigate these questions, six cases from leading studies in the field are described, and decisive success factors are identified. This leads to the conclusion that crucial factors for the success of digital technology in mathematics education include the design of the digital tool and corresponding tasks exploiting the tool's pedagogical potential, the role of the teacher and the educational context.
Keywords: Didactical function; Digital technology; Instrumentation
La tecnología digital en educación matemática: por qué funciona (o no)
La integración de la tecnología digital enfrenta a profesores, formadores de profesores e investigadores a muchas preguntas. ¿Cuál es el potencial de las TIC en el aprendizaje y la enseñanza, y qué factores son determinantes al trabajar en clase de matemáticas? Para investigar estas cuestiones, se describen seis casos de estudio prominentes en el área, y se identifican los factores decisivos para el éxito. Esto lleva a la conclusión de que los factores cruciales para el éxito de la tecnología digital en la educación matemática incluyen el diseño de la herramienta digital y de las tareas apropiadas que exploren el potencial pedagógico de la herramienta, el papel del profesor y el contexto educativo.
Términos clave: Función didáctica; Instrumentación; Tecnología digital
For over two decades, many stakeholders have highlighted the potential of digital technologies for mathematics education. The National Council of Teachers of Mathematics, for example, in its position statement claims that "Technology is an essential tool for learning mathematics in the 21st century, and all schools must ensure that all their students have access to technology" (National Council of Teachers of Mathematics [NCTM], 2008). ICMI devoted two studies to the 2 P. Drijvers PNA 8(1)
integration of ICT in mathematics education, the second one expressing that "…adigital technologies were becoming ever more ubiquitous and their influence touching most, if not all, education systems" (Hoyles & Lagrange, 2010, p. 2).
However, the integration of digital technology still confronts teachers, educators and researchers with many questions. What exactly is the potential of ICT for learning and teaching, how to exploit this potential in mathematics education, does digital technology really work, why does it work, which factors are decisive in making it work or preventing it from working? What does a quarter of a century of educational research and development have to offer here?
Of course, these questions are not clearly articulated. What do we mean by "it works"? Does this mean that the use of digital technology improves student learning, invites deeper learning, motivated learning, more efficient or more effective learning? Does it mean that ICT empowers teachers to better teach mathematics? And, concerning the effect of educational research, do studies on digital technology work in the sense that they provide answers to these questions, or do they just help the researcher to better understand the phenomenon, and as such contribute only indirectly to improving mathematics education? My interpretation of "why it works" in the title of this contribution includes both learning and teaching, and also refers to learning on the part of the researcher.
In this paper I will explore the question of "why digital technology works or does not" by briefly revisiting a number of leading studies in the field, that are paradigmatic for a theme, approach, method, or type of results. For each of these studies, the focus is on what they offer on identifying decisive factors for learning, teaching and research progress. As such, this contribution reports on a concise and somewhat personal journey throughor a helicopter flight overthe landscape of research studies on technology in mathematics education.
FRAMEWORK FOR CASE DESCRIPTION
How to decide which studies to include in this retrospective and even somewhat historical paper? Even if somewhat subjective and personal arguments cannot be completely ignored, the case selection is based on a number of criteria. A first criterion for including a study or a set of studies is that it really contributes to the field, by providing a new perspective, a new direction or is paradigmatic for a new approach to the topic. An indication for this is that the study is frequently quoted and has led to follow-up studies. A second criterion for inclusion is that the study under consideration contributes to theoretical development in the field of integrating technology in mathematics education, and as such promotes thought in this domain. A third and final criterion for the set of cases presented in this paper as a whole, is variation. Variation does not only apply to theoretical perspectives, but also to the mathematical topic addressed in the study, the type of technological tools used, and the pedagogical functionality of the digital tech-Digital Technology in Mathematics Education: Why it Works (or doesn't) 3 PNA 8(1)
nology. Concerning this functionality, we use an adapted version of the model by Drijvers, Boon, and Van Reeuwijk (2010) which distinguishes three main didactical functionalities for digital technology: (a) the tool function for doing mathematics, which refers to outsourcing work that could also be done by hand; (b) the function of learning environment for practicing skills; and (c) the function of learning environment for fostering the development of conceptual understanding (see Figure 1). Even if these three functionalities are neither exhaustive nor mutually exclusive, they may help to position the pedagogical type of use of the

technology involved. In general, the third function is the most challenging one to
exploit.
Figure 1. Didactical functions of technology in mathematics education
CASE DESCRIPTIONS
In this section we will discuss the selected studies in a short frame. To do this in
a way that does justice to them and in the meanwhile serves the purpose of this
paper, we first present a global description of each case, including the mathematical topic, the digital tool and the type of tool use. Next, I will explain what is
crucial and new in the study, and why I decided to include it. Then the theoretical
perspective is addressed. Each case description is closed by a reflection on
whether digital technology worked well for the student, the teacher or the researcher, and which factors may explain the success or failure.
Case 1: Concept-First Resequencing by Heid (1988)
The first case description concerns a study reported by Heid (1988), which is
considered as one of the first leading studies into the use of digital technology in
mathematics education. The study addresses the resequencing of a calculus
course for first-year university students in business, architecture and life sciences
using computer algebra, table tools and graphing tools that were used for concept
development (branch c, Figure 1). The digital technology allowed for a "conceptfirst" approach, which means that calculus concepts were extensively taught,
whereas the computational skills were treated only briefly at the end of the
Didactical functions
of technology in
math education

Learn mathematics
Practice skills
(b)
Develop concepts
(c) 4 P. Drijvers
PNA 8(1)
course. The results were remarkable in that the students in the experimental
group, who attended the resequenced, technology-intensive course, outperformed
the control group, who attended a traditional course, on conceptual tasks in the
final test, and also did nearly as well on the computational tasks that had to be
carried out by hand. The subjects in the experimental group reported that the use
of the computer took over the calculational work, made them feel confident
about their work and helped them to concentrate on the global problem-solving
process.
One of the reasons to discuss the Heid study here is that it is paradigmatic in
its approach in that its results form a first "proof of existence": indeed, it seems
possible to use digital technology as a lever to reorganize a course and to successfully apply a concept-first approach, using digital technology in the pedagogical function of enhancing concept development, without a loss of student
achievement on by-hand skills.
From a theoretical perspective, Heid's notion of resequencing seems closely
related to Pea's distinction of ICT as amplifier and as (re-)organizer (Pea, 1987).
The former refers to the amplification of possibilities, for example by investigating many cases of similar situations at high speed. The latter refers to the ICT
tool functioning as organizer or reorganizer, thereby affecting the organization
and the character of the curriculum. In the light of that time's thinking on the role
of digital tools to empower children to make their own constructions (Papert,
1980), the organizing function of digital technology was often considered more
interesting than the amplification.
So did technology work in this case? Yes, it did at the level of learning: The
final test results of the experimental group turned out to be very satisfying. And
yes, it also worked at a more theoretical level, as the notions of resequencing and
concept-first approach were operationalised and made concrete. Now why did it
work, which factors might explain these positive results? Even if nowadays we
would not consider the digital technology available in 1988 as very sophisticated,
I would guess that at the time the approach was new and motivating to the students, and the representations offered by the technology did indeed invite conceptual development. Decisive, however, I believe was the fact that the researcher herself designed and delivered the resequenced course. I conjecture that she
was very aware of the opportunities and constraints of the digital technology, and
was skilled in carefully designing activities in which the opportunities were exploited, and in teaching the course in a way that benefitted from this. Whether the
course, if delivered by another teacher, would have been equally successful, is
something we will never know.
Case 2: Handheld Graphing Technology
The second case description concerns the rise of handheld graphing technology
in the 1990s. For several reasons, graphing calculators became quite popular
among students, teachers and educators at that time (for an overview, see Digital Technology in Mathematics Education: Why it Works (or doesn't) 5
PNA 8(1)
Trouche & Drijvers, 2010). Teaching materials were designed that made extensive use of these devices and researchers investigated the benefits of this type of
technology-rich activities (Burrill et al., 2002). Very much in line with the work
by Heid (see Case 1), the focus of much of this work is on the pedagogical function of concept development. The main idea seems to be that students' curiosity
and motivation can be stimulated by the confrontation with dynamic phenomena
that invite mathematical reasoning, in many cases concerning the relationships
between multiple representations of the same mathematical object. In many cases
this mathematical object is a function, but examples involving other topics, such
as statistics, can also be found.
As an example, Figure 2 shows two graphing calculator screens which students set up to explore the effect of changes in the formula of the linear functions
Y1 and Y2 on the graph of the product function Y3. This naturally leads to questions about properties of the product function and the relationship with properties
of the two components (Doorman, Drijvers, & Kindt, 1994).
Figure 2. Exploring the product of two linear functions
A paradigmatic study in this field is done by Doerr and Zangor (2000). The researchers report on a small-scale qualitative study, in which 15-17 year old precalculus students study the concept of function using a graphing calculator, with
a focus on the pedagogical tool functionality of concept development (branch c,
Figure 1). The authors identify five modes of tool use, namely computation,
transformation, data collection and analysis, visualisation, and checking. The results show that the teacher was crucial in establishing and reinforcing these
modes of tool use, for example by setting up whole-class discussions "around"
the projected screen of the graphing calculator, to develop shared meaning and
avoid a too individual development of tool use and mathematical insight. The researchers stress that using digital technology in mathematics teaching is not independent from the educational context and the mathematical practices in the
classroom in particular.
The main reason to discuss the Doerr and Zangor study here is that it highlights the importance of the educational context in studies on the effect of digital
technology, and the crucial role of the teacher in particular. The relevance of the
educational context has later been elaborated in the notion of pedagogical map by
Pierce and Stacey (2010). Concerning the teacher, she establishes a culture of 6 P. Drijvers
PNA 8(1)
discussing graphing calculator output in a format that is close to what is called a
"Discuss-the-Screen orchestration" in Drijvers, Doorman, Boon, Reed, and
Gravemeijer (2010) and by these means contributes to the co-construction of a
shared repertoire of ways to use the graphing device.
From a theoretical perspective, Doerr and Zangor (2000) use frameworks on
learning as the co-construction of meaning, and that the "features of a tool are
not something in and of themselves, but rather are constituted by the actions and
activities of people" (p. 146). Even if this may sound somewhat trivial nowadays,
during the period of initial enthusiasm these were important insights with consequences for the role of the teacher, who led the process of sharing and coconstruction, particularly in the case of personal, private technology.
So did technology work in this case? Doerr and Zangor did not assess learning outcomes, but it seems that the students developed a rich and meaningful
repertoire of ways to use the graphing calculator for their mathematical work.
Why did this work, which factors might explain these findings? My interpretation is that the use of digital tools for exploratory activities which target conceptual development is not self-evident, as it is hard for students, without the mathematical background that we as teachers have, to "see" the mathematics behind
the phenomena under consideration. It is here where the teacher comes in, and
where the study becomes very informative for both teachers and researchers. In
this case, I believe that the fact that the teacher herself was skilled in using the
graphing calculator, was aware of its limitations, and was willing to explicitly
pay attention to the co-construction of a shared and meaningful repertoire of tool
techniques explains the results. As in the Heid study described in Case 1, the role
of the teacher seems to be an important factor. The issue of how to deal with private, handheld technology is very relevant nowadays, as many students have
smart phones with sophisticated mathematical applications, and again, teachers
are faced with the danger of too individually constructed techniques and insights.
Case 3: Instrumental Genesis
By the end of the previous century, French researchers who were working on the
integration of computer algebra and dynamic geometry in secondary mathematics education felt the need to go beyond the then current theoretical views. Even
if they still experimented with explorative tasks, such as finding the number of
zeros at the end of K (Trouche & Drijvers, 2010), a theoretical perspective was
needed that would do justice to the complex interaction between techniques to
use the digital technology, conventional paper-and-pencil work and conceptual
understanding. This led to the development of the instrumental genesis framework, or the instrumental approach to tool use (Artigue, 2002; Guin & Trouche,
1999; Lagrange, 2000). Even if there are different streams within instrumentation
theory (Monaghan, 2005), it is widely recognized that the core of this approach is
the idea that the co-emergence of mental schemes and tool techniques while
working with digital technology is essential for learning. This co-emergence is Digital Technology in Mathematics Education: Why it Works (or doesn't) 7
PNA 8(1)
the process of instrumental genesis. The tool techniques involved have both a
pragmatic meaning (they allow the student to use the tool for the intended task)
and an epistemic meaning, in that they contribute to the students' understanding.
Rather than exploration, the reconciliation of digital tool use, paper-and-pencil
use, and conceptual understanding is stressed (Kieran & Drijvers, 2006).
A paradigmatic study in this field is the one by Drijvers (2003) on the use of
handheld computer algebra for the learning of the concept of parameter. Four
classes of 14-15 year old students worked on activities using a handheld computer algebra device both in its role of mathematical tool and for conceptual development (branches a & c, Figure 1) to develop the notion of parameter as a "super-variable" that defines classes of functions and that can, depending on the
situation, play the different roles that "ordinary" variables play as well. The results of the study include detailed analyses and descriptions of techniques that
students use, and the corresponding expected mental scheme development. Figure 3 provides a schematic summary of such an analysis for the case of solving
parametric equations in a computer algebra environment (Drijvers, Godino, Font,
& Trouche, 2012).
Figure 3. Conceptual elements related to the application of the solve command
The main reason to discuss this study here is that by providing elaborated examples it contributes to a concrete and operationalised view on the schemes and
techniques that are at the heart of the instrumental approach. The study shows
that the instrumental approach is a fruitful perspective that can provide tangible
guidelines for both the design of student materials and the analysis of student behaviour.
From a theoretical perspective, apart from the concretisation of the notions of
schemes and techniques, the author integrated this with a more general view on
mathematics education, namely the theory of realistic mathematics education
(Freudenthal, 1991). The two perspectives seemed to be complementary and both
provided relevant guidelines for design and analysis.
An equation should contain an = sign
Indicate the unknown to solve
Notice the scope of
the square root sign
"solve with respect to x" = "express x in terms of b"
Word /letter vars?
A solution can be
an expression 8 P. Drijvers
PNA 8(1)
So did technology work in this case? No and yes. The conclusions on the
learning effects of the intervention are not very clear. Even if the students learned
much about the concept of parameter, their work still showed weaknesses both in
the use of the tool and in the understanding of the mathematics. This suggests an
incomplete instrumental genesis. Factors that may explain these findings are: (a)
the difficulty of the mathematical subject for students of this age, (b) the complexity of the computer algebra tool, and (c) the efforts and skills needed by the
teachers to not only go through their personal process of instrumental genesis,
but also to facilitate the students' instrumental genesis by their way of teaching.
The latter aspect was addressed more explicitly later in the notion of instrumental
orchestration (Drijvers & Trouche, 2008; Trouche, 2004). The study did work in
the sense that it contributed to the researchers' understanding of the complexity
of integrating sophisticated digital technologies in teaching relatively young students. The close intertwinement of the students' cognitive schemes and the techniques for using the digital technology is identified as a decisive factor in the
learning outcomes of technology-rich mathematics education.
Case 4: Online Applications
With the growing availability and bandwidth of internet, researchers became interested in the potential of online interactive applications or applets for mathematics education. The advantages of online content include access without local
software installation, ease of distribution and updating for developers, and permanent availability for users as long as the internet is accessible.
Many studies investigate this potential. For example, Boon (2009) explores
the opportunities for teaching 3D geometry using online applets. Doorman,
Drijvers, Gravemeijer, Boon, and Reed (2012) describe a teaching experiment in
grade 8 focusing on the concept of function using an applet called AlgebraArrows
1
for building chains of operations. Apart from an instrumental perspective
(see Case 3), the theoretical framework includes domain-specific theories on reification, realistic mathematics education and emergent modelling. The applet is
used for concept development (branch c, Figure 1). A third example is the study
by Bokhove, who focuses on acquiring, practicing and assessing algebraic skills
(Bokhove, 2011; Bokhove & Drijvers, 2012). His teaching experiments took
place in grade 12 classes and made use of applets that offer means to manipulate
algebraic expressions and equations
2
. The theoretical framework in this case included notions from algebra pedagogy such as symbol sense, which is expected
to support skill mastery, but also elements from educational science on assessment and on feedback. In contrast to the studies described so far, the role of the
digital tool in Bokhove's work includes the environment to practice skills

1
See http://www.fisme.science.uu.nl/tooluse/en/
2
See http://www.algebrametinzicht.nl/ Digital Technology in Mathematics Education: Why it Works (or doesn't) 9
PNA 8(1)
(branch b, Figure 1), which might be the easiest role, even if the design of appropriate feedback is an issue to tackle.
As a paradigmatic design research study in this field, let us now describe the
work done by Bakker in somewhat more detail (Bakker, 2004; Bakker & Gravemeijer, 2006; Bakker & Hoffmann, 2005). Bakker investigated early statistical
reasoning of students in Grades 7 and 8. In one of the tasks, students investigate
data from life spans of two brands of batteries while using applets to design and
explore useful representations and symbolizations (see Figure 4). Clearly, the
digital tools' pedagogical functionality is on concept development once more
(branch c, Figure 1). The design of the hypothetical learning trajectory and the
student materials was informed by the development of statistics in history. In his
analysis of student data, Bakker uses Peirce's (1931-1935) notions of diagrammatic reasoning and hypostatic abstraction to underpin his conclusion that the
teaching sequence, including the role of digital tools, invited students' reasoning
about a frequency distribution as an object-like entity, as became manifest when
they started to speak about the "bump" to describe the drawings at Figure 4's
right hand side.
Figure 4. Applets for investigating a small set of statistical data
The main reasons to discuss Bakker's work here are not only the originality of
the dedicated digital tools which meet new ideas on statistical reasoning and statistics education, and which were designed in collaboration with others (Cobb,
McClain, & Gravemeijer, 2003), but also the rich relationships with the different
resources and approaches, such as the historical perspective, to inform the design.

From a theoretical perspective, it is interesting to notice that even if technology plays an important role in Bakker's study, the design and analysis are driven
by theoretical perspectives from outside the frame of research on the use of technology in mathematics education, but rather from the world of mathematics pedagogy and beyond. I believe that this is a meaningful and promising approach.
On the one hand, as researchers we should benefit from specific results and theories from studies on the use of digital tools in mathematics education. On the 10 P. Drijvers
PNA 8(1)
other hand, we should not forget to involve theories on mathematics education
and educational science in general.
So did technology work in Bakker's case? Yes, it did in the sense that the author clearly reports on conceptual development by the students involved in the
study. Why did this work, which decisive factors might explain these findings? I
believe that an important lesson to be learnt from this study is that design research on the use of digital technology in mathematics education should not limit
itself to the study of the tools alone, but should include the tasks, and their embedding in teaching as a whole, in order to understand what works and why it
works. In this case, I would guess it is the combination of the digital tools, the
tasks and activities, but also the whole-class discussions, the paper-and-pencil
work, the established mathematical practices, in short the educational context as
a whole, that explains the result. A second lesson to learn for us as researchers is
that a theoretical framework which integrates different perspectives can be very
powerful for generating interesting and relevant research results.
Case 5: Mobile Mathematics
Research on the use of mobile technology in mathematics education is in its early
stages but its importance is rapidly growing. It is evident that mobile technology
and smart phones in particular are very popular among students and more and
more wide-spread. Wireless Internet access allows for the use of mobile applications (also called MIDLETS, Mobile Information Device applications), SMS and
email services offer communication and collaboration opportunities, GPS facilities allow for geographical and geometrical activities and the tool's mobile and
handheld characteristics invite out-of-school activities, for example the gathering
of real-life data that inform biology or chemistry lessons (Daher, 2010).
As a paradigmatic example, I now address the MobileMath pilot study carried out by Wijers, Jonker, and Drijvers (2010). In this study, the tool consisted
of a mobile phone with GPS facilities and a "native" application, designed for the
purpose of this game, which generated the view on the game situation and arranged communication with other teams' devices. The mathematical topic involved is geometry: teams of Grades 7 and 8 students used the GPS and the application to play an outdoor game on constructing parallelograms (including
rectangles and squares), and could eventually destroy other groups' geometrical
shapes. This so-called MobileMath game aims at making students experience
properties of geometrical figures in a lively, embodied game context. While playing the game, students look at the map to imagine where they want to make a
shape, walk to the location for the first vertex to enter this location in the mobile
device, which generates a dot on the map, walk to the location of the second vertex of their imagined shape which provides a line on the screen connecting the
first vertex with the current (moving) location, etc. The map in Figure 5 shows
some student constructions. The deconstruction option brought extra challenge
and competition into the game. From the data the researchers conclude that Mo-Digital Technology in Mathematics Education: Why it Works (or doesn't) 11
PNA 8(1)
bileMath adds a geometrical dimension to the world, transforming it into a game
board. MobileMath also invites mathematical activity, such as the (re)discovery
and use of characteristics of squares, rectangles and parallelograms, and taking
notice of geometrical aspects of the world.
Figure 5. Map of students' parallelogram constructions using GPS
One reason to discuss this study here is that the digital toolthe modern smart
phone with GPS facilities rather than an "old school" computeracts in multiple
ways, and its use includes all branches of the diagram displayed in Figure 1. The
device enables the exploration of properties of quadrilaterals (branch c). It also
allows for practicing the construction of parallelograms, which meets branch b.
And finally, the tool also functions as an environment to outsource the mathematical work, in this case the drawing of the shapes (branch a).
As seems to be the case in other studies on the integration of mobile technology in mathematics education, the theoretical perspective used by Wijers, Jonker,
and Drijvers (2010) is different from the frameworks common in most research
on technology in mathematics education. It is closely associated with frameworks from studies on serious gaming, and focuses (a) on student engagement
and (b) on task authenticity. Enhancing student engagement is seen as an important potential of educational games. In the MobileMath study, student engagement is stimulated by the game's hybrid reality character: On the mobile device's screen, students see the map of the reality in which they are walking, as
well as the virtual geometrical shapes they are creating. Hybrid reality games are
seen as beneficial for student engagement. In addition to this, the authors refer to
Prensky (2001) for a model on heuristics for the design of engaging games,
which include clear rules and goals, outcome and feedback, conflict, challenge
and competition, and interaction. Concerning task authenticity, the authors claim
that the effectiveness of learning activities can be enhanced if the tasks are authentic and realistic. In line with the framework of Realistic Mathematics Education, realistic means that problem situations presented in learning activities 12 P. Drijvers
PNA 8(1)
should be "experientially" real to students and have meaningful, authentic problem situations as starting points, so that students experience the game's activity
as making sense.
So did the digital technology work in this case? As far as engagement and
authenticity are concerned, the answer is "yes". The researchers report that the
students were engaged in the game and experienced it as challenging. Apparently, the game factor, in combination with the possible attractiveness of the digital
device, works out well. A second factor might be the outdoor and physical character of the game, which students may experience as a welcome change from
regular classroom teaching. What is not clear yet, however, is whether these effects will persist if this type of activity were to become more common. Also, the
study presented here has a small-scale pilot character and would certainly need
further replication.
Case 6: Teachers' Practices and Professional Development
If we recapitulate the previous cases, in all but the last one the teachers' practices
and experiences were identified as an important factor explaining why digital
technology worked or why it did not. Therefore, this final case focuses on the
role of the teacher, teaching practices and teachers' professional development.
One of the first studies focusing on teachers' practices and professional development was the one by Ruthven and Hennessy (2002). In this study and in
subsequent work (e.g., Ruthven, 2007) crucial factors are identified that affect
teachers integrating digital technology in their teaching. In relation to the instrumental genesis model, Trouche developed the notion of instrumental orchestration to stress the relevance of teaching practices (Trouche, 2004). Case studies
based on these models describe teachers' practices in relation to their opinions
and beliefs (Drijvers, 2012; Drijvers, Doorman, Boon, Reed, & Gravemeijer,
2010; Pierce & Ball, 2009). Another model on teachers' professional knowledge
is Technological Pedagogical Content Knowledge (TPACK), which became
widespread but is also criticized (Graham, 2011; Koehler, Mishra, & Yahya,
2007; Voogt, Fisser, ParejaRoblin, Tondeur, & Van Braak, 2013).
In addressing the questions of how to prepare teachers for technology-rich
teaching and how to enhance their professional development in this field, in line
with the work done by Wenger (1998) on communities of practice, it is suggested
that the participation in a community of teachers who co-design and use resources for teaching, can contribute to this (e.g., see Fuglestad, 2007; Jaworski
2006). Digital technology in such an enterprise acts on two levels: first, the professional development concerns its use in mathematics education, and second,
digital technology may support the community's work by offering online and virtual facilities for exchange. Digital technology is both the subject at stake and the Digital Technology in Mathematics Education: Why it Works (or doesn't) 13
PNA 8(1)
vehicle to address it. Efforts have been done to exploit digital technology's potential for teachers' professional development by designing online courses
3
.
As a paradigmatic design research study in this field, let us now describe the
work done by Sabra (2011) in somewhat more detail. In his PhD dissertation,
Sabra describes two case studies of teachers' collaborative process of professional development in detail. In the first case ten teachers in the same school collaborate on the design of a final assessment training session and a mathematics investigation task while integrating the use of TI Nspire in their teaching. The second
case study concerns a project in which eleven teachers, all members of the Sesamath community from all over France, collaboratively design resources on the
concept of function that are part of the course manual. The analysis shows that
the two communities develop in quite different ways, but that in both developments some critical incidentscalled documentary incidents in the thesisare
decisive. The digital tools in this case include web facilities for collaborative
work, file exchange and communication; the role they play for the participating
teachers is best characterized by branch a in Figure 1, the role of a tool for doing
mathematics, or rather a tool for collaborating on the design of mathematical resources.
The main reason to discuss this study here is that its rich data including interviews, blogs and observations and its fine-grained data analysis provide a detailed insight in how communities of teachers may work (or may not) and how
technology may support this.
From a theoretical perspective, Sabra uses the notion of documentational
genesis as a main concept. Figure 6, taken from Gueudet and Trouche (2009),
shows how this is analogue to the notion of instrumental genesis, but now addressing the level of teachers using and designing digital resources. The interesting point here, in my opinion, is that a similar framework is applied to and elaborated for different situations and different levels of technology integration.

3
E.g., see http://www.edumatics.eu/ 14 P. Drijvers
PNA 8(1)
Figure 6. Schematic representation of a documentational genesis (Gueudet &
Trouche, 2009)
So did technology work in the Sabra study? Maybe the answer is different for the
two cases that are described. In the case of the team of teachers within the same
school, it seems that the digital technology does not have so much to offer, and
that the professional interest of the community members does not invite a real
engagement in an effective collaboration. As a result, one can wonder whether
the targeted professional development really took place, and whether the community really contributed to it. In the second case of the teachers all over France,
the analysis shows a very lively process of collaboration, which is clearly afforded by the digital technology and would not have been possible without it. Similar
to the other cases described in this paper, it seems that decisive factors that explain the phenomena go beyond the straightforward point of the available technology. My impression is that for a school team of teachers, collaboration is far
from self-evident, whereas teachers who volunteer for a role in the Sesamath project share a professional interest to engage in a virtual community and in a shared
process of distant collaboration. This, I would conjecture, might be the main explanation for the different results in the two cases Sabra describes.
CONCLUSION
Theslightly provocativequestion raised in the title of the paper is why digital
technology in mathematics education works or does not. The underlying aim was
to identify factors that promote or hinder the successful integration of digital
technology in mathematics education. The analysis of the six cases described in
this paper show that the integration of technology in mathematics education is a
subtle question, and that success and failure occur at levels of learning, teaching
and research. In spite of this complexity, three factors emerge as decisive and
crucial: the design, the role of the teacher, and the educational context.
The first factor concerns design. Cases 1, 3, and 4 reveal the crucial role of
design. This concerns not only the design of the digital technology involved, but Digital Technology in Mathematics Education: Why it Works (or doesn't) 15
PNA 8(1)
also the design of corresponding tasks and activities, and the design of lessons
and teaching in general, three design levels that are of course interrelated. In
terms of the instrumentalgenesis model, the criterion for appropriate design is
that it enhances the co-emergence of technical mastery to use the digital technology for solving mathematical tasks, and the genesis of mental schemes that include the conceptual understanding of the mathematics at stake. As a prerequisite, the pedagogical or didactical functionality in which the digital tool is
incorporated (see Figure 1) should match with the tool's characteristics and affordances. Finally, even if the digital technology´s affordances and constraints
are important design factors, the main guidelines and design heuristics should
come from pedagogical and didactical considerations rather than being guided by
the technology´s limitations or properties.
The second factor concerns the role of the teacher, which is crucial in Cases
1, 2, and 6. The integration of technology in mathematics education is not a panacea that reduces the importance of the teacher. Rather, the teacher has to orchestrate learning, for example by synthesizing the results of technology-rich activities, highlighting fruitful tool techniques, and relating the experiences within the
technological environment to paper-and-pencil skills or to other mathematical
activities. To be able to do so, a process of professional development is required,
which includes the teacher's own instrumental genesis, or, in terms of the
TPACK model, the development of his technological and pedagogical content
knowledge. Case 6 suggests that technology can help the teacher to advance on
this, together with colleagues in technology-supported collaboration. What seems
to be an open question is how the role of the teacher changes if we consider the
use of technology in out-of-school learning, gaming, and other forms of informal
education (see Case 5).
The third and final factor concerns the educational context, which includes
mathematical practices and the elements of the pedagogical map designed by
Pierce and Stacey (2010). Case 2 reveals how important it is that the use of digital technology is embedded in an educational context that is coherent and in
which the work with technology is integrated in a natural way. Case 5, the MobileMath example, shows that taking into account the educational context includes attention for important aspects such as student motivation and engagement. Another factor that is not so much elaborated in the case descriptions but is
important to mention here, is assessment, which should be in line with the students' activities with technology; not doing so would suggest that in the end the
use of digital technology is not important. Finally, the use of digital technology
may lead to an extension of the educational context towards out-of-school settings, as exemplified in Case 5.
The three factors identified above may seem very trivial, and to a certain extend they are quite straightforward indeed; however, their importance, I believe,
can hardly be overestimated and to really take them into account in educational
practice is far from trivial. 16 P. Drijvers

DISCUSSION
Let me first acknowledge that the study presented here clearly has its limitations.
The discussion of the studies addressed cannot be but somewhat superficial in the
frame of this paper. Also, the number of studies is small, and the choice of the
studies included is not neutral. This being said, I do believe the article provides
avery roughmap of the landscape of research studies on technology in mathematics education and reveals some trends in the domain over the previous decades.
So what trends can be seen in retrospective? Globally speaking, a first trend
to identify is that from optimism on student learning in the early studies towards
a more realistic and nuanced view, the latter acknowledging the subtlety of the
relationships between the use of digital technology, the student's thinking, and
his paper-and-pencil work. A second trend is the focus not only on learning but
also on teaching. The importance of the teacher is widely recognized and models
such as TPACK, instrumental orchestration and the pedagogical map help to understand what is different in teaching with technology and to investigate how
teachers can engage in a process of professional development. The third and final
trend I would like to mention here concerns theoretical development. Whereas
many early studies mainly use theoretical views that are specific for and dedicated to the use of digital technology (e.g., Pea's notions of amplifier and reorganizer in the Heid study), recent studies often include more general theories on mathematics education or learning in general, and also combine different theoretical
perspectives (e.g., see the work by Bakker, using Pierce, RME, and other theoretical views).
To close off this discussion, I would like to express my strong belief that
these theoretical developments are crucial for the advancements in the field. The
studies addressed in this paper show strong relationships between the theoretical
frameworks, the digital tools and the mathematical topics (Kieran & Drijvers,
2012). We now have a myriad of theoretical approaches available in our work,
including very specific theories on the use of technology in mathematics education, domain-specific instruction theories, and very general views on teaching
and learning. One of the challenges in our work, therefore, is to combine and
contrast the lenses each of these approaches offer (Drijvers, Godino, Font, &
Trouche, 2012). The notion of networking theories (Bikner-Ahsbahs & Prediger,
2010) provides a good starting point that may help to better understand the role
of digital technology in mathematics education and, as a consequence, to contribute to the learning and teaching of the topic.
ACKNOWLEDGEMENT

Digital design:
RME principles for designing online tasks
Paul Drijvers, Peter Boon, Michiel Doorman, Christian Bokhove, Sietske Tacoma
Freudenthal Institute for Science and Mathematics Education, Utrecht University, Utrecht, the Netherlands
Abstract: The theory of Realistic Mathematics Education provides principles that can be applied to task design. In this paper, we investigate how these principles apply to the design of online tasks. To do so, we present examples of tasks on algebra, calculus and geometry designed in the Digital Mathematics Environment. As a result, we conclude that the principles of guided reinvention, didactical phenomenology, and emergent modeling can inform and guide digital design, but that some aspects work out differently compared to the design of paper-and-pencil tasks.
Keywords: Didactical Phenomenology, Digital Design, Digital Mathematics Environment, Emergent Modeling, Guided Reinvention, Realistic Mathematics Education
Introduction
Task design is widely recognized as an important, but complex and subtle activity. Based on the experience of skilled designers, design guidelines and heuristics have been identified (e.g., see Watson & Mason, 2006). Whereas the design and use of digital content nowadays plays an increasingly important role in mathematics education, most of these design principles are based on and applied to the design of paper-and-pencil tasks. The question, therefore, is how such design principles apply to digital design, and how the rich experience and knowledge in the field of designing paper-and-pencil tasks can be transferred to the case of digital design.
To address this question, we limit ourselves to three principles that emerge from the theory of Realistic Mathematics Education and may inform design: guided reinvention, didactical phenomenology, and emergent modeling. We revisit some tasks designed in the Freudenthal Institute's Digital Mathematics Environment in the field of algebra, calculus and geometry education.
RME Design Principles
Realistic Mathematics Education (RME) is a domain-specific instruction theory for the teaching and learning of mathematics. According to RME, mathematics should be seen as an activity (Freudenthal, 1973), and students, rather than being receivers of ready-made mathematics, should be active participants in the educational process, in which they develop mathematical tools and insights by themselves. This point of departure led to the following RME principles that inform task design: guided reinvention, didactical phenomenology, and emergent modeling (Freudenthal, 1973; Gravemeijer, 1994; Van den Heuvel-Panhuizen, 1996).
According to the principle of guided reinvention, students should be given the opportunity to experience a process similar to that by which a given mathematical topic was invented. Even if this primarily is a teaching principle, it has consequences for task design: tasks - or sets of tasks - should invite students to develop 'their own' mathematics. This process, however, needs guidance from the teacher, to help to further develop sensible directions, to leave 'dead-end streets' and to ascertain convergence towards shared knowledge according to the standards within the mathematical community.
Didactical phenomenology concerns the relation between the thought object -the 'noeumenon'– and the phenomenon -the 'phainomenon'– from the perspective of teaching and learning. In particular, it addresses the question how mathematical 'thought objects' can help in organizing and structuring phenomena in reality.
The challenge for the task designer, then, is to find such meaningful phenomena that beg to be organized and structured by the targeted mathematical knowledge.
According to the emergent modeling perspective, a model may play different roles during different phases of activity. Initially, a model is context-specific: it refers to a meaningful problem situation that is experientially real for the student, and is a model of that situation. Then, through working with the model, it gradually acquires a more generic character and develops into a model for mathematical reasoning that is possible because of the development of new mathematical objects in a more abstract framework of mathematical relations that the model starts to refer to. This notion is elaborated into a four-level structure that represents levels of mathematical activity (Gravemeijer, 1994). For the task designer, the challenge is to find suitable situations that ask for the development of such models, and allow for a process of progressive abstraction.
While applying these RME principles to the design of paper-and-pencil tasks is not straightforward, their use for the design of digital content is even more challenging. Although early research on the use of graphing calculators identified opportunities for an RME-based teaching approach (Drijvers & Doorman, 1996), later studies describe the tension between RME principles and the integration of computer algebra software (Drijvers, 2000). Apparently, the match between RME and ICT is not self-evident.
The Digital Mathematics Environment
As technology for teaching mathematics the Freudenthal Institute's Digital Mathematics Environment (DME) is used. The DME integrates a content management system, a learning management system and an authoring environment. The content consists of online modules in the form of Java applets. The learning management system offers means to distribute content among students and to monitor student progress.
The authoring tool is the DME's design environment. Authors, such as teachers, text book authors, or educators, can use the tool for adapting existing online modules or for designing new ones, based on existing materials and basic tools such as graphing and equation editing facilities. While designing, the author can split up the screens in different windows, add applications and tasks, and design feedback. Knowledge of the underlying Java programming language is not required; rather, an intuitive and mathematical interface makes the digital design accessible to a wide audience (Figure 1).

Figure 1 The Digital Mathematics Environment Authoring Tool

Examples of the results of digital design using the DME's authoring tool can be found at www.fi.uu.nl/dwo/demo/en. In this paper, we will briefly discuss some examples from algebra, calculus and geometry from the perspective of the above RME principles.
Digital Tasks for Algebra
As an example of the design of digital tasks for algebra, we consider the work by Bokhove, available at www.fi.uu.nl/dwo/voho/. The digital tasks focus on solving polynomial equations. However, the online units go beyond procedural practice and also focus on the development of symbol sense and strategic skills (Bokhove & Drijvers, 2010, 2012). Crucial factors in the design are the sequencing of the tasks (with sometimes thought-provoking equations) and the design of feedback, and its timing and fading in particular.

Figure 2 Solving an equation with unexpected difficulties (Bokhove & Drijvers, 2010, 2012)

Figure 2 shows an exemplary equation in line 1, and a part of a student's work in lines 2-4. The feedback just refers to the algebraic equivalence of the subsequent equations the student enters; no feedback is provided on the problem solving strategy. This can be seen as a manifestation of the guided reinvention heuristic: this combination of task and tool provides the opportunity for students to reinvent efficient ways of solving equations. Eventually, students can continue entering equivalent equations without coming closer to the solution, but this exploration space is supposed to elicit a wish for efficiency.
From the didactical phenomenology perspective, this task may seem quite poor: what is the phenomenon at stake that would motivate students to engage in mathematics? In defense of this, one can argue that the target group of this online module consists of students in grade 12, who were to do the national examination soon, and who were familiar with the 'world of polynomial equations'. This familiarity makes that these tasks can be appropriate for the mathematization of the field and the development of new problem solving strategies.
Data shows that students work easily with this type of online tasks (Tacoma, Drijvers, & Boon, 2011). Instrumental genesis, the process of developing schemes to use tools to solve the tasks (Artigue, 2002), was an issue to a much lesser extent than in the case of computer algebra (Drijvers, 2002; Drijvers et al., 2012). Apparently, using CAS puts higher demands on instrumental genesis, and this is something to take into account as a designer.
Digital Tasks on Functions and Calculus
As an example of the design of digital tasks for (pre-)calculus we consider the online module Function and Arrow Chain, available at www.fi.uu.nl/dwo/prootool/en. The digital tasks focus on the development of conceptual understanding of the notion of functions, where a function is seen as an input-output assignment, as a dynamic process of co-variation, and as a mathematical object with different representations (Doorman et al., 2012). A crucial factor in the design is sequencing the tasks so these function models emerge in a natural way of increasing complexity and abstraction.

A function as an input-output assignment: braking distance as a function of velocity
Investigation of the co-variation of velocity and braking distance through tracing the graph
Investigation of a family of functions, representing braking distances for three different vehicles

Figure 3 Different views on function in the Function and Arrow Chain module

Figure 3 shows some screens from this module, in which the function gradually develops from a numerical input-output engine, to a process of co-variation and, finally, a mathematical object that is part of a family of functions that can be compared. This sequence of screen shots reflects the emergent modeling heuristic: the context, in this case on of a vehicle's braking distance as a function of its velocity, leads to function models of increasing complexity and abstraction. The digital tool supports this development by means of offering techniques of increasing richness and an increasing repertoire of connected function representations. Of course, this approach requires a context that is suitable for this emergent modeling process. Finding such a context is a question of didactical phenomenology.
In an online calculus course for university freshmen, the co-variation idea is supported by a Geogebra applet for tracing graphs (www.fi.uu.nl/dwo/sk/en/). However, in the context of this intensive and short-period remedial course, the emergent modeling design heuristics was exploited to a lesser extent than was the case for the Function and Arrow Chain course.
Digital Tasks for Geometry
An example of the design of digital tasks for geometry is the module available at www.fi.uu.nl/dwo/dpict/en/. The digital tasks focus on exploring, discovering, and proving properties of bisectors, altitudes and medians in triangles. The latter aspect, the proving, provides a particular design challenge: how to design tasks that offer support and guidance for a proof, but leave room for reinvention?

Figure 4 Proving that three medians of a triangle intersect in one point

While reading the proving task shown in Figure 4, it should be noted that Dutch grade 8 students, the target group for this module, have little experience in proving, and, therefore, need strong guidance: the structure of the proof and the corresponding sequence of images is suggested to the students. Still, writing down the final argument in the reasoning, as is requested in task c, is very difficult to them. The design principle of guided reinvention is easier to apply to tasks in which students explore the properties of bisectors, altitudes and medians in triangles: the dragging options of the dynamic geometry system, in this case Geogebra, in collaboration with DME's feedback, provide a strong learning environment in which students can really experience the geometrical situation and discover the targeted properties.
In the case of this online module, classroom observations show that attention needs to be paid to students' and teachers' instrumental genesis: the interplay between Geogebra and the DME in this module is powerful but it may also be demanding and initially complex to novice users.
Conclusion
In this short paper, we set out to investigate the application of the RME principles of guided reinvention, didactical phenomenology, and emergent modeling for the case of the design of digital tasks in the online DME. To do so, we considered three exemplary tasks. The first example, the task on solving a relatively complex equation, shows that guided reinvention in this case concerns the development of new problem solving strategies, invited by tasks that cannot be solved with the strategies available so far. The didactical phenomenology heuristic here does not lead to the use of real life contexts, but rather takes the world of polynomial equations as a point of departure. In the second example, a real life context -in this case the stopping distance situation- does form the starting point. Emergent modeling heuristics are manifest in the gradual abstraction of the students' view on function. The third example on geometrical proof again takes a guided

reinvention perspective, in which the designers chose strong guidance. Again, the didactical phenomenology here does not lead to a real life problem situation, but to a problem in the world of geometry, that is expected to be experientially real to the students.
What can we conclude about the three RME principles and their application to digital design? The principle of guided reinvention seems to apply well to digital design. ICT offers opportunities for exploration and investigation, and in this way for reinvention. The design choice to confront students with unexpected examples can be seen as a way to invite reinvention as well. In general, this guided reinvention approach might suffer from constraints of the technology that may limit the students' exploration space, such as requirements for input formats and styles, and pre-designed tools that may incorporate too much guidance.
The didactical phenomenology heuristics is also valuable for digital design, but it seems that the phenomena that play a central role in the task do not necessarily come from real life: ICT already forms a meaningful 'world' on its own for the student, in addition to the world of mathematics. Having a real life context as an entrance to these two worlds may lead to cognitive overload. This is a question to be considered carefully in the design process.
Emergent modeling can be a fruitful design heuristics for digital design. As in the case of paper-and-pencil design, the models need to lend themselves for further development towards increasing mathematical abstraction and complexity. Specific for the case of digital design is that these emerging models need to be supported by the digital tools available, for example by an increasing repertoire of representations and techniques in the digital environment, or by increasing options to dynamically use these representations, connect them, and switch between them (Duval, 2006).
As an overall conclusion, this brief exploration of the issue suggests that the three RME principles are valuable for digital design, even if some appropriation is needed compared to the design of paper-and-pencil tasks, such as taking into account the constraints of the digital tools and the fact that the technological environment forms an additional 'world' to the student. The transfer of skills, developed in the ICT environment, to paper-and-pencil, for example, may need specific attention, as well as the instrumental genesis involved in the learning process.

The Graphics Calculator in
Mathematics Education
PAUL DRIJVERS
MICHIEL DOORMAN
Freudenthal Institute
Utrecht, The Netherlands
This article covers a project conducted by the Freudenthal Institute from August 1991 to September 1994 entitled "The graphics calculator in mathematics education." The theory of realistic mathematics education was taken as the point of departure for formulating the hypotheses. The developmental research design was used. Observation of the students' behavior during the experimental lessons supports the premise that the graphics calculator can stimulate the use of realistic contexts, the exploratory and dynamic approach to mathematics, a more integrated view of mathematics, and a more flexible behavior in problem solving.

INTRODUCTION
Teacher:
Johan:
Alex:
Teacher:
Alex:
Erik Jan:
Teacher:
Erik Jan:
How can you shift the graph of y = x2 two places to the right?
y = x2 + 2 (see Figure 1). He enters this and presses GRAPH.) Oh no! y = x2
+ 2?, GRAPH . that's not right either.
y = x2 + 4x + 4, no, that's not right, the graph shifted two places to the left.
So then it is y = x2 - 4x + 4. That's right.
and three places to the right?
(After trying this out on the graphics calculator): y = x2 - 6x + 9. (Rewriting
the formulas gives y = (x - 2)² and y = (x - 3)2.)
And if you have y = x2 + 2– and you shift that three places to the right?
What do you think?
First complete the square, that'11 give you y = (x + 1)2 - 1, and then three
places to the right, so -3 in parentheses, that's y = (x - 2)² - 1.
This conversation took place recently during a mathematics lesson in Class 4
HAVO. L All of the students in this class were supplied with a graphics calculator
for the duration of the project, and by this point they were quite familiar with it.
It is clear that the direct feedback given by such a calculator can help one to
discover the connections between formulas and graphs.

Figure 1.
The development of the graphics calculator has also given rise to a lively
discussion among researchers of mathematics education. How should such a
machine-one that reduces the drawing of graphs to the push of a button-be
integrated into mathematics education? What is the potential of this new technology and what difficulties can one expect to find?
International research in this area has resulted in a stream of publications. An
interesting overview is presented by Wilson and Krapfl (1994). Darien Lauten,
Graham, and Ferrini-Mundi (1994) considered the influence of the use of the
graphics calculator on the understanding of basic calculus concepts. Goldenberg
(1988) investigated the problems that may confront students when working with
a graphics calculator. Ruthven (1992) indicated the potential value of the graphics calculator for mathematics education. Monaghan (1993) investigated the
relation between using the graphics calculator and developing insight. A calculus
textbook in which the graphics calculator plays a major role was developed by
Demana, Waits, and Clemens (1992).
The Netherlands is not lagging behind in such research. During the period
between 1991 and 1994, the Freudenthal Institute, supported by a grant from the
Ministry of Education and Science, conducted a research project entitled "The
graphics calculator in mathematics education." This project focused on secondary education, in particular on the role of the graphics calculator in Math B in
preparation for subsequent exact studies in Class 5 VWO." The decision to focus
2Fifth class of preuniversity education (approximately 17.year-old students). THE GRAPHICS CALCULATOR IN MATHEMATICS EDUCATION 427
on Math B has to do with the fact that the curriculum for this subject in particular
is now under discussion. In addition, it was felt that the graphics calculator
would have a more profound influence in Math B than in Math A. After all, Math
A, which is oriented toward further studies in the humanities, focuses primarily
on the application of mathematics. Formulas used in these applications are an
attempt to represent reality and one can often suffice with approximate answers
due to the model character inherent here (see de Lange, 1987). The use of the
graphics calculator does not affect the fundamentals of Math A. In Math B, on
the other hand, exact answers are generally required. The numerical results
provided by the graphics calculator at times seem to be at odds with this precision. The traditional analysis of functions will change due to the graphics calculator. Graphs are the starting point of further investigations instead of the final
result of the analysis. Different questions come up from the graphical representation that is provided by the machine.
Extensive experimentation using the graphics calculator was conducted at two
different schools in the framework of this project. The students were provided
with a calculator during each lesson. In a later stage of the project they were also
permitted to take their calculator home. On the whole, the students' usual math
textbook was followed during these lessons, but specific units developed by the
research team in which the graphics calculator is used more explicitly were also
part of the program. These lessons in particular, in which this experimental
material was presented, were closely observed. The opening paragraph of this
article is a fragment of one such observational report. Similar observations form
the basis of the theoretical side of this project: providing answers to the research
questions that were formulated at the outset of the project. The results of the
project are published in a research report under the same title (Doorman, Drijvers, & Kindt, 1994). The intent of this article is to offer an impression of the
project and of the most significant results.
The following section first describes the characteristics of realistic mathematics education and how potential contribution by the graphics calculator to this
type of mathematics education is viewed. This leads to the first hypotheses that
form the starting point for the research project at hand. The third section deals
with how the project was conducted. The research method-called developmental research-is described briefly. The development of experimental instructional material is of great importance within this type of research. The choice of
topics for the experimental student material is mentioned here as well. In the
fourth section, a fragment of the developed material is examined more closely.
Data from the observations, described in the fifth section, provide an illustration
of the way in which students dealt with this material. A reflection on the example
given and on the starting points of the research in general is found in the sixth
section. Finally, the last section briefly examines further developments that will
take place in the near future. 428 DRIJVERS AND DOORMAN
REALISTIC MATHEMATICS EDUCATION
AND GRAPHICS CALCULATORS
The domain-specific instruction theory for realistic mathematics education has
acquired a considerable following in The Netherlands during recent decades.
According to this theory, realistic applications should play an important role in
the learning process right from the start. Solution procedures are (re)constructed
by the students themselves through using problems that have meaning in their
reality. Some of the important characteristics of realistic mathematics education are:
l A variety of solution strategies.
l A high degree of student input.
l Use of informal strategies and informal knowledge.
l Footholds for reflection.
l Stimulus for raising the level, for generalization, and for formalization.
For an extensive discussion on the theory of realistic mathematics education, see
Freudenthal (199 1) and Treffers (1987).
How do these general starting points of realistic mathematics education translate to the specific situation of implementing the graphics calculator in math
class? In the course of the research project, this instruction theory became crystallized in five hypotheses.
Realistic Contexts
Mathematical models used in realistic applications often contain "unsightly"
numbers or formulas. For the sake of manageability, reality is sometimes twisted
in order to assure a smooth problem. With the arrival of the graphics calculator,
there is no longer any need to tarnish the realistic quality of the problem. The
machine, after all, takes over the time-consuming technical work, leaving the
student free to concentrate on the process of mathematization, the solution strategy, and the drawing of reasonable conclusions.
The first hypothesis is, therefore:
Using the graphics calculator enables the attention to shift from purely algorithmic
operations to translating realistic problems into a mathematical model and interpreting the results.
In the unit "Optimalization" (Drijvers & Kindt, 1992), for instance, Snellius'
law is mentioned (see also Kindt, 1993). The speeds at which light travels
through the two media are extremely high. By using the graphics calculator,
where a scale model can easily be adapted, this should no longer be a drawback. THE GRAPHICS CALCULATOR IN MATHEMATICS EDUCATION 429
Exploration
Thanks to its direct feedback, the graphics calculator can offer opportunities for
exploratory activities. Even during the initial phase of familiarization, a problem
can often already be investigated graphically. Insight into the structure of a
formula can be acquired through the graphics calculator. Inventory and classification activities can lead to discoveries that then, through reflection and generalization, result in interesting mathematical theorems. This contrasts with the
traditional method, in which definitions and theorems are stated at the beginning
of the learning path in the expectation that insight will be acquired through
repeated application. The second hypotheses is as follows:
Use of the graphics calculator stimulates the posing of new questions and the
generalization of problems. For the student, this involves a broadening of the
mathematical field of vision and a change of attitude with respect to mathematics
from one of "passive performance" to that of "active investigation."
The exploratory potential of the graphics calculator is addressed, for example,
on the worksheet on classifying cubic functions (Drijvers, 1993). The students'
assignment is quite open: Based on the various graphs, they are to try and catalog
all the possible cubic functions. The exploration that is here indispensable is
made possible thanks to the graphics calculator.
Integration
Use of the graphics calculator contributes to the integration of the two classical
components of mathematics: algebra and geometry. Operations with algebraic
expressions via graphic (or geometrical) illustration of functions on the screen
can by this means be performed in a great variety of ways. Algebraic laws and
rules can thereby be discovered and then tested graphically. This leads to a more
visual form of algebra instruction. The class conversation at the beginning of this
article is such an example. It was recorded during a lesson on the unit entitled

"The Algebra of Graphs" (Doorman & Drijvers, 1993).
Conversely, geometrically shaded assignments may evoke algebraic activities.
Examples of such assignments are: "draw regular five-pointed star" or "make a
spiral curve." The student is thus asked to design formulas (input for the ma-
chine) in order to achieve the desired geometric result (output). Hypothesis 3 can
be stated:
Use of the graphics calculator encourages the integration of geometric and alge-
braic activities and continually stimulates the student to create links between the
various aspects of mathematics. 430 DRIJVERS AND DOORMAN
Dynamics
The graphics calculator has a number of dynamic aspects. First, one can quickly
and effectively follow the results of alterations in the problem. The influence of a
given parameter in the formula can easily be made clear by using graphics.
Another dynamic aspect is the ability to trace a graph or curve with the cursor,
while reading off the constantly changing coordinates on the screen. In the unit
entitled "Movements in the plane" (Doorman, Drijvers, & Kindt, 1994a, 1994b),
for instance, the speed of the valve of a turning bicycle wheel is made visible. A
third dynamic aspect is the ability to zoom in and out of the graph. This enables one
to continually alter one's frame of reference from global to local and vice versa.
The fourth hypothesis is, therefore:
The graphics calculator is ideal for visually illustrating the changing behavior of
magnitudes in their mutual relation and, therefore, encourages a dynamic manner
of observing analytical models.
This aspect is examined more closely in van den Brink and Doorman (1994).
Flexibility
Due to the advent of the graphics calculator, the repertoire of techniques and
skills a student must master will markedly change. Freehand drawing of a graph
based on a strictly prescribed analysis of functions-a much practiced skill until
now-will hardly matter. On the other hand, skills such as estimation, reading
graphs, and successive approximation will increase in significance.
One of the first problems students face when making one or more graphs on
the screen is the limitations of the screen itself. The students will have to figure
out on their own the relevant domain (or range) of the variables in the problem at
hand, based on the context of the mathematical model. Ruthven (1992) used the
term trial and improve for this type of technique.
Finally, we should point out that the graphics calculator produces numerical
approximations in its results, even in situations where an exact result is desired.
The student is therefore required to maintain a critical attitude with respect to the
machine's numerical productions.
All in all, we may expect that, due to the influence of the graphics calculator, a shift
in emphasis will occur away from "rigid techniques" and toward a more flexible
solution procedure, in which a critical attitude is developed with respect to numeri-
cal results.
The five points just elucidated form a strong link with the starting points of
realistic mathematics education. The terms exploration and dynamics, by the
way, are frequently used in discussions about the use of the graphics calculator
and computer algebra in education. The development of this terminology in THE GRAPHICS CALCULATOR IN MATHEMATICS EDUCATION 431
didactic practice, however, is not nearly as self-evident and, in a number of
publications, downright disappointing.
DEVELOPMENTAL RESEARCH
The project was conducted according to the method called developmental
research. This involves a cyclical process of consideration and testing, an alter-
nation of thought experiment and educational experiment. In the thought experi-
ment, the designer imagines how the educational process might take place. In the
educational experiment the thought experiment is then tested in actuality. The
curriculum being tested, however, is not simply left unchanged. The experience
acquired is immediately used to adjust the curriculum or to develop new educa-
tional activities. In fact, the new curriculum is created through the experiments:
Development and testing go hand in hand.
The results of the present developmental research consist of experimental
instructional material, observations of the lessons, and reflections based on these
observations. An attempt at answering the research questions, starting from the
observations and the realistic view of education, is found in the theoretical
reflection. For a more extensive description of developmental research-not
connected with the graphics calculator-see Gravemeijer (1994). Examples of
developmental research that focuses on realistic mathematics education are de-
scribed by van Reeuwijk (1992) and de Lange, Burrill, Romberg, and van
Reeuwijk (1993).
As mentioned earlier, the development of student materials plays an important
role in developmental research. Four topics have been selected for units to be
developed, on the basis of the hypotheses already listed and also, of course, on
the basis of less concrete intuition. The following are brief descriptions of each
topic.
Differentiation
Differential calculus plays a crucial part in the mathematics curriculum. The
graphics calculator is an excellent means of approximating differential quotients
and of drawing estimations of graphs of slope functions. This would seem to
offer possibilities for exploratory activities and for supporting concept formation.
Optimalization
Problems of optimalization appear in all sorts of situations and disciplines. The
problem (often originating in reality) must first be translated into mathematical
terms. Then, during the solution stage, a variety of solution procedures often
prove valuable. Here lies the potential for forging links with geometry.
The Algebra of Graphs
The algebra of graphs involves the link between operating with graphs and 432 DRIJVERS AND DOORMAN
operating with formulas. The graphics calculator's ability to quickly investigate
on a graph the results of alterations in the formula is an important aspect here. In
this way, algebraic rules and properties can be linked with graphic characteristics
and, therefore, can become more "real."
Movements in the Plane
The dynamic potential of the graphics calculator can optimally be applied to the
topic "Parametric Curves," where time is often the parameter. Here, as with
"Optimalization," realistic problems and links with geometry play an important
role.
EXAMPLE: ROLLING COINS
What does instructional material involving the graphics calculator actually look
like? A decision was made in this project not to let the machine stand too much in
the spotlight. The point, after all, is still mathematics. The students must often
(to the disappointment of some) put their calculator down and concentrate on the
algebraic calculations or geometrical reasoning.
The following fragment from the unit entitled "Movements in the plane" is
used here as an example. Classroom experience using this material offers an
impression of the ways in which the students made use of the graphics calcula-
tor's potential.
In Figure 2, two guilders lie next to one another. The left guilder is fixed. P is the
point on the edge of the right guilder where it touches the left guilder. The right
guilder is now going to roll around the edge of the left guilder without sliding. The
question is, what path will P describe.
The first assignment contains a concrete orientation. This leads to the choos-
ing of an appropriate coordinate system that is shown in Figure 3, and to the
constructing of the motion equations. Then the students draw the curve, creating
Figure 2. THE GRAPHICS CALCULATOR IN MATHEMATICS EDUCATION 433
a picture of the cardioid, after which they investigate the speed with which the
point passes through the cardioid. By using the graphics calculator to animate the
curve, it becomes clear that this speed is not constant. The speed vector is
calculated using differential calculus. Geometrical observations complement the
assignments on the speed of the movement. Then variations in the assignment are
presented.
1. As the right guilder starts rolling, point Q is found halfway between the center
of the rolling guilder and the origin.
a. How do these motion equations differ with respect to those of P?
b. Draw Q's path.
c. Is Q's average speed the same as P's? Expiain.
Now the experiment becomes more difficult to conduct. We tape a coin
called a rijksdaalder on top of the rolling guilder that, due to its greater
diameter, also covers part of the fixed guilder.
2. The point R is found at (- i/z, 0) at the moment the right guilder starts rolling.
a. How can you change the motion equations of P's path in order to get R's
path?
b. In what way does R's path look different from P's path?
In this assignment, the distance from the moving point to the center of the guilder
has been changed. In the following assignment this is generalized and the stu-
dents must investigate a variety of cases. They are free to classify the graphs they
find as they choose. The focus here is on their own investigation.
3. Assume that a point P lies at a distance a from the center of the rolling guilder.
The radius of the guilder we will still call 1.
Investigate how the form of the path described by P depends on the value of a.
Pay attention to extreme cases as well. Give a brief summary of your results.
OBSERVATIONS IN THE CLASSROOM
How did this assignment actually work in the classroom? The experiment took
place in a Math B group of 18-year-olds in the sixth class of preuniversity 434 DRIJVERS ANDDOORMAN
education. These students had already worked extensively with the graphics
calculator during the previous school year. But we were somewhat concerned:
Would the students' skill with the machine still be at their fingertips? And how
would new students, who had never worked with the machine, adapt to the
situation?
Although some students reacted by giggling, they did start experimenting with
two actual guilders. Later, that proved to be of functional assistance. In particu-
lar, when they began to suspect that P was turning twice as fast around the center
of the rolling coin as that same center was turning around the fixed guilder, many
students reached for the actual coins to verify that suspicion.
At the point in the school year that this assignment was given, circular
movements having a variety of angle speeds and radii had already been handled
extensively. Constructing the motion equations, therefore, was not particularly
problematic. Moreover, the graphics calculator immediately revealed any errors
by drawing an "impossible" curve. This led, on the whole, to an improvement in
the motion equations. For instance, a number of students entered the following:
x(t) = 2 cos t - 1 + cos (2t)
y(t) = sin t + sin (2t).
The drawing in Figure 4 immediately revealed what was wrong.
This now can easily be improved! The students then entered:
x(t) = 2 cos t - 1 + cos (2t + T)
y(t) = 2 sin t + sin (2t + 7-).
These equations resulted in the curve shown in Figure 5 on the screen of the
graphics calculator.
The matter of varying the distance between P and the center of the rolling
guilder was also dealt with later on. The following fragment, taken from an
observational report, gives an impression of this work.
1
Figure 4. THEGRAPHICSCALCULATORINMATHEMATICSEDUCATION 435
Femke is having trouble with Problem 1. She has entered:
x(t) = 2cost - 1 + 5 cos (4t + rr)
y(t) = 2sint + f sin (4t + 7r)
"
.because it's turning twice as fast if it's twice as small."
A cloudlike drawing that is shown in Figure 6 had appeared on her screen.
In a sense she is right, as she is imagining a smaller coin, a dime for instance,
rolling over a guilder. She is running ahead of the spirograph curves. In this case,
however, the rolling coin remains a guilder, but the point whose path is being
followed no longer lies on the edge.
In Problem 2 the observer asks Femke: "And if you now made the factor 14 even
larger?" "Then the loop would get larger," she replies, "and the outside, too."
Problem 3 no longer presents any difficulties. Some students even enter the
parametric equations using a variable:
x(t) = 2cost - 1 + a cos (2t + Tr)
y(t) = 2sint + a sin (2t + 7r).
Interesting drawings result from these so-called Pascal curves (see Figure 7,
p. 436).
During the last 5 minutes of class, the results of Problem 3 are written in a row
on the board (see Table 1).
One student comments on the "dent": "When a is small, the dent is also small,
and when a gets bigger, the dent grows too."
Where the loop is concerned, the teacher asks: "Does it matter how much
greater a is than i?"
Figure 6. 436 DRIJVERS AND DOORMAN
Figure 7.
Student: When a is close to 1, it's small; if a is big, it's big.
Teacher: So does the small one ever catch up with the big one?
Student: No, they'll overlap, they'll get close together.
This brought the unit on the cardioid to a satisfying close.
Thanks to the graphics calculator, the topic "Curves" worked well. The stu-
dents watched the curves being created in a dynamic manner. The path became a
starting point for further study, rather than the static end product of a vast ritual of
investigation into intersections of the axes, horizontal and vertical tangents, and
so on.

REFLECTION AND CONCLUSIONS
Let us glance back at the example presented and at the accompanying observations in the classroom. The five hypotheses in Section 2 serve as the guideline for this. Along with each of the hypotheses, the results of the project on the whole are also summarized briefly. THE GRAPHICS CALCULATOR IN MATHEMATICS EDUCATION 431
Realistic Contexts
The assignment using two guilders worked well. The students were able to get a good picture of the problem. The variations on the original problem also seemed to come across quite naturally to the students. For that matter, the graphics calculator contributed little here. By choosing the radius of the guilder as the unit of length, "unattractive" coefficients could be avoided. So the strength of the graphics calculator in dealing with "unsightly" numbers was not put to use here. The general picture regarding this point is quite positive. Realistic data often lead to complex formulas with unattractive coefficients. The graphics calculator can then overcome the diffculties inherent in the calculating and drawing. True-to-life applications can by this means come within the students' reach. This is particularly desirable in the case of Math A. An additional advantage is the fact that attention can be paid to higher skills, such as constructing the mathematical model and choosing which strategy to use for solving the problem.
One aspect that repeatedly emerges when realistic contexts are used together with the graphics calculator is the difference between the various languages involved: normal language, mathematical language, and machine language. Students, especially at first, do become confused by this. They are being asked to function, as it were, on three fronts. Helping them to handle this flexibly will require the necessary didactic attention.
Exploration
In the example given of the cardioid, the graphics calculator does, indeed, support the exploratory activities. Particularly in the case where the distance from P to the center is varied, the graphics calculator performs a crucial task. The students arrive at a classification that they themselves have developed through their own experience.
On the whole, the project's results on this point are encouraging. The potential of the graphics calculator evidently stimulates many students to engage in informative exploratory activities. The mathematical level of the result, however, tends to be rather varied. Although such exploration can lead to excellent discoveries and insights, the results are at times disappointing. This has to do, on the one hand, with the fact that drawing conclusions from investigative activities places heavy demands on the students. On the other hand, it is also true that students in Math B often have not yet been confronted with open problems, and that an investigative attitude must also be acquired.
Nonetheless, it would seem that this potential for engaging in exploratory activities is one of the most important trump cards of the graphics calculator.
Integration
Laying links between algebra and geometry was brought out fairly well in the lessons on the cardioid. During the investigation into the speed of the point, the graphic image was placed next to the algebraic one. The geometric method, in 438 DRIJVERS AND DOORMAN
which speed vectors are added up, was difficult for the students. Table 1 presents a rather nice classification of the examples that were generated with the aid of the graphics calculator.
On the whole, this integration did not occur without a struggle. Working in different areas and from different viewpoints can produce difficulties, but new insights and an expansion of concepts as well. At first, the students tended to regard the various areas as separate entities and choose one single approach. The graphics calculator, on the other hand, offered them the opportunity to focus more on the entwining of these areas. In the end, the students generally appeared to accept this and to appreciate it.
Dynamics
The topic entitled "Curves in parametric equations" is, of course, particularly suited for a dynamic approach, and the graphics calculator is an excellent aid here. The students in the experimental lesson saw the point on the plane shift and the speed of the movement become visible. The parametric equations that describe the movements on the plane really came to life in this way. A second dynamic aspect that emerged from the observed lessons was the direct feedback the machine offered the students. This feedback made is possible for the students to learn from any errors and to immediately make improvements.
On the whole, the experiences encountered in this project confirmed the idea that the graphics calculator would provide the students with the advantage of a global graphic representation, an initial conceptualization of the problem. The machine removed the students' inhibitions to making a quick sketch. A dynamic aspect here is the fact that the user can see how ,a graph (or a curve or a group of graphs) is created. When the picture is finished, TRACE offers the opportunity to follow the graph point by point and to read the changing coordinates on the screen. The graphics calculator's direct feedback encourages the students to reflect on what they have done. This alternation between experimentation and reflection is an important aspect of concept formation in the realistic approach to mathematics.
Flexibility
The skills a student is expected to have mastered in order to work through the series of problems on the cardioid are different from those required in the traditional textbooks. Drawing the curve, for instance, is something that these students no longer needed to do by hand. On the other hand, it is quite important that the student be able to extract an indication of the exact maximum value from the approximation given by the graphics calculator. Moreover, it is assumed that the student will be able to link the consequences of the alterations in the motion equations with the changes in the curve.
On the whole, the expectation that the arrival of the graphics calculator would cause a shift of emphasis from rigid techniques to a more flexible solution THE GRAPHICS CALCULATOR IN MATHEMATICS EDUCATION 439
procedure was indeed confirmed. In addition, a critical attitude must be developed with regard to numerical results. The importance of mastering routine operations will decline and the necessity of developing a flexible attitude for working with the machine will increase. The students will, as it were, become more mathematically nimble.
AND FURTHER. . .
The research project did not, of course, exclusively confirm expectations and it is not now over and done with. Although, indeed, the experiences on the whole were quite positive, there was insufficient investigation into, in particular, the influence of the graphics calculator on the subject-matter content. This has to do with certain preconditions for the project at hand: The students participating in the experiment were not given permission to use the graphics calculator on their final exam. As a result, it was impossible to diverge too far from the normal program and its traditional approach. A side effect was that the students regarded using the graphics calculator as something of a noncommittal event.
In the subsequent project-which has already begun-this will change.
Based on the realization that the graphics calculator can only attain a satisfactory place in the mathematics curriculum if the machine also plays a role on the exams, an experimental exam project has been set up. The two test schools involved in this project have obtained a divergent regulation regarding the mathematics exams, one that permits use of the graphics calculator. Obviously, these exams will differ from the traditional ones. The first such experimental exams for VWO Math A and Math B are administered in 1996.
Further introduction of the graphics calculator into mathematics education will depend partly on developments of the new curricula for the upper levels of secondary education. In our opinion, it is quite clear that the availability of the graphics calculator will influence the actual content of the units to be developed. Routine analysis of functions, for instance, will diminish in importance.
We expect that the exam experiment involving the graphics calculator will contribute to concrete changes in the subject of mathematics in the upper levels of secondary education. The desirability of introducing the graphics calculator on a national level, particularly considering developments in other countries, is, in our opinion, quite clear, and is scheduled for 1998.

Abstract
The aim of this study was to develop and implement a valid, practical, and effective RME-based

geometry course for Indonesian primary schools using design research approach. The research activities were divided into three stages namely front-end analysis, prototyping stage, and assessment stage that were conducted in a four year period. The focus of the chapter is to present detail and rational regarding the three stages. The result of the study was a high quality RME-based geometry course for teaching geometry at grade 4 in Indonesian primary school consisted of teacher's guide and student book. In the products lies the local instructional theory for teaching geometry that was effective for improving pupils' understanding, reasoning, activity, creativity, and motivation.

1. Introduction to the problem

The study reported in this chapter has been conducted in the period 1998 - 2002. At that time the quality of mathematics education in Indonesia, especially in primary and secondary education, was considered poor (see Soedjadi, 1992, 2000), whilst the mathematics learning and teaching process in the classrooms was dominated by the traditional method (see Somerset, 1997; Marsigit, 2000). The traditional way of teaching had a negative influence on the pupils' attitudes towards mathematics which means that most pupils did not like to learn mathematics, and that some of them were even afraid of mathematics (Marpaung, 1995, 2001). This study aimed to explore whether another approach to mathematics education could address these shortcomings by developing and implementing an exemplary course viz. Realistic Mathematics Education (RME)-based geometry course, for teaching and learning the topic Area and Perimeter at Grade 4 in Indonesian primary schools.

The focus of the study was to develop and implement a valid, practical, and effective RMEbased geometry course by applying design research approach. These processes were guided by the main research question:

What are the characteristics of a valid, practical and effective RME-based geometry course for learning and teaching the topic Area and Perimeter at Grade 4 in Indonesian primary school?

2. Context of study: mathematics education in Indonesia

The general goals of mathematics education in Indonesian primary education were phrased as follows

• Preparing the pupils to be able to deal with the dynamic changes of world situations effectively and efficiently through practical works based upon logical reasoning, rational and critical thinking, caution and honesty.

• Preparing pupils to be able to use mathematics and mathematical reasoning in their everyday life and in studying other sciences.

162

After reading the lofty goals, questions arose as to why the quality of mathematics education in Indonesian primary schools was still poor. The following paragraphs will discuss some primary causes of poor quality of mathematics education in Indonesian primary schools.

The first cause was that the lofty goals have become blurred when they came into practice. The specific instructional objectives from Grade 1 till Grade 6 were still dominated by remembering facts and concepts and reproducing them verbally, studying computational aspects, and applying formulas.

The second reason was poor quality of mathematics textbooks. In the textbooks, many abstract concepts were introduced without paying much attention to aspects such as logic, reasoning, and understanding (Soedjadi, 2000). The topics that were taught seem far removed from pupils' daily life. Even the teachers themselves sometimes did not know the usefulness of the topics they have taught.

A third reason for poor quality of mathematics education in Indonesian primary schools was related to teachers. Most teachers preferred a traditional approach in teaching mathematics. In general, the climate in Indonesian classrooms (see Fauzan, 2000, 2001; Fauzan, Siettenhaar & Plomp, 2002a, 2002b; Somerset: 1997), was similar to that in several African countries as was summarised by De Feiter and Van den Akker (1995) and Ottevanger (2001) as follows:

• 'chalk and talk' is the preferred teaching style;
• emphasis on factual knowledge;
• lack of learning questioning;
• only correct answers are accepted and acted upon;
• whole-class activities of writing/there is no practical work carried out.

The impact of the situations described above was that most students dislike learning mathematics because they were not learning the mathematics they need. They also did not have the opportunity to learn significant mathematics, and lack commitment towards or were not engaged in existing curricula. The other impact was that the students' achievements in mathematics were poor from year to year (see Fauzan 2002). The poor performance of Indonesian students could also be seen from the Trends in International of Mathematics and Science Study (TIMSS) report (Mullis et al., 2000). Related to geometry, some findings indicated that geometry tended to be the most difficult among the mathematics topics not only for students but also for teachers (see Fauzan, 1996,1998; Herawati, 1994; Amin, 1995). The poor performance of the students in geometry and their negative attitude toward geometry became the big challenges for this study. These issues together with the fundamental problems mentioned in section 1 lead to the following questions.

• How to design a high quality course that could promote not only pupil learning but also pupil's attitude in learning mathematics?
• How to support teachers in implementing the course?

The questions, which became the main focus in this study, were addressed in a research project aimed at developing and implementing an RME-based geometry course.

3. Design research as the research approach

This study built upon two "schools of thought" of design research. The first one emerges in the context of more general design and development questions (see Van den Akker, 1999; Van den Akker & Plomp, 1993; Plomp, 2009; Richey & Nelson, 1996). The second one developed within the area of mathematics education by mathematics educators in the Freudenthal Institute (FI), The Netherlands (see Freudenthal, 1991; Gravemeijer, 1994a, 1994b, 1999). In the following part we will characterize how we perceived and used design research in this study.

163

What is design research?

According to Van den Akker & Plomp (1993), design research is characterized by its twofold purpose:

• Development of prototypical products (curriculum documents and materials), including empirical evidence of their quality.
• Generating methodological directions for the design and evaluation of such products.

This study was about development and implementation of an RME-based geometry course that fits the first purpose.

Richey & Nelson (1996) and Van den Akker (1999) distinguish two types of design research. These are summarized by Nieveen et al. (2006) as development studies and validation studies.

• Validation studies have a focus on designing learning environments or trajectories with the purpose to develop and validate theories about the process of learning and how learning environments can be designed. Validation studies aim at advancing learning and instruction theories, such as Realistic Mathematics Education (Gravemeijer & Cobb, 2006).
• Development studies aim at design principles for developing innovative interventions that are relevant for educational practice. "Development studies integrate state-of-the-art knowledge from prior research in the design process and fine-tune educational innovations based on piloting in the field. … By unpacking the design process, design principles that can inform future development and implementation decisions are derived." (Nieveen et al., 2006: 153).

Considering that this study was aiming at developing a high quality RME-based geometry course, it may be categorized as development study type of design research. But as this research also aimed at validating whether the constructivist approach of Realistic Mathematics Education could be successfully applied in the context of Indonesian mathematics education, this research was a validation study type of design research as well.

Important activities in design research are its cyclic nature (of analysis design, development, implementation, evaluation and reflection) and the use of formative evaluation as a key activity to establish evidence of product quality and to generate guidelines for product improvement (Ottevanger, 2001). Related to this, Nieveen (1997) and Van den Akker (1999) mentioned three main stages or phases in design research (see also Plomp, 2009), which are front-end analysis/ preliminary investigation; prototype phase, and assessment phase, consisting of summative evaluation of the final product. Throughout all these activities, a systematic reflection on the development methodology has to take place to produce design principles (Plomp, 2009).

Following these activities and the work of Nieveen (1997) and Ottevanger (2001), the study was divided into three stages namely front-end analysis, prototyping stage, and assessment stage.

During the prototyping stage, the design research approach proposed by Freudenthal Institute (see Gravemeijer 1999; and Gravemeijer & Cobb, 2006) was applied. This approach was followed in developing the content of RME-based geometry course, especially in designing the instructional sequences. Freudenthal (1991, p. 161), in relation to the development of RME, defines design research as:

"Experiencing a cyclic process of development and research so consciously, and reporting on it so candidly that it justifies, and that this experience can be transmitted to others to become like their own experiences"

Gravemeijer (1999; and see also Gravemeijer & Cobb, 2006) states that in this approach researchers direct their attention to developing instructional sequences in learning mathematics. To do so, they start with thought experiments, thinking about the learning route that will be

164

passed through by pupils. By reflecting on the results of instruction experiments in which the results of the thought experiments are tried out, they continue with the next thought experiment. Researchers in this approach have a long term learning process in mind. In this long-term process, the subsequent of thought and instruction experiments are connected. This situation leads to the description that development can be seen as a cumulative cyclic process, as it is shown in Figure 1.

Figure 1: Design research as a cumulative approach (source: Gravemeijer, 1999)

The cycles of the thought and instruction experiment described above indicate the activities carried out on a daily basis developing a learning sequence. For example, the second thought experiment is conducted based on the results of the first instruction experiment. The results of this thought experiments are tested through the second instruction experiment on the next day. This process is continued until the instructional sequences, consisting of a number of lessons for teaching a mathematics topic that work well, are developed. The instructional sequences are called local instructional theories. Gravemeijer and Cobb (2006) call the daily basis of the development a micro cycle and the development of the whole learning sequences a macro cycle (see Figure 2).

Figure 2: Micro and macro cycles of design research (Gravemeijer & Cobb, 2006)

Our study combined the two approaches in design research, as is summarized in Table 1.

Table 1: The summary of design research

Type of research	Design research (development and validation studies).
Main focus	Design and research on the RME-based geometry course and testing of the characteristics.
Aims	To develop a high quality RME-based geometry course that was suitable for learning and teaching the topic Area and Perimeter at Grade 4 in Indonesian primary schools.
Expected results	1. A high quality RME-based geometry course. 2. Lesson learned about: • characteristics of a high quality RME-based geometry course; • development process of the RME-based geometry course; • implementation process (how teachers teach in the classrooms and how pupils learn); • the improvement on pupils' understanding, reasoning, activity, creativity, and motivation; • the local instructional theory for learning and teaching the topic Area and Perimeter.

A high quality RME-based geometry course referred to three quality criteria namely validity, practicality and effectiveness (Nieveen, 1997; 1999).

• Validity refers to the extent that the design of the intervention include "state of the art knowledge" (content validity) and the various components of the intervention are consistently linked to each other (construct validity).
• Practicality refers to the extent that users (teachers and pupils) and other experts consider the intervention as appealing and usable in normal conditions.
• Effectiveness refers to the extent that the experiences and outcomes from the intervention are consistent with the intended aims.

The stages of the research

As mentioned in the previous section, the design research was conducted in three stages (see Figure 3). These processes were realized in a four-year research, which included three fieldwork periods in Indonesian primary schools.

Figure 3: The general research design

In the design, the prototyping stage is presented in two cycles to indicate that there were two consecutive prototypes of the RME-based geometry course that were developed during this stage. The cycles in the design also include the formative evaluations that were conducted in each stage of the study.

4. The results of the study

Following the phases described in Figure 1, the focus, research activities, data collection techniques, and the results of the study in each stage will be elaborated in the next sections.

Front-end analysis

The purpose of front-end analysis is to get a picture of the starting point and the potential end points of the course. The work done in this stage included context and problem analysis, literature review, and analysis of available and promising examples.

The context and problem analysis was conducted by doing several activities such as review of Indonesia curriculum documents and related research results, classroom observations,

interview with principals, the fourth grade teachers and some pupils from six primary schools (3 schools in Padang, West Sumatra and 3 schools in Surabaya, East Java). The schools have been chosen purposively by considering the quality of the schools (high, middle, and low). The summary of these activities has been described in section 2.
The literature review on the RME theory gave the pedagogical direction to design the first draft of the RME-based geometry course on the topic Area and Perimeter for pupils at Grade 4 (pupils around 10 years old). As it was designed based on the RME approach, it needed to reflect the three key principles of RME: guided reinvention, didactical phenomenology and emergent models (Gravemeijer, 1994a, 1999).
The guided reinvention principle was applied to sequence the learning trajectory so that pupils could learn the topic Area and Perimeter as intended based on the RME point of view. The second RME principle was realized by using contextual problems as starting point so that the pupils would experience the process of horizontal and vertical mathematization (see Gravemeijer, 1999). The contextual problems would also facilitate the pupils to use their own models (model of) to solve the problems until one of them emerges into a formal way to solve a mathematical problem (model for).
Based on context analysis (Indonesia) and review of literature and related documents (see Fauzan 2002), it was decided to design an RME-based geometry course with the vision was to broaden the concept of Area and Perimeter. The rationale for broadening of the concepts was that when we talk about Area and Perimeter in our daily life, we are not only dealing with regular shapes such as squares, rectangles or triangles, but also irregular shapes or surfaces of 3-dimentional objects such as cakes, lands, and tiles.
The vision of the RME-based geometry course was elaborated further by broadening the concepts of Area and Perimeter through the following aspects.
• Relating Area and Perimeter to other "magnitudes"
The concepts Area and Perimeter are frequently involved in our daily activities. For that reason, it is considered to be important to relate them to other magnitudes such as costs, weight, paint, rice field, cake and fence. By relating the concepts to other magnitudes, it gives the pupils the opportunity to learn the concepts in a more meaningful way.
• Introducing the exchange of measurement units as a counting strategy
In most literature on traditional mathematics the square is introduced as the only measurement unit. However, in reality we use various non-square measurement units, such as rectangle or triangle tiles. So that, introducing the exchange of measurement units as a counting strategy would be useful for helping pupils to understand area.
• Investigating the relation between Area and Perimeter
There is a strong belief that Area and Perimeter are directly proportional to each other (Gravemeijer, 1992), in which people think that the bigger the perimeters the bigger the areas, or vice versa. To prevent pupils from this confusion, in the RME-based geometry course the concepts of Area and Perimeter are taught consecutively. 167
• Connecting measurement units to reality
This aspect of broadening the concept of area is to make the pupils aware that many objects in their real life can be used as a measurement unit. Moreover, relating the measurement units such as cm
2
, m
2
, and km
2
cm to reality (for examples, the sizes of: the
thumb nails, the surface of the tables, the forests) will help the pupils to understand the idea of the relative sizes of those measurement units as well as the relationship between one measurement unit and the others.
• Making pupils aware of the model-character of the concept (approximation, neglecting irregularities)
Teaching the topic Area and Perimeter in traditional mathematics causes pupils to think that areas of the rectangular shapes are always the product of two lengths and that learning the topic Area and Perimeter is identical with applying the formulas (see Romberg, 1997). In reality we mostly deal with irregular shapes. It means that we need to teach pupils about the idea of approximation regarding Area and Perimeter, in order to make them aware that the measurement is never exact.
• Integrating some geometry activities
In traditional mathematics, the geometry activities for learning the topic area are dominated by counting grids and applying the formulas. In the RME-based geometry course some geometry activities are involved such as re-shaping: cutting a figure into pieces and reallocating these pieces to get another shape, and tessellation: arranging tiles in various ways. Re-shaping is considered as an important activity in the RME-based geometry course because it not only makes it easier for pupils to find areas of various geometry shapes but also makes them aware of the conservation of area. Meanwhile, tessellation will make the pupils aware of the possibilities of compensation. Gravemeijer (1992) argues that the tessellations are just like an excursion in geometry, and at the same time it makes the pupils realize that area units do not have to be squares.
• Involving reallotment problems
Reallotment is a concept in which the area of a shape remains the same when it is reshaped. By working on the reallotment problems, for examples the problems about tessellations, pupils will better understand that: a shape can be seen as the sum of other shapes or as a portion of another shape; a shape can also be arranged to form a different shape by cutting and pasting. The concept of reallotment will also help pupils to realize that the objects that have the same areas can have various shapes.
Based on the vision and the review of related documents, such as the realistic geometry textbooks developed from the Wiskobas project in The Netherlands (see Gravemeijer, 1994a; Klein, 1999; Treffers, 1991), the paper entitled Reallotment written by Gravemeijer (1992), and the book with the same title used in the project Mathematics in Context (MiC) in the USA (see NSF, 1997), the hypothetical learning trajectory in the RME-based geometry course was designed. The detail of the hypothetical learning trajectory can be found in Fauzan (2002).
Prototyping stage
A prototype is a preliminary version or a model of all or a part of a system before full commitment is made to develop it (Smith, 1991). According to Nieveen (1997) the term "develop" in this definition refers to the construction of the final product. So, the prototypes are all products that are designed before the final product will be constructed and fully implemented in practice.
As applying the RME principles into Indonesian context needed some adjustments, the prototyping approach was used in this study because this approach gives the opportunity to 168 develop an RME-based geometry course fitting the Indonesian context (see Goodrum, Dorsey & Schwen, 1993; Nieveen, 1997; Shneiderman, 1992; Tessmer, 1994). Two prototypes of the RME-based geometry course for learning and teaching the topic Area and Perimeter were developed in this stage namely, prototype 1 and prototype 2. The latter was built upon the experiences in prototype 1. Each prototype consisted of a student book and teacher guide for ten lesson periods (one lesson takes 70 minutes). The way that the prototypes were developed followed the design research approach of Freudenthal Institute (see section 3).
Prototype 1 of the RME-based geometry course
It was important to determine that the draft course would fit not only the Indonesian curriculum, but also the ideas underlying RME. For this purpose, prototype 1 was reviewed by two Dutch RME experts (in RME and geometry) and three Indonesian subject matter experts (in mathematics curriculum and also familiar with RME).
The main focus of developing prototype 1 was to reach a valid RME-based geometry course. This activity was guided by the next research question:
What are the characteristics of a valid RME-based geometry course for learning and teaching the topic Area and Perimeter at Grade 4 in Indonesian primary schools?
The investigation into the content validity of the RME-based geometry course was focused on the following issues:
• Does the content of the RME-based geometry course include the subjects/topics that are supposed to be taught for topic Area and Perimeter?
• Does the content of the RME-based geometry course reflect the RME's key principles?
• Does the RME-based geometry course reflect the RME's teaching and learning principles?
• Does the RME-based geometry course reflect the important aspects of realistic geometry? (see De Moor, 1994).
Meanwhile, the construct validity or the internal consistency of the RME-based geometry course dealt with the following questions.
• Is the content of the RME-based geometry course sequenced properly?
• Is the content well chosen to meet the objectives/goals described in the beginning of each lesson?
Research activities in answering the questions above are summarized in Table 2. 169
Table 2: The summary of evaluation of prototype 1

Focus of evaluation (What?)	The purposes of valuation (Why?)	Evaluation activities (Method (How?))	Instruments
Validity of the RMEbased geometry course, focused on the content and construct validity.	To test the characteristics of the RME-based geometry course whether they meet the criteria mentioned in the questions above.	Interview and discussion with the Dutch RME experts and Indonesian subject matter experts, classroom observations, analyzing pupil's portfolios.	Interview guidelines, observation scheme.
The learning and teaching process using the RME-based geometry course.	To assess whether the hypothetical learning trajectory works as intended.	Classroom observations in two schools and interviews with pupils and teachers from those schools.	Observation scheme, interview guidelines.

Based on the results of experts' reviews, it was concluded that the RME experts approved of the content and the construct validity of the RME-based geometry course as well as the hypothetical learning trajectory for learning and teaching the topic Area and Perimeter. Nevertheless, the RME experts recommended that some contextual problems should be improved in order to strengthen the conjectured learning trajectory.
After the revision process, prototype 1 was implemented in two primary schools in Indonesia. The reason to choose the two schools was because they had different conditions. The pupils from school 1 were very heterogeneous in mathematical ability, while the pupils in school 2 were rather homogeneous. It was assumed that the variations between the schools would enrich the results of the classroom experiments. Another reason was the willingness of the two schools, especially the teachers and principals, for collaboration.
Some problems emerged during classroom experiments such as:
• Some pupils could not finish working on the given contextual problems because of several problems regarding their negative attitude (such as very dependent to the teacher and not used to working in-group) and the time constraint.
• There were some contexts that were not used by the pupils when they were solving some contextual problems. This was because the statement in those problems did not guide the pupils to use the contexts. See Fauzan (2002) for more details.
Prototype 2 of the geometry course-based RME
The results of the classroom experiments as described in the previous section led to the development and implementation of prototype 2 of the RME-based geometry course. The main focus of the development and implementation of prototype 2 was to investigate the validity and the practicality of the RME-based geometry course. The validity was re-investigated at this stage because the results of the development and implementation of prototype 1 showed that the validity of the RME-based geometry course needed to be improved. The research question for this stage of the study was:
What are the characteristics of a valid and practical Geometry course-based RME for learning and teaching the topic Area and Perimeter at Grade 4 in Indonesian primary schools?
As mentioned by Van den Akker (1999), practicality refers to the extent that users (and other experts) consider the intervention as appealing and usable under normal conditions. It means 170 that the RME-based geometry course should meet the needs and wishes of pupils and teachers at Grade 4 in Indonesian primary schools. For this purpose, some questions were formulated to investigate the practicality of the RME-based geometry course, for examples:
• Has the RME-based geometry course potential for developing student's understanding?
• Is the student book easy to use?
• Does the learning process progress as intended?
• Do teachers use the teacher guide as intended?
Research activities in developing and implementing prototype 2 of the RME-based geometry course consisted of two cycles, namely expert reviews and classroom experiments as has been elaborated in Table 3.

Prototype 2 of the RME-based geometry course was implemented (by the researcher as a teacher) in two primary schools from two different provinces, after the revision process. The main reasons for choosing the two schools were similar to those when implementing prototype 1. Moreover, the cultures of the two places were different, especially in working habits, so this would probably enrich the results of the research.

The results from the experts' validation showed that prototype 2 of the RME-based course met the criteria of the content and construct validity. However, the experts did have suggestions such as:

• add the contextual problems that would show the idea of approximation and that the results of measurements are never exact;
• relate Area and Perimeter to other magnitudes, reshaping, adding and subtracting area.

The findings from the classroom experiments also indicated that the conjectured learning trajectory for the topic Area and Perimeter worked as intended for most pupils. Based on these results it was concluded that the RME-based geometry course met the criteria of the content and construct validity. It means that the local instructional theory designed in the RME-based geometry course was valid for learning and teaching the topic Area and Perimeter. 171

The experts, supervisors, and principals agreed that prototype 2 of the RME-based geometry course had potential to develop pupils' understanding, reasoning, activity, creativity and motivation. They also agreed that the RME-based geometry course would be usable and useful for teaching the topic Area and Perimeter. Based on the classroom observations, it was observed that the RME-based geometry course could be used by the pupils and teachers as intended. The results from the interviews with the pupils and teachers also indicated that the student book and teacher guide were easy to use. Based on these results it could be concluded that prototype 2 of the RME-based geometry course reached the criteria of the practicality.

At this stage of the study, the practicality of the RME-based geometry course was only evaluated in two schools in which the researcher acted as teacher. Therefore, the course needs to be evaluated in more schools in the assessment stage by involving teachers in the implementation processes, to generate more evidence about its practicality. In addition, the effectiveness of the RME-based geometry course had also to be investigated in order to show its effect on the pupils' learning.

The assessment stage

After the development and implementation of two prototypes of the RME-based geometry course during the prototyping stage, this study moved to the last phase called the assessment stage. In this stage the final version of the RME-based geometry course was implemented in five Indonesian primary schools in order to gain more insights in the practicality and effectiveness. The term further insights means two things: first, the number of schools for the classroom experiments would increase, and five additional classroom teachers would be involved in the implementation to find out whether they could teach the RME-based geometry course. Second, this assessment stage would lead to an opportunity to further evaluate the conjectured learning trajectory.

In preparing the teachers to be able to implement the RME-based geometry course, a series of workshop-based doing mathematics activities (see Gravemeijer, 1994a; Treffers, 1991) and reflections after the teaching practices have been conducted (see also Fauzan, 2002). The research question for the assessment stage was:

What are the characteristics of a practical and effective RME-based geometry course for learning and teaching the topic Area and Perimeter at Grade 4 in Indonesian primary schools?

The RME-based geometry course reached the effectiveness criteria if it would have a positive impact on the pupils and teachers in learning and teaching the topic Area and Perimeter. These criteria were measured using four of five levels of effectiveness mentioned by Kirckpatrick (1987) and Guskey (1999, 2000) namely participants' reaction, participants' learning, participants' use of new knowledge and skills, and impact (the learning outcomes). The participants in this study were the pupils and teachers. The level impact to organization was not used to assess the effectiveness of the RME-based geometry course because it was not applicable to this study. The levels of effectiveness in this study were elaborated upon by posing the following questions:

• Participants' (pupils and teachers) reactions:
Did they like the RME-based geometry course?
Was their time well spent?
Was the RME-based geometry course useful for them?
• Participant's learning:
Did the teachers and pupils acquire the intended RME knowledge? 172
• Participant's use of new knowledge and skills:
Did the teachers and pupils effectively apply the RME knowledge and skills?
• Pupils' learning outcomes:
Were the pupils more confident as learners than before?
What was the impact of the RME-based geometry course on the pupils' performance and achievement?

The learning outcomes in this study consisted of pupils' achievement and reasoning, pupils' motivation, activity, and creativity. In RME pupils learn mathematics based on activities they experience in their daily life; pupils have a big opportunity to construct their knowledge by themselves, etc. These conditions led to a hypothesis that the RME-based geometry course would increase pupils' achievement. Moreover, in solving a contextual problem pupils are always stimulated (written in the teacher guide) to explain "what do they do and why?" This requirement was assumed to have potential to promote pupils' reasoning.

Research activities in the assessment stage are summarized in Table 4.

As mentioned before, the final version of the RME-based geometry course (comprising 10 lesson periods, one lesson takes 70 minutes) was implemented in five primary schools (involving five teachers and seven classes). The results of the assessment stage can be summarized as follows (see also Fauzan 2002):

1. The pupils could use the student book without any difficulties and they could learn the topic Area and Perimeter as intended according to the RME point of view. The teacher guide was useful for the teachers in implementing the RME-based geometry course. Three teachers 173 said that the teacher guide was easy to use, while one teacher suggested that the teacher guide should be elaborated in more detail (note: she used to teach lower grades pupils before). From these findings it can be concluded that the RME-based geometry course met the criteria of the practicality. The practical RME-based geometry course can be characterized as follows:
• The RME-based geometry course had the potential to develop pupils' understanding, reasoning, activity, creativity and motivation in learning the topic Area and Perimeter. These results can be seen on the example of pupils' works below, when finding the areas of rectangle, parallelogram, and trapezoid using their own ideas (the pupils did not know the formulas yet).

The results on the first row show that the pupils used combination of counting and reallotment strategies to find the areas. On the second row, the pupil used global reallotment first, then used counting strategy. There are two important findings showed in the example. The first, the hypothetical learning trajectory worked well (the context used by the pupils to find various strategies). The second, the RME-based geometry course had stimulated pupils' creativity and reasoning in finding the area of a shape.
• The teaching learning process using the RME-based geometry course fostered pupilcentered learning.
• The pupils could use the student book without any difficulties, and they could also learn the topic Area and Perimeter (using the student book) as intended according to the RME point of view.
• The teacher guide was useful for and easy to use by the teachers.
• The RME-based geometry course met the criteria of the effectiveness as it resulted in

some positive impacts on the pupils. The positive impacts of the RME-based geometry course on the pupils are characterized as follows:
- The pupils liked the RME-based geometry course. They said that the RME-based geometry course was useful and gave them more confidence as the learners.
- Most pupils acquired the intended RME knowledge which then enabled them to find out for themselves several concepts included in the RME-based geometry course. They could also use the new knowledge and skills that they had acquired from one lesson in the next lessons.
- The pupils' attitudes in learning mathematics developed in a positive direction. The pupils became less dependent and did engage actively in the learning and teaching processes. They also became more motivated to find different strategies in solving the contextual problems. Their reasoning developed from being very
Another pupil used
global reallotment to
find that the area of the
trapezoid was 24.□ 174
weak at the beginning to being able to reason mathematically by the end of the classroom experiments.
- The pupils actively engaged in the learning process and they also creatively found various solutions in solving the contextual problems in the student book.
- The pupils' achievements (in the experimental classes) in the post-tests were significantly higher than those in the pre-tests. The pupils' achievements in the experimental classrooms were significantly higher than the achievements of the pupils in Grade 4 and 5 who had been taught the topic Area and Perimeter using the traditional method.
- A significant difference was found between the motivation of the pupils before and after they had been taught the RME-based geometry course, especially on the aspect self-concept of mathematical ability (see Blöte, 1993)
2. The teachers liked the RME-based geometry course, and in general they could implement the Geometry course-based RME as intended, although sometimes they still used the traditional way of teaching. It was also observed that at some occasions the teachers could not fully apply the RME knowledge and skills that they had gained from the training probably because they were not yet used to the RME approach.
5. Conclusion
After a four-year study of the development and implementation of the RME-based geometry course at Grade 4 in Indonesian primary schools using design research approach, some conclusions can be drawn (see also Fauzan, 2002):
a. The RME-based geometry course for pupils at Grade 4 in Indonesian primary schools met the criteria of validity (content and construct validity), practicality, and effectiveness. It suggests that the learning trajectory designed in the RME-based geometry course can be used as a local instructional theory for learning and teaching the topic Area and Perimeter.
b. The RME approach could be utilized in Indonesian primary schools. Further, the RME approach could address some problems mentioned earlier in this chapter, especially in changing the classroom climate and providing guidelines in how to develop and implement a good quality course material for teaching mathematics.
c. The two "schools of thought" of design research that were combined in this study resulted a high quality RME-based geometry course and the local instructional theory aimed for.
The results outlined above indicated that the RME approach could be utilized in Indonesian primary schools. Further, the RME approach could address some problems mentioned earlier in this chapter, especially in changing the classroom climate and providing guidelines in how to develop and implement a good quality curriculum material for teaching mathematics.

Ahmad Fauzan (1966) is professor in mathematics education at Faculty of Mathematics and Science, State University of Padang, West Sumatra, Indonesia.
He is one of four Indonesian who get Ph.D scholarship from Indonesian government (PGSM project) to study Realistic Mathematics Education (RME) in The Netherlands. After graduated from University of Twente (in collaboration with Freudenthal Instutute) on 2002, he actively invole in developing and spreading RME in Indonesia through organization namely Realistic Mathematics Education Indonesia (PMRI). This organization has been successesfull in influencing the movement of mathematics education in Indonesia (see the book entitle A Decade of PMRI, published in 2010). His research interests are educational design and design research, especially in RME and students' assessment. He is involved as supervisor of some master and doctoral students of the State University of Padang

Email: ahmad_fz@yahoo.com

Tjeerd Plomp (1938) is professor emeritus of the University of Twente, Enschede, The Netherlands, where he has been professor of curriculum from 1981 - 2002. He was in charge of teaching educational design methodology in the (at that time) Faculty of Educational Science and Technology. He was chair of the IEA, the International Association for the Evaluation of Educational Achievement, from 1989 - 1999. In the IEA he served as chair for the 'Computers in Education' study (Comped), the Third International Mathematics and Science Study (TIMSS) and the IEA Second International Technology in Education Study (SITES). His research interests are educational design and design research, international comparative research, information technology in the curriculum and 21st century skills in education. He has been recently involved as advisor in various research projects and programs utilizing design research, both in The Netherlands and internationally. Tjeerd Plomp has written many articles and chapters in books and has co-edited special issues of international journals and books, most recently Introduction to Educational Design Research (2009), co-edited with Nienke Nieveen.
Email: t.plomp@utwente.nl

Gravemeijer (1946) is professor emeritus in Science and Technology Education at Eindhoven University of Technology in the Netherlands. Earlier he was professor in Mathematics Education at Utrecht University (Utrecht, the Netherlands) and Vanderbilt University (Nashville, USA). His research interests concern design research as a research method, domain-specific instruction theories (such as the theory for realistic mathematics education, RME), and students' use of symbols and modeling. In relation to the latter he developed the so-called 'emergent modeling' design heuristic. Next to his research activities, he also has been involved in instructional design. He has been the leading author of an RME textbook series for Dutch primary schools, and he was involved in the development of the textbook series for the American Middle School, "Mathematics in Contexts" a collaborative project of the Dutch Freudenthal Institute and the University of Wisconsin-Madison.

DEVELOPING A SEQUENCE OF LEARNING EXPERIENCES IN STATISTICS

Planning meaningful learning experiences in a discipline such as statistics, leads to a search for starting points both from a general learning perspective and from the developmental pathways known to contribute to understanding the content chosen. This chapter focuses on the design of a sequence of learning experiences that promotes the development of understanding of statistical covariation and associated graph creation and interpretation skills, facilitated by the software package TinkerPlots: Dynamic Data Exploration (Konold & Miller, 2005). The objective is to demonstrate the importance of the various structural perspectives that contribute to the planning of meaningful learning experiences in relation to learning about statistical covariation as an end point of a learning sequence that takes a developmental approach to introduce students to a variety of graph types. The staged introduction of graph construction and interpretation activities that align with expectations from the curriculum for a variety of graph types with increasing complexity and sample size, offer promise for the most successful learning outcomes for students (Fitzallen, 2012a). The software package chosen for implementation offers affordances that enhance the learning of additional statistical concepts as a consequence of taking an inquiry-based learning perspective.

BACKGROUND PLANNING

Connections to Real World Contexts

Using authentic contexts and data is particularly important in statistics education, as suggested by Gould, Kreuter, and Palmer (2006); Fitzallen and Watson (2010); and Langrall, Nisbet, Mooney, and Jansem (2011). It is also considered important to use real data from a context that students can relate to, particularly for primary school students. The Reality in Mathematics Education (RME) instructional design theory developed by Wiskobas and Freudenthal provides an overarching organiser for structuring statistical investigations that make connections to real world problems. RME is a guide for student learning that focuses on the development of abstract thinking (Stephan, 2009; Treffers, 1993). It allows students to be active participants in the learning process and promotes the development of learning experiences that start with rich contexts that provide real-life sources of mathematics. "The contexts thus serve not only as a source but as an area of application as well" (HeuvelPanhuizen, 2009, p. 12). Although the context underlying a statistical question needs N. FITZALLEN & J. WATSON
264
to be meaningful and motivating to provide real data for analysis, students do not actually have to have experienced the situation but must be able to make thoughtful connections to the context. In addition, active participation is promoted when students make artefacts that are meaningful and useful to them (Bakker, 2004; Stephan, 2009). The RME philosophy also suggests instruction should build students' reasoning gradually from the concrete to the abstract, through the use of manipulatives, diagrams, and other imagery to reinforce students' reasoning. It accommodates the use of graphing software packages because they place an emphasis on student construction of models and symbols to facilitate abstract thinking. Within the RME structure instruction is intentionally designed so that students reorganise their thinking progressively toward more abstract ideas (Stephan, 2009) and then relate those ideas back to the practical context of the situation in order to make sense of the statistical information in that context (Fitzallen & Watson, 2012). Such practices encapsulate a holistic view of learning and actively engage students in the learning process at a deeper level (Ramsden, 2003), thus addressing students' needs and facilitating successful realisation of educational goals and purposes.

Statistical Investigations

In order to focus on the relevant mathematical ideas of covariation, graph creation, and graph interpretation within the broader structure of RME, the Model of Statistical Investigation developed by Watson (2009) detailed in Figure 1, is an essential element of learning sequences. Watson's model starts a statistical investigation with a question. The question sets the scene for an investigation and establishes the context from which the data collected are related. The Data Collection step provides the data that can be represented in a number of forms - numerical, pictorial, or graphical. The data are often reduced using statistical calculations of measures of centre and spread or graphical representations such as a scatterplot. At the final step of Inference, those representations or others are then used to make conjectures about other populations that recognise the uncertainty of the conclusions drawn. Uncertainty emerges from the Chance step of the model. Underpinning all the steps in Watson's statistical investigation model is the concept of variation.

The Data Analysis and Probability Standard of the Principles and Standards for School Mathematics (2000) puts an emphasis on developing statistical reasoning skills and calls for students to formulate questions and collect, organise, and display relevant data to answer questions; to select and use appropriate statistical methods to analyse data; and to develop and evaluate inferences and predictions that are based on data (National Council of Teachers of Mathematics [NCTM], 2000). Similarly Wild and Pfannkuch (1999) offer an extensive four-dimensional model that includes behaviours associated with constructing graphs within an inquiry-based learning perspective. The model relates to the way statisticians work and think statistically and applies to the way in which students engage in statistical investigations. It includes four dimensions: DEVELOPING A SEQUENCE OF LEARNING EXPERIENCES IN STATISTICS
265
Dimension 1: The investigative cycle
Dimension 2: Types of thinking
Dimension 3: The interrogative cycle
Dimension 4: Dispositions

Dimension 1 is related to the thinking processes employed when working through a statistical investigation. This involves planning an investigation, collecting data, analysing data, and drawing conclusions. Dimension 2 is related to the types of problem solving strategies applied when working through a statistical problem. Wild and Pfannkuch (1999) posit that the types of thinking in this dimension are "the foundations on which statistical thinking rests" (p. 227). Dimension 3 adopts a cyclical process of data interrogation that involves thinking critically about the data in order to distil and encapsulate ideas and information. Dimension 4 includes the personal qualities, dispositions, and habits of mind employed when working with data. Dimension 2: Types of Thinking of the Statistical Thinking Model is particularly useful when considering the way in which students work with data when creating graphs (Pfannkuch & Wild, 2004; Wild & Pfannkuch, 1999). The type of thinking most relevant to this chapter is transnumeration. Pfannkuch and Wild (2004) describe transnumeration as changing data representations to engender understanding, capturing the characteristics of a real situation, and communicating messages in data. The notion of transnumeration is extremely important as new technologies that incorporate interactive and dynamic commands as a way of working within software environments foster the manipulation of both data and data representations.

Curriculum Frameworks

In 2007, the American Statistical Association (ASA) commissioned development of the guidelines and curriculum framework detailed in the GAISE Report (Franklin et al., 2007). To support teachers to incorporate statistical activities into learning programs the GAISE Report curriculum framework utilises four problem solving processes that acknowledge the role of variation in statistics: Formulate questions, Figure 1. Model of Statistical Investigation (Reproduced from Watson, 2009, p. 91).N. FITZALLEN & J. WATSON
266
Collect data, Analyse data, and Interpret results. It provides a developmental sequence of learning experiences that incorporates all four problem-solving steps across three levels of development. Although implicitly embedded in all levels of the framework when recommendations are made for the application of scatterplots, covariation, or "covariability" as it is termed in the framework, is included as a point of focus in Level B of the developmental framework. It is also applied in Level A when scatterplots are used to "observe association between two variables (p. 31)" and "look for patterns and trends" (p. 33) in data. At Level B the use of scatterplots is recommended for "measuring the strength of association between two quantitative variables" (p. 48) and "modelling linear association" (p. 51). Similar recommendations are made in Level C.

In the Australian context, The Australian Curriculum: Mathematics (Australian Curriculum, Assessment and Reporting Authority [ACARA], 2012a) introduces the components of a statistical investigation throughout the curriculum, with graphing important at all year levels and the use of digital technologies first mentioned at Year 3. Mention of a "range of graphical displays" occurs in most years but consideration of scatterplots is not included until Year 10. This does not exclude the use of scatterplots to develop understanding of covariation with younger students long before scatterplots are mentioned explicitly.

Development of Understanding

Although curriculum documents identify the content to be covered at particular stages in students' education, they do not provide explicit information about the sequence in which the concepts should be introduced to students and how the concepts may be developed within a learning program. To supplement this deficiency, Watson and Fitzallen (2010) provide hierarchical sequences of graph creation and graph interpretation that have the potential to contribute to the development of sequences of learning experiences. Their graph creation hierarchy involves four cycles of development. It begins with introducing the use of graphs for displaying data about one attribute in Cycle 1 [G1 in Figure 2], progresses to using graphs to summarise data in Cycle 2, which includes the use of graphs for comparing data sets and exploring the relationship between two attributes [G2]. Alternatively after Cycle 1, large data sets [G3] may be used for extending notions of graphing established in Cycle 1. Informal Decision Making for Graphs [G4] in Cycle 3 provides the opportunity to move from the construction and creation of graphs to using them purposefully to answer questions about the data. A time for consolidation and application is offered in Cycle 4 Graph Interpretation [G5]. The graph creation hierarchy can be used to determine students' level of understanding of statistical concepts, such as distribution, covariation, and informal inference. It is applicable in its entirety or parts thereof, to all year levels of the compulsory years of schooling and beyond when students are required to use graphical representations to interpret data. DEVELOPING A SEQUENCE OF LEARNING EXPERIENCES IN STATISTICS
267
Figure 2. Map of cycles and levels of learning in the Watson & Fitzallen (2010) graph creation and interpretation hierarchy.

The Concept of Graph [G1] (Figure 3) in the Watson and Fitzallen (2010) graph creation and interpretation hierarchy includes the basic elements of a graph: Attribute, Data, Variation, and Scale. It suggests an order that describes the process of developing an understanding of the characteristics of a graph and the different levels of understanding that may be realised when drawing parts of a graph together to tell a story about the data. This reflects the findings of research of the importance of developing the ability to see data as an aggregate and gaining a global perspective (Ben-Zvi, Garfield, & Zieffler, 2006). At the relational stage, "students can create a meaningful picture/diagram with appropriate scale and tell the story of variation in the data and what it means for the attribute displayed" ((Watson & Fitzallen, 2010, p. 59). As a foundation for graph creation, The Concept of Graph [G1] underpins all the following cycles. An example of a graph created in this level is provided in Figure 4. The graph is a stacked dot plot created in TinkerPlots.

Figure 3. Developmental sequence for the basic Concept of Graph [G1]
(Reproduced from Watson & Fitzallen, 2010, p. 59).

Figure 4. Stacked dot plot displaying the data for one attribute (Belly Button Height).

The second cycle of graph creation includes two sub-cycles: The Concept of Graph for Multiple Attributes [G2] (Figure 5) and The Concept of Graph for Large Data Sets [G3] (Figure 7). The Concept of Graph for Multiple Attributes [G2] emphasises the different types of attributes, introduces a variety of graphs, and establishes N. FITZALLEN & J. WATSON
268
the need for two dimensional representations to accommodate the measurement of more than one attribute for each case. At the relational level, "students can recognise among the graph types they understand, the one appropriate for particular associations between attributes and apply it to tell the story of the data" (Watson & Fitzallen, 2010, p. 59). An example of a graph created in this level is provided in Figure 6.

Figure 5. Developmental sequence for the Concept of Graph for Multiple Attributes [G2]
(Reproduced from Watson & Fitzallen, 2010, p. 60).

Figure 6. Scatterplot displaying the covariation of two attributes (Foot Length and Belly Button Height. The main cluster of data has been circled using the pencil tool.

The Concept of Graph for Large Data Sets [G3] (Figure 7) introduces large data sets, more complex graphical representations, and data reduction methods. At the relational stage, "students have the ability to select the appropriate graph for a particular data set and attribute" and establish an "integrated understanding of the various representations" used to interpret large data sets (p. 60). Figure 8 shows a graph that displays the relationship between two attributes - Gender and Belly Button Height. The Hat Plot tool in TinkerPlots has been used to summarise the data. The middle 50% of the data is covered by the "crown" of the hat plot. The brims to the left and right of the crown cover 25% of the data each. The Hat Plot is a precursor of the box plot. It is less complex and more accessible for younger students (Watson, Fitzallen, Wilson, & Creed, 2009).DEVELOPING A SEQUENCE OF LEARNING EXPERIENCES IN STATISTICS
269
Figure 7. Developmental sequence for the Concept of Graph for Large Data Sets [G3]
(Reproduced from Watson & Fitzallen, 2010, p. 60).

Figure 8. Graph displaying a large data set for two attributes
(Gender and Belly Button Height).

The third level - Informal Decision Making for Graphs (Figure 9) potentially takes the graph creation process one step further and leads to students making informal inferences. It involves making decisions about creating and choosing appropriate graphs for a particular purpose and recognising the potential different representations have in assisting to draw conclusions and make informal inferences beyond the data.

At the relational level, "all elements need to be integrated for completely justified conclusions to be reached" (Watson & Fitzallen, 2010, p. 61).
*The term informal is used here to distinguish the hierarchy from one that would involve formal statistical tests.
Figure 9. Development sequence for Informal Decision Making for Graphs [G4] (Reproduced from Watson & Fitzallen, 2010, p. 61).N. FITZALLEN & J. WATSON
270
Figure 10 provides an example of a graph created in Level 4. It is a scatter plot displaying the covariation of two attributes, Height and Belly Button Height. The annotations on the graph were made with the pencil tool in TinkerPlots. The two horizontal lines at the top and bottom of the graph indicate the regions of the graph where the data would be considered outliers. The circled data are also considered outliers. The zigzag line that tracks the trend of the bulk of the data in the graph is used to indicate the relationship between the two attributes. The fluctuation in the line indicates that although there is a general trend between the two attributes there is recognition that there is variation evident within the trend (Fitzallen, 2012a). The stack of data points to the right of the graph indicate that there are cases in the data set that do not have data associated with at least one of the attributes.
Figure 10. Scatter plot annotated using the pencil tool in TinkerPlots.
Watson and Fitzallen (2010) stress the importance of providing time for students to consolidate their understanding of graph creation and the role different graph types play in the data analysis process. Not only do students need to understand the elements of a graph but also they need to make connections to the context of the data to make meaningful conclusions and justifications. These aspects of learning also apply to another hierarchical sequence - Graph Interpretation [G5] (Figure 11). It is flexible enough to be applied as a further cycle of learning after consolidation of any of the Concept of Graph cycles and attends to the factors, such as outliers, that potentially impact on the shape of a graph. It also includes a questioning attitude element, which is required for critical thinking and development of statistical literacy skills necessary to interpret unusual or potentially misleading graphs so often encountered in the media (Watson, 2006). The complexity of graph interpretation tasks is determined by which cycle of Concept of Graph applies to the data and questions asked.DEVELOPING A SEQUENCE OF LEARNING EXPERIENCES IN STATISTICS
271
Figure 11. Developmental sequence for Graph Interpretation [G5] (Reproduced from Watson & Fitzallen, 2010, p. 61).
Data Analysis Software
Educational technologies provide many options for displaying data in graphical representations and improving student learning about statistical concepts (e.g., BenZvi, 2006; Fitzallen & Watson, 2010; Shaughnessy, 2007). It is therefore pertinent to consider the graphical representations a particular software package affords when designing a sequence of learning experiences that promotes understanding of statistical concepts. The sequence of learning experiences developed in this chapter takes into consideration the innovative software package, TinkerPlots: Dynamic Data Exploration (Konold & Miller, 2005). TinkerPlots is employed as a tool for students to prepare graphs in order to demonstrate, support, and display their understanding of covariation, graph creation and graph interpretation. As a constructivist software created for students rather than statisticians, the software provides freedom for students to display their understanding in many ways (Fitzallen & Watson, 2010; Watson & Donne, 2009) and also to interpret presented graphs to identify covariation (Fitzallen, 2012b; Konold & Khalil, 2003). The potential to use TinkerPlots to make informal inferences has also been demonstrated (Watson & Donne, 2008).
Discussion of Background Planning
Incorporating all the notions explored in this section in a sequence of learning experiences is complex. To optimise learning opportunities it is important to embed learning of statistical concepts within real world contexts (Stephan, 2009; Treffers, 1993) and explore statistical questions via an inquiry-based learning process (Watson, 2009; Wild & Pfannkuch, 1999). Aligning learning outcomes with curriculum frameworks (ACARA, 2012a; Franklin et al., 2007; NCTM, 2000) is also necessary to provide the opportunity for the development of understanding of statistical concepts within software learning environments (Watson & Fitzallen, 2010).
As the targeted learning outcome of the sequence of learning experiences in this chapter is the development of understanding of covariation, it is also necessary to incorporate pedagogies that address the learning of that statistical concept. The notions in this section could accommodate other learning outcomes such as variation N. FITZALLEN & J. WATSON
272
and measures of centre. Regardless of the targeted learning outcome it is necessary to ensure any sequence of learning is informed by the curriculum, and previous research on the development of the statistical skills and ideas. These aspects of learning about covariation are addressed in the next section where an example of a sequence of learning experiences for covariation is presented.
SEQUENCE OF LEARNING EXPERIENCES
To address the specific statistical concept of covariation in a sequence of learning experiences, the fundamental notions of a teaching experiment based on using "growing samples" is applied (Ben-Zvi, 2006; Cobb & Gravemeijer, 2004; Cobb, McClain, & Gravemeijer, 2003). The lessons gradually introduce increasing sample sizes from the same population, reflecting the hierarchical framework for graphs in Figures 3 and 5. Each lesson requires students to make sense of the data as well as learn about the features of TinkerPlots that potentially support or influence their descriptions of the data and explanations of the conclusions drawn about the sample. Data sets of large and small sample size are compared and contrasted to explore the stability of variation and spread in the varying samples (Ben-Zvi). The lessons, based on explicit consideration of variation and Watson's (2009) investigation model in Figure 1, provide the opportunity for students to think about how certain they are about their conjectures and conclusions drawn. In addition the lessons allow students to use their knowledge of the context to support their thinking and explain how the context of the data influenced their thinking, as advocated by Watson (2006) and supported by the RME instructional design theory (Treffers, 1993).
The sequence of learning experiences developed is made up of seven lessons. In Lesson 1, the intention is to get students to generate data by recording information about attributes familiar to them. Measurements such as height, belly-button height, and foot length are gathered easily by individual students and teachers can then gather large data sets from the CensusAtSchool data base using the random sampler accessed from the education section of the Australian Bureau of Statistics website. (www.abs.gov.au/censusatschool). The data in Lessons 2 and 3 are generated by the students' class. Lesson 4 uses data generated from a second class (Class B) either at the same school or another school. In Lesson 5 the students are introduced to a data set (Class C) generated by the Australian CensusAtSchool database. The Class C data are used in conjunction with the Class B data to compare the two classes for a number of different attributes. Looking at the three data sets (Class A, B, C) collectively in order to compare classes, thinking becomes more abstract by Lesson 6. The focus in Lesson 7 is on comparing the results from interrogating a large data set (n = 200) generated by the CensusAtSchool database and comparing the results with those gleaned from the smaller data sets.
Although each lesson has a particular focus, the aim is to build students' knowledge of and experience with data analysis and then understanding of DEVELOPING A SEQUENCE OF LEARNING EXPERIENCES IN STATISTICS
273
covariation by continually constructing various graph types and using a number of different data sets of different sample size in TinkerPlots. Throughout the seven lessons connections to the context of the data are made explicit by asking students to justify the conclusions drawn and the hypotheses made based on the context of the data and the questions explored.
The progression from small to large sample size and the connections to Watson and Fitzallen's (2010) hierarchy of graph creation and interpretation across the seven lessons are represented in Figure 12. In Lesson 1 the fundamentals of the Concept of Graph [G1] are established. By Lesson 7 there is the expectation that students will have encountered large data sets and constructed graphs to explore the relationship between two attributes, thereby, operating at Level 5 [G5] of the hierarchy to identify outliers, make informal inferences based on the graphical representations of the data, and express an understanding of covariation.
Figure 12. Change in sample size and lesson focus across the sequence of lessons.
It should be noted that the sequence of learning experiences does not detail when and how students learn about using TinkerPlots. Instructional advice about using the software package is not explicitly addressed because it has the potential to draw the focus away from developing an understanding of covariation to highlighting the technical issues associated with using TinkerPlots. Developing an understanding of using TinkerPlots is, however, implicitly embedded in the sequence of learning experiences through the use of multiple graph types - starting with stacked dot plots to display data for one attribute - and the need to construct various graph types and reconstruct them for multiple data sets. Constructing graphs noted in each of the lessons will facilitate beginners' use of TinkerPlots together with building their knowledge of covariation as they progress though the seven lessons. The details for each of the lessons are presented in Table 1 (Appendix 1).N. FITZALLEN & J. WATSON
274
Also worth mentioning is the issue that the seven lessons require students to develop an understanding of statistical concepts other than covariation. This is a consequence of adopting developmental and inquiry-based learning approaches. These approaches promote learning that makes the connections among multiple concepts instead of learning about individual concepts separately without the opportunity to acknowledge the connections among different statistical ideas.
CONCLUSION
The development of the practical learning sequence is embedded in an overarching organiser for structuring investigations undertaken by students because investigations are at the heart of statistics education (Watson, 2009; Wild & Pfannkuch, 1999). A related model for statistical investigations is then introduced and links to the curriculum and research are considered. In particular a framework for graphing is explored because of its intimate links to understanding covariation at the introductory level, which in turn leads to an acknowledgement of the contribution of increasing sample sizes.
Making strong connections to the curriculum is vital when planning learning sequences, not only from the perspective of covering all the required mathematical content at the appropriate time but also from the perspective of including the General Capabilities, which are "key dimension[s] of the Australian Curriculum, [and] are addressed explicitly in the content of the learning areas" (ACARA, 2012b, p. 3). The prominence of the General Capabilities in the Australian Curriculum places an emphasis on providing an integrated approach to learning that encompasses the development of seven capabilities that include critical and creative thinking, information and communication technology (ICT) capability, and numeracy. The sequence of lessons described in this chapter encompasses these three capabilities comprehensively by utilising a statistical investigative approach (critical and creative thinking) to focus on the development of understanding of covariation (mathematical content/numeracy) through the application of TinkerPlots (ICT capability). This has implications for the future implementation of The Australian Curriculum: Mathematics (2012a) as it provides a model that teachers could use to foster the integrated and interconnected mode of learning advocated by the curriculum.
Although the purpose of designing the sequence of lessons was to ensure a developmental approach was taken to the introduction and application of covariation for students, the approach taken could be applied to other content areas in the Statistics and Probability content strand of The Australian Curriculum: Mathematics (ACARA, 2012a). The use of increasing sample size and application of various graphical representations across the sequence of lessons would accommodate an explicit emphasis on other specific statistics content such as measures of centre as well as the big ideas of statistics such as distribution, variation, expectation, randomness, and informal inference.DEVELOPING A SEQUENCE OF LEARNING EXPERIENCES IN STATISTICS

APPPENDIX 1
Table 1. Sequence of Lessons
Lesson Sample Size, Graph Framework, and Lesson Focus
1 Data generated by individual students – G1, G5
Using the features of TinkerPlots and creating stacked dot plots with bins on the horizontal axis initially, and changing the size of the bins. Creating horizontal and vertical value bar graphs. Describing the case-based representation of data. Making connections between the data in the plot and the data on the cards. Accessing reference lines. Exploring variation in an attribute. Discussing the variation in a small sample. Conjecturing about the likelihood of other samples of similar size having the same or different values based on the context of the data. Establishing how the context of the data influenced the data by considering how and from whom the data were collected.
2 Data generated by a class – Class A (n=21) – G1, G5
Constructing graphs. Creating stacked dot plots and making the transition from the axis split into bins to using a continuous scale. Determining the range of the data. Describing variation and spread. Comparing values of data points. Using the mode as a reference point to describe the variation evident. Sorting data. Exploring the variation in other attributes. Comparing the spread and variation evident in the graphs and suggesting reasons for difference based on the context of the data. Hypothesising about where data points would be placed in the graph if new data were collected.
3 Data generated by two classes – Class A (n=21) Class B (n=21) – G1, G3, G4, G5
Constructing various graph types. Creating split stacked dot plots with bins and continuous scales on the horizontal axis. Comparing groups. Identifying outliers. Accessing hat plots. Discussing the differences between the two data sets. Using the context of the data to justify decisions about outliers and support conclusions drawn from the graphs about the data.
4 Data generated by two classes – Class A (n=21) Class B (n=21) – G2, G3, G4, G5
Constructing various graph types for various attributes. Creating scatterplots to display covariation. Describing the spread of the data. Identifying outliers. Removing outliers and then describing the changes to the spread and distribution of the data. Using hat plots to compare groups when comparing the data from the two classes. Using the context of the data to justify decisions about outliers and support conclusions drawn from the graphs about the data. Identifying covariation.

Table 1. (Continued)
Lesson Sample Size, Graph Framework, and Lesson Focus
5 Data generated by Class B (n=21) and the CensusAtSchool sample (Year 5/6 students) – Class C (n=21) – G2, G3, G4, G5
Constructing various graph types for various attributes. Creating scatterplots. Identifying the trend. Hypothesising about the placement of additional data points based on the context of the data. Making connections between the data points and value of the data points using reference lines. Describing the relationship between two attributes to explore covariation. Comparing Class B and Class C for various attributes and using the context of the data to justify decisions.
6 Data from Class A (n=21), Class B (n=21), and Class C (n=21) – G2, G3, G4, G5
Looking collectively at plots from the three data sets and comparing classes using a variety of graph types. Identifying similarities and differences in the spread, distribution, mean, mode, median, and hat plots. Making suggestions for causes of variation from an understanding of the context. Thinking about the messages in the data and making inferences from the data based on the context of the data.
7 CensusAtSchool sample (Year 5/6 students) – (n=200) – G2, G3, G4, G5
Comparing data sets, particularly the differences among small and large data sets for the same attributes. Making inferences from the data. Justifying statements about covariation and the relationships among attributes.

Introduction
This literature review outlines the key issues in relation to the definition and implementation of key competences in school education in Europe, at the classroom/school as well as systemic level. In order to focus the areas explored by our network's team of researchers, a matrix was formulated and agreed upon by all contributors to the literature review (see annex 1). As is evident from the matrix, the key focus is on analyzing implementation policies and practice, which constitutes the network's core remit. The review examines the various interrelated dimensions of innovative learning environments (formal and non-formal), curriculum design, teacher training, pedagogy and socio-economic issues, across a wide range of sources including scientific reviews and books, reports from EU and other international organizations, as well as national key reports about specific relevant initiatives.
The literature review is divided into three sections, each with a specific focus. The first section written by the University of Helsinki examines the implementation of key competences across school education in Europe, from the point of view of practice. The classroom and non-formal learning environments are therefore considered in relation to technology enhanced as well as collaborative and multidisciplinary learning, and the key competences of teachers. The authors consider the approaches to implementation from the national, regional and school levels.
The second section of the review is written by the European Institute of Education and Social Policy (EIESP) and analyzes approaches to the implementation of key competences in school education at systemic level, focusing on curriculum design and implementation and socio-economic aspects, as well as taking a closer look at some of the literature on transversal and cross-curricular key competences.
The final section written by l'Institut Français de l'Éducation (IFE), belonging to l'Ecole Normale Supérieure de Lyon (ENS) provides a specific example of how key competence development has been framed in French-speaking countries, considering particularly the definition and integration of competences in schools in France, and the assessment approaches used.
This general literature review [D3.1 (a)] addressing a variety of issues related to key competence development in schools in Europe is complemented by another review [D3.1 (b) by D. Pepper] specifically on approaches used for the assessment of key competences. Considering the importance of assessment for the successful implementation of key competences in school education, it was decided this topic deserved separate attention.
This current version of the general literature review is in its first draft and will be updated yearly throughout the project's lifetime. The aim of this first version was to cover the bulk of topics detailed in the matrix, and be guided on the basis of these initial findings as to which areas we would like to investigate further in 2013 and 2014. One such area which we plan to explore in next year's update is the extent to which countries use research and evidence to inform the implementation of policy in this area. When such an evidence-based approach is used, what are the outcomes and where evaluations exist what do we learn from them? The intention is to analyze international influences, such as how the latest PISA student data has impacted on various countries' formulation of key competence policy, also looking closely at
4
a very pertinent OECD working paper
1
(published as this first draft of the literature review
was being finalized) concerning how diverse stakeholders at various levels are involved in curriculum innovations in different countries. In the forthcoming updates to the literature review the intention is to better integrate the results of the various sections, and to include more examples of relevant literature emanating from countries represented within the network.
Defining competence – use of terminology
In an attempt to clarify the concept of 'competence', Weinert (2001) relates the term to the Greek notion of arete, meaning excellence, in the sense of being the best; also with the Latin term virtus, a kind of moral excellence, while it is generally understood as being concerned with 'what people can do rather than what they know'. The concept applies to individuals, social groups or institutions, and the words 'competence' and 'competency', or its plural form 'competencies', are often used interchangeably. This use neglects the large variety of meanings of 'competence', that can be captured by the terms 'ability', 'aptitude', 'capability', 'effectiveness' and 'skill'. Resulting from this overgeneralisation, the notion of competence, and its plural 'competences', has been replaced by the narrower version of 'competency', or the plural form 'competencies' recently. The latter denote discrete skills and activities that

individuals can perform (Allan, 2011).
The origin of the discussion on competence can be traced back to 1996 (Dabrowski et al., 2011) when the Council of Europe defined active citizenship as the capacity to accept responsibilities, participate in group decisions, resolve conflicts in a non-violent manner, and play a part in running and improving democratic institutions. In this way, competences are introduced in the rhetoric of official documents with a view to cover essential socio-political aspects in the life of the European citizen. The delineation of 'critical judgment' expresses the need to provide an argument-based 'opposing' force to information dissemination by the mass media and advertisers. Apparently, this policy aims to empower citizens with cognitive tools enabling knowledge expansion beyond the limits of information manipulation and propaganda of the media.
Recent studies and research demonstrate that there is a broad range of terminology used in the 27 member states linked to philosophies of education, history, approaches to learning and to curriculum development, recent reform processes and international influences whether research (e.g. DeSeCo) or policy "learning" through EU and other funded programmes, etc.
2 We have included below 2 boxes with quotes from Hoskins & Deakin Crick (2010) with their suggested definitions of competence and key competences (our bold). Similar terms (once translated into English for the purposes of comparative work) may not cover the same content and approach. Different terms do not necessarily indicate different philosophies, approaches and content.
The level of influence of the vocational sector and the labour market is variable among the countries, but may be significant.

"What is a Competence?
3
A competence refers to a complex combination of knowledge, skills, understanding, values, attitudes and desire which lead to effective, embodied human action in the world in a particular domain. One's achievement at work, in personal relationships or in civil society are not based simply on the accumulation of second hand knowledge stored as data, but as a combination of this knowledge with skills, values, attitudes, desires and motivation and its application in a particular human setting at a particular point in a trajectory in time. Competence implies a sense of agency, action and value.
To understand competences, the spotlight is on the accomplishment of 'real world tasks' and on a multiplicity of ways of knowing – for example, knowing how to do something; knowing oneself and one's desires, or knowing why something is important, as well as knowing about something. This is similar to Delors' 4 pillars of learning developed for UNESCO: "learning to live together, learning to know, learning to do and learning to be."(Delors, 1996). Importantly, competences are expressed in action and by definition are embedded in narratives and shaped by values – this action, or way of doing something is more important or desirable than that one because it leads to a particular end. Just as a competence is recognised in the context of the real world, the development of competences is also based in real world experiences and takes into account the full spectrum of learning opportunities (informal, nonformal and formal learning) throughout the life span. Perhaps the most thorough recent exploration of the concept was undertaken by OECD in DeSeCo1. Drawing on this work, the term competence was defined by Rychen and Salagnick (2003, p. 43) as:
the ability to successfully meet complex demands in a particular context through the mobilisation of psychosocial prerequisites (including cognitive and non-cognitive aspects) and as
the internal mental structures in the sense of abilities, dispositions or resources embedded in the individual" in interaction with a "specific real world task or demand."
Source: Hoskins & Deakin Crick (2010)
"What are key competences?
4
The DeSeCo programme identified four analytical elements of key competences: they are multifunctional; they are transversal across social fields; they refer to a higher order of mental complexity which includes an active, reflective and responsible approach to life; and they are multi-dimensional, incorporating know-how, analytical, critical, creative and communication skills, as well as common sense. Within this project, a number of OECD countries were asked to list which competences they considered to be key competences. Four groups were frequently mentioned in the country reports: (i) Social Competences / Cooperation; (ii) Literacies/Intelligent and applicable knowledge: (iii) Learning Competences/Lifelong Learning; and (iv) Communication Competences (Trier, 2002)."

6
In terms of the logic that underpins competence development, A. Tiana et al (p308) refer to Basil Bernstein's work in the 1990s on the difference between the economic and social logics in the term competence with the social logic focusing on the democratic perspective of social development while the economic logic focuses on human capital. They quote from Bernstein on the characterisation of the social logic of competence:
a) The anticipation of a universal democracy of acquisition: all persons are intrinsically competent and they are all in possession of common procedures, so there is no deficit as such;
b) The individual is active and creative in building a valid world of meanings and practices: in this case, differences emerge between persons, but not deficit;
c) The individual is self-regulating with a positive evolution, this development does not overtake via formal instruction: official socialisers become suspect, because the acquisition of these procedures constitutes a tacit, invisible act that is not subject to public regulation;
d) A critical and sceptical view of hierarchical relations, derived from the fact that, in certain theories, the role of socialisers should be limited to facilitation, adaptation and organisation of context: from this perspective, competence theories smack somewhat of emancipation." (Bernstein, 1996). P308
They go on to quote Angel Pérez Gómez (Pérez Gómez, 1983) asserting in what has become a classic Spanish text on pedagogy, "the student's learning in the classroom is much more complex than the learning gained from laboratory experiments. It is a situational learning, contextualised according to the structure of academic tasks and the ecological climate created through the negotiation of the social group' (Tiana et al 2011 p309).
And the purpose of key competences:
Adequate skills and competence are crucial to participate in working life, but also in social and civic life. They are the basis of community cohesion, based on democracy, mutual understanding, respect for diversity and active citizenship. Creativity, openness and interpersonal competences are also necessary for personal fulfillment and happiness.

Competence frameworks and levels
The European Reference Framework and other international frameworks
The European Reference Framework of Key Competences for Lifelong Learning (OJEU, 2006) defines key competences as knowledge, skills and attitudes applied appropriately to a given context (Pepper, 2011). The Framework identifies eight key competences as necessary for personal fulfilment, active citizenship, social inclusion and employment; communication in the mother tongue; communication in foreign languages; mathematical competence and basic competences in science and technology; digital competence; learning to learn; social and civic competences; sense of initiative and entrepreneurship; and cultural awareness and expression. Each has a concise definition of its scope and all emphasise critical thinking, creativity, initiative, problem solving, risk assessment, decision taking,
7
communication and constructive management of feelings. The latter are also known as 'transversal skills'.
Seemingly, the need to interpret the concept of 'competence' leads to its fragmentation instead: key competences, competencies and transversal skills appear on stage. Moreover, considering the feature of cultural diversity that characterises Europe, a unifying pattern for a pan-European consistent application of the term constitutes a utopia rather than an achievable goal. To add to the blurriness of the situation, the central decision to leave further interpretation to Member States depending upon the specific contexts of their education systems acknowledges the incompatibility of a 'melting pot' ideology with the pluri-cultural nature of Europe.
The discussion surrounding key competences in Europe is related to a wider, international push for educators, policy makers, citizens, and learners to come to terms with the changing living and working ecologies of this 21
st
century. These frameworks share overlapping
themes.
The transversal skills outlined in the European Reference Framework are in particular closely related to the recommendations set by other organisations, as well as scholars. The OECD, for example, has focused on three broad areas: The capability to use tools (including language) interactively, the capability to interact in heterogeneous groups, and the capability to act autonomously (OECD, 2005). The organization frames these competencies as a response to the demands of modern life.
Tapio Varis has emphasized the importance of critical thinking, problem solving capacity, improvements in expression communication and interaction and civic participation and active citizenship, in the UNESCO framework of competences for the 21
st
century, further stating
that "Instruction must offer tools for finding out the causes and effects of different phenomena and for drawing conclusions, which at its best leads to growth into active, critical and mediacritical world citizens" (Varis, 2011, p. 10). In the UNESCO report, ICT Transforming Education (2010), technological development is seen as integral in the development of new skills and ways of learning.
The World Bank has focused on Technology literacy, information management, communication, working in teams entrepreneurialism, global awareness, civic engagement, and problem solving (Wagner, 2012). Similarly the industry funded Assessment and Teaching of 21
st
Century Skills (AT21CS) consortium advocates for four categories: ways of thinking, ways of working, tools for working, and living in the world.
Wagner (2010) argues that the set of core competences every student must master before the end of high school is:
1. Critical thinking and problem solving (the ability to ask the right questions)
2. Collaboration across networks and leading by influence
3. Agility and adaptability
4. Initiative and entrepreneurialism
5. Accessing and analysing information
8
6. Effective written and oral communication
7. Curiosity and imagination
Critical scholars such as Gardner (2011) and Jenkins (2006) call for a focus both on creativity and critical thinking.
Themes that underlie all these frameworks, include increased collaborative, student driven, and technologically enabled learning, the cultivation of creative thinking, as well as fostering students' problem solving abilities and meta-cognitive resources, which have all been major themes in education science and scholarship.
National sets and frameworks
The European Reference Framework of key competences is generic in so far as it addresses all audiences of learners, children and adults, no matter their age or stage in their learning journey. This raises questions about its adaptability to different audiences. In the member states approaches skills, competences, key competences, etc. are grouped in many different ways. The table annexed maps the terminology used by the different member states with examples of how it is used in policy and curriculum. As much as possible the terms used have been given in the language of the country (see Annex 2).
An issue for reflection is what is meant by a "framework";
- In qualification terms it generally includes a notion of reference levels and progression routes. For example in the case of a National Qualification Framework (NQF) or a European Qualification Framework (EQF).
- Set of competences to be attained - by when?
- Set of competences with stages appropriate to ages/grades/levels and/or objectives.
- Foundation that underpins the curriculum (that may be otherwise subject based) or runs transversally across it.
This issue should be raised because of its likely implications for implementation and assessment.
The following table summarises the scope of the key competences as they are defined and used in different countries:
Types of approaches: Examples of countries:
Sets of broad cross-curricular skills or competences that are designed to ensure continuity across the formal learning system from early years education to higher education
None of the EU Member States.
Goals and/or cross curricular competences or skills that cover the whole school system
Austria (social and personal competences)
9
(primary education to the end of secondary school)
Belgium (NL), Bulgaria, Czech Republic, Estonia, Finland, Ireland (3 sets but similar), Sweden (early years, school and extracurricular activities), UK: Wales (3 to 19 curriculum), Northern Ireland, Scotland
Cross-curricular competences that address specifically compulsory or basic education only or mainly
France, Belgium (FR), Luxembourg (crosscurricular key competences currently in the process of being implemented do not yet

address also the upper secondary cycle).
Sets of key competences or skills or aims that
address specific levels of the school systems
(primary, lower secondary and upper
secondary or basic/primary education and
upper secondary)
Cyprus, Germany, Netherlands, Portugal,
Slovenia (VET only), Spain,
UK (England)
Sets of key competences / cross-curricular
key competences that are valid for students
and for teachers
None of the EU Members States

Levels
A further issue raised by the notion of framework is that of levels or reference levels. The different frameworks in Europe (the Key Competences Framework, EQF, Common European Framework of Reference for Languages, the Common European Principles for Teacher Competences and Qualifications) contain two different approaches. Frameworks that serve for validation purposes identify reference levels and are linked to assessment systems (whether formal or through the validation of non-formal and informal learning). This is the case at EU level for EQF and the CEFRL. The other type describes learning outcomes desired at the end of a period of learning or discernible in an individual's professional qualification. These competences are still under review in terms of if and how to measure them. This is the case for the framework of key competences, the teacher competences as well as the Tuning generic competences that were developed for for higher education. They all contain elements of cross-curricular key competences whether or not they are made explicit
5
.
Some of the country approaches include an adaptation appropriate to the age of the pupils though not all are specific about how this aspect is implemented (see Annex 2). A useful example of an approach to social and emotional learning competences that were fully developed across a set of levels is contained in the report prepared in 2006 for the Welsh Assembly Government, Developing a Universal Toolkit for Measuring the Impact of Provision on the Outcomes Achieved by Young People for Extending Entitlement and Learning

5
Gordon et al. Op cit.
10
Pathways 14-19
6
(AlphaPlus 2006). A table showing an example of competences and levels from this report is in Annex 3.
The issue for further examination and implementation is about if and how countries build into their curricula age or grade appropriate adaptations of the skills/competences. Theoretically choices could move towards a level approach where pupils in the same year may have attained different levels for certain competences or an age-linked approach. There is an input and an output element to this discussion: whether competences are broken down by expectations in each school year/grade or whether pupils' attainment of the competence is assessed against a set of reference levels that is not totally based on the year/grade. This question is relevant for the transversal key competences in particular rather than for those that tend to be linked to a school discipline. In terms of implementation, the need to adapt the EU key competences to be acquired by all pupils by the end of, for example, compulsory education, is an area for further reflection.

1. Key Competences for Europe
The interconnectedness sustained by technological advancement in the 21st century allows for the creation of a trans-European educational space mobilized by networks of institutions and experts (Lawn & Grek, 2012). These transnational flows of people, ideas and practices across borders also generate the necessity for a unifying pattern of principles targeting a consensus in terms of educational goals, teacher accreditation and comparable learning outcomes. Toward this end, the concept of competence has been embedded in the rhetoric of official documents and influenced the curricula of teacher education since the early 1990s, thus mapping out standards and frameworks across Europe.
The implementation of these intentions, however, is far from unproblematic. Research findings conducted by the Council of Europe indicate that, in many parts of the continent, initial teacher education did not adequately prepare beginning teachers to cope with the diversity they met in their classrooms (Council of Europe, 2008). On the contrary, the application of competence-based standards acted as enabler of stratifications encouraging a rigid over a complex type of thinking. According to the survey results, existing standards firmly entrench teachers' novice and incompetent identities rather than promote student teachers' thinking (Roy, 2003).
The problem that arises then (through our reflections upon Allan's (2011) considerations of the ways teachers integrate competences to diversity) addresses the multiple appearances of the concept. Does a competence-oriented pedagogy embrace educational needs across member-states? Does such targeting cater for a 21st century pedagogy committed to performance and values rather than being dissociated from the latter?
In this chapter, in view of the complexity associated with defining competences as referred to in the introduction of this literature review, we understand 'competence' as a generic term which denotes the knowledge, skills and attitudes that enable learners to cope with the requirements generated by rapid socio-technological changes in the new era.
1.1. Challenges to the situated competence-based learning perspective
Defining learning in terms of competences underscores the importance of considering knowledge in action and highlights the need for tying up knowledge acquisition with task resolution. In this respect, the development of key competences requires situated learning, or learning linked to a specific context and to concrete tasks to acquire the necessary competence.
The situated learning perspective emerged during the 1980s, when social scientists began to analyse cognitive processes as aspects of interaction, and some cognitive scientists to consider the social arrangements of learning as fundamental in determining what is learnt. Suchman (1987) argued that the cognitive concept of action, a process governed by plans with adaptations to unanticipated aspects of situations, is inferior to an account in which plans constitute resources but do not determine the course of situated action. Therefore, the perspective for the organisation of action as an emergent property of interactions between actors, and between actors and the action environment was established (Suchman, 1987; Lave et al., 1991). Analysis of problem solving in everyday settings indicated that problems involving mathematical reasoning were better understood as emerging from interactions between people and resources than as products of mental operations with and on symbolic
14
representations. Hutchins' (2000) studies of reasoning and representational practices by navy ship-navigation teams and of remembering by the system of people and technological resources in an airplane cockpit constitute influential analyses of cognitive processes as aspects of social practice.
The application of the situated competence-based model to practice, however, resists the consistency and systematic approach required for a unifying European educational space. In a discussion on the findings of an OECD report concerning a survey conducted in 17 EU countries in 2009, Pepper (2011, pp. 340-41) reveals that few of the participating countries appeared to have either specifically defined the terms or developed clear assessment policies in relation to them. As Pepper (2011, p. 341) argues, difficulties in assessing competences arise from unpacking learning outcomes. This, in turn, is linked to a multiplicity of interconnected factors, such as the need to address knowledge, skills and attitudes, the application of competences to a range of real or authentic contexts and the threshold at which a certain level of competence is acquired.
Another challenge relates to the specification of key competences in sufficient detail to plan and assess learning on the one hand. On the other, this specification process should not exceed beyond the level where competence development is reduced to a series of procedural tasks that are completed without full appreciation of underlying concepts.
The subsequent implication of varying interpretations of competence between and within countries couples with varying unpacking of learning outcomes in relation to competences. To add to these, the consideration of the previously discussed dissociation of teachers from their own value system for the benefit of performance, as expressed by Allan (2011) is in agreement with Pepper's (2011) underpinning the need to prioritise concept understanding over procedural knowledge.
The issue of delineating the optimal conditions for learning key competence arises.
According to Tiana et al (2011, p. 318), a new professional culture based on a shared desire of all educational agents to create the most favourable learning conditions is essential for the future of education.
1.2. Toward a new school culture
Educational research emphasizes the need to understand the learners' active cognitive operations (Dewey, 1938), strategies, stages of conceptual development and the nature of the experiential processes of assimilation and accommodation. Perception-conception and action are seen to mutually interact (Dewey, 1896: coordination). A social perspective emphasizes the view that the environment includes (often physically but always conceptually) other people with whom the learner participates in activity systems (Vygotsky, 1978; Wertsch, 1991). The individual and society are mutually interchanging: 'culture is the capacity for constantly expanding the range and accuracy of one's perception of meanings' (Dewey, 1916, p. 123).
At a European level, therefore, the emergence of a culture supportive of the reframing and reorientation of a competence framework would need to incorporate:
☐ integrated curricular development
☑ changes in practices towards environments that facilitate learning
☐ coordinated teaching, and
15
☐ teaching models leading to tasks aiming to generate competence and experiences through different forms of cultural expression (e.g., knowledge, values, rules etc.)
While inspired in part by a radical shift in the structure of labour and technology, the Key Competences relate to long-standing educational theories, as we shall discuss further in the following section. However, we also propose that in order to encourage the development of transversal skills, the cross-disciplinary competences that are echoed as well in other frameworks, learners, teachers and communities should be supported in developing new concepts through innovative, non-traditional avenues and venues in which learning can take place.
Considering the Knowledge, Skills, Attitudes, Values, and Ethics (KSAVE) model (Binkley et al., 2012) that conceptualises 21

st
century skills as a framework of four overarching
categories, in the following sections we discuss ways of thinking, and ways and tools for
working that can be part of educational curricula across Europe. This integration allows for
the necessary conditions to emerge so that teaching and learning environments contribute to
the development of competences aiming for improved life and career opportunities at the
individual level. And, at the collective level, for improved well-being through active
citizenship, and an enhanced personal and social responsibility.
1.3. Pedagogy for competence development and the importance of transfer
One of the underlying aims of Key Competence development is fostering life-long learning,
the capability of students to use what they have learned in schools, but more importantly, to
continue learning throughout the lifespan. This is intrinsically liked to the idea of transfer
(Thorndike and Woodworth, 1901), that is, the capability of students to transfer knowledge,
skills, and meta-cognitive skills to new situations, and ultimately to the "real" world outside of
school. This is a long-term goal of educational theorists, which educational science has
been actively addressing. The key outcomes of this research emphasize the need for
contextualised learning, constructivist approaches that combine student experimentation with
explicit content teaching, and dynamic assessment—aspects of what Bransford and
Schwartz (1999) have called Preparation for Future Learning.
Pedagogy, therefore, that would aim for competence development would also enhance
learner efforts for meaningful experiences through goal-directed, active, authentic and
collaborative tasks (Jonassen et al., 2008). These would tie with flexible national curricula
that consider project-based learning as an organic part along with systems of evaluation
catering for the needs of innovative learning environments. The teaching methods, then,
required for the development of key-competences should be oriented towards
interdisciplinary, cross-subject teaching, and team oriented learning blended
withindividualised approaches and project-based work. (Gordon, Halasz, Krawczyk et al.,
2009, p. 162).
In this way, as Gordon, Halasz, Krawczyk et al. (2009, p. 227) argue, effective pedagogy in
competence development can become an attainable goal, given that it is life-long oriented;
promotes active engagement; fosters individual and social processes and outcomes;
depends on the learning of all those who support the learning of others; and is built upon
consistent frameworks that focus on convergent aims.
16
2. Key competences and transversal skills: examples from
education research
2.1. Key competences
The framework of key competences and transversal skills underscores the need for complex,
collaborative and trans-disciplinary learning environments. In this section, brief examples of
such environments are given relating to each of the eight key-competences, as well as
examples of particular schools and curricular reforms that have fostered the development of
key competences. Within Europe and worldwide, there is an established wealth of research
to draw upon regarding the development of key competences. While emerging technologies
present exciting ways to transform the teaching of key competences, and broaden students'
educational experiences, methods for developing key competences should also draw from
established programs that have shown to be successful over time. Thus it should be noted
that barriers to implementation, addressed again below, are more likely to be those of
administration, evaluation, and fiscal resources; many schools are already engaged in
exemplary teaching of Key Competences.
The key themes in teaching Key Competences for the twenty-first century relate to creating
meaningful education based on real problems and engagement, interdisciplinary
environments, and the explicit teaching of self-management (meta-cognition and selfregulatory skills).
Communication in the mother tongue
Using location-based technologies and the story-telling approach, Hansen and colleagues
(2012) investigate the development of drama spanning from pure art pieces to structured
learning experiences. According to the researchers (Hansen et al, 2012), the evidence of the
whole operation indicates the educational value of the technology-based intervention that,
rather than focusing on the use of technology, uses the technology to transform an
educational experience. Moreover, the application of drama techniques opens up
perspectives for mother language teaching and learning.
Communication in foreign (multiple) languages
Within European educational systems, the issue of education for competence in multiple
languages moves past the idea of foreign languages. It includes language education in
nations that have a plurality of official and unofficial languages. Multilingualism is a key goal
for maintaining national languages, and in many respects shares the pedagogy of first
language learning.
Students can be engaged in multiple language learning through experiencing its usefulness.
Travel and study abroad are not economically feasible for all students, however, the ability
for technology to facilitate intercultural communication where travel is not possible is
promising. Fisher, Evans and Esch (2004) report on a program that encouraged the
structured use of communications technology to enhance student learning of French,
involving students in Belgium, England, France and Senegal. This program encouraged
young people to learn autonomously and communicate freely, but with scaffolding and
stimulated activities to inspire their work. Not only did students have the opportunity to
communicate with native speakers, the research suggested they developed selfmanagement skills, collaborative skills, and intercultural learning. Thus, an environment was
17
created that was also conducive to the development of other key competences and
transversal skills.
Foreign language learning
Mobile learning has been used to support a range of learning activities, for example
language learning using text messaging (Cavus & Ibrahim, 2009; Kennedy & Levy, 2008; Lu,
2008).
Math competence and basic competences in science and technology
Games have been widely implemented in teaching children math. For example, Moreno &
Durán (2004) conducted a study about discovery-based learning through computer game.
Other examples of successful integration of games into math curriculum could be found in
the literature, such as, Clements and Sarama (2007) and Kebritchi, Hirumi, and Bai (2010).
Another key example for mathematics is the Realistic Mathematics Education curriculum,
developed in the Netherlands by Fruedenthal and colleagues to address the problem of
transfer (Fruedenthal, 1968) and discussed further below. This shares the theme of offering
students with real problems that promote transfer, problem solving skills and engagement.
Similarly, Schwartz and Moore (1998) find students better understand and are able to
transfer their statistical learning when it is grounded first in their own experimentation.
Grounded in several different fields of learning science, student experimentation with
meaningful problems combined with explicit instruction has been shown to be a strong model
for competence development. The idea of engaging students in inquiry and experimentation
in mathematics and science is further discussed in the section on innovative learning
environments below.
Digital competence
Digital competence moves past the idea of simply being able to consume digital media, but
to have the critical thinking and creative skills that citizens need in order to be effective
receivers and creators in the digital realm.
Zahn, Pea, Hesse and Rosen (2010, p. 410) describe students developing websites for an
online history museum while developing skills in critical thinking, creativity and collaboration.
Trans-disciplinary, inquiry based learning can foster key competences and content learning
at the same time that transversal skills are developed.
It is important to note the digital competence increasingly is important to general literacy, as
well as to social and civic competence, discussed further below.
Learning to learn
Uncertain economic outlooks and the need for flexibility in working life have inspired a
European focus on life-long learning. True lifelong learning is centred on the idea of learning
how to learn, that is, the problem solving skills, self-regulation, self-efficacy and creative
flexible thinking needed to master new tasks and environments.
Blending a problem-based estimation scenario in a mobile-device-supported cooperative
learning environment, Lan and colleagues (2010) examined the ways elementary students'
cooperative skills and estimation strategies improved. This creative intervention benefited the
development of metacognition knowledge of the students' estimation strategies.
18
Ultimately, learning to learn comes back to the idea of transfer (Bransford & Schwartz,
1999), a key theme in the education research discussed here, and one that points towards
certain modes of education: constructivist and experiential surely, but also grounded in
explicit teaching and teaching of self-management.
Social and civic competences
Social and civic competences can on one hand be seen as building the capacity for young
people to function in a pluralistic society where collaboration and cooperation are important.
An example of such a project is when digital storytelling techniques on mobile devices were
applied in a project that involved guiding visits to cultural heritage sites (Lombardo &
Damiano, 2012). The experience confirmed the importance of the approach in the emotional
engagement of the audience. This indicates the presence of aspects of embodied cognition
on the one hand; on the other, the potential of mobile technologies to contribute to the
establishment of social bonds among the members of a group is made visible.
Another important aspect of social and civic competences is the potential for citizens to
contest policy, resist influence and develop their sense of agency (or self-efficacy, see
Bandura, 2000) as democratic citizens. This is a difficult goal for traditional some structures.
In this report, innovative environments that foster creativity and agency, and technology
learning that fosters critical literacy, both discussed further below, are also seen as key
elements of social and civic competences.
Sense of initiative and entrepreneurship
Initiative and entrepreneurship are dependent on students' development not only of skill, but
of a sense of agency. That is, they are highly dependent on students' self-efficacy and
perseverance in difficult tasks. It is not only individual self-efficacy that is important, but
collective self-efficacy as well as Bandura (2001, pp. 17–18) argues:
"As globalization reaches ever deeper into people's lives, a strong sense of collective
efficacy to make transnational systems work for them becomes critical to furthering
their common interests…The magnitude of human problems also undermines
perceived efficacy to find effective solutions for them. Worldwide problems of growing
magnitude instil a sense of paralysis that there is little people can do to reduce such
problems. Global effects are the products of local actions"
Self-efficacy and collective efficacy are theorized as being developed through mastery
experiences as well as social modeling. The 21
st
Century classroom, through providing
open-ended challenges and scaffolding collaborative work needs to serve as a testlaboratory for students in developing their self-efficacy and developing initiative and
entrepreneurship competence.
Young people will "… have to cultivate multiple competencies to meet the ever-changing
occupational demands and roles" (Bandura, 2001, p. 11). To turn other competences into
initiative and entrepreneurship action, students need to be armed with self-efficacy.
Cultural awareness and expression
New techniques, such as collaborative digital storytelling on mobile devices have been
applied also to cultural and creative education. As discussed previously in the social
competences section, in a project that involved guiding visits to cultural heritage sites
(Lombardo & Damiano, 2012), project researchers used a location-based character-enacted
19
storytelling technique. Through this use of a character-based movie, a memory of the
learning experience emerged. Such approaches integrate technology with cultural and
creative education. Collaborative projects designed for sharing, such as digital storytelling,
also open the possibility of creating educational venues for international learning, as stories
are shared between and created across cultures.
2.2. Transversal skills
Critical thinking, creativity and collaboration
Transversal skills like critical thinking and creativity need to be situated within the
environment of the 21
st
Century. As Hennessy et al. (2005, p. 179) note, critical thinking can
be lost in the deluge of information available on the Internet. Lewis et al. (2010, p. 7) argue
that in order to be prepared as critical consumers and users of modern media and
technology, youth also need to understand how to be producers and creators of it:
By together questioning texts and situations, conceptualizing problems, designing
solutions, building artefacts, redesigning, re-conceptualizing and reinterpreting,
people generate forms of public knowledge that in turn provide conceptual and
relational support for further interacting and learning.
To be creative and critical in the digital media environment, however, depends on a high
level of technological competency, and self-efficacy with learning new media and mastering
new tools. The argument is that in order to be competent, productive and critical in this
century, one should endeavour to have a basic understanding of the languages and
processes that underlie our daily lives today. This implies a basic understanding of computer
coding and algorithmic thinking (Goode and Margolis, 2010).
One example of designing technology environments for education that enable the
development of transversal skills in the MoViE platform from Finland, which provides the
capability of sharing and remixing of videos easily online for digital storytelling, designed to
facilitate collaborative learning (Multisilta, 2012), and used successfully for digital storytelling
by students at both the elementary and middle school ages (Tuomi & Multsilta, 2012). The
ability of these new tools to make use of the collaborative potential of Web 2.0, and allow for
active participation and critical thinking through remixing of media (Jenkins et al., 2006),
increases the potential of digital storytelling to promote learning for the 21
st
century. In
addition, critical thinking (Figg, McCartney, & Gonsoulin, 2009) and increased collaboration
(Sadik, 2008) have been outcomes of early studies of digital storytelling in the classroom.
Problem solving
The development of an ability to solve problems and make decisions is very important
learning outcome of education. Problem solving could be developed in problem-based
learning. This learning theory is a student-centred learning approach helping learners to
acquire and develop the knowledge, skills and capabilities needed to solve problems
effectively (Engel, 1997). The problem based learning aims to prepare students to encounter
ill-structured problems normally encountered in real life. Such problems are usually complex
and can have multiple solutions. The main principles of problem based learning -
contextuality, collaboration and experientialism (Boud & Feletti, 1991) are fruitful to utilize in
elementary, primary and higher education.
20
Self-management
Self-regulation is important to problem solving, directing attention, and managing emotion

(Malmivuori, 2006, pp. 158-160). As such, it underlies other key competences, particularly learning to learn. The goal of fostering a sense of initiative and entrepreneurship is really a goal about providing students with the skills and self-regulation to become independent, creative and critical contributors. There are many different ways of discussing and evaluating self-regulation, or, for example self-control and executive function, but the evidence suggests that the existence of a unified underlying concept (Duckworth & Kern, 2011).
Strategies for self-regulation can be learned. There are examples of students using ICT to develop self-awareness of their self-regulation with regards to their work, and support in changing existing patterns of behaviour (i.e., Niemi et al. 2003). Such skills are increasingly necessary in complex, individualised learning environments.
2.3. School-level spaces for teaching key competences and transversal skills:
real-world examples
Self-learning is an important key competence and it can be structured as in Burnfoot Community School in Hawick (Scotland) that has been working with personal learning plans since 1999. Often the students are encouraged and advised to undertake efforts to learn by themselves. When they gather some experience, the next step is to give them the possibility to practise self-assessment and peer assessment. This kind of experience is very important for the preparation for lifelong learning. It also contributes directly to the development of the learning to learn competence (Gordon et al., 2009). Very popular and effective method to teach key competence is project-based education (Ravitz, Hixson, English, & Mergendoller, 2012). This method is strongly encouraged, for example, by the Austrian Ministry of Education.
There have been many studies carried out, investigating the effectiveness of project-based learning. For example, Boaler (2002b) compared student mathematics achievement in two similar British secondary schools, one using traditional instruction and the other using project-based instruction. After three years, students in the project-based-learning school significantly outperformed the traditional-school students in mathematics skills as well as conceptual and applied knowledge. Furthermore, Thomas (2000) found some evidence that project-based learning is effective for teaching problem solving and decision making.
Sherman Oaks Elementary, a school in San Jose, California is an example school that teaches by project-based learning. It features a dual immersion English/Spanish language program and project-based learning culminating in widely attended student exhibitions. According to the school Web site, the Sherman Oaks program focuses on "strong academics built around real-life learning" and has "significantly raised student achievement levels." Also Applied Learning Academy, Fort Worth, Texas (a year-round campus and a school of choice) gives students an opportunity to learn through real-world experience in an environment that "fosters critical thinking, creativity, and collaboration with Fort Worth's arts, business, and scientific communities." Students create portfolios, design high tech projects, collaborate with a local theatre company, and produce and field test documents for the school district. The school Web site reports TAAS (Texas state test) scores that are considerably above average - as well as positive attendance rates.
21
In Sweden, the advent of friskolar or independent, non-fee paying schools coincided with an increase in schools built around innovative and specialist curricula. While this has not been uniformly positive (especially with regards to equity, discussed further below), it has also created notable successes. One such school is the private Marina Laroverket in Danderyd, Sweden, which was ranked the best school in the Stockholm region by Sveriges Kommuner och Landsting (the Swedish Local Authority administration, SKL) most recently in 2011 due to academic performance and retention of students. The school, which does not charge tuition, combines vocational with academic programs and sends students to study aboard a sailing ship four weeks at a time, during which they focus on learning subjects such as astronomy and marine biology, but also ways of working and self-management. While this example is not scalable, and its finances are dependent on the local economy, it is one example of a local success in creating an interdisciplinary learning environment that engages students in the learning of Key Competences.
Many examples of using innovative pedagogy to develop key competences without the use of ICT can be found in the area of vocational education. In Germany, efforts are being undertaken to increase in-company training, thereby promoting the acquisition of key competences such as the capacity to work in a team, responsibility, self-organisation and linking content-related knowledge with the ability to apply it (Gordon et al., 2009).
2.4. Examples of nation-wide curricular reform for teaching key-competences
While many of the examples in this section stress interdisciplinary examples, an established example of success within mathematics is the Realistic Mathematics Education (RME) developed in the Netherlands by Hans Freudenthal and colleagues to address the problem of transfer in mathematics education (Fruedenthal, 1968). The curriculum fosters co-operative learning (e.g. Terwel, Herfs, Mertens and Perrenet, 1994), as well as engagement with problem solving grounded in realistic examples. This nation-wide reform now has an established record (Vos, 2010) that speaks directly to the building of mathematics competence, but also addresses issues of ways of working, cooperation, problem solving and metacognition. Most importantly, it is designed to promote the transfer of learning. Transfer of learning, as discussed previously in this report (section 1.6, p. 12), entails the application of knowledge, skills and meta-cognitive abilities to real-life situations and, therefore, by no means constitutes a straightforward process. Nevertheless, these good practices indicate that interdisciplinary tasks implemented within a cross-curricular framework can be the vehicle for competence and transversal skills development. According to the Analysis of the Mapping of Key Competency Frameworks (Pirrie, 2004), competence-oriented cross-curricular reform has been an educational goal for nations across Europe aiming, among others, to upgrade the status of competence at all curricular levels (e.g. in Romania, Hungary and Ireland), to use related benchmarks and indicators (in Germany and Malta) and to pilot new standards for reading, languages, mathematics and sciences (e.g., in Austria and Cyprus).
Beyond the complexity inherent at the pedagogical level, as the same Analysis (Pirrie, 2004, p. 9) stresses, large-scale curricular innovations should consider implications arising from contextual factors as well. These can include established European states' practices of subject-dependent teacher training programmes; lack of flexibility in school timetables; the degree of autonomy at school level and the lack of a universal definition of 'cross-curricular' competences.
22
Another pedagogically related theme in the development of curricula for key competences is the innovation in learning environments that must take place. However, it should also be noted that innovative contexts are not enough. The examples above also emphasize the importance of explicitly teaching ways of working and self-management skills, that is, of modelling for students how to learn and inquire independently. In the following section, there is a more in-depth exploration of innovative learning environments for teaching and learning key competences and transversal skills and this theme of intertwining innovative environments with explicit teaching and scaffolding remains.
3. Formal and non-formal learning spaces and applications for key competences
As de Corte (2010) cites the US attempts to define '21st century skills': 'today's students to be prepared for tomorrow's workplace (. . .) need learning environments that allow them to explore real-life situations'. Therefore, new learning environments are needed that support development of problem solving, critical thinking, creativity, initiative, problem solving, risk assessment and decision taking.
3.1. Learning theories behind interactive learning environments for formal and non-formal learning
There are several learning theories that can be used to explain how participants learn in interactive learning environments which could be used for developing Key Competences such us problem solving, critical thinking, creativity, initiative, problem solving, risk assessment, decision taking and constructive management of emotions. By interactive learning environments we mean learning environments that supports active learning i.e. learning with simulation and games, learning with mobile devices and with mobile social media.
First, in interactive learning environments that aim to develop Key Competences, learning is no longer a process of knowledge transfer from the expert to the novice but learners need to construct the knowledge themselves by interacting with the environment. Constructivist learning theories posit that knowledge is built by the learner, not supplied by the teacher, thus constructivism is one of theories that provide a strong rationale for using interactive learning environments to support learning (Kriz, 2010). Constructivism focuses on the process of knowledge construction and the development of reflexive awareness of that process (Bednar, Cunningham, Duffy, & Perry, 1992). Learners must individually discover and transform complex information, check new information against old rules and revise them when they no longer work. Learning also must be situated in a rich context, reflective of realworld contexts for this constructive process to occur and skills are developed through working on the problem, i.e., through authentic activity. This approach represents the concepts of "active" or "autonomous" learning (Johnson, Johnson, & Smith, 1999). It is also argued that interactive learning environments, through linking knowledge and doing, support the idea of learning-by-doing (Barab, Hay, Barnett, & Squire, 2001). Schank (2005) argues that learning-by-doing is always more effective than learning-by-telling and that the former is best accomplished through complex, high fidelity simulations that engage learners at the highest possible level.
23
The "active" instructional approaches propose supporting or complementing traditional teaching methods with active learning experiences such as role-playing, simulations, selfpaced or team-based exercises, and other types of open-ended problems requiring critical or creative thinking. In addition, students are more highly motivated by interactive learning environments such us games than by more traditional instructional presentations (Lepper & Henderlong, 2000; Garris, Ahlers, & Driskell, 2002).
Further, interactive learning environments provide a meaningful environment for problembased learning (McFarlane, Sparrowhawk, & Heald, 2002) therefore educators have developed learning environments that support complex problem solving (Suomala, 1999).
Problem solving can be associated with discovery learning because interactive learning environments allow students to discover new rules and ideas rather than memorizing the material that have been presented to them. Discovery learning is one of the instruction models based on constructivism; it is an approach to instruction through which students interact with their environment by exploring and manipulating objects, wrestling with questions and controversies, or performing experiments (Rieber, 2000). The idea behind discovery learning is that students are more likely to remember concepts that they discover on their own (de Jong & van Joolingen, 1998). In many forms of interactive learning environments, students learn by doing, by trying new strategies and by making mistakes. They construct the knowledge internally by immersing themselves into the learning environments. Furthermore, in these environments, participants collaborate with each other and group work helps them to share and develop alternative viewpoints. In interactive learning environments, collaborative learning is often implemented, which supports the use of effective discursive learning methods (make explicit, discuss, reason, and reflect, convince) while allowing for the acquisition of essential social and communication skills (Dillenbourg, Baker, Blaye, & O'Malley, 1995). The main idea of collaborative learning is that collaborative knowledge construction, co-ordination of different perspectives, and shared evaluation of group activities enable a group to create something that goes beyond what any one individual could achieve alone (Bereiter, 2002; Stahl, 2003).
Therefore, learning in these environments is not the lonely act of an individual but a matter of being initiated into the practices of a community (Lave & Wenger, 1991). The learning process is seen as mediated in a social context in situated learning (Winn, 2002) and the socio-cultural approach. In a social context physical artefacts (or tools) are a good facilitator for learning new concepts, as they give a shared starting point and potentially show the student new ways to proceed (Wenger, 1999; Wertsch, 1991, 1998).
Developing Key Competences through interactive learning environments could be also associated with other learning theories for instance activity theory (Kuutti, 1996). These environments have been characterized also as a form of experiential learning (Kolb, 1984) because the process of knowledge creation relies on the transformation of self-experience (Haapsalo & Hyvönen, 2001). For example, according to Gredler (1996) educational games are experiential exercises. They offer here-and-now concrete experiences to validate and test abstract concepts presented in the gaming environment. Such concrete experiences are the heart of this approach in which knowledge is constructed, not transmitted, as a result of experiencing and interacting with the environment (Kebritchi & Hirumi, 2008). This is a key theme in the idea of meaningful transfer (Bansford & Schwartz, 2001), that formal learning be grounded in experience—particularly in experimentation.
24
3.2. Examples of formal and non-formal learning environments
Games have been widely implemented in teaching children math. For example, Moreno & Durán (2004) conducted a study about discovery-based learning through computer game and verbal guidance for teaching addition and subtraction of integers. Clements & Sarama (2007) described training of early childhood mathematic skills through different drill-andpractice type mini-games. Further, Barendregt, Emanuelsson & Lindström (2009) study showed evidence for improving early arithmetic skills for preschool children through drill and practice game that uses a specifically designed tactile interface. There has been also an interest for investigating how commercial games can enhance learning (Keskitalo, Pyykkö, & Ruokamo; 2011). In addition, research on social networking tools such us Facebook is booming, for example on educational usage of Facebook (Mazman & Usluel; 2010) or on using the Facebook group as a learning management system (Wang et al.; 2012).
3.3. Barriers for using interactive learning environments at schools
In spite of many positive benefits of technology enhanced learning environments, these environments have been also criticized (Buckingham & Scanlon, 2002). In short, the barriers for using these learning environments in an educational setting include: time scheduling, physical setting, class expectations, teacher background, genre knowledge, technical problems, experience with group work, teacher preparation, class size and prioritizing (Egenfeldt-Nielsen, 2004).
Two major negative sides of using technology-enhanced learning environments are:
1. costs involved, because of the costs poorer schools and students can end up being disadvantaged;
2. students, and sometimes teachers, can get too immersed in the technology aspect, rather than the subject content.
There have been a lot of studies carried out, investigating if use of computers improve learning but the results are mixed. First, little evidence has accumulated of the positive impact of ICT on student learning outcomes in schools (Dillenbourg, 2000). Some of the negative factors that have been mentioned in the literature (Deryakulu, Buyukozturk, Karadeniz, & Olkun, 2009) which influence the use of technology enhanced environments are lack of appreciation from colleagues, the difficulty of classroom management in computer labs, inappropriate teaching materials (e.g. textbooks, software), large class sizes and the rapidly changing nature of ICT. Due to the rapidly changing nature of ICT teachers need to continuously update their knowledge. All of these issues affect negatively the ICT teachers' effectiveness and efficiency in their classes. However, the positive side of the ICT in education has to be mentioned, for example one advantage is the unprecedented possibilities computers present for active or research-oriented learning (Jakkola, 2012; Veermans, de Jong, & van Joolingen, 2006).
3.4. Mobile technology for interactive learning environments
With the increasing popularity of mobile devices, non-formal learning (learning through games or mobile devices) has attracted the interest of educators and researchers. The most

25
important benefit offered by mobile technologies is that they can provide anytime and anywhere functionality. Therefore, mobile devices can support the great amount of learning that occurs during the many activities of everyday life and learning that occurs spontaneously outside of school. These devices enable learning that occurs across time and place as learners apply what they learn in one environment to developments in another (Sharples, Taylor & Vavoula, 2005; 2007).
3.5. Developing science and mathematics competences with social and civic engagement
There is also the potential for schools, particularly with the advent of technology, to connect learners to authentic experiences of scientific discovery. Citizen science has successfully engaged the public, including youth in mapping invasive species (Jordan et al., 2012), identifying new planets, (Fischer et al., 2012), and perhaps most surprisingly, discovering a new algorithm for folding protein structures through engaging players in an online game (Khatib et al., 2011). Such opportunities present additional ways for learner engagement in real, original science and discovery. Table 1 below illustrates some 'Real Science' examples for competence development.
Table 1: REAL SCIENCE FOR DEVELOPING COMPETENCE and CIVIC ENGAGEMENT: Examples of new environments for involving students in real science research
Zooniverse An online collection of some of the world's biggest citizen science initiatives, created by the Citizen Science Alliance in cooperation with many universities and other organizations. Includes extensive information for teachers, and opportunities for laboratory as well as observational science.
FoldIt Supported by the University of Washington, this online game helps scientists solve problems relating to protein folding, linked ultimately to treatments for AIDS, Cancer and Alzheimer's.
CamClicker Teaches animal observations skills while students work on real tasks to help with data collection, one of the many collaborative programs from the Cornell University ornithology labs
Evolution MegaLab A citizen science project hosted by the Open University monitoring evolution of organisms in Europe, which resources for teachers
BeeID A project that monitored the population of pollinators in the British Isles using Flikr and Facebook
Planet Hunters Using data from the NASA Kepler mission to, among other things, discover new plants.
Part of the Zooniverse
26
Biology and ecology are particularly fertile areas for this sort of participatory science. Researchers in the United Kingdom, for example, used online social networks such as Facebook and Flikr to successfully improve the monitoring of the bee population in the British Isles (Stafford et al., 2010). In fields such as ornithology, participatory data gathering has a long history, and is becoming only more important with the advent of web-enabled communities of citizen scientists (Sullivan et al., 2009). The use of citizens for data collection is expanding and changing the way scientists think of data collection (Silvertown, 2009). Many of these programs welcome youth and provide outreach and support for teachers to engage with their students in these real scientific endeavours.
The growing capabilities of technology also increase the ability for schools to make use of such community activities. "Currently, mobile devices include GPS, compass and accelerometers that can produce contextual data for applications. This kind of contextual data can also enrich future mobile learning applications." (Multisilta, 2012, p. 284). Such technology will increasingly enable learners to take advantage of out of class, in the field, science. It can also be used to link students up with real-world science problems and to become participants in meaningful research.
In mathematics learning, online communities implicitly teach collaborative and social skills while members engage in a task of common interest. For example, the NRich mathematics website hosted by the University of Cambridge provides basic to complex mathematical problems, as well as moderation by mathematics students that supports peer-learning by scaffolding, encouraging students to persevere in problem solving rather than simply ask for an answer (Jared, 2010), thus fostering transversal skills such as problem solving, initiative and self-efficacy in addition to mathematics learning. Curated by faculty and students of the University of Cambridge, the NRich program is also an example of a new kind of university partnership with educators and learners.
These are collaborative, interactive, technology enabled activities present a new significant change in the ways that young people can engage with science and learning that reaches outside the classroom. Not only do such approaches increase engagement by linking inquiry learning with real world problems, but they are interdisciplinary by nature, having the potential to combine elements of digital, math and science competences with problem solving, critical thinking, and initiative.
3.6. Innovative technology learning for participatory literacy and civic competence
Digital competence is one of the seven key competences, but it is also a vehicle for 21 st
century literacy skills and developing civic competence. Many students are already adept consumers of technology. Some youth have also taken hobbies, such as game design to advanced levels. Kafai and Peppler (2011, p. 89) write regarding participant driven learning communities that "Educators should be especially interested in DIY [do it yourself] communities given the amount of time youth voluntarily spend in intense learning as they tackle highly technical practices, including film editing, robotics, and writing novels among a host of other activities across various DIY networks". Such informal networks, such as those surrounding the program language Scratch used, among other things, for game development, are driven by student initiative, and fertile ground for the development of key competences and transversal skills like creativity and problem solving.
27
These activities are important because they give students more than a set of digital skills. They are opportunities for students to create, foster dispositions towards innovation and entrepreneurship as well as developing technology literacy. This is an important issue for critical citizenship. The argument is being made that traditional conceptions of computer competence are not longer enough Kafai and Peppler argue that, "we should be as equally concerned with "opening the black box" of digital technologies as we are about media ownership and controls issues... Such understandings are crucial for today's citizenship, as more aspects of life have moved into the digital domain" (Kafai & Peppler, 2011, p. 112). The challenge for schools systems is to facilitate access for all students.
Thus, the online environments listed in Table 2 should not be conceptualised as vehicles for students to develop technical skills only. Rather, they are free, openly available resources for promoting in young people the ability to create media, and also understand how media is created so that they can both contribute actively, and be critical consumers and citizens.
Table 2.: CREATIVE and CRITICAL TECHNOLOGY COMPETENCE: Examples of tools and communities for learning programming and creating media online
Hacksaurus.org A tool for remixing and examining the underlying design of websites aimed at teenagers
School of Webcraft From Peer to Peer University at p2pu.org, webbased, free peer learning on a variety of programming languages
Scratch.mit.edu A powerful visual programming tool, also used for creating art and games with a related community for educators, ScratchEd
Gamestarmechanic.com A website for making and designing games
Processing.org Supports programming in the visual arts
This participatory involvement in technology (Jenkins et al., 2006) has not been realized widely, yet it will increasingly become a part of participatory civic competence. Schools need to foster the capabilities of students to take part in creative, entrepreneurial work with technology, and doing so may necessitate the development of rigorous computer science curricula for all students (i.e., Goode and Margolis, 2010).
3.7. Hands on learning environments
Experiential learning is used to motivate and engage students. However, such environments are also important in developing interdisciplinary key-competences, such as innovative capacity and civic competence, as well as transversal skills like collaboration, problem solving, and self-management.
Example of one hands on program the explicitly aims to teach those transversal skills is the FIRST Lego league, popular throughout Europe and beginning with programs for students as young as six. Simple robotics clubs and competitions provide opportunities for students to collaborate, create, and use technology to solve problems. Some programs aimed at increasing student engagement have targeted even younger students (Cejka et al., 2006). In Belgium, Denis and Hubert (2001) analysed the collaboration of small groups of learners, 10 years of age, working on Lego robotics projects. They find students developing collaborative
28
skills, as well as 'strategic competencies', which they relate specifically to metacognition (Denis & Hubert, 2001, p. 467) along with skills such as computer programming.
At the secondary level, programs such as robotics clubs, offer the opportunity to manage team finances, engage in high level engineering, and access mentorship from community professionals, opportunities rarely available in a typical school. Furthermore, by engaging students in real problem solving within a social environment, students develop strong bonds and have the opportunity to develop key competences such as initiative, as well as transversal skills like cooperation, leadership and self-management (Saari, 2012).
Participants also seem to be showing increased understanding and interest in technology and science related fields (Welch and Huffman, 2011, Mellchior et al., 2005). The competitions are characterised by the depth of their difficulty and their open-ended nature. Such programs are also example of frameworks in which schools and local industry can create mutually enriching partnerships to foster key competences. However, they are not available to all students.
3.8. When and where should learning take place?
Jenkins et al., noting the promise of these afterschool clubs recommend that 'Afterschool programs should be a site of experimentation and innovation, a place where educators catch up with the changing culture and teach new subjects that expand children's understanding of the world' (Jenkins et al., 2006, p. 59).
Livingstone (2012, p. 21) describes the changes that occurring as our conceptions of where learning takes place expand: "...we are witnessing some genuinely new learning opportunities, centring on possibilities of child-oriented digital creativity and on collaborative communication with those who share similarly specialist or rich forms of interest and expertise." (Livingstone, 2012, p. 21). These environments not only teach specific skills, perhaps most importantly they are sites for learning transversal skills, developing creativity and the potential of offering complex and productive environments for learners. Their value might in part be that they are not connected to a particular time or place. This makes administering and ensuring equal access to such environments a challenge for policy makers and school leaders.
3.9. The difficulties of equitable implementation revisited: Administration, resources and the problem of equal access to innovative environments
The alternative environments discussed in this section are largely freely available programs and resources. Elsewhere we have mentioned the availability of open-source materials. However, accessing these implies not only the availability of computers or mobile devices, but of knowledgeable teachers who have the time in their curriculum to make use of these resources. Affluent schools are already doing so; the challenge to policy makers is whether or not to support less affluent schools in doing so.
The problem with these innovative environments is that it would be easy to leave students to access them, or not, according to their own interest, or lack of interest. But this also implies leaving student exposure dependent on a student's own resources—or lack of resources. Such an approach promises to widen the divide between students.
29
A curriculum-integrated approach, however, could enhance equal access, as, compared to after-school programs, integration has a higher potential for systemic impact (Repenning, 2012, p. 39). The United States National Science Foundation Innovative Technology Experiences for Students and Teachers (ITEST) program enabled the application of a gamedesign computational thinking (CT) strategy to middle school curricula in school sites in Alaska, California, Georgia, Ohio, S. Dakota, Texas and Wyoming. During implementation, over 10,000 games and simulations were created by students, which linked with the initial study aim for increased exposure and maximised participation. From a pedagogical point of view, scaffolding was found to be the main common factor supporting motivational levels and skills across different school contexts, gender and ethnicity (Repenning, 2012, p. 40).
Implementation of such an approach is likely to be local. Within Europe, the difference between schools varies greatly from country to country (Green, 2011). Thus an equitable implementation is more possible in some locations versus others. Even in comparatively equal societies such as Sweden, however, a proliferation of innovation, such as occurred with the advent of publically funded free-schools primarily at the upper-secondary level, also coincided with a rise in equality (Skolverket, 2003), perhaps as navigating the educational choices, and the quality of new programs became more taxing for families with less resources. Since then, Swedish policy makers have instigated tighter regulation.
For the sake of both innovation and equal access, schools should offer students the skills needed to take advantage of the exponential growth in participatory possibilities online and in their communities.
4. Key competences for teachers
4.1. Teachers, school culture and leadership are central
The research above highlights some of the methods research has revealed to be promising in promoting learners' development of key competences for the 21st century. The emphasis is on complex, open-ended learning environments, enabled by evolving technology and taking place in and outside schools. Rather than replacing teachers, this new ecology suggested here places new demands on teachers. In turn, the implication is that teachers will need meaningful support and training. Just as youth are asked to increase their skills in collaborative learning, networking and digital literacy, so their teachers must do the same.
4.2. Teacher Networks and Collaborative Learning
Collaborative learning is also important for the success of teachers. Programs such as the Helsinki Media Centre (Niemi et al., 2012) provide opportunities for teachers to share resources. This is particularly important because 'teaching with technology requires teachers to expand their knowledge of pedagogical practices across multiple aspects of the planning, implementation, and evaluation processes' (Ertmer & Ottenbreit-Leftwich, 2010, p. 260).

This learning is an on-going process; learning about technology is equivalent to asking teachers to hit a moving target. Teachers will never have "complete" knowledge about the tools available, as they are always in a state of flux' (Ertmer & Ottenbreit-Leftwich, 2010, pp. 260-261). Some schools, such as the KoulunMestarin Koulu in Espoo, Finland, have
30
embraced the idea of learning from students as well using students' expertise to facilitate technological integration.
4.3. Challenges for teachers
Over the past decades, research has repeatedly shown that individual teachers exercise important influence over the meaningful adoption of new policies and technologies. Prescriptive policies advocating, for example, the use of specific technological tools will not produce change in the classroom. Due to top-down measures, in some countries teachers can feel pressured to adopt technology, the use of which can seem forced, rather than coming out of a true pedagogical need (Hennessy et al., 2005, p. 170). Teachers may be more likely to adopt and integrate ICT if they see it as adding value rather than 'bells and whistles' (Hennessy et al., 2005, p. 172), that is, rather than being used primarily for appearance, or to be able to check a regulatory box.
In order to realize the transformation of the classroom suggested by key competences, then, particular attention must be played to supporting teachers as they work towards fostering a new complex ecosystem in their classrooms. Smith et al. (2012) considered the impact of technology on teachers' pedagogies to range from traditional+ (adding a new element to an existing classroom structure) to transformational. It is a transformational pedagogy that would include the sorts of activities indicated by the key competencies, learning activities that would use the new opportunities provided by technology to reach across the traditions bounds of the school and take advantage of open-ended learning in the community and the wider world. However, keeping the adoption of new technology and programs motivated by pedagogically is a key factor in the success of the model: '...the unavoidable challenges and disappointments with classroom technology have not been felt as keenly here: keeping the tools subservient to the teaching mission has kept "the horse before the cart" (Smith et al., 2012, p. 491).
Another challenge for teachers is the evaluation in these complex, individualised environments. There may be a mismatch between the instructional method, and outcomes as defined by local governments (Livingstone, 2012, p. 17). There is also the difficulty of monitoring students in ICT environments that have not been designed to do so (Hennessy et al., 2005, p. 171). New forms of evaluation may be more time consuming as well.
4.4. Key competences for Teachers
Investigations into the adoption of technology into education has been shown to be highly teacher dependent. It is likely that the successful adoption of technologically enabled key competences will follow similar patterns. While online communities may provide students space for independent and individualised learning, not all students will access these resources without the intervention of teachers as mentors. Some of the activities mentioned above that are most likely to promote the interdisciplinary and transversal skills are highly teacher dependent.
Just as students are encouraged to develop key competences, so must teachers be supported in developing competences and transversal skills. Somekh (2008) suggests giving teachers time to play with technology as a way of encouraging exploration and growth. Programs such as the European Project Teacher Education on Robotics-Enhanced
31
Constructivist Pedagogical Methods (TERECoP), engage students in the same open-ended learning opportunities recommended for students (See e.g., Alimisis 2009). In Taiwan, courses in Lego robotics were shown to increase pre-service teachers' self-efficacy, (Liu et al., 2010) and important factor in adopting new practices into the classroom.
It is important to note that what researchers find is not the skill of the teacher that is particularly important, but the relevance of the tool to the teacher pedagogically: 'This highlights the requirement for teachers to understand fully the affordances of a technology, not necessarily aiming for higher but for more purposeful technology uptake.' (Mama & Hennessy, 2010, p. 274). Simply demanding use does not result in transformation. It takes a supportive school culture.
4.5. Cultural and organizational support in schools
Successful transformations, such as those described by (Smith et al., 2012, p. 491) are dependent on a culture of support and resources. "We have argued that any facility supporting such collaborations is by its very nature as much a social system as any kind of technical system. Intentionally engaging in the support and furthering of the social dynamic is productive, sustaining participation and continuation of participants over time, and sustaining a welcoming and supportive environment for individuals or working groups to explore new ways of teaching and working.'
Indeed, in an extensive research project in Finnish schools, Niemi et al. (2012) found that the success was dependent on the school culture, particularly one that valued sharing, teamwork and risk-taking. That is, the environment of the teachers reflected the environment sought for students, one that combines collaboration and the initiative of entrepreneurship. Thus it is important to focus on the support and environment in which the integration of new classroom structures occurs: 'The wider implications entail a shift away from a technologically-driven model of ICT integration towards one based on teacher involvement. This means an emphasis on developing and sharing pedagogic expertise concerning ICT use in subject teaching and learning...'(Hennessy et al., 2005, p. 187). Ultimately, for students to access, though school, the complex and open-ended learning environments that seem poised to best promote the transversal skills outlined above, teachers need support in continuous, iterative learning and the time and space to engage in peer-to-peer networking in order to take advantage of emerging programs and learning opportunities for their students. Part of the support for the development of school and teacher level competences can be furthered through innovations in the relationship of universities and education research with teachers and schools, discussed in the next section.
5. Using resources effectively
5.1. Taking a long view of technology investment: mobile technology, open source and freely available programs
While currently facing barriers to implementation, in the long run, mobile technology may be a more affordable solution for educational innovations as smartphones decrease in cost. Already, developing countries are looking towards mobile technologies as an efficient way of fostering access to learning (Haßler, Hennessy, Lord, Cross, Jackson, & Simpson , 2011).
32
While technology without context will not foster Key Competences, increasingly students without access to the interactive online world will be at increasing disadvantage. Mobile devices, cheap and more replaceable elements like interactive whiteboards and desktop computers, are a rapidly evolving alternative.
Technology innovation need not be expensive. If teachers are given the support and time, open source alternatives (Haßler & Jackson, 2010) exist for nearly all commercially available programs and operating systems. Tools like GeoGebra (Hohenwarter, 2006), an opensource program for mathematics that surpasses commercially available tools, also provide gateways into students developing technology competences, as they have the opportunity to contribute to their development.
Finally, and again depending on the availability of hardware, free tools for video conferencing, video editing, chatting and so on provide opportunities for students to develop language competences, but also civic competence and gain intercultural experiences. Curating such activities, however, is not an easy task, and teachers need the time and resources, and perhaps most importantly the space created by alternative assessments, to engage their students in these environments.
5.2. Fostering complex learning environments means funding educational projects with multidisciplinary goals
In the previous sections, examples of learning environments that have been shown to address key competences and transversal skills have been given. One of the overarching themes emerging from education science gathered here is that these learning environments reach several key educational goals simultaneously. For example, the French language learning program researched by Fisher, Evans and Esch (2004) referred to previously did not only give students access to peer learning with native speakers, it also was a site for learning autonomous working skills (independence and self-management) as well as developing civic competences like intercultural understanding. Such programs suggest that funding should not be given for each competence. Rather it suggests the need to support schools and teachers in developing integrated approaches. While many of the examples given here are made possible with technology, the use of technology does not simplify the teacher's role in designing these learning environments, scaffolding student progress, and evaluating complex outcomes. Rather, these suggestions imply that the role of the teacher is more demanding, and resources must be allocated accordingly.
5.3. Ensuring equal access to new educational environments
Some of the learning environments that look most promising for the development of key competences are either expensive, or based in spaces outside of school. As such, funding structures must work to extend these opportunities to less advantaged students. As Livingstone (2011, p. 20) argues, ' ...new opportunities, especially if they rely on out of school resources, generate new inequalities. Only publicly funded institutions, schools especially, but also youth and community centres, can work to make this fairer.'
Secondly, teachers at all schools, not only well-resourced schools, must be supported in accessing resources such as networks and grants that will enable them to grow their curriculum in innovative ways. However, this is also problematic, as discussed above. More active teachers at better-resourced schools are more likely to have the time and skills to be
33
successful in grant applications. Less active teachers may be in need of the most help, and yet they are the least likely to access resources. Thus, there is the potential of funding to exacerbate existing inequalities (Green, 2011). As the Swedish case of free-schools demonstrates, the proliferation of innovation can coincide with increasing inequality (Skolverket, 2003) even in a comparatively equal society such as Sweden.
An example of coordinated efforts of local and educational authorities to encourage active participation in innovative learning environments are the cases of Kirkkonummi schools in Helsinki, Finland, and the 2
nd
and 6
th
Primary schools in Artemis, Attica, Greece. In these areas, fund allocation aims to increase access and thus benefit less technologically savvy schools, a shared vision and goal for local authorities, school administration and teachers. The integration plan is still in progress and, therefore, it is left to implementation and project evaluation to show in what ways and to what extent technology-enhanced tasks and activities promote key-competence development.
Seemingly, shared vision and technology are significant aspects in mobilizing change processes inherent in a competence-based pedagogical framework. School change, however, requires the synergy of multiple resources to be a tangible goal. The findings of a study on the integration of Key Competences in six Normal Schools in New Zealand (Boyd and Watson, 2006) suggest that only a realistic, multi-dimensional competence-based plan can facilitate change, i.e., one that links new with established school practices; that combines real-world with virtual environments aiming for authentic learning experiences; that allows for teacher integrated planning, experimentation and reflection; and that enables students to connect their in- school with out-of-school lives. Embedded within change management, then, is the management of both human (i.e., teachers and students) and non-human resources (e.g., funds, time, materials, space) between and across schools at the local, regional and national level.
6. Implementation of learning programmes for key competences
The teaching methods outlined for the production of key-competences can be described as being oriented towards interdisciplinary, cross-subject teaching, team oriented learning, individualised approaches (e.g., individual study plans) and project-based work. (Gordon, Halasz, Krawczyk et al., 2009, p. 162). These approaches are already used by many educators, but widespread implementation will mean a change in culture for many schools, particularly schools in challenging environments. Such approaches demand flexibility at the national, local, and classroom levels. Furthermore, to realise the potential of local partnerships, implementation plans must recognize the complexity of the school context. That is, top down, one-size fits all approaches are unlikely to work, and furthermore they would limit the potential of schools to take advantage of their local contexts. Rather, a leadership environment must be created at the national, local, and school level where diversity and innovation can be supported. What is needed is not a one-time reform followed by stasis. Rather, it is to develop the habit of perpetual revolution: a system structure that encourages constant innovation.
34
6.1. National, regional, and institution level dimensions
Such an approach implies a flexible national curriculum (Gordon, Halasz, Krawczyk et al. 2009, p. 221), as is the case in Finland, and systems of evaluation that take complex, project-based learning into account. At the regional and local level, successful implementations have demanded collaborations between administration, universities, and schools. Innovative environments require collaboration and support in order to flourish, as studies in Finland regarding the pedagogical integration of technology have shown (Niemi et al., 2012).
International examples of successful, collaborative projects for promoting key competences include the River City project, based at Harvard University in the United States. An interdisciplinary, inquiry based project in an online, collaborative environment, the project implementation required researchers to modify the program for different school environments, and develop on-going relationships with educators and administrators (Clarke & Dede, 2009). Detailing the development of a new, rigorous and inquiry based learning curriculum in Los Angeles, California, Goode and Margolis (2011) describe an iterative process, dependent on strong relationships between researchers, administrators and teachers that was highly dependent on individual school environments.
In another example of networked researcher and educator collaborations, in Finland, Mylläri, Åhlberg and Dillon (2010) researched a network developed through the Environment and School Initiatives programme and as part of a United Nations Educational, Scientific and Cultural Organization (UNESCO) initiative to promote education for sustainable development. Using online collaboration tools to support educators and best practices, the research concluded that a centralized, "expert centralisation" (p. 384) of a collaborative network was beneficial. Community building was also seen as critical for long-term benefits of the programme (p. 386).
Indicative of the need for policies of educational and research environment integration in cooperation with the surrounding community is the case of Linnaeus University in Sweden (Tågerud, 2010). Linnaeus, being the offspring of the Kalmar and Växjö University merge, as Tågerud (2010, p. 57) discusses, would need to maintain the holistic view and strategic goals by combining positive experiences from "parent" institutions. Of these, Kalmar University had adopted a connective approach at an inter-institutional level in the process of redefining pedagogical competence and providing a description of the expected documentation. To achieve this end, discussions held at Kalmar were used; also the model for Lund University's Faculty of Engineering; the formulations from Uppsala University; and the definition

developed in the Mälardalen University project along with the inspiration day held in November 2008 at Kalmar University within the framework of the project "Strategic Development of Pedagogical competence". Building upon foundational work toward the establishment of its own policies and principles, then, Sweden's youngest University bears the culture developed within and across some of the country's institutions with regard to the development of its teachers' competences.
Competence, however, changes over time and generates the need for encompassing adaptation and development strategies that supersede the formal education level and combine joint local, regional and trans-sectorial initiatives. In the Netherlands (ECBO, 2008), for example, learning and working 'infoshops' are implemented at local/regional level aiming to provide 'life-long learning' incentives to the employed, unemployed and those receiving social security benefits. The programme is the outcome of collaboration between the
35
Ministries of Education and Social Affairs and involves the Employment Service, benefits agencies and municipal councils. The 'infoshops' are intended for anyone with questions relating to study, career advice, competence testing, etc. Initiatives at sector level known as 'career projects' (e.g., for construction workers, the painting and decorating trade etc.) serve similar purposes.
Evidently, the multi-level interaction of implementation strategies for competence development, as discussed in Gordon et al. (2009), is a complex process that involves not only horizontal exchange of actors at the macro-, meso-, and micro-level. Of equal significance, is also a vertical collaboration, between and among policy makers, curricula planners, administrators, university and schoolteachers, and life-long learning organizations.
6.2. Scalability
The studies mentioned here are examples of implementations of new, complex curricula that meet some of the criteria of educating for key competences. They involve long-term, iterative collaborations between administrators, educators, and researchers. Such designs do not lend themselves to traditional methods of education research, nor are they easily spread from a top down approach. Rather, they demand a shift in the relationship between universities, administrations, and schools. One framework for such partnerships can be found in the literature surround design-based research in education, which Sandoval and Bell (2004, p. 201) describe as an ideal method for studying new technologies and complex learning environments within the ecologies of authentic, real-life classrooms. Furthermore, it is a `` methodology designed by and for educators that seeks to increase the impact, transfer, and translation of education research into improved practice.'' (Anderson & Shattuck, 2012, p. 167). However, it requires an on-going relationship between the researchers and the researched.
The River City project mentioned above, for example, firmly situates the program with design-based research, noting a design that shifted ownership of the project from researchers and developers to users, and established strong bonds between researchers and schools (Clarke & Dede, 2009). However, the researchers and developers are positioned here as key agents and disseminators of curricular innovation. As the work by Mylläri, Åhlberg and Dillon (2010), also suggests, universities and education researchers, then, are also important as agents for scalability of innovative curricula and pedagogical practices.
Just as key-competences requires school systems and teachers to re-think the evaluation of students, so does it require researchers to reconsider school-university partnerships as well as the aims and requirements of education science within the academy. Developments of key competences also imply an increased tolerance for innovative learning environments, including schools learning to take advantage of informal and non-traditional learning spaces.

46

1. Approaches to implementation at system(ic) level:

1.1 Curriculum design and implementation (frameworks, etc.)

1.1.1 The different country approaches

This section draws essentially on the work of the Gordon et el (2009) report on key competences and provides a background about the approaches used by EU member states with some examples of the content they put behind the terms in use and also makes use of data collected for Leney et al 2008 on the Shift to Learning Outcomes.

7

The data comes from
the country fiches prepared for the study. The document in Annex 1 is a "mapping" of major categories of terminology about competences and skills used in the EU 27.
Although it is not easy to establish a typology of the policy formulations regarding key competences, it is possible to propose a rough classification by taking the dominant approach in each country as a criterion. It is illustrated in the table below and then more detailed explanations are given.

Functional approaches:
Mostly skills or competence-based
Cyprus, Germany, Ireland, Lithuania, Poland,
Slovenia, and United Kingdom.
Mostly subject-based Bulgaria, Italy, Malta and Portugal
Thematic approaches

Mostly through major issues of society Denmark and Slovakia
Mostly through developing personal qualities Austria (primary school), the Czech Republic, Greece, Hungary and Luxembourg
Goals and principles based Finland, Latvia, the Netherlands and Sweden
(see Annex 3)
Mixed approach (functional and thematic) Belgium, Estonia and France.
Source: G. Halasz & A. Michel (2011)
The acquisition of key competences by every young person is one of the long term objectives of the Updated strategic framework for European cooperation. The focus is on acquiring

7
Gordon et al. Op cit. and Leney et al (208)
47
learning outcomes for professional and private life in a perspective of lifelong and life-wide learning. Emphasis is placed on the quality of teachers and on the autonomy of schools which should be open to civil society and enterprises and put in place appropriate approaches to quality assurance.
For the countries that specifically used the term "competences", there is, firstly, general agreement that it is about the application of knowledge and skills and secondly that it includes knowledge, skills and attitudes. In Portugal competence relates to the integrated development of skills and attitudes conducive to the use of knowledge in different situations (familiar or not). That is the third aspect included in definitions. Furthermore in Portugal the notion of Competências essenciais (essential competencies) refers to the body of general and subject specific knowledge that is considered indispensable for all citizens in today's society. In particular, it is essential to identify the knowledge which enables pupils to develop their understanding of the nature of each subject and its processes, as well as a positive attitude towards intellectual activity and the practical work it entails. In the Maltese system, 'Competence' is the proven ability to use knowledge, skills and other abilities to perform a function against a given standard in work or study situations and in professional and/or personal development. This definition introduces a fourth notion, that of a standard to be reached. In Italy, knowledge and abilities are defined that each pupil will turn into personal competencies with the help of the school. They are indicated for each subject and cycles of primary education. This is perhaps a fifth notion that competence is individual.
The notion of key competences (AT, BG, CY, CZ, DK, LT, MT, NL, RO, SK, Slgenerally refers to subject-independent competences which are seen as providing a "core" or basic set (as in Spain) or a "foundation" (as in Belgiium-Fr, France and Luxembourg with the "socle" of competences). In France the "socle" includes both the discipline based and cross-curricular aspects. The French "socle" emphasises that it is the basis on which lifelong learning can be constructed which is an important element in terms of the purpose of the reforms and in line with the EU policy thrust. The Danish example of the definition of key competences is interesting as it makes explicit their role "acting as axes of rotation, activating professional competences and serving as a pre-requisite for the acquisition of professional competences". In Slovenia key competences include: Learning to learn, Social skills, ICT, Planning and developing career, Entrepreneurship, Environmental responsibility, Safety at work.
Cross-curricular key competences are explicitly defined in the German system as general (subject-independent) competencies essential in order to operate effectively at personal and professional level. They are not limited to cognitive abilities and represent complex operational competencies. They:
- are required for and supported by different subjects and subject areas,
- help solve complex, holistic tasks in real-life contexts,
- can be transferred to new situations not covered by the curriculum,
- can be characterised as general abilities.
In Austria, the term, dynamic skills (Dynamische Fertigkeiten) refer to subject-independent transversal competences which introduces a nice sense of interaction and development. In the Netherlands they are referred to as core objectives (which relate to subjects) and general objectives (which are cross-curricular). We come back to the reference to objectives later in the section.
Taking one country as an illustration, Estonia clearly differentiates between general and the domain-specific competence and cross-curricular themes. General competence
48
(üldpädevus) is used in the national curriculum and consists of four competences (learning, activity, value and self-definition competence) while domain-specific competence (valdkonnapädevus) consists of seven that should cover each aspect that a person has with the world surrounding him/her as well as her/himself. Finally the compulsory cross-curricular themes (kohustuslikud läbivad teemad) are not taught as a separate subject but have to be covered while learning other subjects.
Reform in Hungary with the inclusion of key competences in the primary school curriculum demonstrates in an interesting manner one possible expression of cross-curricular key competences. Most of them are expressed as capabilities and the notion of values is included.
Hungary: the strategy of the ministry contained a list of specific key competence to be developed in primary school:
☐ the capability of using various learning techniques
8
☐ the capability of intelligent learning
☐ the capability to apply knowledge
☐ instrumental competences (like communication, mathematics or ICT-related competences)
☐ social competences
☐ value orientation (the capability to understand and use norms and values) "
It is interesting to compare that list to the notion of essential used in Portugal: "it is essential to identify the knowledge which enables pupils to develop their understanding of the nature of each subject and its processes, as well as a positive attitude towards intellectual activity and the practical work it entails" in so far as the two approaches appear to differ on the importance placed on content or process competence.
In Finland (similarly to Estonia) the cross-curricular aspect is through themes that are educational challenges with social significance. At the same time, they are current statements on values. In practical terms, cross-curricular themes are policies that structure the upper secondary school's operational culture and priority areas that cross subject boundaries and integrate education. They deal with issues concerning the way of life as a whole. For the upper grades of basic education, the cross-curricular themes are:
☐ Growth of the person
☐ Cultural identity and internationalism
☐ Media skills and communication
☐ Participatory citizenship and entrepreneurship
☐ Responsibility for the environment, well-being and a sustainable future
☐ Safety and traffic competences
☐ Technology and the individual
The above examples all refer either to the idea of a foundation which underpins the curriculum, or are intended as threads running transversally across it.

8
This notion is considered to be close to "learning to learn".
49
The Lithuanian example is interestingly different as recent reforms, while stressing the need to develop citizenship, entrepreneurship, digital competences, learning to learn and cultural awareness competences, also state that to ensure the quality of education development the content of education need to be related to new competencies of an individual. The orientation is towards the development of general abilities, values, the provision of the necessary competencies based not so much on the transfer of knowledge, as on their analysis, critical assessment and practical application; such competencies shall relate the contents of education to actual life, actual problems and their solutions.
The question is whether those countries using the term "skill" are close to the above notions or to the definition of Chisholm (2005): a skill is "an ability, usually learned, and acquired through training to perform actions which achieve a desired outcome". In Hungary the term "kompetencia" is a frequent synonym of "képesség" which might be translated as aptitude or skill. In Austria, the term basic skills (Grundfertigkeiten) is used to convey the notion in its broadest sense. The terms skills, core skills and key skills are the common ones in use in the four countries of the UK and in Ireland all of which are very similar in the choice of skills to highlight in the schools' curriculum. While Ireland has developed a separate (though similar) framework for each age group (primary, junior secondary and senior secondary), Wales has one framework from age 3 years to 19. The skills embedded into the curriculum contain many elements present in the cross-curricular key competences in the EU framework including the aim that young people should become "full, active and responsible" members of society (see below Scotland). The ideas contained in learning to learn, entrepreneurship and interpersonal and civic competences in the EU framework are present in these different formulations of core/key skills. The emphasis is quite strong on personal "capabilities", a term used specifically in the Northern Ireland curriculum which has echoes of the Chisholm definition.
Like the French "socle", the Northern Irish curriculum puts explicit emphasis on the development of skills and capabilities for lifelong learning as well as for contributing effectively to society. These whole curriculum skills and capabilities consist of the CrossCurricular Skills (Communication, Using Maths and Using ICT) and Thinking Skills and Personal Capabilities - TSPCs - (including Managing Information, Thinking, Problem Solving and Decision-Making, Being Creative, Working with Others, and Self-Management). These skills are embedded and infused throughout the revised Northern Ireland Curriculum at each key stage and it is intended that pupils have opportunities to acquire, develop and demonstrate them in all areas of the curriculum. The notion of capabilities is linked here to a set of skills with quite a functional orientation while it is linked to a set of competences in the case of Hungary (see above) with a more transversal focus.
The Irish Key Skills Frameworks:
Primary - the ability to: Question, Analyse, Investigate, Think critically, Solve problems
Junior secondary: Interact effectively with others: Communication and literacy, Numeracy, Manipulative skills, Information technology, Thinking and learning, Problem solving, Personal and interpersonal, Social
Key Skills Framework senior cycle: Information processing, Critical and creative thinking, Working with others, Communicating, Being personally effective.
50
Scotland – Core Skills:
Core Skills describe the broad, transferable skills that people need to be full, active and responsible members of society. The core skills include:
☐ Communication
☐ Numeracy
☐ Problem solving
☐ Using information technology
☐ Working with others.
One country that explicitly mentions cross-curricular, transversal skills is Poland for primary education. They reflect the cross-curricular elements of the EU framework and include:
1. planning, organising and assessing pupil's learning, taking responsibility for one's learning process,
2. effective communication in various circumstances, presenting one's viewpoint and acknowledging the views of others, proper use of language, preparation for public presentations,
3. effective cooperation within a group, building interpersonal relations, taking individual and collective decisions,
4. solving problems in a creative way,
5. searching for, ranging and using information from various sources, effective usage of ICT,
6. using the acquired knowledge in practice an creating of necessary experiences and patterns of behaviour,
7. developing personal interest, acquiring methods of negotiating and solving conflicts and social problems.
A third group of countries define goals and objectives. Flanders defines development (Ontwikkelingsdoelen) and final (Eindtermen) objectives. Whereas developmental objectives are minimum objectives which the education authorities consider desirable for a specific pupil population, the final objectives are objectives with regard to knowledge, insight, skills and attitudes, which the educational authorities consider necessary and attainable for a specific pupil population. Similarly the Swedish system is geared towards the idea of 'steering through goals' which are decided at the central level though it is the responsibility of the decentralised authorities (such as the municipalities) to fulfil these goals. There are goals to strive for (quality of education process) and the goals to be attained (learning outcomes). Amongst the goals, the knowledge, skills and attitudes corresponding to particular key competences are found. The goals are not ranked in terms of importance and hierarchy and present a range of capabilities or qualities or skills or competences that is broad and developmental. These goals cover all aspects of education from pre-school through to the end of secondary education. (See Annex 1 for the list.)
Another system in which the competences are implicit in the goals is Latvia which has goals common for all general secondary education and which, among others, aim to encourage the development of the student's personality and of their physical and mental capacities, and to develop their understanding of health as a condition for the quality of life; They also aim to encourage the development of positive, critical and socially active attitudes, and to develop
51
understanding of rights and obligations of Latvian citizens; to develop the ability to study independently and improve knowledge as well as create motivation for lifelong learning and a purposeful career. The latter group are very similar to cross-curricular key competences mentioned earlier in the section.
In Hungary the National Core Curriculum also refers to basic goals which include the development of key competencies as well as a number of other areas. It also contains the principles which underpin and structure the NCC. The NCC published in 2003 also contained a thesaurus which defined the notion of "competence-based" and the relation between "competence" and "knowledge". According to this, "The 'competence based approach means a commitment that determines the taxonomy of the curriculum. In the background of this approach there is a theory of personality which considers the competences (personal, cognitive, social and special competences) as the main components of the personality... [This approach] links the competences to specific activities and tasks that are achieved by the human being: someone is competent in relation with an activity if he/she is capable to achieve the tasks related with this activity." This was the basis for restructuring the NCC so that instead of the element of national culture ("knowledge") it was focusing on specific developmental tasks that are supposed to develop specific competences.
Two illustrations of a values base are included here while bearing in mind that these are policy statements; the mechanisms and tools of implementation may produce outcomes other than those expressed.
In Finland, for example the values base is very strong and clearly stated.
Students will be educated in tolerance and international co-operation. Upper secondary

school instruction is based on respect for life and human rights. The educational ideal of the upper secondary school comprises the pursuit of truth, humaneness and justice. General upper secondary education must promote open democracy, equality and well-being. Students are seen to be the constructors of their own learning, competence and views of the world. Instruction must take into account the fact that human beings observe and analyse reality using all their senses. Educational work will place emphasis on co-operation, encouraging interaction and honesty. The aim is for students to know their rights and responsibilities and to grow to assume adult responsibility for their own choices and actions. During their upper secondary school years, students must be provided with experiences of how to shape the future through joint decisions and efforts. Upper secondary school instruction must encourage students to recognise conflicts between stated values and reality and to ponder critically the disadvantages and opportunities of Finnish society and international development. During their upper secondary school years, students must become able to form a structured understanding of basic civil rights in Finland, the Nordic countries and the European Union, their meaning in practical terms and ways to uphold and promote them. Upper secondary school must highlight the principles of sustainable development and provide capabilities to face the challenges posed by the changing world. The basic values of upper secondary school are consolidated by the cross-curricular themes set out in Section 5.2, which are value-based positions on current challenges in education and schooling.
England: values underpinning the curriculum:
52
Education should reflect the enduring values that contribute to personal development and equality of opportunity for all, a healthy and just democracy, a productive economy, and sustainable development. These include values relating to:
- the self, recognising that we are unique human beings capable of spiritual, moral, intellectual and physical growth and development
- relationships as fundamental to the development and fulfilment of ourselves and others, and to the good of the community. We value others for themselves, not only for what they have or what they can do for us
- the diversity in our society, where truth, freedom, justice, human rights, the rule of law and collective effort are valued for the common good. We value families, including families of different kinds, as sources of love and support for all their members, and as the basis of a society in which people care for others. We also value the contributions made to our society by a diverse range of people, cultures and heritages
- the environment, both natural and shaped by humanity, as the basis of life and a source of wonder and inspiration which needs to be protected.
At the same time, education must enable us to respond positively to the opportunities and challenges of the rapidly changing world in which we live and work. In particular, we need to be prepared to engage as individuals, parents, workers and citizens with economic, social and cultural change, including the continued globalisation of the economy and society, with new work and leisure patterns and with the rapid expansion of communications technologies.
Some issues arising:
The different approaches in the EU countries cover a broad variety of skills, competences, values, themes, etc. but the following aspects are less or not at all present:
- The need for students to understand about how one learns best, that is one's individual learning patterns and preferences, is not well developed.
- There is little reference to the need to develop a sense of self and of understanding of self. The main references are the interpersonal skills/competences with a strong emphasis on interactions with others, social aspects, etc. This is well-covered in the psychological literature but not well adapted into learning frameworks.
- Few of the definitions and usages refer to values, to the values with which children and young people will relate to each other and to the world around them.
- The relationship to the environment in both senses: the wider world around and issues of the survival of the planet are dealt with in a limited manner.
Country Example: Scotland
This example is presented since the curriculum is built out of the overarching framework of aims and principles of the Curriculum for Excellence which aims to achieve a transformation in education in Scotland by providing a coherent, more flexible and enriched curriculum from aged 3 to 18 and includes the totality of experiences which are planned for children and young people through their education, wherever they are being educated. The purpose is encapsulated in the four capacities - to enable each child or young person to be a successful learner, a confident individual, a responsible citizen and an effective contributor. To reach these outcomes it is recognised that children need to be safe, healthy,
53
achieving, nurtured, active, included and respected and responsible which is illustrated in the following wheel. This is an example of taking a holistic perspective of children as foundational to the learning activities and content. It links formal education with health and well-being outcomes and to this end support has been developed practitioners in all sectors and services and in local authorities.
http://www.educationscotland.gov.uk/thecurriculum/whatiscurriculumforexcellence/index.asp
54
1.1.2 How have approaches been designed?
This section presents 3 examples of how key competences have been introduced into national systems: Spain, Poland and France. The Spanish and Polish examples refer to articles published in the European Journal of Education, vol. 46, No. 3, September 2011 on Key Competences in Europe. They present different contexts and approaches. The article on Spain illustrates a government led approach through a core curriculum while the Polish example illustrates the influence of international bodies on the school curriculum in transition countries. The French example refers to articles published in the Administration et Education, the journal of the French Association Française des Acteurs de l'Education, No. 2 2012 that focused on l'Ecole du Socle (the foundation of competences). It is an example of an iterative process over quite a long period between expert groups and government steering.
SPAIN
A. Tiana, J. Moya & F. Luengo, "Implementing key competences in basic education: reflections on curriculum design and development in Spain" (EJE, 3/2011)
The authors observe that in Spain the reference to competences, understood as a way of defining educational intentions, was introduced almost simultaneously in the curricula of basic, compulsory and higher education (Bolivar & Moya, 2007). In the case of school education the Recommendation of the European Parliament and of the Council of 18 December 2006 on key competences for lifelong learning was very important whilst for higher education the key influence was the Bologna Process. Tiana et al point out that in both cases, "the incorporation of competences seeks to underline that the knowledge acquired at school or university cannot be easily transferred outside the educational context and that there is a lack of systematic work to develop basic skills that permit reaction to the
55
changing situations of life and work which require complex responses". The Organic Education Act (LOE, 2006) was being drafted, debated and passed at the same time as the preparation of the European Recommendation, hence the reason that Spain was one of the first EU member states to include a reference to key competences in their legislation. Prior to this, the notion of competence had been used in vocational training in Spain in the 1990s and was given a legal basis through the Organic Qualifications and Vocational Training Act of 2002 (LOCFP, 2002) in which professional competence was defined as "the set of knowledge and skills that a professional activity to be exercised in accordance with production and employment demands", whereas a professional qualification was defined as "the set of professional competences with significance for employment that can be acquired through modular or other kinds of training and through working experience".
Consequently key competences were also included in the law in reference to student assessment, diagnostic evaluation and qualification at the end of Compulsory Secondary Education so that competences served both as a reference to assess educational results and included in grade promotion and certification on completion of compulsory education. However the legislation did not specify what these key competences should be. This was carried out subsequently and gave rise to the establishemnt of the enseñanzas mínimas (core curriculum).
enseñanzas mínimas
"the Spanish education system is highly de-centralised and curricula are drawn up on a shared basis. Initially, the central government sets out the basic aspects of the curriculum, in other words, it determines the objectives, key competences, contents and evaluation criteria for each level, cycle or year and subject. These elements, thus defined, are known as enseñanzas mínimas, a misleading expression, which many interpret as 'minimum education' that all students must acquire, although this is not its meaning. In reality, they represent a core curriculum which must be respected throughout the State. Subsequently, the Autonomous Communities established the curricula for each level, cycle, year, area and subject, which must necessarily include the enseñanzas mínimas defined by the Government nationwide (this is the true meaning of minimum). These curricula then serve as a reference for schools in every Autonomous Community. On the basis of these curricula, schools and teachers draft their respective projects for each grade, area or subject. This curricular development process, carried out in several successive phases, ensures that both Government and Autonomous Community responsibilities are respected, giving schools their margin of autonomy and teachers their academic freedom. With this cascaded decision system, where each decision is derived from a previous one and included in it, the initial curricular design is given shape and permitted to grow in depth and breadth, whilst avoiding the many obstacles that may arise in its path and allowing adaptation to the specific environment through which it flows.
Once the law had been approved, the government defined the key competences that all students must develop by the end of compulsory education for primary and compulsory secondary education in Royal Decrees. Given that this approach was very new, it was decided to proceed "cautiously and gradually". The Royal Decrees provided a general framework with the description, purpose and distinctive aspects of each key competence, as well as the development level which should be reached by all students on completion of their basic education. They include how each knowledge areas in primary education and subject in compulsory secondary education contributes. This was a break with standard practice in
56
which curricula established objectives, contents, methodology and evaluation criteria for each area and subject.
At the school level the authors point out that the curriculum developed by the school will be the set of experiences offered to its students which is qualitatively different from curricular design and cannot be "reduced to the decisions adopted by public authorities when selecting learning (key competences, objectives and evaluation criteria) and the related cultural elements (curricular areas and contents). Curricular design conditions but does not determine the school curriculum, as there is considerable scope for freedom and responsibility to transform curricular design into real curricula." Hence in this context the importance of school autonomy and education practices if the construction of an integrated curriculum is to be adapted to the specific conditions and characteristics of each school which become organisations run on a project basis. Thus the authors also insist that this is fundamentally about how they manage their own resources and activities on the basis of their own projects. The importance of schools becoming learning associations is underlined and the authors emphasise that "The integrated development of the curriculum to whatever level a school can attain has a single purpose: to increase learning opportunities and improve the results of each and every student."
POLAND
M. Dabrowski & J. Wisniewski, "Translating key competences into the school curriculum: lessons from the Polish experience" (EJE, 3/2011)
This article which focuses on general education in primary and secondary schools is set in the context of the transition process in Poland in which the challenges to education and learning have been compounded by major economic and social changes and the democratisation of structures and processes. It was written by authors who played a significant role in this period. The article underlines the complexity of the reform process and how the introduction of outcomes based approaches and key competences have affected mindsets and attitudes of all the functions and actors in the education system (governance, the role of principals and teachers, teacher training, parents, etc.). "Polish schools in the second half of the 20th century were institutions where encyclopaedism, teacher-oriented classrooms, and lack of autonomy and democratic procedures prevailed."
Though the process of education reform was at the outset limited it had a great symbolic value for Polish society as it was assumed that "values such as democracy, freedom of the individual, respect for the law, and tolerance should form the basis of the education system. Promotion of these values could be achieved by including them in the curricula and in the way schools operated, including organisational and teaching culture. These aspects of school operations also created the conditions for developing key competences." Lack of funds and the economic situation created a major obstacle which included reducing the number f teachers and the class hours, etc. while maintaining all subjects and this led to the need to establish minimum curriculum requirements which turned out to be the first step in developing a core curriculum.
The debate on key competences started in Poland due to the results of the International Adult Literacy Survey (IALS) in 1994 which caused dismay and led to an initial list of competences being developed for Polish schools in 1996. They were: preparing for team work, preparing for oral and written communication, preparing for using the latest information media, problem-solving skills, and preparing for continuous learning, retraining and re-
57
skilling. This debate about using competences at work and in social interactions also led to reflection on how to measure competences and evaluate their acquisition. Thus the IALS results and the debate were the "beginning of a new paradigm to define goals for the education system' and was made concrete in the Kreator project launched in 1995 with EU Phare funding. It aimed at developing a method for including specific key competences in the teaching of individual subjects and applying adequate methods. The competences defined were: planning, organising and assessing one's learning; successful communication in various situations; successful teamwork; constructive problem solving; and proficient use of computer and Internet technology. This project, which unfortunately only lasted as long as the EU funding, also looked at the organisation of lessons in order to better support pupils' acquisition of knowledge and development of competences. See box below:
1. Commitment: During the first stage of the lesson, its topic is clearly presented, which motivates students. It is important to accurately formulate the goals and instructions and create an atmosphere that is conducive to commit students to problem solving. The organisational framework of the class is established at this stage (e.g. students are divided into groups).
2. Researching: Students individually analyse the tasks. This stage is devoted to discussion, analysis, negotiations, and relating to previous experience and acquired knowledge. Hypotheses are made and doubts are voiced. Teachers become observers and listeners; they verify how much knowledge and experience students contribute.
3. Processing: At this stage of the lesson, knowledge gained at the previous stage is organised and used in a creative manner. Students present their proposals as to how to

solve the problem they have faced. The success of this stage is subject to cooperation by students, their inventiveness and commitment. They deepen their understanding of the problem, assimilate knowledge and learn how to use it.
4. Presentation: At this stage, representatives of individual groups report on the results of their work to a wider audience, be it a class or group. When presenting the results of group work, students can compare the solutions that have been applied to a given problem and results achieved by other teams.
5. Reflection: The closing stage of the lesson is indispensable and very demanding on the teacher and students. Students conduct self-assessment, define what and how they have learnt, the purpose of the working methods adopted and how they could continue the work and use the acquired experience. Students and the teacher attempt to answer the following questions: What have we done? What have we achieved? What could we have achieved? What were the principles for our learning? How can we use the experience?
The Council of Europe also had an influence in Poland through the results of its symposium on Key Competences for Europe in 1996 which defined five sets of key competencies with which schools should "equip" young Europeans (Council of Europe, 1996). See box below:
1. Political and social competencies such as the capacity to accept responsibilities, to participate in group decisions, to resolve conflicts in a non-violent manner, and to play a part in running and improving democratic institutions.
2. Competencies relating to life in a multicultural society, such as accepting differences, respecting others and the capacity to live with people of other cultures, languages and religions.
58
3. Competencies relating to the mastery of oral and written communication, which are essential for work and social life to the point that those who lack them are henceforward threatened with social exclusion. In this same register of communication, the mastery of more than one language is taking on growing importance.
4. Competencies associated with the emergence of the information society. The mastery of these technologies, the understanding of their applications, strengths and weaknesses, and the capacity for critical judgement with regard to information disseminated by the mass media and advertisers.
5. The capacity to learn throughout life as the basis of lifelong learning in both occupational contexts and individual and social life.
This informed the work of a group of experts set up in Poland by the Ministry of Education and which led to Regulation no. 8 on Core Curricula for Obligatory General Education Subjects (1997), which was the first of its kind in Polish legislation on education.
"Its philosophy and structure differed greatly from previous solutions. The education process was divided into two- or three-year stages which replaced the traditional division of curriculum into one-year cycles. The curriculum was divided into 21 subject areas, including those which were totally new for Polish schools, such as media education, health education, reading education and information education. It is clear that some of these subject areas were closely related to cross-curricular key competences." One important aspect was that the document addressed schools and not individual teachers. However a change of government led to its implantation being delayed till 1999 and then modified going back to instructions for individual teachers.
FRANCE
C. Lelièvre, "La difficile (et chaotique) histoire de la mise en place du socle", Administration et Education (2/2012).
The author traces the history of the reflection in France about a common foundation (socle commun) or a minimal knowledge (savoir minimal) or a shared basic culture (culture commune de base) that should be acquired by all pupils back to the legislation in 1959 making 16 years the end of compulsory schooling for children who had reached the age of 6 years old in 1959. This measure led throughout the following period to a discussion not only about the structure and organisation of secondary schools to respond to the longer compulsory schooling but also to its content and whether different streams should address the needs of what were considered to be the most competent pupils, the average pupils and those in difficulty. This led during the presidency of Giscard d'Estaing in the second half of the 1970s to a fierce debate about the meaning of a minimum common knowledge for all pupils with the word "minimum" creating the heat of the debate.
Lelièvre traces the iterative reflections from that period on between a succession of expert groups and ministers of education. He draws attention to the fact that for a long period, 30 years, the debate about the common or minimal knowledge that pupils should have acquired by the end of compulsory education was regularly buried due to its sensitivity. Under the presidency of François Mitterand, Pierre Bourdieu was commissioned to draft a report on the "fundamental principles for the future of the education system" in 1984 that recommended a "fundamental and obligatory core of knowledge and skills that all citizens should possess.
59
Ten years later in 1994 the philosopher, Luc Ferry in his role as chair of the National Council of Programmes submitted a report recommending a "common foundation of knowledge and competences, including practical and reflexive competences" that should be for all pupils regardless of their level and capacity. In 1999 the sociologists Marie Duru-Bellat and François Dubet undertook a consultation in secondary schools concluding on the need for serious reflection on the competences and knowledge that should form the common foundation for a generation. But it was not until the commission on the national debate, led by Claude Thélot in 2005 that led to legislation establishing a "socle commun de connaissances et de competences". A further advance in this period was the confirmation that competences are all equally important for young people and cannot be compensated for, i.e. acquiring one but not another is not acceptable. The final stage was in 2005 under the newly formed High Council on Education which added to the 5 competences already defined (mastery of French; a foreign language; basic competence in mathematics and a scientific and technological culture; mastery of information and communication technology; and a humanistic culture) two others based on the EU framework of competences: civic and social competence; and autonomy and initiative.
This article demonstrates interestingly the importance of the history and culture of an education system and the importance of debates being embedded in the culture of the system. It is also an interesting example of role played by French experts nominated by successive ministers to examine what were seen as critical issues but plagued by sensitive debates.
1.2. Contributions from outside the formal education system:
This section looks both at non formal environments and the contribution of NGOs to the implementation of key competences (that are implemented in formal environments). The first example is ISSA, an international NGO that has had considerable influence in early childhood education and care policy and the professional development of teachers and educators over the last decade in a number of central and eastern EU member states as well as candidate and partner countries.
International Step by Step Association http://www.issa.nl/
The International Step by Step Association (ISSA) is a spin-off from the Open Society Institute (OSI) from which it receives support. They connect professionals and organisations working in the field of early childhood development and education, promoting equal access to quality education and care for all children, especially in the early years of their lives. ISSA was established in the Netherlands in 1999 and are now present in about 30 countries, including in Central and Eastern Europe where they implement the Step by Step Programme initiated by the OSI in 1994 and other programmes. Members of the ISSA network work closely with local and national educational authorities and other key stakeholders in the countries. Their services include professional development programmes for staff in preschool and primary-school.
Competent educators of the 21st Century (Step by Step, 2010) defines what they consider to be quality pedagogy for early years education and care,. It was developed with the support of a group of international experts in this field, to further the ISSA vision: "With support from family and community, every child reaches his or her full potential and develops the skills necessary for being a successful and active member of a democratic knowledge society'.
ISSA promotes:
60
- Equal access to quality education and care opportunities;
- Child-centred, individualised teaching and learning, combining high-level instruction with support for the needs of each child;
- Development of skills and dispositions for lifelong learning and participation in a democracy; (Our bold)
- Recognition of educators' many roles as facilitators, guides, and role models in the learning process and as active members of their communities;
- Family involvement in children's development and education;
- Community engagement in public education;
- Respect for diversity, inclusive practices, and culturally appropriate learning environments and methods; and
- Self-improvement and on-going professional development
ISSA's quality approach takes as its foundations the United Nations Convention of the Rights of the Child as well as other major international documents and inspiration such as the Council of Europe programme, Building a Europe for and with Children and the OECD Starting Strong reports. They consider that what constitutes high quality in education is a "complex and multi-faceted matter, including structural conditions (e.g. group size, adult/child ratio, etc.), as well as process factors (e.g. sensitivity of the adult, quality of interactions and curricula, etc.)" that should support professional autonomy. They first adopted standards to help practitioners their everyday performance through the principles of learner-centred, interactive pedagogy, the development of life-long learning skills, and cooperation with families and communities. They are widely used in their programmes and in working with authorities and stakeholders. A practice of mentoring to assist educators in improving their performance based on the standards has been adopted. Continuous improvement and integration of new findings, such as neuroscience, has led to the development of Competent educators of the 21st Century which consists of seven focus areas that reflect ISSA's main beliefs about quality pedagogy and identify ways to aspire to excellence:
1. Interactions
2. Family and Community
3. Inclusion, Diversity and Values of Democracy
4. Assessment and Planning
5. Teaching Strategies
6. Learning Environment
7. Professional Development
The seven areas promote "practices guided by humanistic and socio-constructivist principles, emphasizing developmentally appropriate practices, an individualised approach, and the idea that learning occurs in interaction, and is a dialogue between children and adults, as well as between children, which is marked by respecting each other, stimulating and giving autonomy to the learner, and assuming that children are competent and full citizens even while they need support from adults". This supports the development of lifelong learning competences, including:
61
- interpersonal and civic competences,
- awareness about environmental issues and sustainable development,
- intercultural understanding,
- entrepreneurship, and
- ICT skills.
An important aspect is that teachers and educators are seen as having an important role in helping children to develop self-esteem, self-confidence, learning skills, the disposition for living and working with others and respect for diversity. ISSA considers that they therefore need space for their own development on both a personal and pedagogical level to be able to model and share with children.
Bertelsmann Stiftung: Selbsevaluation in Schulen
http://www.bertelsmann-stiftung.de/cps/rde/xchg/SID-A71F7D30-C0E78958/bst/hs.xsl/5278.htm
The second example in this section is from a self-evaluation tool built by the Bertelsmann Foundation for use by schools. The Bertelsmann Foundation has developed SEIS (Selbsevaluation in Schulen), which is a self-evaluation instrument for schools that can be administered through a computer or in a pen and paper format. It was originally developed in the mid-nineties in the context of the Bertelsmann Award for Innovative Systems when they began to identify through the process what good school quality implied. This led in 2003 to developing the software for delivering the self-evaluation. Several thousand schools use SEIS in different Länder of Germany. (Gordon et al, 2009-2010) The data obtained is for the school in a perspective of school development and improvement. There are specific questionnaires for students of different ages (e.g. up to grades 6 and grade 7 and above), teachers, support staff and parents. The data belongs to the school and is confidential but comparisons can be made with aggregated data from other schools. Bertelsmann Foundation also manages a programme called 'Good and Healthy Schools' (Anschub.de) and for these schools there are extra questions pertaining to that project. The types of outcomes expressed as skills that are contained in the student survey are of interest for this literature review. This example (with the items re-organised into categories selected by the author) is taken from the questionnaire for grade 7 and above students.
Personal well-being - setting personal goals for improvement
- explain ideas well in writing and orally
Relationships Relationship with teachers
- support from teachers
- encouragement
- promoting
- pay attention
Feeling that the class has taught to:
- work well with others, respecting & paying attention;
62
participating in group work; solving tasks, confidence, do groupwork
- get along with others
Impact of
environment: school,
community or home
(in this case school)
Feeling that the class has taught to:
- to recognise strengths & weaknesses
- learn from mistakes
- solve a task
- recognise what I am good at & what needs improving
Perception that school has helped to:
- learn new things
- organise time
- be healthy
- protect the environment
- think about what I see in media

- solve problems in different ways
- explain thought process when solving a problem
- make decisions
Satisfaction with going to school:
- overall satisfaction
- feeling that school promotes talent
- feeling that school treats students fairly
- satisfaction with teaching & learning methods
- satisfaction with what needs to be done to achieve academically
- pupils assess lessons
- school recognised good effort & achievement
- school provides healthy and nutritious meal plans
- active promotion of health is important at school
Activities and agency School has helped:
63
- act as leaders in a group
- solve disagreements
Participation with extra-curricular activities at school
- Use of school campus beyond class time
Student opinion is considered on decision that affect students
- Feeling safe in school
- school is welcoming and friendly
- existence of counsellors & support services for parents
- student council can influence decisions regarding school life & work
- students are involved in planning of school life
Support:
- Teachers effectively deal with bullying and bad treatment by other students; inappropriate behaviour
- students with personal problems receive help & support
- someone to turn to in school for assistance
Source: Gordon et al, 2009-2010
Learning for Well-being
http://www.eiesp.org/site/pages/view/80-learning-for-well-being-conference-february.html
In 2009, co n ve n e d b y th e U n i ve rs a l Ed u cati o n Fo u n d ati o n , a group of foundations established the 'Learning for Well-being' Consortium of Foundations in Europe
9
to articulate a new vision of Learning for Well-being. The Consortium participates in Learning for Well-being, which is a global initiative of partners that work together to develop and support the process of how each child and young person learns to realize their unique potential in harmony with others and the environment. In this way, it contributes to an inclusive society where more and more children and youth learn how to live joyful, meaningful and healthy lives. During 2010 to early 2012 the Consortium developed and launched, Learning for Well-being; a Policy Priority for Children and Youth in Europe: A Process for Change. In the wake of the financial crisis, new stimulus has been given to the challenge of formulating policies that take us beyond the economic imperatives, and aim to increase Well-being for All. The policy glossary represents a cross-sector perspective developed through a consultative process involving a broad range of stakeholders. To ensure integration of state-of-the-art research and policy, there were consultations with OECD, the Council of Europe, the EU and many experts, foundations,

9
The current members are: Bertelsmann Stiftung, Evens Foundation, Fondation Roi Baudouin, Freudenberg Stiftung, Guerrand-Hermès Foundation for Peace, Fondation M, Robert Bosch Stiftung and Universal Education Foundation.
64
youth organizations, government and non-government organizations across education, health, social affairs, children's rights, media, ICT, family, etc. Very briefly stated, the policy glossary identified five priority principles as foundational for a Learning for Well-being approach:
1. Need for all of society to contribute
2. Sectors working together in integrated, proactive, multi-dimensional approaches
3. Children and Youth are part of the policy process
4. Learning for Well-being: A Process Approach
• Take the child's perspective
• Encourage expression of each child's unique potential
• Focus on strengths and inner differences
• Emphasize the nature and quality of relationships
• Be holistic
5. Measuring what matters
Learning for Well-being has developed, including through working with research partners, a conceptual framework and a first set of core capacities (as well as a pilot Voice of Children survey):
65
Core Capacities:
Unfolding Unique Potential ☑ Awareness of one's life purpose
☐ Awareness of sacredness of life - mindfulness towards all beings
☑ Appreciation and gratitude for one's self
☐ Autonomy (to know oneself as independent & unique)
☑ Awareness of one's particular gifts & contributions
☑ Being at peace with one's way of being
Appreciating/Understanding Inner Diversity
☑ Being appreciated and respected
☐ Awareness of one's learning processes/needs
☑ Knowing about one's inner world
☐ Understanding the uniqueness of others
Relationships/Communication ☑ Self-esteem/self-worth
☐ •Knowing one's communication needs/processes
☐ •Knowing one's feelings/beliefs
☐ •Empathy
☑ •Curiosity
☐ •Playfulness
Participation/Engagement ☒ Capacity to choose (sense of agency)
☐ Self-motivation
☐ Capacity to plan/organize
☐ Connecting to inner resources (creativity, intuition, somatic experiences)
☐ Knowing how to engage/disengage using your own limits and boundaries
☐ Knowing one's responsibility/duty
☐ Awareness of one's contribution/role in the current circumstances
Systems Perspective/Selforganization
☐ Understanding interdependence & interconnectedness
☐ Knowing oneself as a whole system: knowledge of mind-body connection
☐ Sensory awareness (inputs of all kinds)
☐ Seeing/recognizing patterns - macro/micro
☐ Universal sense of belonging and connectedness
Others ☒ Consciousness (being awake/mindful)
☑ Knowing how to care for one's physicality
☑ Relaxation (all levels)
☑ Coping with stress, difficulties, and trauma
☑ Emotional self-regulation
Adapted from Lippman & O'Toole, 2011

2. Socio-economic issues:
2.1. Schools as learning communities to combat disadvantage
The arguments in the literature on education and disadvantage tend to focus on:
- Education as a route out of poverty whether for adult learners of young people in terms of supporting future employment
- The role of schools in creating a learning community embedded in the local community, welcoming, supportive and accepting diversity.
- Some literature, either related to neurosciences or to social and emotional learning, indirectly addresses the disadvantage issues by emphasising the conditions under which children can or cannot learn - if you are hungry, afraid, in pain, etc. your learning will be less effective.
However, the research literature on disadvantage does not address directly the issue of competence development. The articles taken from the INCLUDE-ED project, focus strongly on the participation and engagement of pupils and their families/communities in developing the educational project of the school and learning communities.
Three of the articles in this section were based on the work of the INCLUD-ED project funded by FP6 from 2006-2011, Strategies for inclusion and social cohesion from education in Europe. The project website is a rich source of data for this theme and for the role of local communities: (http://creaub.info/included/results/ - see Project 2 on effective educational practices).
P .Melgar, R. Larena, L. Ruiz & S. Rammel, "How to Move from Power-based to Dialogic Relations? Lessons from Roma Women" (EJE, 2/2011).
The emphasis in this article is on transforming power-based relations between the education professionals and Roma parents into dialogic ones, by which they are referring to dynamic relations between stakeholders where dialogue and exchange become the foundation of cooperation. Thus in the case of the INCLUDE-ED project sites (parents http://creaub.info/included) proposals put forward by the professionals did not take priority over those of the Roma parents. Instead the aim was to undertake a collective approach to understanding what will improve the quality of education. Recognising Roma culture and contributions was very important and ensuring that their voices, experiences, skills and knowledge of participate in the decision-making spaces. In parallel to co-creating strategies for Roma children to succeed in developing their capacities in school, the authors underline the importance of implementing effective strategies for Roma women to enter the labour market in appropriate areas that use their skills and the effect this has overtime on reducing poverty. The project also supported family education classes, such as literacy or courses so that Roma mothers could work as canteens supervisors and observed the importance of the presence of Roma mothers in schools for the continuing presence of girls. In this article the emphasis is not so much on specific key competences as such but on the importance of creating a learning community within schools that involves families in ways that are empowering and change the way that schools "look at" children living in poverty and vice versa, the experience of the school by the pupil and their families.
67
INCLUDE-ED focused on developing Successful Education Actions in schools where there are a high percentage of children living in poverty, with a migrant or minority status and/or other forms of disadvantage. The outcomes of the project funded under FP6 focus on the improvements experienced in schools after five years of implementation of the SEAs. School widely reduced early school leaving, improved pupil's academic results and eradicated conflicts fostering social cohesion in the community. The project team observed that successful actions do not require additional resources but rather a reorganization of the existing ones in the classroom and in the school with a focus on nurturing learning communities. The interest for the key competences network is in the partnerships created between schools, authorities and families to better support children's learning.
R. Valls & M. Padrós, "Using Dialogic Research to Overcome Poverty: from principles to action" (EJE, 2/2011)
This article which draws on the experience and data of the INCLUDE-ED programme, focuses on using the Critical Communicative Methodology inaction research to contribute to alleviating effects of poverty and disadvantage taking account of the fact that there is an increasing agreement among policy-makers that it is crucial to include the voices of those who are living in poverty in order to fight exclusion most effectively. The article argues that egalitarian dialogue, successful actions' approach and informing effective policies facilitate the engagement between researchers, end-users, and all the other involved stakeholders and therefore the move from principles to action in the process of overcoming poverty in Europe. Education is seen to be a major player in that process. The authors argue that for education to be an effective tool in fighting poverty, one must include all voices, especially those of people who are more socially vulnerable, stressing the impact of collaboration within the whole community and between schools and their contexts, valuing the potential of all students and families to support and collaborate with teachers.
An example of the dialogic process in Spain is examined especially as it led the stakeholders and community members to ask the researchers to extend the same procedure to transform the entire neighbourhood and to an agreement between the City Council of Albacete and the Research Centre on Theories and Practices that Overcome Inequalities (CREA) that coordinates INCLUD-ED to ground an URBAN programme3 (2007-2013). This time the transformation was planned and undertaken "with" the neighbours in the same critical communicative procedure that had been previously applied with success in the school.
J. Diez, S. Gatt & S. Racionero, "Placing Immigrant and Minority Family and Community Members at the School's centre: the role of community participation" (EJE, 2/2011)
This article takes as its starting point that schools alone cannot reverse the high rates of school failure in the poorest communities in Europe; they need the contributions of the entire community. Coordination between families, the larger community, and the school has proven crucial to enhance student learning and achievement, especially for minority and disadvantaged families. However, families from such backgrounds often participate in their schools only peripherally because the schools take a "tourist" approach, call parents to inform them about school projects and teachers' programmes, or consult them about decisions to be made by professionals, rather than engaging them in their children's education. In contrast, the INCLUD-ED project studied schools across Europe whose students are culturally diverse and from low SES backgrounds; here, the communities are deeply involved in the schools and the students do well academically. This article focused on three strategies used by these successful schools to engage immigrant and minority community members in more active,
68
decisive, and intellectual ways and thus have greater impact on the school and the students' learning:
1. Overcoming Intentions, Ensuring Participation: The article reports that staff in schools where a real effort was made to ensure the participation of minority and immigrant

families in the governance structures had a positive impact on the school life, helping them reach out to more families who could better understand how the school worked, thus improving home-school coordination; it also provided positive role models for the children.
2. Creating Informal Spaces for Dialogue and Participation where all parents are encouraged to participate in discussing issues related to the school and their children's learning.
3. From Folkloric to Intellectual Contributors: A crucial element identified was when teachers had high expectations of the families no matter their literacy status, capacity to speak the language of the country, etc..
4. Though the schools studied use different practices, the three strategies were found to contribute to a transformative result in all schools: moving minority and disadvantaged families from the periphery of school participation to the centre.
Early childhood education and care in promoting educational attainment, including the social development of children from disadvantaged backgrounds and in fostering social inclusion (EU-Australia joint study).
This study is currently underway, led by the Sofreco and so any comments and references are preliminary to its finalisation and approval. The combined influence of schools and the environment do not start with compulsory education. In early childhood education and care, and focusing here in particular on the pre-school phase (generally about age 3 - 6 years or to the start of compulsory education), multiple factors affect children in vulnerable situations
10
and how they learn. This study is underway for DG EAC and it includes an extensive literature review and case studies which will be completed in the autumn. Preliminary findings emphasise that poverty is one of several risk factors facing poor children, as well as readiness of kindergartens to accept diverse children; the level of preschool attendance; the quality of kindergartens; the nurturing capacity or educators and the extent of their outreach to parents; the level of parental behaviour, education and language mastery; prenatal exposure to alcohol, tobacco and depression leading to high infant mortality rates, low birth weight and special needs in infants.
2.2. School in its local environment
The first article included is about creating the conditions where the whole community (parents and school) will participate in establishing a solid basis on which children's learning can take place. As work on the social determinants of health has demonstrated, health, physical emotional and mental have an effect on learning.

10
This notion covers a broad range of situations such as children living in poverty; children from low-income immigrant backgrounds; children from illiterate or poorly educated parents; children from second language backgrounds; children from marginalised rural areas; and specific groups such as Roma children. It also in some case covers children with a physical, sensory or learning disability.
69
A. Flecha, R. Garcia & R. Rudd, "Using Health Literacy in School to overcome inequalities" (EJE, 2/2011)
This article is focusing on the notion of cultural intelligence and improving the health literacy of adults from vulnerable groups. It is based on the key idea that "Health literacy interventions could be broader in scope and include the cultural intelligence of adults from vulnerable groups throughout the life cycle of the programmes: from design, through organisation, to implementation." It entails residents in the community being perceived as capable of entering into dialogue with professionals and making decisions about the life they want for themselves and for their children in relation to health. The article, drawn from the INCLUDE-ED research, explores the outcomes of a community-based approach to empowering adults (parents of pupils) to make appropriate decisions about health issues and access services. This includes incorporating healthier habits into their daily lives (and those of their children) and regardless of their overall literacy status, becoming active in overcoming health inequalities and strengthening social cohesion. Transformation based on dialogue.
2.3. School in its virtual environment
J.F. Cérisier & A. Popuri, "Computers and School: Indian and French students' discourse". (EJE, 3/2011)
This article which describes a survey carried out in schools in India (621 usable responses) and France (339 usable responses) with pupils aged 11 - 18 years old. The aim was to explore students' perspectives and the impact that school computers have on their school and personal lives. Hence the survey was exploring the dynamics of students' relationships with computers at school and how they differ from their relationships with computers in general. The results show the extent to which their behaviours are determined by local cultures which in fact illustrate intersections between digital competence and social competence and expectations. For the French students there is a clear issue of conquering "margins of freedom" both in school and at home. Interestingly their results showed differences with comparable surveys some years ago when the use of the computer was very important for communicating with friends whereas in the current survey a lot of communication related activities appear to have migrated to mobile phones. On the other hand using computers to search for information showed an increase in this survey. The authors suggest that in school information searching which is assisted by staff gives way to networking and collaborative working at home that includes instant messaging. Their research shows the importance young people attribute to technology in the way they conduct their social lives, i.e. in the case of French students using technologies to shape private and community spaces partly because of the huge lack of public spaces that respond to their needs. Technology is also a form of emancipation from very organised and full timetables! This contrasts with more circumscribed and normative uses in school. The authors conclude: "policy makers would also benefit, both in India and in France, from a study of how young people make the best of the small gaps left to them by the educational system and which they use to create their own private culture and world that they share with their peers".
2.4. Individual students background
This section looks at three aspects of students' individual background:
a) The socio-economic aspects
70
b) Supporting students to become learners
c) Whole child approaches
a) The socio-economic aspects:
Andy Green, "Lifelong Learning, Equality and Social Cohesion" (EJE 2/2011)
This article compares the evidence from the 2009 PISA survey on the distribution of skills amongst 15-year-olds in different regions and country groups and explores how education systems in these regions contribute to different levels of inequality. In the second part, it presents evidence from surveys on adult skills and attitudes on how skills inequality affects social attitudes and social cohesion. It argues that the evidence for developed countries is that education and training are major determinants of an individual's life chances, not only in employment, but also in terms of the broader social outcomes. The author refers evidence that more educated people tend to be healthier, to live longer, to commit fewer violent crimes (McMahon, 1999) and to experience a greater sense of well-being (Schuller et al., 2001), are more likely to be tolerant of others and other cultures, to trust other people and institutions, and to be active citizens, participating in their communities and engaged in politics (Putnam, 2000). Though these associations can be found in most developed countries in individual level analysis they do not necessarily hold in cross-country analysis because other contextual factors come into play (Green, Preston, & Janmaat, 2006). The article examines the importance of how education and skills are distributed, rather than the average levels of education noting that education and training systems shape social outcomes both in the way they socialise children and in the way they distribute skills. The author analyses data from PISA including the influence of socio-economic backgrounds and family background. The principal message from the research is about the importance of educational equality in particular in social cohesion. Green concludes that "Countries which achieve more equal education and which, on our evidence, benefit thereof in terms of social cohesion, are countries which believe in the virtues of equality and design their education systems to enhance it".
I. Nicaise,"A Smart Social Inclusion Policy for the EU: the role of education and training", (EJE, 2/2012)
This article by Nicaise focuses on education and the cycle of disadvantage and the strong correlation between the poverty risk of households and the level of education of their head in so far as families with a low-educated head face a poverty risk which is twice that of those where the head has completed secondary education (24% versus 13% on average for the EU27). The article examines how young people born and growing up in poverty have far fewer opportunities to benefit from education and have less access to good quality services in early childhood, participate less in kindergarten, start primary school with more arrears, accumulate larger deficits throughout their education careers, are more often referred to special education, are systematically orientated into lower-quality vocational tracks, and drop out more easily without any qualification. It refers to empirical research for the EU that has shown that children living in low income households, whose parents have low qualifications, are unemployed or are at risk of "in work poverty", who live in inadequate housing and disadvantaged neighbourhoods, and/or who come from a migrant or ethnic minority background are much less likely to obtain good qualifications at school (Machin, 2006).
71
The author refers to the theoretical literature on equality in education thatdistinguishes between three sources of inequality at the individual level: unequal "talents" (mostly interpreted as genetic endowments); unequal effort or preferences, which are the responsibility of the individual; unequal opportunities relate to causes that are exogenous to the education system, such as the living conditions of disadvantaged groups. And adds a fourth which he suggests is probably the most important source of inequality: unequal treatment or discrimination. This includes the more frequent referral of children from immigrant or poor backgrounds to vocational tracks or in some countries the fact that Roma children may attend totally different and lower level school. Nicaise argues that "By the end of basic education, children from socially disadvantaged or minority backgrounds may have accumulated such deficits in verbal ability that it is almost impossible for them to enter general secondary education. If the curriculum in primary school had better valued instrumental forms of knowledge, it would have generated more equal success scores of lower-class pupils and led to more positive motivation and orientation. " He discusses the link between early school leaving and social disadvantage, including the need for crosssectoral policies involving education, social work, youth, employment and social protection as well as education system reforms that reduce stratification, disenchantment and exclusion of vulnerable groups as well as early targeting. He concludes on the need for massive investment in education, especially in basic skills and echoes existing research that suggests that both the fairness and the efficiency of education systems can be significantly improved by pulling down barriers in E&T systems and calls for a consensus "on the human rights perspective that the 'right to learn' is intimately linked with human dignity (and therefore rather absolute), irrespective of social background, ethnicity or indeed (perceived) talents."
b) Supporting students to become learners:
Farrington, C.A., Roderick, M., Allensworth, E., Nagaoka, J., Keyes, T.S., Johnson, D.W., & Beechum, N.O. (2012). Teaching adolescents to become learners. The role of noncognitive factors in shaping school performance: A critical literature review. Chicago: University of Chicago Consortium on Chicago School Research.
This literature review was produced by the University of Chicago Consortium on Chicago School Research in partnership with Lumina Foundation and Raikes Foundation. The aim was to develop a coherent and evidence-based framework for considering the role of noncognitive factors in academic performance and to identify critical gaps in the knowledge base and in the link between research and practice. The review sees this as a prerequisite for policymakers, practitioners, and education funders who would wish to assess the potential of non-cognitive factors as levers for increasing student educational attainment. The review found evidence to suggest that the best leverage points for improving student performance are in helping teachers understand the relationship between classroom context and student behaviours, providing teachers with clear strategies for creating classrooms that promote positive academic mindsets in students, and building teacher capacity to help students develop strategies that will enhance their learning and understanding of course material. The study acknowledges that while a growing body of knowledge suggests that non-cognitive factors play a key role in student success, it is unclear how all the different types of noncognitive factors interact to shape academic performance or what their implications are for educational practice. The report reviews the research on non-cognitive factors with a focus on students in the middle grades in high school in the USA and in the transition to college. They focus on identifying which non-cognitive factors matter for students' long-term success, clarifying why and how these factors matter, determining if these factors are malleable and
72
responsive to context, determining if they play a role in persistent racial/ethnic or gender gaps in academic achievement, and illuminating how educators might best support the development of important non-cognitive factors within their schools and classrooms. They identify five general categories of non-cognitive factors related to academic performance:
ACADEMIC BEHAVIORS: Going to Class, Doing Homework, Organizing Materials, Participating, Studying
ACADEMIC PERSEVERANCE: Grit, Tenacity, Delayed Gratification, Self-Discipline, SelfControl
ACADEMIC MINDSETS: I belong in this academic community. My ability and competence grow with my effort. I can succeed at this. This work has value for me.
LEARNING STRATEGIES: Study Skills, Metacognitive Strategies, Self-Regulated Learning, Goal-Setting
SOCIAL SKILLS: Interpersonal Skills, Empathy, Cooperation, Assertion, and Responsibility
c) Whole child approaches:
This third example is taken from My transition Guide, which was developed by the children's services with the Scottish Highland Children's Forum in order to help young people plan their transition from school, to see the skills and achievements they already have and how to use them to make plans. The aim is that young people are engaged in their transition, they know who they are, where they want to go and what they need to get there. The guide presents a methodology for planning and as part of that lists of questions that echo the Curriculum for Excellence aims.
http://www.highland.gov.uk/NR/rdonlyres/C4A1C8E0-577A-431E-8C63-500DFDC4BF32/0/transitionguidepgp.pdf
What is interesting in this example is the use of the transversal aims for children and young people in the Curriculum of Excellence in the specific situation of transition from school to work which means broadening the items from classroom learning to their lives in general around three pillars: How I grow; What I need; and My wider world (see diagram below).
Am I Safe, Healthy and Nurtured? Do I
• have a place to live where I feel supported, happy and cared for?
• feel secure in my home and community and safe from people who could harm me?
• have confidence to be able to plan for myself and to take informed risks?
• maintain a healthy body and mind?
• know how I feel and have someone to talk to?
• feel confident to be able to get support to make informed and healthy choices?
Am I Included and Active? Do I
73
• have the support to be accepted and understood as an equal at home, work

and play?
• like and respect myself and am I willing to 'have a go'?
Am I Respected and Responsible. Am I a Responsible Citizen? Do I
• feel heard and involved in decisions that affect me and others?
• have opportunities and encouragement to be confident?
• understand the values and beliefs of others and look at the wider world?
Am I a Confident Individual? Am I an Effective Contributor? Do I
• feel comfortable with myself and others?
• set achievable goals for myself?
• understand the skills and needs of others and myself?
• understand the importance of being a team player?
Am I a Successful Learner? Do I
• have curiosity; do I want to learn?
• have enthusiasm; am I keen to learn?
• have determination; do I keep trying?
Am I achieving my wishes? Do I
• feel supported to achieve my goals?
The aims of the Transition Map are to
• help you to think about your own wishes.
• help you to think about the support you might need.
• give you a tool to help you to plan and be heard.
74
They are illustrated in this star and the image below:
75
3. Specific key competences
This section considers two out of the four transversal competences within the European Reference Framework. The competences 'learning to learn' and 'sense of initiative and entrepreneurship' will be considered in the next updated version of this literature review. The key competences that tend to be more linked to specific school disciplines are not included in this section, i.e.
☒ Communication in the mother tongue;
☒ Communication in foreign languages;
☒ Mathematical competence and basic competences in science and technology;
☒ Digital competence;
3.1. Social and civic competences
This section addresses on the one hand social and emotional literacy/learning and on the other hand civic competences.
3.1.1. Social and Emotional Learning/Literacy:
In recent years there has been a growth of programmes in schools to develop more personalised approaches to learning and different groups of competences for example social and emotional literacy, competences for citizenship and democracy, health promoting programmes, rights promoting programmes, etc. Researchers, such as Michel Fielding, maintain that: "education must be person-centred, democratic and aim at the flourishing of each individual as a human being". Other approaches emphasise process, for example the work of the iNet project, which focuses on system redesign as a path to educational transformation, defining the challenge as 'getting schools from mass production to mass customisation" with the aim that more of the educational needs of more of the students are met more fully than ever before. This includes moving from teaching to learning and to the "deep learning" that will equip students for the 21st century world of work. This approach identifies and develops "nine gateways" clustered into four areas through which a school may successfully explore personalising learning (deep learning (assessment for learning, student voice, learning to learn); deep support (mentoring & coaching; advice & guidance); deep experience (new technologies, curriculum); deep leadership (design and organisation; workforce reform). According to their definition, one of the outcomes for a learner experiencing "deep learning" through personalisation of their learning will be linked to the general well-being: "An articulate, autonomous but collaborative learner, with high metacognitive control and the generic skills of learning, gained through engaging educational experiences with enriched opportunities and challenges, and supported by various people, materials and ICT linked to general well-being but crucially focused on learning, in schools whose culture and structures sustain the continuous co-construction of education through shared leadership".
It is interesting to note that all of these approaches, whether focused on content on process, highlight some of the same capacities for children and young people to develop. They all emphasise albeit in different ways:
- Addressing the 'whole' child;
- The need for learning to be person-centred or human-centred;
- Capacities that will support the child's flourishing;
76
- The transformative capacity of learning.
They are illustrated here by looking in more detail at social and emotional literacy, sometimes referred to as social and emotional education or learning, other times as a form of literacy (or sometimes termed skills). Whatever the title used, the intention is to stimulate well-rounded growth in young people and to enhance their academic achievement. It serves as a preventative strategy as well as also contributing to the improvement of their physical and mental health (Clouder 2008, p12). Furthermore proponents of this type of approach, such as the authors contributing to the two international publications on Social and Emotional Education (2008 & 2011) published by the Fundación Marcelino Botín, emphasise the importance of training adults (teachers, parents, professional, etc.) as a prerequisite in working towards developing the well-being of children and young people. There is an interesting assumption in this report that certain capabilities or competences are human rights to which all children should have access as it is vital for the sake of the health of future societies. They are:
- The ability to relate well to others
- To cooperate
- To manage and resolve conflict
- To act autonomously
- The ability to act within the larger context
- To form and conduct life plans and personal projects
- To defend and assert one's rights, interests, limits and needs
- To use language, symbols and texts
- The ability to use knowledge and information interactively and the ability to use technology interactivity.
The Introduction emphasises that "a child needs to understand her own feelings in order to recognize those in others" (p40) which echoes both the "learning to be" and the "learning to live together" pillars of the UNESCO report.
Depending on the context, approaches to emotional and social learning may involve introducing specific modules into the curriculum or ensuring that children and young people have the opportunities to develop the competences identified across the whole curriculum and through all the different types of classroom and extra-curricular activities proposed in a school.
Very substantial work in this field has been carried out in the USA by CASEL, the Collaborative for Academic, Social and Emotional Learning (http://casel.org/), which addresses five essential areas of social and emotional development:
- Self-awareness (recognising one's capacities, strengths, emotions and values)
- Self-management (managing emotions, and behaviours, persevering in overcoming obstacles)
- Social awareness (showing understanding and empathy for others)
- Relationship skills (forming positive relationships, teamwork, conflict resolutions)
- Responsible decision-making (making ethical, constructive choices about personal and social behaviour).
77
The CASEL research suggests that benefits of paying attention to social and emotional learning include the following:
Better academic performance: Students who participated in SEL programs increased achievement scores an average of 11 percentile points versus students who did not participate.
Improved school attitudes and behaviours: SEL instils greater motivation to learn, deeper commitment to school, increased time devoted to schoolwork, better classroom behaviour, and improved attendance and graduation rates.
Fewer negative behaviours: Among students receiving SEL instruction, disruptive class behaviour, noncompliance, aggression, delinquent acts, and disciplinary referrals decrease significantly.
Reduced emotional distress: Reports of student depression, anxiety, stress, or social withdrawal significantly decrease among students receiving SEL instruction.
Kevin Haggerty, Jenna Elgin, Andrew Woolley, (2011) Social-Emotional Learning Assessment Measures for Middle School Youth, Social Development Research Group, University of Washington. Commissioned by the Raikes Foundation
This is a review carried out to identify solid assessment tools for social and emotional learning from among the tools that exist for use by US schools. For the purpose of the review, the researchers used the social and emotional competencies identified by the CASEL as a framework for identifying and reviewing various assessment measures. The five interrelated social and emotional competencies as described by CASEL include:
- Self-Awareness. Accurately assessing one's feelings, interests, values, and strengths; maintaining a well-grounded sense of self-confidence.
- Self-Management. Regulating one's emotions to handle stress, controlling impulses, and persevering in addressing challenges; expressing emotions appropriately; and setting and monitoring progress toward personal and academic goals.
- Social Awareness. Being able to take the perspective of and empathize with others; recognizing and appreciating individual and group similarities and differences; and recognizing and making the best use of family, school, and community resources.
- Relationship Skills. Establishing and maintaining healthy and rewarding relationships based on cooperation; resisting inappropriate social pressure; preventing, managing, and resolving interpersonal conflict, and seeking help when needed.
- Responsible Decision Making. Making decisions based on consideration of ethical standards, safety concerns, appropriate social norms, respect for others, and likely consequences of various actions; applying decision-making skills to academic and social situations; and contributing to the well-being of one's school and community.
The rational of the review is that children with strong Social-Emotional Learning (SEL) skills have been shown to excel in school, both socially and academically and it is considered that SEL programmes are imperative to address the social, emotional, and academic needs of students
The research conducted an extensive review of the literature on social and emotional learning in US middle school students and identified and evaluated 73 instruments. The criteria used were: what the constructs measure, target age group, strengths and
78
weaknesses of the tool, reliability and validity. The aim was to test which tools have sound psychometric properties, are suited for programme evaluation, are readily available for schools to access and were not developed for use with a specific programme. 73 instruments were reviewed and 10 met their criteria for inclusion in this report.
In addition to improving students' social-emotional skills, the review reports that SEL programmes improve students' performance in the classroom (Payton et al., 2008) with an increase of 11% to 17% in test scores (Payton et al., 2008). The researchers conclude that SEL is 'absolutely crucial to children's success in school, both academically and socially'.
Hence reliable and valid assessment tools are necessary to conduct needs assessments and monitor the success of SEL programmes over time.
Immordino-Yang, M.H., Damasio, A. (2007) 'We Feel Therefore We Learn: The Relevance of Affective and Social Neuroscience to Education'. Mind Brain and Education.
In their article, We Feel Therefore We Learn: The Relevance of Affective and Social Neuroscience to Education, Mary Helen Immordino-Yang and Antonio Damasio explore how the connections between emotion, social functioning and decision-making have the potential to revolutionize our understanding of the role of affect in education. The authors emphasise that recent findings underscore "the critical role of emotion in bringing previously acquired knowledge to inform real-world decision-making in social contexts, they suggest the intriguing possibility that emotional processes are required for the skills and knowledge acquired in school to transfer to novel situations and real life". They conclude by saying that when "we educators fail to appreciate the importance of students" emotions, we fail to appreciate a critical force in students' learning.
C. Pert & N. Marriott, "The Science of Emotions and Consciousness" in Goleman D. et al, (2008) Measuring the Immeasurable; the scientific case for spirituality, Sounds True.
The research of Candace Pert, a neuroscientist and pharmacologist, explores the importance of emotions to learning based on a theory of emotions and on the notion of a vast network of communication coordinating the brain and body that she calls the "bodymind". Two important notions developed are that people acquire knowledge with their entire "bodymind" and that learning is an emotional event impacted by how one feels. She discusses how the experience of reality is filtered through memories, which give a specific interpretation and meaning to each person's experience in so far that everything that is learned is filtered through past experience: "what you experience as reality is your story of what happened". She links this to trauma, but also to the ordinary scars of growing up that continue to affect our lives. Her research and that of others suggests that recall is stored throughout the body in a psychosomatic network extending through all the systems of the organism and that much of memory is emotion-driven with two possible effects. Emotions can bring a recollection to the surface or bury a memory below awareness where it can affect perceptions, behaviours, health, etc.
3.1.2. Civic competences
W. Edelstein, "Education for Democracy: reasons and strategies", (EJE, 1.2011)
The author argues that major developments in Western industrial societies towards individualism, increasing social complexity and globalisation present serious threats to basic requirements of stable societies and expose democracy to the corrosion of its socio-moral resources such as social trust and civic commitment to the public good. In order to grow and
79
to flourish, the competences and capabilities that constitute these resources require systematic cultivation through educational processes. HE argues that the school is the only institution that can provide the appropriate experience of a democratic life to all members of society. At present, however, schools are generally far from this goal. This article describes strategies for providing the experience of schools as democratic life-worlds from an early age: classroom councils as tools for democratic self-government and sites for socio-moral learning; projects of service learning in the community which can be successfully organized by these councils; and early experiences of civic engagement in community contexts as part of democratic classroom practice.
3.2. Cultural awareness and expression
The next contribution moves from the immediately "local" environment to partnerships in the case of Creative Partnerships:
McLellan, R., Galton, M., Steward, S. and Page, C. (2012). The Impact of Creative

Partnerships on the Wellbeing of Children and Young People. Newcastle: CCE
http://www.creativityculture education.org/the-impact-of-creative-initiatives-on-wellbeing-aliterature-review
This study aimed to explore how the Creative Partnerships programme had affected student wellbeing and the degree to which creative approaches had become embedded in areas of the curriculum other than those directly involving creative practitioners. The researchers discuss approaches to creativity and creative learning, including the Creative Partnerships programme, the notion of wellbeing and interests in measuring it, and motivation as the link between creative learning and wellbeing. The research draws on self-determination theory (SDT) where the achievement of learning goals associated with developing expertise and metacognitive wisdom, result in a sense of psychological wellbeing through satisfaction of core needs. This theory suggests that people's innate needs include competence, autonomy and relatedness, and the findings of this report suggest that these are the very qualities that underpin the central aim of the Creative Partnerships programme. Important themes are discussed in the report, including student voice, school ethos, the development of creative transferable skills, the effects of performativity culture, collaborative approaches, levels of student engagement, positive relationships in the classroom, and pastoral care.
Impact on primary schools
- Creative Partnerships' approach to fostering wellbeing was radically different from that in the other case study schools. In the latter wellbeing was a means to an end whereas in Creative Partnerships schools no distinction was made between creativity and wellbeing which meant that creative learning tended to permeate the whole curriculum.
- Student voice was crucial to promoting wellbeing and in helping students to function effectively both personally and socially. The extent to which students were able to have their views recognized and contribute to decision making had been taken further in Creative Partnerships schools.
- There was little evidence to suggest that there was a typology of creative practices. Where differences did exist this could be attributed to the fact that Creative Partnerships schools were at different stages of their learning journey, rather than because they adopted different approaches for developing their pupils' creativity.
80
- There was little evidence that creative learning was promoted through specific 'arts based' approaches to learning. In all Creative Partnerships schools the emphasis was on generic pedagogies rather than pedagogic subject knowledge. Specialist knowledge and skills were only introduced when it helped students to develop their own ideas. The emphasis was mainly on helping students to think flexibly, strategically and creatively.
Impact on secondary schools
- In general, the survey indicated that there were no overall differences in wellbeing between students attending Creative Partnerships schools and other schools. Issues in the matching of schools at secondary level, together with previous research indicating that variation in wellbeing scores attributable to between school differences is small, might have accounted for this finding.
- The qualitative data can provide insight into how Creative Partnerships work impacts upon student wellbeing but as schools have many strategies in place to support wellbeing disaggregating the impact of any one strategy is difficult. The context within which secondary schools operate cannot be ignored, particularly the performativity culture with its focus on examination results. This has implications for student wellbeing in terms of lack of choice and exam pressures can be controlling and therefore thwart the need for autonomy, and can also lead to a de-valuing of creativity and wellbeing.
- The main motivation for schools joining the Creative Partnerships Programme was school improvement. Creative Partnerships work had generally focused on one departmental area or an identified group of students (e.g. disaffected Year 9 boys) in the first instance, although the number of departments and variety of projects undertaken increased as schools gained more experience of Creative Partnerships work. There was little evidence in the two case studies that where creative practitioners had worked with teachers to improve practice, this had impacted on pedagogy in other lessons beyond the Creative Partnerships projects.
- Self-determination theory was applied to identify elements of Creative Partnerships work that promoted wellbeing through the satisfaction of the core needs for autonomy, competence and relatedness. A number of projects were seen to meet these needs in different ways and particularly promoted interpersonal and perceived competence wellbeing. There was less evidence that Creative Partnerships work influenced life satisfaction. It also had the potential to have a positive impact on wellbeing through factors not captured by SDT, e.g. aspiration and teacher wellbeing. In a small number of cases, Creative Partnerships work also had the potential to reduce wellbeing in the way it had been implemented, i.e. depending on the quality of the work.

85
The framework of exchange and discussion regarding competences has, until recent years, been more of a theme in the French-speaking world as a whole than in each individual French-speaking country. Before the development of the European Reference Framework for Key Competences, Belgium (Missions decree - 1997) and Québec in Canada ('Pedagogical renewal' reform since the beginning of the 2000s) had indeed put the notion of competences at the heart of their reforms, and in doing so provoked scientific writing on the subject which has been widely circulated in the French-speaking community in Europe (Belgium, France, Luxembourg and Switzerland) and in North America (Québec) as well as in the African French-speaking countries.
Debates and experiences regarding competences have thus been included in the development of local educational culture and policy, rather than adhering to the frameworks of key competences, such as those which have been subsequently developed by the European Union.
1. The approach to competences in France and in the Frenchspeaking World
1.1. Professional origins of the notion
The notion of competence developed mainly in the professional world in the 70s, where it progressively replaced the notion of qualifications, to better consider the role of the person and the responsibility of the employee in unforeseeable circumstances (Legendre 2008). Secondly, the notion was encompassed in the context of adult education and vocational training, in order to identify the underlying "knowledge in action" of efficient activity and, if possible, ensure their application (Ropé and Tanguy, 1994). In the domain of adult education, still today the notion of competences is mentioned the most spontaneously, particularly with regards to life-long education (CAFOC, 2012).
It was only at a later stage in the 90s, that competence was encompassed in the context of school education, to characterise the unique competences of adaptation of an individual to new situations, and their evolutionary competences based on advances in technology and society (Rey, Carette, Defrance and Kahn, 2006).
Parallels were drawn between the separation of micro-objectives of the school curriculum (behavioural theory of pedagogy by objectives) and a Taylorist economy on one hand, and the approach by competences and a modern economy mainly based on people's autonomy and flexibility (Jonnaert, Barette et al). 2004).
One of the leading theorists on competences, Guy Le Boterf, is a consultant in human resources management, and has studied the notion of competences primarily in the context of training within professional organisations. He believes that the defining of competence as an extension of knowledge, skills and attitudes is too weak. His view is that competence is the combination of abilities or aptitudes for resolving a given problem. It consists in "knowing

how to act", which is the combination of - and not the addition of - various resources in a working environment:
- Knowing how to mobilize others;
- Knowing how to integrate;
- Knowing how to transfer.

86
Competence is in mobilisation. For the individual, it is a question of going from knowing how to knowing how to act in a particular unforeseen situations (le Boterf, 2010)
1.2. The opening up of schools to the divisive outside world
The "professional" origins of the notion of competences have provoked opposition, in that the notion stifles educational ambition and leads to a utilitarian perspective (Crahay 2006, Boutin 2004).
For some researchers, education stakeholders or schools of thought, the notion of competence is a Trojan horse for employers - possibly backed up by international organisations and States, in order to adapt their education systems to their own needs - going against the transferral of heritage or critical thinking in education which schools should focus on, in their eyes (see for example Del Rey, 2010; Hirtt, 2010; Laval, Vergne, Clément and Dreux, 2011).
Equally, some intellectuals in France are very keen on the teaching of the "great works" in literature, history or art - subjects which are sometimes classified as Humanities or Humanistic Culture, a notion which was added to the French socle commun (core curriculum) of knowledge and competences in 2005 (Lelièvre, 2009).
This humanistic culture, which is essentially found in the school context, would, according to some, be threatened by the transformation of subjects into competences, in which the study of literature or civilisation would be, for example, diluted as "written or oral expression" or "communication".
These suspicions should be put in the context of the educational institution in France, particularly with regards to its political role in the fabric of the Republic and then national socialisation, something which one famous French sociologist calls the programme institutionnel (institutional programme) of schools (Dubet, 2002).
Conversely, for other researchers, it is precisely this better, desirable link between school and a society which pleads for recourse to competences.
Philippe Perrenoud (2004, 2011) has therefore worked for some years on the best way, for schools to prepare students for their personal, social, economic and civic lives.
His view is that getting through school is not an end in itself: the student should be capable of applying his educational achievements outside of school, in different unforeseen and complex situations. In doing so, this leads to an interest in building competences for the transfer of knowledge to other situations through their integration into wider competences, incorporating further concepts of reflection, decision making, action and adaptation.
He argues for educational content to be significantly more controlled with regards to social, cultural and professional life as "if school prepares for life, changes in the world and to people's lives should logically be the main factor determining evolution of the curriculum, at least as much as the transformation of knowledge is. Ultimately, it should only be the knowledge that affects people's lives and their understanding of the world that should be the force behind changes to educational programmes.

11
" (Perrenoud, 2008).

11
Please note that all quotations in this section of the literature review have been translated from the original French into English by a subcontracted translator.

87
Other experts note that existing disciplines are often a creation of teaching itself, particularly in Secondary Education, however they do not really correspond to the creations of the worlds of science, culture or economics (Gauthier, 2006).
For sociologist Denis Meuret, schooling in France was marked by the heritage of conceptions made by the early 20th century sociologist Emile Durkheim, as a result of which school is seen as a front to protect individuals from unwholesome influences in the world - an idea which creates a negative view of everything external to schools, and furthermore makes structuring of teaching very difficult alongside what pupils learn and experiment with in their lives outside of school (Meuret, 2007).
He believes that this tradition has favoured the changes necessary to integrate advances of a scientific and technical nature that arose in the form of academic knowledge, but it is significantly less suited to "post-modern" strategic changes, in which case the quality and competences of the person should be improved first, giving more meaning to learning.
1.3. The dominant definitions of competence in the context of education in the French-speaking world
In the French language and in daily life, competence can assume very different meanings: legal authority (the legitimacy of an institution to act in a particular domain, for example), overall quality given to an individual, technical ability in a domain, etc.
In education, it can also define an overall competence (close to a key competence), such as the ability to express oneself in public, as well as elementary parts of knowledge or expertise: learning a spelling rule or ability in using a tool, for example.
Some researchers use the term competence without distinction in a number of ways (competence in mathematics, competence in spelling, competence in writing comments on texts) to describe all learning in school, at a level of detail which has little to do with the concept of key competences (Morlaix, 2009).
Other works on the other hand look to define competences with a holistic and integrated view, closer to the definition of key competences.
Competence-based approaches aim principally to break from the traditionally dominant method of teaching by objectives seen in schools during the 20th Century, which separates the transmission of knowledge within disciplines into objectives to be reached at each level of schooling.
Here however, the integration of learning into an overall logic is favoured, with the concern that the final aim of the competence to be acquired is not only at the end of this process, but is included from the outset and conditions the very way in which the different constituent parts of the competence are built by the student. In this sense, it is knowledge in action, built for action in problem-solving situations, series of tasks, etc.
The complex skills in the field of competences rest in putting into use multiple elements of knowledge and expertise to enable an integration of achievements into teaching. (Roegiers, 2000).
The knowledge put into use are transformed and re-contextualized. It is in carrying out actions that competences must be inferred, which is where the importance of evaluation in

88
appropriate situations lies. This also raises the issue of "attitudes", otherwise difficult to evaluate with indirect evidence (Scallon, 2007). Being confronted with a concrete situation is essential, and competence is rarely demonstrated by a figure or a numbered result, but by means of an overall judgement. It is not an abstract ability separate from any context: competence is finalised and contextualised.
In Québec, a number of studies on competence have been made with regards to the Observatory of Educational Reforms, leading to the creation of a UNESCO chair on curricular development at the University of Québec in Montréal.
According to the researchers involved, at least three constant elements appear to make up the concept of competence in contemporary literature:
- Competence is based on the putting to use and coordination of a variety of resources by a person in a particular situation;
- A competence can develop only in that situation;
- A competence can only be attained if fully completed.
However, in their opinion, this is not a sufficient curricular definition for the creation of study programmes. In particular, the question of coordinating resources is often misunderstood, in most cases being reduced to juxtapose existing disciplinary elements. However, more than the sum of resources, competence is the result of the efficient coordination of such resources (Jonnaert, Barette et al., 2004). The "explicit and thought-out competence" seems to be largely absent in thoughts on contemporary teaching and learning when considering competence in education. Nevertheless, the researchers warn that "if situations are important, they are not enough".
When discussing competences as a new educational paradigm, we are therefore referring to the possibility for an individual to apply an integrated set of resources to oneself, to solve a series of problem situations, as defined by X. Roegiers (2004).
The taking into account of competences in the world of training denotes, in a general way, the gradual shift from a focus on knowledge, considered as a preamble to activity and so often decontextualized, to a consideration of activities in which this knowledge embodies itself (Legendre, 2008).
We are no longer in a framework of stable knowledge in its disciplinary configuration, but rather in one of knowledge in a state of dynamic construction, where knowledge is constantly reconstructed by the student. The aim is not so much to convey a science of academic knowledge passed down through heritage, as to be productive in the application of knowledge that is expressed by practical results and the demonstration of expertise. Therefore knowledge is called upon to become competences, through activity-centred teaching (Lemaître & Hatano, 2007).
For Bernard Rey's team at the Université Libre de Bruxelles, the main interest in competence is to make students work on sufficiently wide-ranging activities, which are meaningful and whose function is evident to them, even if it is often difficult to determine which competences are directly relevant to their social and professional lives.
Three degrees of competences are distinguished, of which only the last two can really deserve to be called "competences":

89
- An elementary competence: knowing how to carry out a task in response to a signal (automated procedure, skill)
- A competence framework: to be able to interpret an unknown situation and choose the elementary competence most suited to it;
- A complex competence: to choose and combine multiple competences to respond to a new and complex situation (Rey, Carette, Defrance & Kahn, 2006).
2. The establishment of competences in France
The teaching of competences did not wait for the 2005 law to establish itself, although sometimes referred to by different names. For example, this is the case in many primary schools where the learning of certain competences coexists with the teaching of traditional school subjects, in particular in schools which experiment with different teaching techniques, such as Freinet's Pedagogy (Reuter, 2007).
It is also the case in certain secondary schools, which promote interdisciplinary work, contextualize grades, and insist on cooperation or creativity, in the framework of experimental lower secondary Schools (Cédelle, 2009) or regular lower secondary schools, where they use their ability to experiment as permitted by law (Di Martino and Sanchez, 2011; Duffez, 2012).
2.1. The law on compulsory schooling implemented in 2005
In the autumn of 2003, the French government established a commission headed up by an expert, Claude Thélot, to arrange a significant consultation on the future of the French education system. The conclusions from this consultation were submitted in a report published in 2004 entitled Pour la réussite de tous les élèves (For the success of all students) (Thelot, 2004), clearly evoking a base of "essential" knowledge that a school must allow students to acquire.
One result of this consultation would lead to the law on the French socle commun de connaissances et de compétences (core curriculum of knowledge and competences), passed on the 23rd April 2005, dealing with four areas: command of the French language, command of the principal elements of mathematics, a culture of humanities and science giving the ability to freely live as a citizen, and a command of common techniques in information and communication (Raulin, 2006, 2008).
A further decree in 2006 made this base clearer, and was composed of 7 major competences, each one broken down into knowledge, skills and attitude, largely inspired by the European Key Competences:
- command of the French language;
- use of a foreign language;
- basic competence in mathematics, science and technology;
- command of common techniques in ICT;
- humanistic culture;
- social and civic competence;
- Autonomy and initiative.

90
It can be noted that the "French" version of the competences transforms "sense of initiative and entrepreneurship" into simply "sense of initiative", to prevent ideological clashes, and raises humanistic culture to the rank of the major competences, while the European framework speaks only of "cultural awareness and expression".
In many ways, this law is a milestone in the history of French education. This is one of the few times where legislation has intervened in the field of education, and is almost without precedent since the late 19th Century, when political power dictated the curricula with the introduction of the concepts of ''common'' and of ''competences''. This in an education system which was one of the last in the Western World to develop a common lower secondary teaching system (the "collège unique") in which disciplines are organised within a structured framework at an academic and institutional level (Gauthier and Le Gouvello, 2010; Rey, 2010).
However, some believe that the way in which the socle commun (core curriculum) is written in such a way that it "refers to the old teaching by objectives method in three fields of classification: knowledge, attitudes and skills" (Clerc, 2012) behind the apparent distribution between knowledge, attitudes and skills. Others are concerned that the description of the main areas, similar to the European Key Competences, do not mention the issue of specific skills which are useful in everyday life, nor, more importantly, do they describe specific situations or series of situations (Perrenoud, 2011). Is there not the risk then that we fall back on the closest possible meaning of what we commonly call subject "competences", which are more familiar and already used?
New concepts and rapid change, mixed with the frequent hesitancy of successive governments led to many reports highlighting that the introduction of measures relating to primary and secondary schooling was half-hearted, slow and incomplete (Grosperrin, 2010, HCEE 2011).
In some areas, the competence approach was more easily adopted due to the existing widespread use of the concept. This is the case in physical education and sport, Modern Foreign Languages (influenced by the European Framework for Languages) or in ICT (Cerisier, Devachelle, Rizza and Nguyen, 2008).
In other areas, competences were often heavily assimilated to related subject teaching (native language teaching, mathematics, history) or the lack of conformity was difficult to police.
This is particularly true in the case of competences "social and civic competences" and "sense of autonomy and initiative" which raised concerns among teachers as it seemed to

lead more to influencing attitudes rather than objective knowledge.
2.2. Subjects and Competences
The implementation of competences through a common framework is hampered by reluctance expressed variably by some teachers, trades unions, and associations who are attached to the subject framework, and fear that the competence-based approach means that subjects in the socle commun (core curriculum) are weakened or watered-down.
This reluctance is mainly found in secondary education, which is mainly structured around subjects, rather than in primary education.
91
For certain actors in the education field, academic subjects represents a framework of protection for schools against the pressures of society and employers, and in a more general way against a utilitarian view of the school which the competence approach is suspected of causing.
Despite there seemingly being a prevailing consensus in France that there are no allencompassing competences which can be acquired outside of the learning of subjects, some of those involved in the sector and some researchers are continually concerned that "knowledge" becomes watered-down within transversal "competences".
With regards to research on the subject, these concerns are found in a number of articles.
The most well-known is that of Marcel Crahay (2006), where he discounts the idea that knowledge is secondary in the competence approach, and that the ability to react to a particular situation tends to lead to forgetting the necessary decontextualisation at the heart of all processes of cognitive construction.
Maggay Schneider-Gilliot (2006) also believes that by focussing on competences common to multiple disciplines, the myth of transferability leads to the elimination of the specifics of the theories relating to knowledge and thereby creating a phenomenon of "decategorisation" of the issues studied in school.
2.3. Upper Secondary School (Lycée)
Beyond compulsory education, the issue of competences is also raised in an indirect manner, notably in the context of upper secondary education, which corresponds to "Lycée" in France.
In both technological and general education, a recent reform (Moisan and Cook, 2011) notably provides for the creation of a "personalised teaching" system, giving attention margin of manoeuvre to the local initiative of teachers and schools. The general aim is to assist Lycée students to build on competences which have otherwise been poorly acquired during traditional lessons. This can be found in certain personalised teaching systems in activities which resemble either the key competence of "learning to learn", or parts of the key competences (such as oral communication) which are not explicitly developed within the framework of standard subjects.
2.4. Assessing Competences
The Theoretical Model
It can be noted that in all countries that have introduced a competence-based approach assessment is a crucial factor and therefore needs to be considered at the same time as curricular reform and not afterwards, as is so often the case (De Ketele, 2009).
Scallon's view (2007) is that it is fundamentally important to distinguish between the recall of knowledge and its use. In response to the use of standardised tests, performance should be considered and focussed on, taking into account many features:
1) challenging situations, to encourage giving a relatively advanced and more complex response, rather than simply tickling a box
2) authenticity - to come as close as possible to a situation where real-life questions are evaluated
92
3) Interactivity
4) The multi-dimensional aspect of learning, to take good account of abilities, as well as self-motivation and self-confidence
5) Requirements, expectations and standards. A threshold of expected success or levels of competences should be defined, rather than fixing a cut-off point which separates students who fail from those who succeed; as is the case with the measurement model.
6) The importance of judgement to carry out a complete evaluation without merely confronting isolated work and one-offs.
7) Processes as elements to be assessed, to give importance to path monitoring (process) and the growth of the individual, not only the final result (product)
8) Integration and assessment of learning, considering the notion of interactive regulation of teaching
9) the participation of the student in assessment as well as self-assessment, intended as a constituent part of competence (i.e. having the ability to think about one's own progress)
Among the multiple possible definitions, there is common agreement that a competent student is one who is capable of resolving complex and unforeseen tasks that require an element of choice and a combination of learned procedures (Carette, 2009, 2008). The idea of previously unseen and complex tasks is clearly in contrast with current mainstream school assessments. In other words, in order to resolve the problem, the student must choose and combine procedures having identified those which are most relevant to the situation in hand, and this process of "framing" is an essential component of competence.
Nevertheless, there should be no confusion made between a "complex" situation and a "complicated" situation. This is not a matter of having students confront infeasible or overlycomplicated tasks for their level; it is more a question of encouraging an alternative application of solutions already known or used (Gérard, 2008).
For most French-speaking researchers, the competence approach requires input based on the situation, not based on knowledge (Ayott-Beaudet & Jonnaert, 2011; Perrenoud, 2011, Beckers and Voss, 2008). Every competence has a situation and a group of situations relating to it, in which the competence develops and grows. This leads to the provision, for public policy, of a bank of situations or a similar pooling device aiding the assessment of competences for teachers.
If the competence is demonstrated during assessment, the "perceived" competence should also be considered, i.e. the feeling of being more or less competent in relation to a proposed task (Van Der Maren & Loye, 2011). The question of being able to reflect and give a meaning to learning is just as, if not more important than what could be considered as a purely behavioural dimension.
Being competent does not mean adding skills and attitudes to knowledge, but knowing what one knows, how one knows it, and with what force to react to confront a new situation (Clerc, 2012).
Assessment of Competences and Traditional Assessment
Grade-based assessments usually appear to be poorly compatible with an assessment of competences. This is particularly the case where the result is a certification based on an
93
average grade weighted over multiple disciplines (Dauvisis, 2007). In certain countries, as is the case in France or in some cantons of Switzerland, many experiments are trying and have tried to find alternatives to marking. At primary school level, if assessment notebooks, portfolios or coloured symbols ("traffic lights") are fairly common experiments designed to eliminate marking at the beginning of secondary education still frequently provoke debate and come across opposition, especially from parents. These are parents who fear the loss of a "simple" method of evaluating their child's performance at school, as well as the fear of falling behind the rest of the school system still measured by competition based on grades.
The system also sends discouraging signs concerning this type of experiment, by maintaining marking systems based on traditional programmes alongside competence-based programmes, as is the case in France where the "Brevet" exam at age 14-15 has been maintained alongside the socle commun (core curriculum) (Colsaët and Mevel, 2011).
Some researchers have devised a multi-level assessment to evaluate the ability to classify and mobilise resources when attempting to master a competence, above and beyond mastering procedures (Rey, Carette, Defrance & Kahn, 2006). Their aim is to first evaluate complex competences, in other words, the ability of students to select and combine multiple competences from those already acquired, in order to adequately resolve a previously unseen problem. To do this, they have conceived an assessment method made up of three successive tests from the most complex (the competence) to the most simple (the procedure).
However, as one of the researchers involved points out, this system is not completely infallible: individuals do not demonstrate the same behaviour when faced with situations which nevertheless require the same "mental reasoning" but in different forms (Kahn, 2012).
Various tools are used in the French-speaking world in support of the assessment of competences, among which portfolios, learning files, and concept maps (Tardif, 2006).
In France, the assessment of competences is carried out using a tool called the "livret personel de compétences" (personal competences book) (Houchot and Robine, 2007; Delatouche 2012), which has been strongly criticised by teaching staff for a number of reasons:
- the numerous items behind each competence (dozens of times each time) which makes it seem as a sort of "tick box factory" and can create an artificial certification of competences by adding micro-tasks;
- a lack of coherence between competences, the book and traditional programmes;
- a binary certification of achieved/not achieved which does not reflect the progressive nature of learning;
- unrealistic or misunderstood levels of expectation;
- Certain traditional tests such as the "Brevet des collèges" (at the end of lower secondary education) coexisting with the certification of competences in the book at the end of Year 10, both having a different logic behind them.
The chaotic implementation of the competence book in the French context is a demonstration of the fragile nature of the changes which began with the 2005 law. As is often the case, assessment methods concentrate and bring out all of the debates and problems which have not previously been solved, among which:
1) a major reform, the socle commun (core curriculum), which has not been directly challenged but the political leadership of it was only intermittently sustained, leaving many ambiguities pending with regards to issues concerning compulsory education;
94
2) a fundamental and controversial question in teaching, grading and examinations, discussed in a time of confusion and mix-ups, when in fact what is at stake is a symbolic and practical representation for teachers and students, but also as a way of evaluating education for parents and other people involved in the system.
3) The assessment of competences is a difficult challenge, for which the solution is yet to be found for most of those who are involved, outside of mainland France, while the atmosphere around the education system is somewhat anxious meaning that the lack of certainty, guesswork and improvised teaching methods is difficult to accept (Rey, 2012).

Annex 1: KeyCoNet Literature Review Matrix
In this review we are trying to gain an understanding of:
- What types of research have been undertaken for the topics and issues that interest us and what are the key results and outcomes that influence how KCs are being developed and implemented in different countries?
- What are the major contributions of international (including European) organisations and research centres?
- What are the main issues or messages that will influence our work?
- Are countries designing and implementing KC (or other terminology) frameworks based on research or on other criteria?
- Do we know if KCs make a difference to learning and if so how? What is their contribution?
- Is there evidence to suggest that the EU framework could usefully be fine-tuned?
- Etc.

Topics and issues	Scientific review/books	Reports international organisations/EU organisations	Key reports about initiatives (EU MS + other countries)
KC Theoretical framework: Research on the 8 KCs + key research on transversal skills and other foundational competences/capacities e.g. resilience, self-efficacy, etc. (UH, using ATC21s scientific reviews)			

100
KC Implementation
Approaches to implementation at practice level (classroom/learning environment): (UH)
Themes:
- carefully designed & appropriately orchestrated implementation strategy,
- appropriate resources used effectively
- pedagogy of competence development,
- innovative learning environments,
- intensive use of ICT facilities,
- project work & teamwork,
- individualised techniques of organising learning

To be considered at:
- School level (including networks, learning organisations)
- Local/regional
- National
- Interaction of all levels
- non formal environment (local and/or virtual)

Approaches to implementation at system(ic) level:
101
Curriculum design and implementation (frameworks, etc.) (EIEPS + EUN)
Teacher training: (EUN)
Consequences and implications for:
- Defining and acquiring their own KCs to facilitate learning of KCs
- Initial and continuous Professional Development (CPD)

Assessment of key competences
Issues: e.g. "measuring what matters"
New assessment methods
School organisation: (EUN)
- Opening to and partnership with the surrounding community
- Role of teachers (in the school) and team work at teacher level
- Etc.

Non formal learning environments: (UH + EIEPS contribution)
- Better suited/more efficient for some specific competences?
- Which complementarity with formal environment?
- Etc.

Socio-economic issues: (EIEPS)
- schools as learning communities to combat disadvantage
- school in its local environment
- school in its virtual environment (?)
- individual students background

102
Research and evidence based policy implementation (EIEPS + EUN)
Research:
How countries use research or not and of what types? With what outcomes?
Policy formulation: what do we learn about different approaches to formulation in terms of outcomes?
Policy evaluation: is there any? who does it? how? What does it tell us?
International influences on policy and research:
E.g: DeSeCo, PISA, etc.
103
Annex 2: Major categories of terminology about competences and skills used in the EU
The data in this table was collected through country "fiches" used for J. Gordon, G. Halasz, M. Krawczyk, T. Leney, A. Michel, D. Pepper, E. Putkiewicz, J. Wisniewski, Key Competences in Europe: Opening doors for lifelong learners across the school curriculum and teacher education, (Warsaw, CASE-Center for Social and Economic Research) undertaken for the Directorate General Education and Culture of the European Commission, (2009). The examples are not exhaustive, but are given as illustrations.

Major category of terminology	Sub-categories	Countries examples
Competences (HU): "kompetencia". A frequent synonym is "képesség" which can be translated as aptitude or skill. (see below also under key competences)		
(IT) Competenze: knowledge and abilities that each pupil will turn into personal competencies with the help of the school. This was first introduced in the Portfolio delle competenze (portfolio), through the reform of 2003.		
(PT): competência - knowledge in action or in use. It refers to the integrated development of knowledge, skills and attitudes for all stages of basic education. Thus, competence does not involve adding a set of skills and attitudes to a certain body of knowledge. Instead, it relates to the promotion or integrated development of skills and attitudes which are conducive to the use of this knowledge in different situations with which the pupil may or may not be familiar.		
(Sl): Kompetenza tends to be used. (traditionally Slovenian term was zmoznost.): Developing and demonstrated abilities of individuals which enable them to act creatively, effectively and ethically in complex, unforeseeable and changed circumstances in professional, social and private life.		
Competence has three components:		
- Acquisition of theoretical, conceptual and abstract knowledge;		

104

- Developing skills, expertise and procedural knowledge to solve problems;		
- Developing an autonomous and ethical stance towards other people, community and environment – responsibility and autonomy.		
These are identified as cognitive, functional and socialisation perspectives.		
Key competences (AT) The terms Schlüsselqualifikationen (key qualifications), Schlüsselkompetenzen (key competencies) and, in particular, dynamische Fertigkeiten (dynamic skills) are used when talking about subject-independent, transversal competencies. The terms Grundfertigkeiten (basic skills) and Grundkompetenzen (basic competencies) are used when trying to convey the notion in its broadest sense.		
All subject-specific competence must therefore be supported and complemented by Sozialkompetenz (social competence, i.e. taking on responsibility, co-operation, initiative, active participation, team spirit) and Selbstkompetenz (personal competence, i.e. development of individual talents and capabilities, being aware of one's own strengths and weaknesses, self-reflection). Promotion of these two dynamic skills should prepare pupils for real-life situations that cannot be addressed through the simple recall of information. Coping with such situations requires self-esteem, initiative, acceptance of responsibility, and cooperation with others.		
(see below basic competences)		
(BG) *Ключови компетентности* no legal existence but used by teachers and decision-makers		
(CY) Key competences as core knowledge		
(CZ) *Klíčové* kompetence		
(DK) Nøglekompetence generally refers to the ability to apply knowledge and qualifications to differing situation but not part education terminology. The National Competence Account has identified competencies for professional life and personal development (environmental and natural competencies, physical competencies, social competencies and learning competencies) based on the DeSeCo Report. They are:		
- social competence,		

105

- literacy competence,		
- learning competence,		
- communicative competence,		
- self-management competence,		
- democratic competence,		

- ecological competence,
- cultural competence,
- health, sports and physical competence,
- creative and innovative competence.
(FI) Avaintaito = key competence & avaintaidot = key competences (see below cross-curricula themes)
(HU) The strategy of the ministry contained a list of specific key competences to be developed, as follows:
- the capability of using various learning techniques (NB this is close to learning to learn)
- the capability of intelligent learning
- the capability to apply knowledge
- instrumental competences (like communication, mathematics or ICT-related competences)
- social competences
- value orientation (the capability to understand and use norms and values)
(LT): Esminė kompetencija or Bendrasis gebėjimas
(MT): Key competences- 'Competence' is the proven ability to use knowledge, skills and other abilities to perform a function against a given standard in work or study situations and in professional and/or personal development. In the EQF, "competence' is described in terms of responsibility and autonomy.
Educational objectives are defined and explained in a competence format, under the headings
knowledge/information, skills, and attitudes as follows:
- Self-awareness and the development of a System of Ethical and Moral Values;
- The Development of Citizens and a Democratic Environment;
- Developing a Sense of Identity through Creative Expression;
106
- Religious Education;
- Strengthening of Gender Equality;
- Education on Human Sexuality;
- Preparing Education Consumers;
- Media Education;
- Effective and Productive Participation in the World of Work;
- Education for Leisure;
- Wise Choices in the Field of Health
- Greater Awareness of the Role of Science and Technology in Everyday Life;
- Competence in Communication;
- Preparation for Change.
Key Competences are listed as part of the National Qualifications Framework rather than as part of the curriculum (which predates the NQF). They are available for levels 1 to 3 of the NQF (up to the Secondary Education Certificate) and mirror the EU framework.
'The learning how to learn, self-directed learning and autonomous learning are the means for further personal development and keys to personal success in a career. There will hardly be any attempt at learning and training later on in life if the child is not equipped with literacy and numeracy, the ability to obtain and pass on information, the use [of] information and communication technology, the ability to analyse, to plan, to execute, the evaluate, the ability to work in a team - as a leader, as a team player, the need to be creative and entrepreneurial. This knowledge and these skills are essential elements of the National Framework curriculum."
(NL) Encompetenties (meaning, literally, core competencies). (See also below under general objectives)
(RO) Competenţă cheie
(SK) Kľúčové kompetencie
(SI) Key competences now described as: learning to learn; social skills; ICT; planning and developing one's career;
107
entrepreneurship; environmental responsibility; safety at work.
Cross-curricular
key competences
(DE): general (subject-independent) competencies essential in order to operate effectively at personal and professional level. They are not limited to cognitive abilities and represent complex operational competencies:
- are required for and supported by different subjects and subject areas,
- help solve complex, holistic tasks in real-life contexts,
- can be transferred to new situations not covered by the curriculum,
- can be characterised as general abilities.
Basic
competences
(AT) Grundkompetenzen- used to convey the notion in its broadest sense.
(EL) ΒΑΣΙΚΕΣ ΔΕΞΙΟΤΗΤΕΣ - referring to IT skills
ΕΠΙΚΟΙΝΩΝΙΑΚΕΣ ΚΑΙ ΚΟΙΝΩΝΙΑΚΕΣ ΔΕΞΙΟΤΗΤΕΣ - communications and social competencies
(ES) Competencias Básicas. The Spanish Royal Academy gives the following definition for Competencia: Skill, aptitude, suitability to do something or to take part in a subject. They are part of the enseñanzas mínimas, the core curriculum defined by central government (objectives, key competences, contents & evaluation criteria) that serves as a reference for the Autonomous Communities. The key competences respect at least 3 criteria: within reach of the majority, relevant in a wide range of areas of life, contribute to lifelong learning. They are:
- Competence in linguistic communication
- Mathematical competence
- Competence n knowledge of and interaction with the physical world
- Information processing and digital competence
- Social and civic competence
- Cultural and artistic competence
- Learning to learn
- Autonomy and personal initiative
Tiana et al (2011)
108
Foundation of
competences
(BE-fr) In compulsory education there is the Socles de compétences (foundations of competences) and the compétences terminales (final competences achieved). The socles de compétences are a "formal system of reference that sets out, in a structured way, which competencies must be exercised until the end of the first eight years of compulsory education, and those for which proficiency must be attained at the end of each stage, because they are considered necessary for social insertion and the pursuit of studies". As guarantors of school democratisation, learning guides, and assessment watchdogs, the socles de compétences mark out the difficult path that must lead not only to equal access to school, but also to equal results from education and to equal requirements for all children. They include both interdisciplinary and cross-curricula competencies, which, when gradually acquired, ensure the development of the pupil and his/her personality, and subject-related competencies.
(FR) Socles de connaissances et de compétences :
- Command of the French language
- Command of at least one modern foreign language
- Command of the main elements of mathematics and of science and technology
- Practical knowledge of information and communication
- Cultural education/awareness to enable participation in society/the exercise of citizenship
- Civic and social competences
- Autonomy and initiative
(LU) Socle de compétences. In German the term is: Kompetenzorientierte Bildungsstandards:
- Logical reasoning - mathematics
- Language, Letzeburgesch and opening to languages
- Discovery of the world by all the senses
- Psycho-motor skills, corporal expression and health
- Creativity, awakening to aesthetics and culture
- Living together and values.
There are transversal competences: citizenship, autonomy and personal aspirations
109
Final competences
(to be achieved)
(BE-fr) Compétences terminales (see above)
General
competences
(EE) üldpädevus - general competence is used in the national curriculum and consists of four competences:
- learning competence - the ability to manage one's learning activities by using efficient learning strategies and suitable learning style; to motivate oneself to learning, to search for necessary information, have an overview of one's knowledge, to relate one's knowledge to that created by other people and create new knowledge, to monitor and assess one's thinking and learning activities.
- activity competence - ability to notice problems and to solve them, to plan one's activities, set goals and foresee expected results, to choose activity means, to assess the results on activities, ability to cooperate.
- value competence - ability to perceive one's relation to other people, to one's own and other cultures nature and things created by humans to assess relations between people and activities in relation to general moral norms.
- Self-definition competence - ability to understand and assess oneself, understand the meaning of one's activities and behaviour sin society, to shape one's personality.
They are specified depending on the age group. There are also subject competences which describe the content of each subject (see section 1 for the list of subjects). As a result of the integration of subject competences and general competences students will have domain-specific competences:
- valdkonnapädevus - domain-specific competence. There are seven domain-specific competences that are wider than those covered by individual subjects and should cover each aspect of the interaction a person has with the world surrounding him/her as well as her/himself. They are: nature competence; social competence; reflection & interaction competence; communication competence; technology competence; art competence; mathematics competence. There are expected outcomes per age group.
- kohustuslikud läbivad teemad - compulsory cross-curricular themes. There are four that are not taught as separate subjects (although they can be) but have to be covered while learning other subjects. They are: environment and sustainable development, career & career planning, media studies, ICT & security.
- ainealased teadmised ja oskused - skills and knowledge in specific subjects. The second part of the national curriculum that consists of subject curricula states the competences for each one to be attained by all pupils at a specific school stages.
New competences (LT) The Provisions of the National Education Strategy 2003-2012 stresses the need to develop citizenship, entrepreneurship, digital competences, learning to learn and cultural awareness competences. It refers to cross
110
curricular competences: To ensure the quality of education development the contents of education shall be updated and related to new competencies of an individual: a more consistent transition to the new contents development policy oriented towards development of general abilities, values, provision of the necessary competencies based not so much on the transfer of knowledge, as on their analysis, critical assessment and practical application; such competencies shall relate the contents of education to actual life, actual problems and their solutions.
Essential
competences
(PT) Competências essenciais (essential competencies) constitute the body of general and subject specific knowledge which is considered indispensable for all citizens in today's society. In particular, it is essential to identify the knowledge which enables pupils to develop their understanding of the nature of each subject and its processes, as well as a positive attitude towards intellectual activity and the practical work it entails.
At the end of basic education, it is expected that pupils should have acquired the following general essential competencies, involving the ability to do the following:
- mobilise cultural, scientific and technological knowledge to understand reality and deal with everyday situations and problems;
- use languages from the different fields of cultural, scientific and technological knowledge to express themselves effectively;
- use the Portuguese language to communicate proficiently and structure their thoughts;
- use foreign languages to communicate proficiently in everyday situations and assimilate information;
- adopt personalised working and learning methodologies geared to achieving set objectives;
- investigate, select and organise information in order to transform it into knowledge that can be mobilised;
- adopt appropriate problem-solving and decision-making strategies;
- carry out activities independently, responsibly and creatively;
- cooperate with others in common tasks and projects.
Capacities (UK - Scot.) The purpose of the Curriculum for Excellence is encapsulated in the four capacities - to enable each child or young person to be a successful learner, a confident individual, a responsible citizen and an effective contributor.
111
The curriculum aims to ensure that all children and young people in Scotland develop the knowledge, skills and attributes they will need if they are to flourish in life, learning and work, now and in the future. Each one is expressed as attributes and capacities to be achieved through learning experiences and outcomes which are a set of statements which describe the expectations for learning and progression for each curriculum area.
Competence
Account
(DK) Nationalt Kompetenceregnskab National Competence Account - key competences defined as acting as axes of rotation, activating professional competences and serving as a pre-requisite for the acquisition of professional competences.
Skills (UK- Eng.) Skills:
- personal learning and thinking skills
- key skills/functional skills
- cross-curricular themes/whole curriculum dimensions
The personal learning and thinking skills (PLTS) framework contains six groups of skills: independent enquirers; creative thinkers; reflective learners; team workers; self-managers; effective participators. There are also crosscurriculum dimensions which can provide a focus for work within and between subjects and across the curriculum. They include: identity and cultural diversity; healthy lifestyles; community participation; enterprise; global dimension and sustainable development; technology and the media; creativity and critical thinking.
UK (Nn. Ire.): At the heart of the curriculum lies an explicit emphasis on the development of skills and capabilities for life-long learning and for contributing effectively to society. These whole curriculum skills and capabilities consist of:
- Cross-Curricular Skills (Communication, Using Maths and Using ICT)
- Thinking Skills and Personal Capabilities - TSPCs - (including Managing Information, Thinking, Problem Solving and Decision-Making, Being Creative, Working with Others, and Self-Management)
They are embedded and infused throughout the revised Northern Ireland Curriculum at each key stage and pupils should have opportunities to acquire, develop and demonstrate these skills in all areas of the curriculum.
112
UK (Wales): Skills Framework for 3 to 19 year olds:
- Developing thinking: Learners develop their thinking across the curriculum through the processes of planning, developing and reflecting.
- Developing communication: Learners develop their communication skills across the curriculum through the skills of oracy, reading, writing and wider communication.
- Developing ICT: Learners develop their ICT skills across the curriculum by finding, developing, creating and presenting information and ideas and by using a wide range of equipment and software.
- Developing number: Learners develop their number skills across the curriculum by using mathematical information, calculating, and interpreting and presenting findings.
Basic skills (AT) Grundfertigkeiten- used to convey the notion in its broadest sense. (see also above under key competences)
Dynamic skills (AT) Dynamische Fertigkeiten (dynamic skills) - subject-independent transversal competencies. . (see also above under key competences)
Skill / aptitude (HU) "kompetencia" - a frequent synonym is "képesség" which might be translated as aptitude or skill (see also above under competences)
Key skills (IE) Key Skills Framework:
- Primary: the ability to question, analyse, investigate, think critically, solve problems
- Junior secondary: interact effectively with others: communication and literacy, numeracy, manipulative skills, information technology, thinking and learning, problem solving, personal and interpersonal, social
- Senior cycle: information processing, critical and creative thinking, working with others, communicating,

being personally effective.
Cross-curricular
skills
(PL) A number of cross-curricular transversal skills are mentioned:
- planning, organising and assessing pupil's learning, taking responsibility for one's learning process,
- effective communication in various circumstances, presenting one's viewpoint and acknowledging the
views of others, proper use of language, preparation for public presentations,
113
- effective cooperation within a group, building interpersonal relations, taking individual and collective
decisions,
- solving problems in a creative way,
- searching for, ranging and using information from various sources, effective usage of ICT,
- using the acquired knowledge in practice an creating of necessary experiences and patterns of behaviour,
- developing personal interest, acquiring methods of negotiative ways of solving conflicts and social
problems.
Goals and
objectives
Core objectives (NL) Core objectives (which relate to subjects) and general objectives (which are cross-curricular) are used.
Development
objectives and final
objectives
(BE-fl) Ontwikkelingsdoelen and Eindtermen
Final objectives are minimum objectives with regard to knowledge, insight, skills and attitudes, which the
educational authorities consider necessary and attainable for a specific pupil population. Developmental objectives
are minimum objectives which the educational authorities consider desirable for a specific pupil population (Decree
4 February 2003). The final objectives and developmental objectives define which knowledge, insight, skills and
attitudes society considers necessary or desirable for pupils at the various levels of education. Thus, final
objectives and developmental
Goals to be
achieved and
goals to strive for
(LV) The National Standard for General Secondary Education determines the goals common for all general
secondary education curricula:
- to provide pupils with knowledge and skills enabling them to prepare for further education;
- to encourage the development of their personality and of their physical and mental capacities, and to
develop their understanding of health as a condition for the quality of life;
- to encourage the development of positive, critical and socially active attitude, and to develop
understanding of rights and obligations of Latvian citizens; to develop the ability to study independently
and improve knowledge as well as create motivation for lifelong learning and a purposeful career.
114
(SE) The term "key competences" does not figure in the documents determining the Swedish education system.
Instead the concept of goals is used: goals to strive for (quality of education process) and goals to be attained
(learning outcomes). Amongst the goals are the knowledge, skills and attitudes corresponding to particular key
competences. The goals are not ranked in order of importance. There is a nation-wide curriculum for pre-school,
compulsory school and upper secondary school. (See annex 1 for list)
General Objectives (NL) General objectives are regarded as important for all learning areas in the primary curriculum are:
• A good working attitude
• Use of learning strategies
• Reflection on one's own actions and learning
• Expression of one's own thoughts and feelings
• Respectful listening to and criticising of others' opinions
• Acquisition and processing of information
• Development of self-confidence
• Respectful and responsible dealing with others
• Care and appreciation for the living environment
Secondary level: the six general objectives are:
- Cross-disciplinary themes: Within the context of broad and balanced consideration of people and society,
pupils should obtain a certain level of insight into their position within their immediate personal
environment, as well as the wider social environment
- Learning to do: In situations as close as possible to real life, pupils should learn how to develop further
certain skills acquired at school, making use of ICT where appropriate.
- Learning to learn: Pupils should learn to acquire knowledge and skills, making use of ICT where
appropriate. To this end, they should learn (amongst other things) certain strategies for improving the
learning process.
- Learning to communicate: Pupils should learn how to develop further certain social and communicative
skills, on an interactive basis where appropriate. T
- Learning to reflect upon the learning process: Pupils should learn to be analytical about and to control the
learning process, by reflecting upon their own performance.
115
- Learning to reflect upon the future: Pupils should learn to be analytical about their options for the
future/prospects and interests, by reflecting upon their own performance.
Training objectives (CY) TVET Curriculum includes training objectives (the content, the teaching materials, the students' profile and
suggested approaches and methods in order to achieve the training objectives.)
Goals in the
curriculum
(HU) The NCC contains the following parts: (1) the description of the role of the NCC in public education, (2) the
common values of education, (3) the basic goals (including the development of key competencies and the
development of a number of other areas), (4) the principles of differentiation, (5) equity principles, (6) the principles
of the elaboration of school level curricula with references to other national regulatory documents, (7) the
standards themselves.
In the NCC the standards are defined as learning outcomes, i.e. knowledge, skills, competencies, attitudes etc. To
be possessed by the pupils by the end of the specific cycle.
The NCC 2003 also contained a thesaurus which defined the notion of "competence based" and the relation
between "competence" and "knowledge". According to this. "The 'competence based approach means a
commitment that determines the taxonomy of the curriculum. In the background of this approach there is a theory
of personality which considers the competences (personal, cognitive, social and special competences) as the main
components of the personality... [This approach] links the competences to specific activities and tasks that are
achieved by the human being: someone is competent in relation with an activity if he/she is capable to achieve the
tasks related with this activity." This was the basis for restructuring the NCC so that instead of the element of
national culture ("knowledge") it was focusing on specific developmental tasks that are supposed to develop
specific competences.
Cross-curricular
themes
(FI) The national core curriculum defines the goals, main content of the various subjects & cross-curricular themes.
They are intended as an explicit part of the curriculum to be taught across the whole curriculum, and anchored in
particular areas of the subject curriculum. They are educational challenges with social significance. At the same
time, they are current statements on values. The objectives behind them are
- observe and analyse contemporary phenomena and operating environments;
116
- express justified ideas of a desirable future;
- assess their own lifestyle and prevailing trends from a future perspective; and
- make choices and take action for the future that they consider as being desirable.
For the upper grades of basic education, the cross-curricular themes are:
- Growth of the person
- Cultural identity and internationalism
- Media skills and communication
- Participatory citizenship and entrepreneurship
- Responsibility for the environment, well-being and a sustainable future
- Safety and traffic competences
- Technology and the individual
For all upper secondary pupils in both the general and vocational strands the cross-curricular themes are:
- Active citizenship and entrepreneurship
- Welfare and safety
- Sustainable development
- Cultural identity and knowledge of cultures
- Technology and society
- Communication and media competence
117
Annex 3: Sweden: goals to strive towards and goals to attain
The 'goals to strive towards' detailed in the curriculum documents include that schools should ensure that all pupils:
- Develop the ability to form and express ethical viewpoints based on knowledge and personal experiences.
- Respect the intrinsic value of other people.
- Reject the oppression and abusive treatment of other people and assist in supporting them.
- Can empathise with and understand the situations other people are in and can develop the will to act with their best interests at heart.
- Show respect for their immediate environment as well as for the environment in its wider perspective.
- Develop a sense of curiosity and the desire to learn.
- Develop their own individual way of learning.
- Develop confidence in their own ability.
- Feel a sense of security and learn to consider and show respect in their dealings with others.
- Learn to carry out research, and to learn and work independently and together with others.
- Acquire good knowledge in school subjects and subject areas to develop themselves and prepare for the future.
- Develop a rich and varied language and understand the importance of cultivating this.
- Learn to communicate in foreign languages.
- Learn to listen, discuss, reason and use their knowledge as a tool to formulate and test assumptions as well as to solve problems.
118
- Reflect on their experiences and critically examine and value statements and relationships.
- Acquire sufficient knowledge and experience to be able to make well considered choices over further education and vocational orientation.
- Take personal responsibility for their studies and working environment.
- Gradually exercise increasingly greater influence over their education.
- Have an understanding of democratic principles and develop their ability to work democratically.
- Acquire sufficient knowledge and experience to be able to examine different options and make decisions concerning their own future.
- Develop the ability to assess their results themselves.
'Goals to attain' in the compulsory school include to:
- Have mastered Swedish and to be able to listen and read as well as to express ideas and thoughts in the spoken and written language.
- Have mastered basic mathematical principles and be able to use these in everyday life.
- Know and understand basic concepts and contexts within the natural sciences as well as within technical, social and human areas of
knowledge.
- Have developed the ability to express themselves creatively and be interested in participating in the range of cultural activities that society has
to offer.
- Be familiar with central parts of the Swedish, Nordic and Western cultural heritages.
- Be aware of the culture, language, religions and history of national minorities.
- Be able to develop and use their knowledge and experience in as many different forms of expression as possible covering language, images,
music, drama and dance.
119
- Have developed their understanding of other cultures.
- Be able to communicate in speech and writing in English.
- Know the basis of society's laws and norms as well as their own rights and obligations in school and society.
- Be aware of the interdependence of countries and different parts of the world.
- Be aware of the requirements for a good environment and understand basic ecological contexts.
- Have a basic knowledge of the requirements to maintain good health and to understand the importance of lifestyle for health and the
environment.
- Have some knowledge of the media and of their role in relation to the media.
- Be able to use information technology as a tool in their search for knowledge.
- Develop their learning and to acquire deeper knowledge in a number of individually selected subject areas.

Knowing myself Reflection Has a tendency to
brood about past
failures. Can become
depressed.
Personal reflection
often leads to a
somewhat negative
outlook on life.
Spends more time
thinking about the
past than the future.
Uses personal
reflection to adopt a
more positive
approach to life.
Reflects on past
experience in order to
adopt a more positive
view of life.
Is mostly forward
looking and knows
how to learn from
personal experience.
Is very forwardlooking. Learns well
from personal
experience.
Knowing myself awareness of
own qualities
and options for
change
Has no significant
awareness of own
qualities and options
for change.
Has little awareness
of own qualities and
options for change.

Has a limited
awareness of own
qualities and options
for change.
Is aware of own
qualities and options
for change.
Shows a broad
awareness of own
qualities and options
for change.
Is well aware of own
qualities and options
for change.
Is fully aware of own
qualities and options
for change.
Knowing myself planning and
implement
changes
Does not plan ahead.
Is not interested in
implementing
changes in personal
development.
Rarely plans ahead.
Has little interest in
implementing
changes in personal
development.
Occasionally plans
ahead. Makes an
effort to implement
changes in personal
development.
Makes some effort to
plan ahead but lacks
organisation. Is
interested in
implemented
changes in personal
development.
Usually plans ahead.
Is interested in
implementing
changes in some
aspects of personal
development.
Almost always plans
ahead. Is keen to
implement changes
in personal
development.
Always plans well
ahead. Knows how
to implement
changes in personal
development and
does so.

Coping with
Feelings
understanding
feelings and
how they
influence
thinking and
behavior
Always displays
continuous outbursts
of temper. Reacts
negatively to any
criticism. Unable to
identify and name
own feelings
Nearly always
displays frequent
outbursts of temper,
unable to take
criticism, unable to
name or identify own
feelings and the
affect on their
reactions
Frequently displays
outbursts of temper,
reacts defensively to
criticism. Able to
name and describe
feelings. Often able to
identify and name
own feelings, but
displays lack of
understanding of the
impact on their
reactions
Displays occasional
outbursts of temper
or extreme mood
swings due to factors
beyond their control.
Can accept criticism
but does not take
positive action. Can
identify their own
feelings but do not
always reflect on how
it affects their
reactions
Occasionally loses
their temper with
others or in stressful
situations. Usually
accepts criticism and
sometimes takes
positive action as a
result. Can identify
their feelings and
sometimes show
understanding of how
it influences their
reactions
Rarely loses their
temper with others or
in stressful situations.
Accepts most
criticism and often
takes positive action
as a result. Can
identify their feelings
and understand how
it influences their
reactions
Never loses their
temper with others or
in stressful
situations. Accepts
criticism and takes
positive action as a
result. Can identify
their feelings and
understand how it
influences their
reactions and the
reactions of others.
Coping with
Feelings
appropriate
expression in
situations and
linking feelings
to actions
Finds considerable
difficulty expressing
personal feelings. Is
unable to link feelings
to actions.
Is largely unable to
express personal
feelings. Has little
ability to link feelings
to actions.
Can sometimes
express personal
feelings. Has a
limited ability to link
feelings to actions.
Displays some ability
to express personal
feelings. Can
sometimes link
feelings to actions.
Is usually able to
express personal
feelings. Is mostly
able to link feelings to
actions.
Is good at expressing
personal feelings. Is
able to link feelings to
actions in most
situations.
Expressed personal
feelings with
complete ease. Is
always able to link
feelings to actions.
Coping with
Feelings
recognise
feelings
produced by
prejudice and
discrimination
Shows no awareness
of the feelings
produced by
prejudice and
discrimination.
Shows little
awareness of the
feelings produced by
prejudice and
discrimination.
Shows a limited
awareness of the

feelings produced by prejudice and discrimination.
Shows some awareness of the feelings produced by prejudice and discrimination.
Usually shows awareness of the feelings produced by prejudice and discrimination.
Almost always shows awareness of the feelings produced by prejudice and discrimination.
Is always sensitively aware of the feelings produced by prejudice and discrimination.
Coping with feelings
understand and respond to feelings of others
Shows no awareness or understanding of the feelings of others.
Shows little awareness or understanding of the feelings of others.
Shows some awareness and understanding of the feelings of others but makes little attempt to respond to them.
Shows some awareness and understanding of the feelings of others and responds to a limited degree.
Usually shows awareness and understanding of the feelings of others and is able to respond in a suitable way.
Almost always shows awareness and understanding of the feelings of others and makes an effort to respond appropriately.
Shows a sensitive awareness and understanding of the feelings of others and always responds sympathetically.

Holding Beliefs put forward your opinion, appreciate others and recognise their influence
Never puts forward an opinion. Does not appreciate others or recognise their influence.
Rarely puts forward an opinion. Has a very limited appreciation of others and usually fails to recognise their influence.
Will put forward an opinion but with little confidence. Has some appreciation of others and can sometimes appreciate their influence.
Is wiling to put forward an opinion on occasions and makes a real effort to appreciate others and recognise their influence.
Is able to put forward an opinion with some conviction. Shows some appreciation of others and can recognise their influence.
Usually puts forward an opinion confidently. Mostly appreciates others and recognises their influence.
Puts forward an opinion with confidence. Always appreciates others and recognises their influence.
Holding Beliefs understand what beliefs are and how they affect attitudes and behavior
Shows no understanding of the beliefs of others. Is insular in outlook. Prefers not to mix with people of different beliefs.
Shows little understanding of the beliefs of others. Has little interest in how beliefs affect attitudes and behaviour.
Makes some effort to understand the beliefs of others. Limited understanding of how they affect attitudes and behaviour.
Shows some understanding of what beliefs are and how they affect attitudes and behaviour. Can be suspicious of people with different beliefs.
Usually shows understanding of the beliefs of others. Realises how they affect attitudes and behaviour.
Almost always shows understanding of the beliefs of others and how they affect attitudes and behaviour.
Shows a deep understanding of the beliefs of others. Is very open-minded and receptive to the beliefs of others.
Handling Relationships
recognise and use skills to make and keep different types of relationship
Is unable to recognise and use skills to make and keep different kinds of relationships.
Has difficulty in recognising and using skills to make and keep different kinds of relationships.
Has a limited ability to recognise and use skills to make and keep different kinds of relationships.
Shows some ability to recognise and use skills to make and keep different kinds of relationships.
Is usually able to recognise and use skills to make and keep different kinds of relationships.

Is almost always able
to recognise and use
skills to make and
keep different kinds
of relationships.
Is always able to
recognise and use
skills to make and
keep different kinds
of relationships.

Eindhoven, The Netherlands
Introduction
There is a saying, "In education everything happens 50 years later". If
true, this may have been not too problematic in older times, when changes
were slow, but in times like ours where changes are extremely fast, it will be
disastrous. Instead of being behind, education should be ahead. Primaryschool, for instance, will have to prepare today's students for their entrance
in society, which will be about twenty years from now. However, this is not
the case. Instead, Tony Wagner (2008) speaks of an "achievement gap" between what schools (in the USA) are teaching and what students will need
to succeed in today's global knowledge economy. He argues that, "students
are simply not learning the skills that matter most for the twenty-first century" (ibid, 8-9). And he goes on to say that, "Our system of public education—our curricula, teaching methods, and the tests we require students to
take—were created in a different century for the needs of another era. They
are hopelessly outdated." (ibid, 8-9). If we focus on employability, we may
observe, that future employees in countries such as the USA will have to
compete with colleagues in other countries with similar skills who work for
lower wages. But, more importantly, the skills that the current and future
jobs require anywhere, differ significantly from what current education offers. Wagner interviewed numerous CEO's of large companies and he found
a strong communality in what they look for in new employees; as one of
them phrases it: "First and foremost, I look for someone who asks good
questions." (ibid, 2). The underlying rationale is that these employees will
have to function in dynamic organizations. Employees today continuously

have to learn new things. From this perspective, asking the right questions,
is an important skill. In this respect, there is, however, a huge gap between
what society demands and what schools offer. Prevailing language educa-Aiming for 21
st
. Century Skills 31
HMS i JME, Volume 4. 2012
tion, for instance, aims at technical reading skills, but does not ask students
to think about what they read. Mathematics instruction also often focuses on
skills, instead of understanding. Schools, Wagner (ibid) goes on to say, are
not designed to support students in learning to think. The reason for that, he
argues, is that we as a society never asked schools to teach students to think.
This is reflected in national tests that are not designed to assess the ability to
reason and analyze. The point is, the world has changed, schools have not.
Next to the dynamics of the modern workplace, there is also a shift in
the type of work people do. Empirical research by the economists Levy and
Murnane (2006) shows that employment involving cognitive and manual
routine tasks in the USA dropped between 1960 and 2000, while employment involving analytical and inter-active non-routine tasks has grown in
the same period. This change especially concerned industries that rapidly
automatized their production. Parallel to the development in industry, similar changes occurred in other areas where a strong computerization took
place. This change happened on all levels of education. Jobs with a high
routine character are disappearing. Jobs that will be offering good prospects
for the future, are jobs which concern non-routine tasks, which are tasks that
require flexibility, creativity, problem solving skills, and complex communication skills. Autor, Levy, and Murnane (2003) refer to examples such as
reacting to irregularities, improving a production process, or managing people. The jobs of the future are the ones that ask for flexibility, creativity,
lifelong learning, and social skills. The latter are jobs that require communication skills, or face-to-face interaction—such as selling cars or managing
people. These changes do not only affect the decline or rise specific jobs;
existing jobs are changing as well. Secretaries, and bank employees for instance have got more complex tasks since word processors and ATM's have
taken over the more simple tasks.
Earlier, Friedman (2005) pointed to the fact that the effects of computerization and globalization overlap and reinforce each other. Routine tasks
can easily be outsourced, since information technology enables a quick and
easy worldwide exchange of information. The latter also makes it possible
to outsource business services, such as call-centers, or the work of accountants and computer programmers. Another effect of globalization is that it
forces companies to work as efficient as possible. This requires companies
to immediately implement computerization and outsourcing when it is economically profitable and strengthens the market position of the company. It
also demands of the company to be on the lookout for opportunities to im-32 Koeno Gravemeijer
CIEAEM 64- Proceedings
prove efficiency. As a consequence, working processes will have to be
adapted continuously. This in turn, puts high demands on the workers, who
have to have a certain level of general and mathematical literacy to be able
to keep up.
In summary we may conclude that schools will have to change to comply with the requirements imposed by our rapidly changing society. In this
paper we will especially look into the consequences for mathematics education. We will start by taking a closer look at the 21
st
century skills. This will
reveal the need for changes in the nature of the instructional process, and we
will discuss what this means for mathematics education by reviewing the
main characteristics of, annex requirements for, problem-centered, interactive, mathematics education. Next we will turn to the content of mathematics education, which also has to change. Will we start with the 21
st
century
skills.
21
st
century skills.
Voogt & Pareja Roblin (2010), who reviewed the literature around five
theoretical frameworks on 21
st
century skills, observe that the need for 21
st
century skills is mostly addressed by private or business initiatives, while
educational leaders, practitioners and the educational community do not actively participate in the debate. The frameworks they reviewed concern: the
'Partnership for 21st century skills' (Partnership for 21
st
century skills,
2008), 'EnGauge' (North Central Regional Educational Laboratory and the
Metiri Group, 2003), 'Assessment and Teaching of 21st Century Skills'
(ATCS) (Binkley, Erstad, Herman, Raizen, Ripley & Rumble (2010), 'National Educational Technology Standards' (NETS) (Roblyer, 2000), and
'Technological Literacy for the 2012 National Assessment of Educational
Progress' (NAEP). Dede (2009) compares similar frameworks in his review
of 21
st
century skills. Both review studies show that the frameworks appear
to strongly agree on the need for skills in the areas of communication, collaboration, ICT literacy, and social/cultural awareness. We may take Wagner's (2008) list of what he calls, 'the new survival skills', as exemplary:
1. critical thinking and problem solving
2. collaborating and leading by influence
3. agility and adaptability
4. initiative and entrepreneurism
5. effective oral and written communication
6. accessing and analyzing information
7. curiosity and imagination. Aiming for 21
st
. Century Skills 33
HMS i JME, Volume 4. 2012
We may also follow Wagner (ibid) in arguing that the 21
st
century skills
are not just about employability
1
. They will also have to include broader
goals, such as becoming a responsible, active and well-informed citizen.
Wagner (ibid) typifies this broader goal by asking if the students would
eventually be well-equipped for acting as a member of a jury within the US
legal system: "Would they know how to distinguish fact from opinion,
weigh evidence, listen with both head and heart, wrestle with the sometimes
conflicting principles of justice and mercy, and work to seek the truth with
their fellow jurors?" (Wagner, 2008, xvi-xvii). This characterization resonates with the theme of this conference: "Democracy in mathematics curriculum", and the corresponding issue of contributing to critical thinking
and decision-making in the society. This begs the question of how to translate these lofty goals into instructional practice.
Mathematics education for 21
st
. century skills
Most publications on 21
st
century skills do not discuss how these goals
might be achieved in education. It seems fair to say, however, that adopting
21
st
. century skills as educational goals will primarily affect the way instructional practice is shaped. Mathematics education seems to be a good place to
incorporate these goals. Dam, & Volman (2004), for instance, conclude on
basis of a review study that critical thinking is best developed in conjunction
with science and mathematics education. But also in a more general sense, it
may be argued that interactive, problem-centered, mathematics education
will contribute to most 21
st
. century skills. However, if we want to integrate
the objective of fostering 21
st
. century skills with attaining the regular goals
of mathematics education, we will have to find a way by which problem
solving, collaborating, communicating etc. serves the mathematics goals. In
theory this is not too problematic, since the literature on reform mathematics
points to this very type of activities—problem solving, collaborating, communicating etc.—as necessary conditions to enable students to construct
meaningful mathematics. "In theory", because we know that creating
mathematics classrooms which can be characterized as interactive and problem-centered is not easy. We will discuss this issue by reviewing the main
characteristics of, annex requirements for, problem-centered, interactive,
mathematics education.
Local instruction theories
By reform mathematics we mean an approach to mathematics education
that assumes that students have to construct or reconstruct mathematics by 34 Koeno Gravemeijer
CIEAEM 64- Proceedings
themselves with help of the teacher and the textbook. Instead of reconstructing, one may also speak of reinventing—following the tradition of realistic
mathematics education (RME) (Gravemeijer, 2008). One of the prerequisites for fostering reinvention—which has been a focus of RME research—
is the availability of local instruction theories that serve the need for guidelines about the routes along which students might reinvent pieces of mathematics. A local instruction theory consists of a theory about a possible learning process for a given topic, and the means of supporting that process.
Mark that a local instruction theory should not be confused with a scripted
textbook. The local instruction theory is meant to function as a framework
of reference for teachers.
Hypothetical learning trajectories
On the basis of such a framework of reference a teacher may design socalled 'hypothetical learning trajectories' (Simon, 1995) for the actual instructional activities in his or her classroom at a given moment in time. With
the term hypothetical learning trajectory, Simon (1995) refers to the notion
that a teacher has to deliberate on what mental activities the students might
engage in as they participate in the instructional activities, he or she is considering. A decisive criterion of choice then will be how those mental activities relate to the chosen learning goals. He emphasizes the hypothetical
character of those learning trajectories; the teachers are to analyze the reactions of the students in light of the stipulated learning trajectory to find out
in how far the actual learning trajectory corresponds with what was envisioned. Based on this information the teacher has to construe new or adapted
instructional activities in connection with a revised learning trajectory.
Classroom social norms
In addition to a sound planning of the instructional activities, another
prerequisite for inquiry mathematics concerns the participation of the students. For the point is that students do not easily engage in problem solving
and reasoning in regular classrooms (Desforges & Cockburn, 1987). Cobb
& Yackel (1996) argue that this is not surprising, because students are often
familiar with a classroom culture in which the classroom social norms
(Cobb & Yackel, 1996) are that the teacher has the right answers, that the
students are expected to follow given procedures, and that correct answers
are more important than one's own reasoning. In this type of classrooms
teachers usually ask questions of which they already know the answer.
Apart from being used to this situation, students have learned what to expect Aiming for 21
st
. Century Skills 35
HMS i JME, Volume 4. 2012
and what is expected from them. In relation to this, Brousseau (1988) speaks
of an implicit 'didactical contract'. Significant, however, is that the students
have learned this by experience, not because the teacher told them so.
In contrast to what is common in school mathematics, the classroom has
to work as a research, annex learning, community. To make this happen, the
students have to adopt classroom social norms that fit an inquiry-oriented
classroom culture. These encompass, the obligation to explain and justify
one's solutions, to try and understand other students' reasoning, and to ask
questions if one does not understand, and challenge arguments one does not
agree with. In addition to those social norms, Cobb & Yackel (1996) observe that the teacher also has to establish socio-mathematical norms, which
relate to what mathematics is. This is expressed in norms about issues such
as, what counts as a mathematical problem, what counts as a mathematical
solution, and what counts as a more sophisticated solution. In regard to the
latter, we may argue that socio-mathematical norms lay the basis for the intellectual autonomy of the students, as it enables them to decide for themselves on mathematical progress.

Task orientation
In addition to appropriating inquiry-based norms, students also have to
be inclined to invest effort in solving mathematical problems, discussing solutions, and discussing the underlying ideas. Students may engage in learning activities for different reasons. The attitude of students in a mathematics
classroom can be broadly divided in two categories, ego orientation and
task orientation (Jagacinski & Nicholls, 1984). Ego orientation implies that
the student is very conscious of the way he or she might be perceived by
others. Ego-oriented students are afraid to fail, or to look stupid in the eyes
of their fellow students, or the teacher. As a consequence, they may choose
not to even try to solve a given problem, in order to avoid embarrassment.
Task orientation on the other hand implies that the student's concern is with
the task itself, and on finding ways of solving that task. Research shows that
task orientation and ego orientation can be influenced by teachers.
Cobb, Yackel & Wood (1989) report on a study on a socio-constructivist
classroom, where task orientation was fostered. Part of their approach was
to change the classroom culture from one of competition, where students
compare themselves with each other, and with the criteria set by the teacher,
into a classroom culture, where students would measure success by comparing their results with their own results earlier. We may think of the latter
perspective as one similar to that of an amateur painter or amateur musician. 36 Koeno Gravemeijer
CIEAEM 64- Proceedings
An amateur musician would not think of comparing him- or herself with
others; there would always be many people performing better. Instead an
amateur musician would be pleased if he or she would master a piece, which
he/she could not play some time ago. A similar situation is possible in a
mathematics classroom, where the goal for the students would be personal
growth. Here, experiencing an 'Aha-Erlebnis', for instance, may function as
an incentive. In such a classroom, students might even protest to be given
'the solution', for that would deprive them from the satisfaction of figuring
out things for themselves. The aforementioned research of Cobb et al.
(1989) shows that a classroom culture that emphases the exchange of ideas,
and the development of mathematical understanding as a collaborative endeavor, may foster the task orientation of the students.
Mathematical interest
In connection with student motivation, we may add that next to the obvious "pragmatic interest", which realistic problems appeal to, students will
also have to develop "mathematical interest" (Gravemeijer & Van Eerde,
2009). This concerns the preparedness of the students to the investigate solution procedures, concepts and so on, from a pure mathematical perspective. This is a necessary condition for construing more sophisticated mathematics. Mathematical interest will rarely come naturally, but has to be cultivated by the teacher by
asking questions such as: What is the general principle here? Why does this work? Does it always work? Can we describe it in a
more precise manner? We may assume that the teacher can foster the students' mathematical interest by making mathematical questions a topic of
conversation, and by showing a genuine interest in the students' mathematical reasoning.
Framing topics for discussion
Another essential role of the teacher concerns the orchestration of productive whole-class discussions. For this the teacher has to identify the differences in mathematical understanding which underlie the variation in student responses (Cobb, 1997). Next, he or she has to frame these underlying
mathematical issues as topics for whole-class discussions. And finally, he or
she has to orchestrate a productive whole-class discussion on those topic in

order to foster higher levels of understanding.
In a similar feign, Stein, Engle, Smith, & Hughes (2008), espouse five
practices for promoting productive disciplinary engagement: anticipating
students' mathematical responses, monitoring student responses, purpose-Aiming for 21
st
. Century Skills 37
HMS i JME, Volume 4. 2012
fully selecting student responses for public display, purposefully sequencing
student responses, and connecting students responses. The first two overlap
to some extent with Simon's hypothetical learning trajectory, whereas the
last three are related to identifying, framing, and discussing mathematical
issues. Although a difference may be that Stein et al. (2008) seem to try to
address both mathematical ideas and the solution strategies of the students,
while Cobb (1997) emphasizes the mathematical issues that underlie student
solutions, and tries to steer away from a focus on solution strategies as such.
21
st
Century mathematical skills
The publications on 21
st
century skills mostly list general skills. Elaborations of what changes are needed in the content of the various topics that are
taught, are very scarce. With some exceptions, there is also little attention is
given to the content of the mathematics curriculum. One of the reasons may
be that one of the effects of computerization is that mathematics becomes
invisible. Mathematics is hidden in integrated systems, such as spreadsheets,
automatics cashiers, and automated production lines. However, a consequence of this is that many people become "mathematics consumers" , as
Levy en Murnane (2006, 19) put it. They argue that people who use computerized systems are expected to make decisions on the basis of the output
of hidden mathematical calculations. The computerized equipment does the
actual calculation. However, they go on to say, if the decision maker does
not understand the underlying mathematics, he or she is very vulnerable to
serious errors of judgment. If we follow this line of reasoning, we may discern two seemingly conflicting tendencies. On the one hand, we appear to
need less and less mathematics, since various apparatus take over a growing
number of mathematical tasks. On the other hand, we will need more
mathematics as we develop into 'mathematics consumers', who become increasingly dependent of the quantitative information and mathematical
models—which we ought to understand.
The aforementioned hidden character of mathematics in the information
society makes it difficult to establish, what mathematics students will have
to learn to become sensible mathematics consumers. To answer this question, we will follow two tracks. The first concerns research of mathematics
at the workplace, the second concerns an analysis of the role of computers
as interface between the physical world and the computer user. 38 Koeno Gravemeijer
CIEAEM 64- Proceedings
Techno-mathematical literacy's
When trying to relate the goals of mathematics education to the requirements of the workplace, a complication is that the mathematics that is
used at the workplace is strikingly different from conventional mathematics
(Hoyles & Noss, 2003; Roth, 2005). To describe this specific kind of
mathematics, Hoyles and Noss (2003) coined the term "technomathematical literacy's"—or TmL's for short. TmL's are defined as idiosyncratic forms of mathematics that are shaped by work-place practices,
tasks, and tools. Acting successfully at the workplace is dependent on a
combination of mathematical knowledge and contextual knowledge.
In a recapitulatory report, Hoyles, Noss, Kent & Bakker (2010) mention
as one of their key findings, that artefacts comprising symbolic information
in the form of numbers, tables and graphs are often understood as "pseudo
mathematics". This means that these representations are conceived as labels
or pictures, without an understanding of the underlying mathematics. They
argue that, "Symbolic information thus failed to fulfill its intended role in
facilitating communication across 'boundaries' between communities within
and beyond the workplace" (ibid, 196). Important mathematical skills that
come to the fore in their research are: reading tables and graphs, identifying
and measuring key variables, reasoning about models in terms of the key relationships between variables, and representing and interpreting data.
We may further note that the role of TmL's does not simply boil down to
applying mathematical knowledge. Students will have to be able to flexibly
adapt their existing mathematical knowledge or adopt new knowledge. This
asks for experience with a variety of non-canonical forms of mathematics.
Quantitative models of reality
Apart from studying mathematics at the workplace, we may trace
mathematical skills that are needed in a computerized environment, by analyzing the role computers and computerized appliances play as interfaces
between the users and the concrete reality. In relation to this, we may discern the following processes:
- reality is quantified to make it accessible for computers—as computers only work with numbers;
- these numbers are processed by the computer on basis of models that
describe interdependencies between variables;
- the output, which often has some mathematical form, is interpreted.
Thus in order to understand how a computer deals with reality, one must,
- have some idea of what quantifying (or measuring) entails; Aiming for 21
st
. Century Skills 39
HMS i JME, Volume 4. 2012
- understand at some level, what a variable is, how we can reason
about interdependencies between variables, and how computer models represent reality;
- has to be able to interpret the output of computers.
An important aspect of a measuring is that there will always be some inaccuracy and uncertainty involved. In general students do not realize that
there will always be some measurement error, or that a repeated measurement may result in a different outcome. Nor do they realize that variance is
part of industrial production, even though they will be aware of the phenomenon of natural variance in nature. We would argue that it is important
for students to develop this kind of understanding, for many of the numbers
they will have to work with will be the result of sampling. We may further
follow Jones (1971) in his observation that measuring an object comprises
assigning a value to a variable; what is measured is not the object but a
property of that object. The significance of this observation comes to the
fore when we look at co-variation. In such cases we do not compare the individual lengths and weights of certain persons, but we study how "length"
varies with "weight".
Fortunately information technology offers eminent possibilities for creating educational tools for helping students to come to grips with these
ideas. Hoyles et al. (2010), for instance, report on the use of interactive
computer tools that present symbolic information such as graphs, models
expressed in algebraic symbols, or numerical measures. Experiments with
such computer tools (which they call, technology-enhanced boundary objects) show that they can be employed successfully in enhancing the meanings of the symbolic information by making them more visible and manipulable, and therefore more accessible. We may note that this use of computer tools is in line with Kaput's, faith in the educational potential of information technology that allows for the use of dynamic representations (Kaput &
Schorr, 2007). Computers can show the numerical results or graphical representations of measuring activities real time on a screen, but also offer representations of simulations that can be manipulated at will.
We may mention two examples of the educational use of dynamic representations in service of the mathematical objectives mentioned above. One
concerns a simulation of a train on a rail track, which is accompanied by a
graphical representation of the speed of the train, which can be used to foster an understanding of co-variation and informal calculus (Galen &
Gravemeijer, 2010). A second example concerns an introduction to explora-40 Koeno Gravemeijer
CIEAEM 64- Proceedings
tory data analyses with the help of so-called computer minitools (Gravemeijer & Cobb, 2006), that allow for a variety of representations and ways of
structuring of data sets. While analyzing data with the help of these minitools, students may develop a qualitative notion of a distribution of data as
an object with certain characteristics, such as shape and spread.
Conclusion
We started by observing that there is a significant gap between what
students learn at school and what modern society demands. Computerization
and globalization result in a change in job requirements that involves a shift
from routine tasks towards non-routine tasks. The jobs of the future require
flexibility, creativity, problem solving, life-long learning and complex
communication skills. Our fast changing information society not only put
new demands on workers, it also affects our roles as learners and citizens.
In relation to this, we referred to Wagner's (2008) benchmark that the students eventually would have to become well-equipped for acting as a member of a jury in the US legal system.
Similar to Wagner, many publications in this area use the term, "21
st
century skills"; skills that may be summarized as flexibility, critical thinking, problem solving, collaborating, and communicating. We argued that
these skills fit very well with problem-centered, interactive, mathematics
education, and we reviewed the most important characteristics of this type
of mathematics education.
We further discussed what changes in the content of mathematics education would be needed. Both research on mathematics in the workplace, and
an analysis of the role of computers as interface between the physical reality
and the user, point to topics such as, measuring, tables, graphs, variables,
models of relationships between variables, and elementary statistics.
Finally we indicated how computer tools may help students in coming to
grips with the aforementioned mathematics, by offering dynamic representations. In conclusion, we want to stress the urgency of a reconsideration of
the goals of mathematics education in light of the demands of the 21
st
century, and the need to start experimenting with educational practices that may
foster these goals.
Notes Aiming for 21
st
. Century Skills 41
HMS i JME, Volume 4. 2012
1. Mark that most publications on 21
st
century skills stem from Western
countries, which implies a certain bias. We may argue, however, that
the 21
st
century skills that are identified will be or become significant
for other countries as well.

CONTEXT PROBLEMS IN REALISTIC MATHEMATICS
EDUCATION: A CALCULUS COURSE AS AN EXAMPLE
ABSTRACT. This article discusses the role of context problems, as they are used in the Dutch approach that is known as realistic mathematics education (RME). In RME, context problems are intended for supporting a reinvention process that enables students to come to grips with formal mathematics. This approach is primarily described from an instructional-design perspective. The instructional designer tries to construe a route by which the conventional mathematics can be reinvented. Such a reinvention route will be paved with context problems that offer the students opportunities for progressive mathematizing. Context problems are defined as problems of which the problem situation is experientially real to the student. An RME design for a calculus course is taken as an example, to illustrate that the theory based on the design heuristic using context problems and modeling, which was developed forprimary school mathematics, also fits an advanced topic such as calculus. Special attention is given to the RME heuristic that refer to the role models can play in a shift from a model ofsituated activity to a modelfor mathematical reasoning. In light ofthis model-of/model-for shift, it is argued that discrete functions and their graphs play a key role as an intermediary between the context problems that have to be solved and the formal calculus that is developed.
1. INTRODUCTION
The role of context problems used to be limited to the applications that would be addressed at the end ofa learning sequence – as a kind ofadd on. Nowadays, context problems have a more central role. They are endorsed because of today's emphasis on the usefulness of what is learned, and because of their presumed motivational power. Context problems play a more encompassing role in the Dutch approach that is known as realistic mathematics education (RME). In RME context problems play a role from the start onwards. Here they are defined as problems ofwhich the problem situation is experientially real to the student. Under this definition, a pure mathematical problem can be a context problem too. Provided that the mathematics involved offers a context, that is to say, is experientially real for the student.
In RME, the point of departure is that context problems can function as anchoring points for the reinvention of mathematics by the students

themselves. *Moreover*, guided reinvention offers a way out ofthe generally perceived dilemma ofhow to bridge the gap between informal knowledge and formal mathematics. This issue is at the heart ofthis article: How can we help students to come to grips withformal mathematics?
We will take a calculus course as an example, and show that in the reinvention approach, the role ofcontext problems and ofsymbolizing and modeling are tightly interwoven. Actually, we build upon the work that has been done on symbolizing and modeling in primary-school mathematics (Streefland, 1985; Treffers, 1991; Gravemeijer, 1994, 1999). We try to show that the framework that has been developed for primary school can also be used for such an advanced topic as calculus.
We start by following Tall's critique on a formal approach to calculus teaching, by explicating the problems of instruction based on formal logical analysis. Next we discuss some alternatives before moving on to an elaboration ofthe RME approach.
The RME calculus sequence is inspired by the history ofmathematics. We will describe some elements ofthe history ofcalculus from the findings at the Merton College in the 14th century until Galileo that are interesting from an instructional design point of view. We argue that discrete functions and their graphs played a key role as an intermediary between the context problems that had to be solved and the formal calculus that was being developed. We will finish with a discussion of the RME approach of creating the opportunity to let formal mathematics emerge, instead of trying to bridge a gap between formal and informal knowledge.
2. TRADITIONAL CALCULUS INSTRUCTION AND SOME ALTERNATIVES
Traditional set up
According to Tall (1991), mathematicians tend to make a typical error when they design an instructional sequence for calculus. The general approach of a mathematician is to try to simplify a complex mathematical topic, by breaking it up in smaller parts, that can be ordered in a sequence that is logical from a mathematical point ofview. 'From the expert's viewpoint the components may be seen as part ofa whole. But the student may see the pieces as they are presented, in isolation, like separate pieces of a jigsaw puzzle for which no total picture is available.' Tall (1991, p. 17). It may be even worse, ifthe student does not realize that there is a big picture. The student may imagine every piece as an isolated picture, which will severely hinder a synthesis. The result may be that the student constructs113 an image of each individual piece, without ever succeeding in bringing all pieces together in one whole.
As an example, Tall describes a possible sequence for differentiation. He presents the following line of reasoning. To be able to understand the derivative f
0
.x/, one has to have the concept of a limit at one's disposal.
For, one has to take the limit ofthe difference quotient .f.xCh/–f.x//=h where h tends to zero. Thus the concept of a limit has to precede the derivative. Furthermore, one might decide that it is easier to take the limit in the case where x is fixed. The next step then would be to let x vary, to introduce the idea of a derivative in this manner.
For the student, however, the introduction ofthe limit concept suddenly appears for no reason, with all the cognitive problems this may bring. The next big problem is in the shift from a limit with a fixed x to a varying x, since taking a limit in one point is substantially different from perceiving f
0
.x/ as a function ofwhich the values describe the gradient of a graph of f.x/.
Alternative approaches
A sensible alternative, according to Tall, would be to look for situations that can function as informal starting points, from which cognitive growth is possible. In this context, Tall (cited in Bishop et al., 1996) argues for more emphasis on visualizing mathematical concepts and more enactive experiences in mathematics education. The students should first experience a qualitative, global, introduction ofa mathematical concept. This qualitative introduction then should create the need for a more formal description ofthe concepts involved. 'Graphic calculus' is such an alternative approach developed by Tall (1985, 1986).
What is characteristic in Tall's approach is the dynamical aspect. The dominant perspective is that of a running variable. Here the graph plays a central role: the graph is used to see how the dependent variable (e.g. y, or f.x/) changes when the independent value (x) changes at a constant rate. What is looked at primarily, are the changes in the dependent variable and the rate ofthese changes, which can be described in terms ofincrease, decrease, and gradient. This helps the students develop an intuitive feel for the derivative. However, the notion of the derivative as a measure for the rate of change stays rather implicit, since the primary focus is on the gradient ofthe graph.
Tall (cited in Bishop et al., 1996, p. 314) observes that the problem for a calculus course is in the transition from meaningful discussions based on visual imagery to formal mathematical reasoning. Students interpret a definition that is based on visual imagery as a description, as a model of114 the picture, instead ofa mathematical definition that can be used for formal reasoning.
Maybe the visual exploration stands too much on its own. In Tall's proposal, the relationship between graphs and real-life phenomena is restricted to a short introductory phase; for the main part, the functions and graphs are contained in a mathematical world.
Linking authentic experience and a mathematical symbol system
In contrast to Tall, Kaput (1994a), emphasizes the relationship between mathematical symbol systems like graphs and everyday reality.
The problem, in his view, is the gap between the island offormal mathematics and the mainland of real human experience. He elucidates this gap with the difference between mathematical functions that are defined by algebraic formulas, and empirical functions that describe everyday-life phenomena. To underscore his point, he quotes Thomas Tucker's rhetorical question: 'Are all functions encountered in real life given by closed algebraic formulas? Are any?' (cited in Kaput, 1994a, 384). He observes that most educational software available does not address this problem. This, he argues, also holds for computer programs that link functions and graphs. For, in terms of the island metaphor, both algebraic functions and graphs of algebraic functions belong to the island of formal mathematics. To attack the island problem, Kaput seeks situations where the students can maximally exploit their own authentic experience to investigate, and to come to grips with these formal representations. He tries to create such a situation with software he is developing under the name of Math Cars. The power ofthe device is in the internal linkage between the various display systems. In this way, the everyday experience of motion in a vehicle can be linked to the formal graph representations. This linkage then offers the students the opportunity to test the conjectures they develop about the graphic representations.
We may note that Kaput takes the ready-made symbol system as point ofdeparture, which is consistent with his concept ofa mathematical system that is distinct from our everyday-life experience. Others, however, try to help students develop or reinvent this symbol system themselves.
Inventing graphing
DiSessa, Hammer, Shern, and Kolpakowski (1991), who describe an instruction period where the students invented graphing, for instance, report such an approach. Albeit, not as a result of ample instructional planning. As a matter of fact, the invention process was more or less incidental. The students had been programming simulations of real-life motions with a115 Logo-like turtle that left a trail of dots across the screen. Next, the students were asked to come up with a paper-and-pencil way to represent the motion story of one of the simulations they worked on. The solutions of the students, that were to some extent inspired by the dot-track of the computer simulation, formed the starting point for a series of discussions and activities, in which a graph-type representation of this motion story emerged.
While acknowledging that the guidance by the teacher may have influenced the invention process more than the notion of invention suggests (DiSessa et al., 1991), we can argue that, if it would be possible to have the students invent distance-time and speed-time graphs by themselves, the dichotomy between formal mathematics and authentic experience Kaput presupposes, would not arise. For the mathematical ways of symbolizing would emerge in a natural way in the students' activities, and the accompanying formal mathematics would be experienced as an extension oftheir own authentic experience.
Following Meira (1995), we can take this line of thinking one step further, by acknowledging a dialectical relation between notations-in-use and mathematical sense making. According to this dynamic point ofview, it is in the process of symbolizing that symbolizations emerge and develop their meaning. In this process, notational systems shape the very activities from which they emerge, while at the same time, the activities shape the meanings that emerge.
Discussion
Looking at the alternatives to traditional calculus instruction presented above, we may discern the following characteristics. The overall goal is to design an insightful instructional sequence. Furthermore, the students should be given the opportunity to ground their understanding in their own informal knowledge. Finally, the instruction should be based on the students' own contributions to the teaching-learning process. We may discern three different orientations within these alternatives:
- Helping the students to develop qualitative (generic) notions that can function as a basis for their understanding;
- Creating a learning environment where the students can come to grips with the basic ideas by developing and testing hypotheses;
- Fostering the (re)invention of calculus.
A difference between the first two and the third is that the first two try to help the students bridge the gap between their informal knowledge and the formal mathematics, where the third tries to transcend this dichotomy by116 aiming at a process in which the formal mathematics emerges from the mathematical activity of the students. This is also the objective of RME, where instructional design is aimed at creating optimal opportunities for the emergence of formal mathematical knowledge.
3. GUIDED REINVENTION AND PROGRESSIVE MATHEMATIZATION
The underlying thread of all the alternative approaches is the belief that learning mathematics should have the characteristics of cognitive growth, and not of a process of stacking pieces of knowledge. This perspective is consistent with a more general view that the way in which mankind developed mathematical knowledge, is also the way in which individuals should acquire mathematical knowledge. A view that is, for instance, advanced by Polya (1963), and Freudenthal (1973, 1991).
Freudenthal's point of departure is in his critique of traditional mathematics education. He fiercely opposes what he calls an anti-didactical inversion (Freudenthal, 1973), where the end results of the work ofmathematicians are taken as the starting points for mathematics education. As an alternative he advocates that mathematics education should take its point ofdeparture primarily in mathematics as an activity, and not in mathematics as a ready-made-system (Freudenthal, 1971, 1973, 1991). With this adage, he has laid the foundation for RME. For him the core mathematical activity is 'mathematizing', which stands for organizing from a mathematical perspective. Freudenthal sees this activity ofthe students as a way to reinvent mathematics.
Note that the students are not expected to reinvent everything by themselves. In relation to this, Freudenthal (1991) speaks ofguided reinvention; for him, the emphasis is on the character of the learning process rather than on invention as such. The idea is to allow learners to come to regard the knowledge they acquire as their own private knowledge, knowledge for which they themselves are responsible. The latter implies that certain social norms (Yackel and Cobb, 1996) have to be in place. For instance, norms like: you do not learn mathematics by guessing what the teacher has in mind, but by figuring things out for yourself.
According to Freudenthal, mathematizing may involve both mathematizing everyday-life subject matter and mathematizing mathematical subject matter (Freudenthal, 1971). He does not see a fundamental difference between the two activities. Therefore, education might start with mathematizing everyday-life subject matter. Reinvention, however, demands that the students mathematize their own mathematical activity as well. In

relation to this, Treffers (1987) discerns horizontal and vertical mathem-117
atization. Horizontal mathematization refers to the process ofdescribing a
context problem in mathematical terms – to be able to solve it with mathematical means. Vertical mathematization refers to mathematizing one's
own mathematical activity. Through vertical mathematization, the student
reaches a higher level of mathematics. It is in the process of progressive mathematization – which comprises both the horizontal and vertical
component – that the students construct (new) mathematics.
Freudenthal (1971, p. 417) expresses this as 'the operational matter on
one level becomes a subject matter on the next level'. Although Freudenthal
has micro levels in mind, a connection can be made with Sfard's (1991)
more macroscopic account ofmathematical development based on historical analyses. She observes that the history ofmathematics can be characterized as an ongoing process ofreification in which processes are reinterpreted as objects. One ofthe examples she gives is that of functions. They
firstly appear as calculational prescriptions. This process takes so much
attention that the character of the operations does not get much attention.
Gradually, however, distinctions are made, and various sorts of functions
are discerned. More and more, functions are treated as objects, with certain characteristics. Sfard's analysis suggests that students will have to go
through the same process; students will only be in the position to grasp
the notion of a function as an object, if they have ample experience with
functions as procedures.
An instructional design perspective
In a reinvention approach, context problems play a key role. Well-chosen
context problems offer opportunities for the students to develop informal,
highly context-specific solution strategies. These informal solution procedures then, may function as foothold inventions, or as catalysts for curtailment, formalization or generalization. In short, in RME, context problems
are the basis for progressive mathematization. The instructional designer
tries to construe a set of context problems that can lead to a series of
processes of horizontal and vertical mathematization that together result
in the reinvention ofthe mathematics that one is aiming for. Basically, the
guiding question for the designers is: How couldIhave invented this? Here
the designer will take into account his/her own knowledge and learning
experience. Moreover, the designer can look at the history ofmathematics
as a source of inspiration, and at informal solution strategies of students
who are solving applied problems for which they do not know the standard
solution procedures yet (see Streefland, 1990; and Gravemeijer, 1994 for
examples).118
Figure 1. Solving 35 C : : : D 64 on the empty number line
Figure 2. Modeling 95 – 19 D 95 – 20 C 1.
Research on the design ofprimary-school RME sequences has shown,
that the concept of emergent models can function as a powerful design
heuristic (Gravemeijer, 1999). Here, the point of departure is in situationspecific solution methods, which are then modeled. First context problems are selected that offer the students the opportunity to develop these
situation-specific methods. Then, if they do, these methods are modeled.
In this sense, the models emerge from the activity ofthe students. Even if
the models are not actually invented by the students, great care is taken to
approximate student invention as closely as possible by choosing models
that link up with the learning history ofthe students. Another criterion is in
the potential of the models to support vertical mathematizing. The idea is
to look for models that can be generalized and formalized to develop into
entities of their own, which as such can become models for mathematical
reasoning.
As an example we may take an instructional sequence in which a ruler
comes to the fore as a model of iterating measurement units, and develops into a modelfor reasoning about mental computation strategies with
numbers up to 100 (Stephan, 1998; Gravemeijer, 1999). In this sequence,
the students measure various lengths by iterating some basic unit ofmeasurement, and a larger measurement unit consisting often basic units. This
measuring with 'tens' and 'ones' is modeled with a ruler of 100 units,
made ofunits often and one. Then the activity ofmeasuring is extended to
incrementing, decrementing and comparing lengths. These situations give
rise to counting strategies that are represented by arcs on a schematized
ruler or as an 'empty number line' (Whitney, 1988; Treffers, 1991) (see
Figure 1).
Eventually, the symbolizations on the empty number line representation will be used to explain and justify strategies like solving 95-19 by119
subtracting 20 and adding one (see Figure 2). In this manner, the number
line functions as a model for mathematical reasoning.
The shift from model of to model/for concurs with a shift in the way
the student thinks about the model, from models that derive their meaning
from the modeled context situation, to thinking about mathematical relations. In the latter phase, thinking about number relations will dominate the
use ofthe number line. In relation to this, we can discern different types of
activity (Gravemeijer, 1994; Gravemeijer, Cobb, Bowers and Whitenack,
in press):
(1) activity in the task setting (measuring with units often and one)
(2) referential activity (interpreting positions on the ruler as signifying
results ofiterating a measurement unit)
(3) general activity (using the ruler/number line to reason about computation methods)
(4) formal mathematical reasoning (reasoning with number relations within the mathematical reality of a framework ofnumber relations).
Note that, the term 'model' must be understood in a holistic sense. It is not
just the inscription
1
, but everything that comes with it that constitutes the
model in RME. Furthermore, the same model may encompass a cascade of
inscriptions (Lehrer and Romberg, 1996); e.g. from regular ruler to empty
number line. The label 'emergent' emphasizes the continuity in this process. This label is also used to refer to the fact that the model emerges from
the activity ofthe students. In addition, the mathematics that one is aiming
for (e.g. the development of a framework ofnumber relations), emerges in
the subsequent process.
We may note that the goal is not only to help the students elaborate their
informal understanding and informal solution strategies in such a manner
that they can develop more formal mathematical insights and strategies.
The objective is also to preserve the connection between the mathematical
concepts and that which these concepts describe. The students' final understanding of the formal mathematics should stay connected with, or as
Freudenthal would say, should be 'rooted in', their understanding ofthese
experientially real, everyday-life phenomena.
In relation to this, we want to emphasize that we see modeling and
symbolizing as an integral part of an organizing activity that aims at coming to grips with a problem situation. In other words, the development
of the model and of its constituting symbolizations/inscriptions go hand
in hand with the development of the mathematical conceptualization of
the problem situation. On one hand, the symbolization derives its meaning from the situation that it describes. At the other hand, the way the
problem situation is perceived is highly influenced by the symbolization120
'through which' the situation is seen. In this sense, we agree with Meira
(1995, p. 270) who advocates a dynamic activity-oriented view, according
to which symbolizations and meaning co-evolve in a dialectic process.
In the following we want to try to cast the design of the RME calculus course in terms of this emergent-models design heuristics. We will
start out by sketching a few important moments in the history of calculus.
Since, although reinvention does not necessarily imply that the history of
mathematics has to be the point of departure, this RME calculus course
happens to be an example of how inspiring the history of mathematics
can be for mathematics educators. Moreover, the history ofcalculus offers
some insight into what might be constituted as the emergent model in
calculus.
4. A HISTORICAL SKETCH
The emergence ofkinematics at Merton College
In the first half of the 14th century logicians and mathematicians associated with Merton College, Oxford, investigated velocity as a measure of
motion. They tried to find a description ofthe distance traversed by a body
moving with a uniform accelerated motion (Clagett, 1959). This problem
was not easy because the velocity of the body constantly changes and
the concept of motion and change of motion was defined very generally
according to Aristotle. Change and motion referred to temperature, size
and place (Lindberg, 1992). All these qualities of a body could change.
The interpretation of motion as change of place became the central issue
studied at Merton College; Clagett describes this as 'the emergence of
kinematics at Merton College'.
In those days the scientists at Merton College used the notion of instantaneous velocity and descriptions of the velocity of a moving object.
But there was no clear definition ofvelocity such as: the distance covered
divided by the traversal time (1s=1t). And surely no definition ofinstantaneous velocity as a limit ofthis division (ds=dt), because they could only
work, in the tradition ofEuclid, with proportions of equivalent units.
The most important result that was achieved is 'Merton's rule': When
the velocity of an object increases with equal parts in equal time intervals
from zero to a velocity v in a time interval t, then the distance traveled is
equal to halfthe distance traveled by an object that moves with a constant
velocity v in that time interval t. In modern symbols s.t/ D 1=2 v t.121
Figure 3. Velocity represented by the height ofthe rectangles.
Figure 4. Oresme's proof(pictures from a 15th century copy ofOresme's 'De configurationibus qualitum' reprinted from Claget, 1959).
They added the conjecture that the distance covered in the first half
of such a motion is one third of the distance covered in the second half.
However, this appeared to be hard to prove.
The graph as a model ofvelocity-time problems
It was Nichole Oresme (ca. 1360) who started to draw graphs of situations
in order to visualize the problem. He described how geometrical elements
like lines or rectangles can be used to represent the value of a variable:
the length of a line or the area of the rectangle represents the value of the
variable. These elements can be put along a horizontal line that represents
time.
When investigating the distance traveled by an object that moves with
constantly changing velocity Oresme knew that the velocity increases with
equivalent quantities in equivalent time intervals
2
. A graph where the velocity is represented by the height ofa rectangle, and the chosen time interval
by the width ofit, is shown in Figure 3.
Oresme could approximate the distance traveled in each time interval
by taking into account the length of the interval and the 'constant' velocity during the interval. The area ofthe rectangle represents this distance.
Oresme called the diagonal top-line of the graph, which results when you
choose the time-intervals very small, 'the line ofintensity'. He noticed that
it is a straight line and that the sum of the areas of all the rectangles is an
approximation ofthe area ofthe triangle between the line of intensity and122
the horizontal axis. As a result the distance traveled equals the area ofthe
triangle: 1=2 v t (Figure 4).
The power of this graphical representation comes to the fore when
you try to prove the hypothesis: the distance covered in the first half of
a uniformly accelerated motion is one third of the distance covered in the
second half. This can be deduced easily with the areas in the graph.
Galileo investigatingfreefall
The interesting fact of these results is that they dealt with abstract phenomena. Kinematics was an argumentative science, not an experimental
science. It was Galileo in the seventeenth century that made the shift to
experimental physics. He conjectured that an object in free fall moved with
a constantly increasing velocity. He designed experiments with objects
moving with a uniform acceleration and applied the Merton rule to a real
motion.
Furthermore, Galileo gave an explanation for the quadratic relation
between time and distance, using sums and differences. He argued that
the ratio between the distance traveled in two equal time intervals is 1:3;
if you divide time into four equal intervals it is 1:3:5:7; and it continues
as such a ratio determined by a sequence of odd numbers. Galileo knew
that these sequences added up to a square and with this property he tested
his conjecture. He designed a slide with nails on one side. The distances
between the nails were proportional to the odd numbers above. It appeared
that a rolling ball needed the same time too pass each consecutive nail.
Galileo's experiments confirmed that the falling distance increased linearly during each time-interval and from this result he concluded that the
relation between distance and time must be quadratic. The integral of the
linear function was thus found; an actual start with calculus was made. We
leave history here, to consider what we can learn from this.
Looking through the lens ofemergent models
Looking at the history of calculus from a modeling perspective, we see a
development ofcalculus that starts with modeling problems about velocity
and distance. Initially these problems are tackled with discrete approximations, inscribed by discrete graphs. Later, similar graphs – initially discrete
and later continuous – form the basis for more formal calculus. From
a modeling perspective, we could say that graphs of discrete functions
come to the fore as models of situations, in which velocity and distance
vary, while these graphs later develop into modelsfor formal mathematical
reasoning about calculus. In relation to this we can speak of a process of
reification. However, it is not the graph that is reified, it is the activity that is123
Figure 5. Sums and increments.
reified. E.g. the act ofsumming (differentiating) is reified, and becomes the
mathematical object 'integral' ('derivative'). The inscription – the graph –
visually supports both the activity and its reification.
We want to add that we do not take this notion ofreification too literally
here. For many students, the end result will be something in between a
process and an object – especially in the case of calculus. To emphasize
that the underlying process will be an integral part of the mathematical
object that is developed in this manner, Tall (cited in Bishop et al., 1996)
uses the term 'procept'. Moreover, it should be acknowledged that the development will not be as linear as our description suggests. Students may
shift back and forth between process and object conceptions, depending on
the problems they have to solve.
In looking at the history of calculus, Kaput's (1994b) characterization
ofcalculus as 'the mathematics ofchange' comes to mind. In the process of
trying to get a handle on change, the method of approximating a constant
changing velocity with the help of discrete functions plays a key role. In
a sense, the sum- and difference-series can be seen as a crude predecessor
of calculus. This idea can be exploited in instructional design by starting
the sequence with investigating discrete patterns. Moreover the mathematics of sum- and difference-series offers the opportunity of reinventing a
discrete variant ofthe main theorem of calculus in an early stage.
Another aspect ofthe history that seems relevant for instructional design
is the embedding in the context of speed and distance. This seems to be
a context that is suited for high school students. For, in general, speed
is a concept they still grapple with. Moreover the idea of instantaneous
velocity seems to be more assessable than a seemingly simple concept
such as average speed.124
5. RME CALCULUS COURSE

These deliberations are elaborated in a calculus sequence that is developed
for students of 16–17 years, in science-oriented high school classes
3
. The
unit starts with activities on series. Properties of, and the relations between
series, their sums and their increments are investigated by the students (see
Figure 5). In this process, the students develop (algebraic) tools that can
be used for problems later on. Moreover, it is a first introduction to the
relationship between sums, summation symbols, increments and difference
symbols. The notion of limit is only used in an intuitive way until the end
ofthe unit.
The relationship between sums and differences is represented with the
introduced symbols by: 1n
2
D 2k C 1 and
P
.2k C 1/ D n
2
. These
properties are also visualized with graphs. In general the discrete case of
the main theorem is posed: 1S.n/ D D.k/ and
P
D.k/ D S.n/ − S.0/.
Students use graphic calculators when dealing with these investigations.
From graphs and tables they can deduce that 13
n
D 2 3
k
and, with the
theorem they can prove that
P
3
k
D 1=2.3
n
− 3
0
/.
After this discrete analysis the shift towards modeling oftime/distance/
velocity is made. Note that a key element ofthe notion ofemergent models
is that the models first come to the fore as models of situations that are
experientially real for the students. It is in line with this notion that discrete
graphs are not introduced as an arbitrary Symbol System, but as models
of discrete approximations of a motion. Since the students are already
familiar with continuous graphs, an approach to graphing speed that is
not familiar to the students, is chosen. The point of departure is in the
medieval notion ofinstantaneous speed. The issue of symbolizing speed is
introduced in the context ofa narrative about Galileo's work. The students
are informed about the definition of instantaneous velocity in Galileo's
time in terms ofthe distance that is covered ifthe moving object maintains
its instantaneous velocity for a given period of time. In this context, the
problem is posed of how to visualize the motion of an object that moves
with varying speed. While struggling with this problem, the students may
come up with the idea ofsymbolizing instantaneous velocities with bars. If
not, this option may be presented to them, after they have been struggling
with this problem for a while.
As an aside, it may be noted that there will always be a tension between
a bottom-up approach that capitalizes on the inventions ofthe students and
the need, (a) to reach certain given educational goals, and (b) to plan instructional activities in advance. As a consequence, a top-down element is
inevitable in instruction. The key consideration for us, however, is that the125
Figure 6. A discrete approximation ofa constant changing velocity.
students experience these top-down elements as bottom-up: as solutions
they could have invented for themselves. For the instructional designer,
this boils down to striving to keep the gap between 'where the students
are' and what is being introduced as small as possible. Furthermore, the
teachers will be able to reduce the gap in interaction with their students.
Returning to the content, we want to stress, that although the idea of
using bars (i.e. small rectangles) may be handed to the students, this does
not mean that there are no problems left to solve. A central problem is that
of coordinating the height and the width of the bars when using them to
visualize a discrete approximation of a movement.
Next, the topic of investigation will be the relation between the 'area
of the graph', and the total distance covered over a longer period of time.
Figuring this out demands ofthe students that they come to grips with the
relationship between the motion, the representation, and the approximation. The whole process, in which the way of modeling motion, and the
conceptualization of the motion that is being modeled, co-evolve, can be
seen as a form of guided reinvention that can be contrasted with learning
some rule which magically equates area with distance.
The students are told the story ofGalileo, who presumed that the motion
of a free-falling object was with constantly increasing velocity. They are
asked to graph the discrete approximation of such a motion (see Figure 6).
Subsequently Galileo's problem is posed: What distance is covered by
the object? Here, after solving the discrete approximations, the students are
expected to make the connection between the area of the discrete graph,
and the area ofthe triangle that is created by the continuous graph: s.t / D
.1 10t/=2 D 5t
2
. This resulting formula reveals the quadratic relation
between time and distance that Galileo used to test his hypotheses empirically. With this calculation, the first step is made in a process in which the
attention shifts from describing motion, to calculating primitives.
After this introduction to integral calculus, students work on problems
that deal with differential calculus. That is, they have to determine velocities from distance-time graphs and formulas. In subsequent activities,126
the model will begin to function as a model for reasoning about integrating/differentiating arbitrary functions on the one hand, and of standard
algebraic functions on the other hand. At the same time, a shift is made
from problems cast in terms of everyday-life contexts to a focus on the
mathematical concepts and relations. To make such a shift possible for the
students, they will have to develop a mathematical framework ofreference
that enables them to look at these types of problems mathematically (see
Gravemeijer, 1999). It is exactly the emergence of such a framework that
this sequence tries to foster.
In the envisioned process ofprogressive mathematization, symbolizing
and modeling play a key role. The central model is that of a discrete function, in combination with the inscription of a discrete graph. This model
is the basis for both integration and differentiation through sums and differences. Although the discrete function can be seen as the backbone of
the model, the visual representation also plays an important role. In line
with Latour (cited in Meira, 1995) we would argue that the use of visual
representations helps one to focus on the mathematics.

6. DISCUSSION, CREATING MATHEMATICAL REALITY

The question we asked at the beginning of this article was: How can we
help students to come to grips with formal mathematics? Central in our
exposition was the RME approach. This approach distinguishes itselffrom
many other approaches, in that it tries to transcend the dichotomy between
informal and formal knowledge, by designing a hypothetical learning trajectory along which the students can reinvent formal mathematics. Ideally,
the actual learning trajectory unfolds in such a manner, that the formal
mathematics emerges in the mathematical activity of the students. This
ideal is connected to Freudenthal's (1991) contention that 'mathematics
should start and stay within common sense'. Freudenthal intended this
adage to be interpreted dynamically and argued that common sense is not
static. He noted, for example, that what is common sense for a mathematician differs significantly from what is common sense for a lay person. In
addition, he emphasized that common sense evolves in the course oflearning. Thus, in the first phase ofthe sequence, describing momentary speed
in terms of the distance that would be covered in case of constant speed,
is a common-sense activity. In a similar manner, a discrete approximation
of varying velocity can be seen as a common sense activity. By the end
ofthe sequence, acting in an environment structured in terms of areas and
gradients ofgraphs will have become common sense for the students.127
This development can also be taken to exemplify what is meant by
context problems in RME. As we indicated earlier, context problems are
defined as problem situations that are experientially real to the student.
The above example shows that this experiential reality grows with the
mathematical development ofthe student. Freudenthal explicates: 'I prefer
to apply the term "reality" to that which at a certain stage common sense experiences as real' (Freudenthal, 1991, p. 17). This use ofthe term reality in
RME is highly compatible with Greeno's (1991) environmental metaphor.
From this we conclude that the overall goal of instructional design is to
support the gradual emergence of a taken-as-shared mathematical reality.
If the students experience the process of reinventing mathematics as expanding common sense, then they will experience no dichotomy between
everyday life experience and mathematics. Both will be part of the same
reality.
We may note a reflexive relation between the use of context problems
and the development ofthe student's experiential reality. On the one hand,
the context problems are rooted in this reality, on the other hand, solving
these context problems helps the students to expand their reality. Notwithstanding this dynamic character of reality that defines context problems,
starting points for instructional sequences will often link up with everydaylife experience of students. It is precisely the connection with velocity
and distance that offers the students the means to reason and act in a
meaningful manner from the start.

NOTES

1
Following Lehrer and Romberg (1996) we use the term inscriptions to refer to
symbolizations that have physical form.
2
Some mathematicians argue that Oresme's proof of Merton's rule is not allowed.
First he should have defined velocity as a differential quotient and then deduced
the distance traversed by graphical integration. The mathematical historian Dijksterhuis discusses this and defends Oresme by stating: It is a situation which occurs
regularly in the history ofmathematics: mathematical concepts are often – maybe
even: usually – used intuitively for a long time before they can be described accurately, and fundamental theorems are understood intuitively before they are proven
(Dijksterhuis, 1980).
3
The sequence is called Sum & Difference, Distance & Speed (Som & Verschil,
Afstand & Snelheid – Kindt, 1997). One ofthe chapters ofthis sequence is based
on a text ofPolya on the history ofGalileo (Polya, 1963). Our description does not
correspond with the existing unit in every detail, but anticipates certain revisions.128

Design research on IT ORD-2003 1
Design research on how IT may support the development of symbols and meaning
in mathematics education
Arthur Bakker, Michiel Doorman and Paul Drijvers,
Freudenthal Institute, Utrecht University
Introduction
This paper sketches the methodology and some results of three studies that were part of a comprehensive research project called "IT and mathematics education". With the theory of Realistic Mathematics Education as a background, the project investigated the contribution of IT tools for the guided reinvention of mathematical concepts and the influence of IT use on the students' process of symbolising. Each of the studies focussed on a different mathematical topic and used different types of technological tools. The three studies that are discussed in this paper combine the methodology of design research with a prominent role for the Hypothetical Learning Trajectory as a research instrument in all phases of design research (design, teaching experiment, retrospective analysis).
In the first section we state the overarching research question. In section 2 we describe the research methodology. Each of the phases of the research cycles is addressed: the preliminary phase in which a Hypothetical Learning Trajectory and instructional activities are designed, the teaching experiment phase and the phase of the retrospective analysis. In section 3 we address each of the three studies subsequently and present some exemplary results. Section 4 contains a discussion, and section 5 states common conclusions from the three studies.
1. Research Question
One of the salient characteristics of mathematics is the use of symbols. This is not merely an external characteristic, as mathematical symbols are an integral part of mathematics. It is hard to think about algebra without the use of literal expressions, or to understand calculus without pointing to tangents and areas beneath graphs, or to grasp the notion of a normal distribution in statistics without referring to an image such as a bell shape. This intertwinement of meaning and visual representations poses a problem for mathematics education. Experts - like teachers and instructional designers - tend to see these symbols as carriers of meaning. For them, those graphs and literal expressions are transparent; they can "see the mathematics through it", so to speak. The students, however, do not have the necessary mathematical background to interpret those symbolic representations in that manner. As a consequence, teachers will have to explain to the students what there is to see, and how to reason with those symbolic representations. This, Cobb et al. (1992) point out, leads to proceduralising and algorithmetising and the loss of meaning - or to, as van Oers (2000) calls it, "pseudo mathematics". To find a way out of this dilemma, one may consider the history of mathematics to investigate how meaning and symbols emerged. It turns out that mathematical symbols did not arrive ready-made, with full-fletched meaning. Instead, one can discern a reflexive process in which symbolising and the development of meaning co-evolve (Meira, 1995). Symbolising, here, refers to inventing and using a series of symbols. In relation to this, Latour (1990) and others (e.g. Roth & McGinn, 1998) speak of a "cascade of inscriptions". This notion of a cascade of inscriptions has its counterpart in semiotic concepts as "chain of signification" (Walkerdine, 1988; Whitson, 1997).
The current challenge for mathematics educators is to develop mathematics education that is in line with these dynamic conceptions of symbolising and development of meaning. The task of researchers is to shed light on the key elements of this type of mathematics education.
In 1998 a group of projects was started around the premises that IT could be used to support the aforementioned type of mathematics education. Symbolic representations could be embedded in various IT tools such as computers and hand-held calculators. Furthermore, this type of learning environments might create opportunities for exploration and reflection. This group of projects was Design research on IT ORD-2003 2
funded by the PROO (a branch of the Netherlands Organisation for Scientific Research, NWO) as a comprehensive research project entitled "IT and mathematics education" (grant number 575-36-003). This research encompassed five projects, three of which we will discus in this paper. These three projects focussed on the research question:

How can the use of IT in mathematics education help students reinvent mathematical concepts and representations?
This overarching question is elaborated on for three topics, the notion of distribution in statistics, calculus or, as Kaput calls it, "the mathematics of change and variation", and the concept of parameter in algebra. For each research project, this implies a dual goal:
- On the one hand, answering the question on how to shape the teaching and learning process on this specific topic while integrating IT in it, and
- on the other hand, investigating the role of IT, and, more specifically, the reflexive relations between IT-embedded symbol use and the development of meaning.
Given these goals, we chose what is called design research, or developmental research (Gravemeijer, 1994b, 1998), as our research method. Following Brown (1992), Cobb, Confrey, diSessa, Lehrer and Schauble (2003) refer to this type of research as design experiments, which they elucidate in the following manner:
Prototypically, design experiments entail both "engineering" particular forms of learning and systematically studying those forms of learning within the context defined by the means of supporting them. This designed context is subject to test and revision, and successive iterations that result play a role similar to that of systematic variation in experiment.
(Cobb, Confrey, diSessa, Lehrer & Schauble, 2003, p. 9)
In this description, the two aspects of our research goal come to the fore in (a) the design of means of support for particular forms of learning, and (b) the study of those forms of learning. In each of the research projects under discussion, the backbone of the design is formed by the design, development and revision of a hypothetical learning trajectory (a term that we will elaborate on later). The enactment of the instructional activities that are part of the hypothetical learning trajectory in teaching experiments creates the opportunity to study IT-embedded symbol use and the development of meaning in the context of the actual learning trajectory.
2. Design Research Methodology
The design research approach we follow in the three projects has a cyclic character: each design research study consists of research cycles in which thought experiments and teaching experiments alternate. We distinguish macro cycles that concern the global level of the teaching experiments, and micro cycles that concern the level of subsequent lessons. Gravemeijer argued that the micro cycles lead to a cumulative effect of small steps, in which teaching experiments provide "feed-forward" for the next thought experiments and teaching experiments (Gravemeijer, 1994a). A macro cycle of design research consists of three phases: the preliminary design phase, the teaching experiment phase, and the phase of retrospective analysis.
A second characteristic of design research is the importance of the development of a learning trajectory that is made tangible in instructional activities (Gravemeijer, 1994a). The design of instructional activities is more than a necessity for carrying out teaching experiments. The design process forces the researcher to make explicit choices, hypotheses and expectations that otherwise might have remained implicit. The development of the design also indicates how the emphasis within Design research on IT ORD-2003 3
the theoretical development may shift and how the researcher's insights and hypotheses develop. As Edelson argues, design is a meaningful part of the research methodology:
(...) design research explicitly exploits the design process as an opportunity to advance the researchers understanding of teaching, learning, and educational systems. Design research may still incorporate the same types of outcome-based evaluation that characterise traditional theory testing, however, it recognizes design as an important approach to research in its own right.
(Edelson, 2002, p.107)
This is particularly the case when the theoretical framework involved is under construction.
One approach to design research is to immediately adapt the instructional activities after every lesson according to the experiences. This leads to many short micro cycles and can be an effective method, as shown by the following quotation that describes a situation where adaptations "on the fly" led to a micro cycle method:
The time pressure was considerable, but it had one advantage: experiences in the classroom could be incorporated immediately. Consequently, practical experience assumed great significance as a 'feed forward'; the components of the curriculum, which were still to be developed, could be adjusted directly on the basis of classroom experiences. (Gravemeijer, 1994a, p. 36)
In these studies, however, we started the teaching experiments with a complete set of instructional activities. Due to practical circumstances in two of the projects, adaptations were limited to decisions on skipping tasks or stressing other assignments. Therefore, the cyclic character of the research primarily concerns the macro cycles.
2.1. Hypothetical learning trajectory
Within each macro level research cycle, we distinguish three phases: the preliminary design phase, the teaching experiment phase, and the phase of retrospective analysis. The first phase of preliminary design includes two related parts, the development of a Hypothetical Learning Trajectory (HLT) and the design of instructional activities. In the next four sections we elaborate on each of these (partial) phases. Of course, each phase was slightly different in the three projects; here we describe common aspects of each phase within the different projects.
The first phase of each research cycle includes the development of a "Hypothetical learning trajectory" - a term that is taken from Simon (1995). Originally, Simon used the HLT for designing and planning short teaching cycles of one or two lessons. In our study, however, we developed HLTs for teaching experiments that lasted for sequences varying from 8 to 20 lessons. As a consequence, the HLT comes close to the concept of a local instruction theory (Gravemeijer, 1994a). Also, this interpretation of the HLT is close to the scenario concept as it is used by Klaassen (1995). A second difference with Simon's approach is that Simon took a teacher's perspective, whereas we take a researcher's perspective.
The development of an HLT involves the choice or design of instructional activities in relation to the assessment of the starting level of understanding, the formulation of the end goal and the conjectured mental activities of the students. Essential in Simon's notion of a HLT is that it is hypothetical; when the instructional activities are acted out, the teacher - or researcher in our case - will be looking for evidence of whether these conjectures can be verified, or should be rejected.
For the design of the student activities, their motivation and the estimation of their mental effects, the designer makes full use of his domain specific knowledge, his repertoire of activities and representations, his teaching experience, and his view on the teaching and learning of the topic. After Design research on IT ORD-2003 4
a field test by means of a teaching experiment, the HLT will usually be adapted and changed. These changes, based on the experiences in the classroom, start a new round through the mathematical teaching cycle, and, in terms of the design research method, the next research cycle.
The concept of the HLT may seem to suggest that all students follow the same learning trajectory at the same speed. This is not how the HLT should be understood. Rather than a rigid structure, the HLT represents a learning route that is broader than one single track and has a particular bandwidth.
Because of its stress on the mental activities of the students and on the motivation of the expected results by the designer, the HLT concept is an adequate research instrument for monitoring the development of the designed instructional activities and the accompanying hypotheses within design research. It provides a means of capturing the researcher's thinking and its development throughout the research and helps in getting from problem analysis to design solution.
2.2. Design of instructional activities
The preliminary design phase of the design research cycles includes the development of the HLT and the instructional activities. Of course, the development of an HLT and the design of instructional activities are closely related: the HLT guides the design of the instructional activities, but choices made in the design process may lead to reconsideration of the HLT. The expectations of the students' mental activities established in the HLT are elaborated into specific key activities in the instructional materials. In this section, we describe our design method and principles.
The design of instructional activities in these studies included the development of student text booklets, teacher guides, solutions to the assignments, tests and software. While designing these materials, choices and intentions were captured and motivated, to inform the teacher and to keep track of the development of the designer's insights. When the materials were about to be finalised, these aims and expectations were described at the task level. Key items, that embodied the main phases in the HLT, were identified. These items reflected the relevant aspects of the intended learning process and were based on the conceptual analysis of the topic. The identification of key items guided observations and prepared for the retrospective data analysis. Finally, teacher guides as well as observation instructions were written, to make intentions and expectations clear to teachers and observers. During the design phase, products were presented to colleagues, teachers and observers. This led to feedback that forced the researcher to be explicit about goals and aims, and that provided opportunities for improving all the materials.
While designing instructional activities, the key question is what meaningful problems may foster students' cognitive development according to the goals of the HLT. Three design principles guided the design process: guided reinvention, didactical phenomenology and mediating models.
The design principle of guided reinvention involves reconstructing the natural way of developing a mathematical concept from a given problem situation. A method for this can be to try to think how you would approach a problem situation if it were new to you, or, as Gravemeijer phrases it, "think how you might have figured it out yourself" (Gravemeijer 1994, p. 179). In practice, this is not always easy to do, because as a domain expert it is hard to think as if you were a freshman. The history of the domain can be informative on specific difficulties concerning concept development (e.g. Bakker, 2003; Gravemeijer & Doorman, 1999).
The second design principle, didactical phenomenology, was developed by Freudenthal (Freudenthal, 1983; Gravemeijer, 1994a; Gravemeijer & Cobb, 2001). Gravemeijer explains it as follows:
Didactical phenomenology points to applications as a possible source. Following on the idea that mathematics developed as increasing mathematisation of what where originally solutions to practical problems, it may be concluded that the starting points for the re-invention process can

be found in current applications. (Gravemeijer 1994, p. 179) Design research on IT ORD-2003 5
Didactical phenomenology aims at confronting the students with phenomena that "beg to be organised" by means of mathematical structures. In that way, students are invited to build up mathematical concepts. Meaningful contexts, from real life or "experientially real" in another way, are sources for generating such phenomena (de Lange, Burrill, Romberg, & van Reeuwijk, 1993; Treffers, 1987). The question, therefore, is to find meaningful problem contexts that may foster the development of the targeted mathematical objects. The context should be perceived as natural and meaningful, and offer an orientation basis for mathematisation.
The last remark leads to the third design principle, the use of mediating models (Gravemeijer, 1994a). In the design phase we try to find problem situations that lead to models that initially represent the concrete problem situation, but in the meantime have the potential to develop into general models for an abstract world of mathematical objects and relations.
2.3. Teaching experiments
The second phase of the design research cycle is the phase of the teaching experiment, in which the prior expectations embedded in the HLT and the instructional activities are confronted with classroom reality. The term "teaching experiment" is borrowed from Steffe (Steffe & Thompson, 2000). The word "experiment" is not referring to an experimental group - control group design. In this section we explain how the teaching experiments were carried out; in particular, we pay attention to the data sampling techniques used during the teaching experiments.
The research questions share a process character: they concern the development of understanding of mathematical concepts. Therefore, we focussed on data that reflected the learning process and provided insight into the thinking of the students. The main sources of data, therefore, were observations of student behaviour and interviews with students. The observations took place on three levels: classroom level, group level and individual level. Observations at classroom level concerned classroom discussions, explanations and demonstrations that were audio and video taped. These plenary observations were completed by written data from students, such as handed in tasks and notebooks.
Observations at group level took place while the students were working on the instructional activities in pairs or small groups. Short interviews were held with pairs of students. In addition to this, the observers made field notes.
The lessons were evaluated with the teachers. These discussions led to consequences for the following lessons, as is characteristic with design research micro cycles. In particular, the organisation of the next lesson and the content of the plenary parts were discussed. Also, decisions were taken about skipping (parts of) tasks because of time pressure. Such decisions were written down in the teaching experiment logbook.
2.4. Retrospective analysis
The third phase of a design research cycle is the phase of retrospective analysis. It includes data analysis, reflection on the findings and the formulation of the feed-forward for the next research cycle. In this section we focus on the data analysis method.
The first step of the retrospective analysis concerned elaborating on the data. A selection from video and audiotapes was made by event sampling. Criteria for the selection were the relevance of the fragment for the research questions and for the HLT of the teaching experiment in particular. Data concerning key items was always selected and these selections were transcribed verbatim. From the videotaped work of pairs of students, only a limited part of the registered time was transcribed verbatim, as students often proceeded slowly while working on their own, and did not always explain their method. In such cases, the tapes were summarised into descriptions. Long plenary explanations and classroom discussions were summarised as well, unless they contained interesting student contributions. Registrations where students were not working at all, or where organisational matters were discussed, were not elaborated on. The written work from the students was surveyed and Design research on IT ORD-2003 6
analysed, especially the work on key items, tests and hand-in tasks. Results were summarised in partial analyses.
The first phase of the analysis consisted of working through the protocols with an open approach that was inspired by the constant comparative method (Glaser & Strauss, 1967; Strauss & Corbin, 1988). Remarkable events or trends were noted as conjectures and were confronted with the expectations based on the HLT and the instructional activities. The second phase of analysis concerned looking for trends by means of sorting events and analysing patterns. The findings were summarised illustrated by prototypical observations. These conjectures were tested by surveying the data to find counterexamples or other interpretations, and by data triangulation: we analysed the other data sources, and in particular the written student material, to find instances that confirmed or rejected the conjectures. Analysis of the written materials often evoked a reconsideration of the protocols.
Analysis was continued in this way until saturation, which meant that no new elements were added to the analysis and no conclusions were subject to change.
The third phase in analysing the data was the interpretation of the findings and the comparison with the preliminary expectations of the HLT. Also, explanations for the differences between expectations and findings were developed. These conclusions and interpretations functioned as feed-forward for the formulation of new hypotheses for the next cycle in the research.
3. Exemplary cases from the three projects
3.1. A case from the statistics project
Background
The aim of this project, entitled "symbolising in statistics education", was to develop an instruction theory for early statistics education, with a focus on the notion of distribution of univariate data in relation to sampling. Students tend to perceive a data set as a collection of individual data points (Hancock, Kaput, & Goldsmith, 1992), whereas statistical data analysis is mainly about describing and predicting aggregate features of data set. The end goal of the instructional unit was that students should come to view a data set as a whole and develop a notion of distribution as an object that can have different features. The notion of distribution is a key concept of statistics and it is intimately tied to the idea of shape. A common representation of the normal distribution, for instance, is the bell shape. Such shapes are, of course, not just visual images, but signify how the data are distributed in terms of frequency or density. This means that students need to develop the meaning of such distributions before they can interpret conventional shapes such as the bell shape as symbols with meaning.
The teaching experiment that we report on here was in an eighth-grade class (second class havo-vwo) with 30 students, and lasted for ten lessons of 50 minutes. The students had learned about means and bar graphs, but no other statistical concepts or graphs, before the start of the teaching experiment.
Design of the HLT
The representational backbone of the Hypothetical Learning Trajectory (HLT) was the series of graphs in Figure 1. Students started with value-bar graphs of minitool 1; they could hide the bars, so that only the endpoints remained. If these endpoints were dropped (mentally), they got the dot plot of minitool 2. In minitool 2, students can organise data sets into equal intervals (precursor to histogram), two equal groups (median), four equal groups (box plots), and so on. While solving statistical problems with these minitools, students reasoned with different aspects of distribution, such as mean, spread, majority and outliers. We then wanted students to reason with continuous shapes, as opposed to discrete dot plots. Our conjecture was that this transition from a discrete plurality of data values to a continuous entity of a distribution is important for fostering a notion of distribution as an object. Once shape would be an object that students could reason about, the next step was to distinguish different shapes that are precursors to different distributions (uniform, symmetrical, skewed). Design research on IT ORD-2003 7
Figure 1. Minitool 1, with and without bars, and minitool 2 (the last two are the same data set).
Teaching experiment phase
One of the conjectures that emerged during an earlier cycle of design research was that experience with a so-called growing sample would help the students to reason about shapes of distributions, which is seen as a pre-stage to working with distribution as an object. The task of the students was to predict graphs of data of hypothetical situations with a particular sample size and compare their predictions with actual data. Then a larger sample had to be predicted and compared with actual data. In this way the shape of a distribution in relation to particular distribution aspects could become a topic of discussion.
In the first cycle of growing a sample, students had to predict weight data of ten eighth graders. We give examples of the work of three students that form a representative group of the class. Figure 2 shows the different graphs that were made: value-bar graphs, only the endpoints of the bars, and dot plots. These graphs correspond to the minitool graphs students had worked with in previous lessons (Figure 1). When comparing their own graphs with real data graphs, students often used informal attributes such as "together" and "spread out" to indicate range and spread.

Figure 2. Students' predictions of sample size 10, and three actual samples of 10.
Christel: The middle-most [graph with actual data] best resembles mine because the weights are closely together and that is also the case in my graph. It lies between 35 and 75 [kg]. Design research on IT ORD-2003 8
Susan: The other [real data] are more weights together and mine are further apart.
In the second cycle of growing a sample, students had to predict data for a whole class and for three classes after the feedback of the samples of ten data points in dot plots.
Figure 3. Susan's predictions for one and three classes and an actual sample of three classes.
Rikkert: My spread is different.
Christel: Mine resembles the sample, but I have more people around a certain weight and I do not really have outliers because I have 10 about the 70 and 80 and the real sample has only 6 around the 70 and 80.
Susan: With the 27 there are outliers and there is spread; with the 67 there are more together and more around the average.
In contrast to the first cycle, students used nouns instead of just attributes for comparing the graphs. This might seem trivial, but statistically it makes a difference whether we say, "the dots are spread out" or "the spread is large". Once spread is an object that can be talked about, it can be measured, for instance with range or interquartile range.
Figure 4. Students' predictions of shapes in the third cycle of growing a sample.
In the third cycle of growing samples students made their first remarks about shape. The continuous shapes that they proposed were pyramid, semicircle and bell shape. Using these shapes in the sixth lesson, students came to reason about different aspects of distributions, including mean, outliers and skewness, in relation to sampling.
Retrospective analysis
From the analysis we concluded that students' experience with the minitools supported their reasoning about growing samples and that this activity of growing samples in turn supported the development of Design research on IT ORD-2003 9
a notion of distribution in relation to sampling. In the lessons after this fourth lesson, students could work with growing samples in the second minitool. We claim that the activity that students worked on in the fourth lesson fitted well in the HLT. One indication for this is that a considerable part of the HLT was retrieved in one lesson. In fact, Treffers and colleagues use this as a criterion for the quality of an activity in a learning trajectory that aims at guided reinvention.
What becomes visible in the cross section of solutions of the complete group at a certain moment is the longitudinal section of the learning trajectory that has to be followed by each student. (Treffers, Streefland, & de Moor, 1994, p.147; translation from Dutch)
And indeed we encountered the whole representational backbone of the HLT in the fourth lesson:
1. Value-bar graph of minitool 1;
2. Only the endpoints of the bars;
3. Dot plot of minitool 2;
4. Dot plot with continuous shape on top of it;
5. Continuous shape.
From the analyses of students' reasoning with these graphs and shapes (symbols), we can infer that students did indeed start to develop meanings as intended. From a systematic analysis that was inspired by the constant comparative method of Glaser and Strauss (1967), we concluded that students in all seventh and eighth-grade classrooms tended to think of distributions as consisting of low, average, and high values. While working with diagrams both on paper and the computer screen, they started to develop a more subtle view on distribution.
The semiotic framework of diagrammatic reasoning (Peirce, 1976) helped in describing the process of meaning development in relation to statistical diagrams, in particular in the formation of mathematical objects. Not all of the students developed a notion of distribution as an object, but they did learn to reason about shapes in relation to frequency and density. Diagrammatic reasoning consists of constructing diagrams, experimenting with them, and reflecting on the results. It proved useful to let students invent their own diagrams and let them compare these with other students' diagrams. The minitools were used optimally during the experimentation phase, which formed the basis for reflection during class discussions.
The insights that have been developed in this project are of course domain-specific and situated in the Dutch context. In that sense, the theoretical contribution of such design research is "humble", as Cobb et al. phrase it (2003, p. 9). Yet, the fact that the HLT is theoretically and empirically grounded and is tailored to a specific domain makes it directly applicable to educational practice. Because the HLT has proved viable in different classrooms in different variants (also in the USA) we assume it can form the basis for a more general instruction theory on early statistics education.
3.2. A case from the calculus study
Background and design of HLT
The aim of this project, entitled "design research for the teaching and learning of calculus and kinematics with ICT", is to find out how students can learn the basic principles of calculus and kinematics by modelling motion. Many alternatives to the traditional transfer method stress the importance of modelling activities. In these alternatives two approaches are recognised. One uses simulations for exploratory modelling and the other uses (computer) tools for expressive modelling. Exploratory approaches stress the discovery of concepts while students work with formal representations in computer simulations. In the expressive approach, students' expressions during their modelling activities are the starting points for evolving concepts. This approach has many similarities with the importance of mediating models in realistic mathematics education. The expressive approach also fits the discussion about a dialectic relation between symbolising and development of understanding. With symbolising we refer to theories on how we create, use and adapt symbols and Design research on IT ORD-2003 10
how this relates to concept development as presented in the previous statistics study. In this project we focus on the role of graphical representations in the process of learning the principles of calculus and kinematics.
Nowadays, graphs are used in calculus and kinematics education as representations for describing change of velocity or distance travelled during a time interval. Students are expected to give meaning to the relation between distance travelled and velocity through characteristics of these graphs such as area and slope. The use of such instructional materials is based on a representational view (Cobb et al., 1992), which assumes that instructional materials can represent scientific knowledge, and that scientific concepts can be made accessible without fully taking into account the limitations of the knowledgebase of the students into which they have to be integrated. Elements of this view can still be found in exploratory approaches.
Cobb et al. oppose this view. In line with their reasoning, we claim that symbolisations and knowledge of motion can co-evolve in a learning process. Theories on symbolising give rise to heuristics for designing a learning route within which the mathematical and scientific knowledge emerges from the activity of the students (Gravemeijer et al. 2000). In this route, the creation, use and adaptation of various graphical representations are interwoven with learners' activities in a series of sciencepractices, from modelling discrete measurements to reasoning with continuous models of motion. Mathematical and physical aspects are integrated in these activities. Our focus is on students' contributions during these practices. Consequently, for understanding their reasoning we use the design research approach of planning and testing the envisioned trajectory in classroom situations, a research approach that aims at creating an educational setting for investigating how a trajectory works, instead of trying to decide whether it works.
The learning route - inspired by the domain history - is tried out and revised during teaching experiments in three tenth-grade classes. We collected data by video and audio taping whole class discussions and group work. The videotapes were used to analyse students' discourses and students' written materials with respect to the conjectured teaching and learning process.
Teaching experiment phase
We illustrate the change in how students think and talk about a model with the following episode. The trajectory starts with questions about a weather forecast. The teacher discusses the change of position of a hurricane with students: when will it reach land? This problem is posed as a leading question throughout the unit as a context for the need of grasping change. After the emergence of time series as

useful tools for describing change of position, students work with situations that are described by stroboscopic photographs. The idea is that students come up with measurements of displacements, and that it makes sense to display them graphically for finding and extrapolating patterns. Two types of discrete graphs are discussed: graphs of displacements (distances between successive positions) and graphs of the total distance travelled. Note that discrete graphs are not introduced as an arbitrary symbol system, but emerge as models of discrete approximations of a motion, that link up with prior activities and students' experiences. By using the computer program Flash students are able to investigate many situations. During these activities their attention shifts from describing specific situations to properties of these discrete graphs and the relation with kinematical concepts.
Our findings confirm such a change in reasoning. In the beginning students refer to distances between successive positions. After a while they reason using the global shapes and properties of graphs and motion. An example of such reasoning concerns an exercise about a zebra that is running at constant speed and a cheetah that starts hunting the zebra. The question is whether the cheetah will catch up with the zebra. In the graphs the successive measurements of the zebra and the cheetah are displayed.
The following discussion takes place between an observer and two students (Rob and Anna). Design research on IT ORD-2003 11
Figure 5. Distance-travelled and displacement graphs in Flash.
Observer: Oh yes. So why did you choose the one for the total distance [left graph in Fig. 5]?
Rob: Because it's the total distance that they cover and then you can-
Anna: Then you can see if they catch up with each other.
Observer: And can't you see that in the other [right graph]? There you can also see that the red [grey] catches up with blue [dark grey]?
Rob: Yes, but -
Anna: Yes, but that's at one moment. That only means that it's going faster at that moment but not that it'll catch up with the zebra.
Retrospective analysis
A difference between the displacements graph and the distance-travelled graph is the difference between the interpretations of the horizontal (time) axis. A value in the distance-travelled graph represents a distance from the start until the corresponding time, while a value in the displacements graph represents a distance in the corresponding time interval. Anna's last observation is an important step in the process of building the model of a velocity-time graph (and everything that comes with it). The qualitative analyses show that during the practices students re-invent and develop graphical symbolisations, as well as the language and the scientific concepts that come with them. However, these inventions only became explicit after interventions by an observer or by the teacher. Additionally, we found that the teacher had a crucial role during the classroom discussions. It was not always easy to organise the discussions in line with the intended process. Sometimes the teacher reacted to students' contributions in terms of the inscriptions or concepts aimed at. In those cases students awaited further explanation. The discussions appeared to be especially productive when the teacher organised classroom discussions about students' contributions in such a way that the students themselves posed the problems that had to be solved, and reflected on their answers. In a second teaching experiment we arranged a setting where the teacher had more information about the possible contributions of the students and the way in which they could be organised. Additionally, we designed activities for classroom discussions. In this experiment we found that this resulted in discussions where students anticipated on the intended concepts and reflected on their contributions.
In this approach the construction and interpretation of graphs and the scientific concepts are rooted in the activities of the students through emerging models. This ensures that the mathematical and physical concepts aimed at are firmly rooted in students' understanding of everyday phenomena. On the basis of our findings we conclude that classroom discussions where students discuss their solutions and pose new problems to be solved, are essential for a learning process during which symbolisations and knowledge of motion co-evolve. Design research on IT ORD-2003 12
3.3. A case from the algebra study
Background
The aim of the third project, entitled 'Learning algebra in a computer algebra environment', was to investigate the contribution of computer algebra use to the development of algebraic concepts and techniques. A computer algebra system (CAS) is a software package, available on both PCs and hand-held devices, which is able to carry out algebraic procedures such as solving equations, substituting expressions and simplifying formulas. The availability of such powerful tools for algebra raises the question of how this kind of technology can be integrated into algebra education and how this integration affects the role of by-hand algebra skills. What is the relation between the work in the computer algebra environment, the paperand-pencil work, and the students' mental understanding?
One perspective for investigating this question is the instrumental approach to using technology. By instrumentation we mean the process of developing techniques in the technological environment (Artigue, 2002). Such a technique is built up by the students for solving a specific type of task, and is condensed into so-called instrumentation schemes. An instrumentation scheme includes technical knowledge and skills for manipulating a technological tool, in this case the computer algebra environment, as well as conceptual knowledge that gives meaning to these technical manipulations. This intertwinement of technical aspects related to the tool, and mental aspects related to the students' conceptual understanding makes the instrumentation perspective relevant for our purpose.
Our claim here is that this instrumental approach allows for understanding the interaction between student and technological tool, and in particular the difficulties that are encountered (Drijvers, 2000). Furthermore, we argue that a carefully orchestrated instrumentation of the technological tool, both by the instructional activities and the teacher, may improve conceptual understanding, which also affects paper-and-pencil techniques.
The teaching experiments in which we found evidence for these claims took place in ninth- and tenth-grade classes of high achieving students (in the Dutch school system: vwo3 and vwo4) and lasted 15 - 20 lessons each. Before the experiments, the students had some experience with algebra, but little experience in using technology for learning mathematics. During the teaching experiments, they used the TI-89 symbolic calculator as computer algebra environment. We illustrate our claims with an example on substituting expressions.
Design of HLT
The pre-test of one of the teaching experiments revealed that hardly any of the students were able replace y in the equation x
2
+ y
2
= 10 by a - x , in other words to substitute y = a - x into the equation x
2
+ y
2
= 10.
During the teaching experiment the students carried out such substitutions using the computer algebra device. Fig. # shows the syntax of the substitution using the vertical substitution bar. Entering expression1 | variable = expression2 results in replacing all instances of variable in expression1 by expression2.
Figure 6. Substituting an expression in the CASDesign research on IT ORD-2003 13
While carrying out such substitutions, the students had to build up the substitute instrumentation scheme. This scheme involved:
1. Noticing that a substitution is required to obtain a result;
2. Remembering the way substitution is carried out in the computer algebra environment: the meaning of the vertical bar symbol and the syntax of the command;
3. Realising which expressions play the roles of expression1 and expression2, and in particular considering expression2 as an object instead of a process;
4. Being able to type in the command correctly;
5. Accepting the resulting expression as a satisfying answer in spite of its "lack-ofclosure" (see below).
Steps 2 and 4 of this scheme have a primarily technical character, whereas the other steps are mainly conceptual. One of the first examples of substitution concerned substituting the expression for the area of the bottom of a cylinder into the volume function:
V = A•H | A = π•R
2
. The fact that the problem situation was meaningful to the students helped them to understand the substitution. Meanwhile, the fact that the result, V = π•H•R
2
, still contained multiplication symbols was not satisfying to some of the students, as they wanted to be able to carry out the multiplications to get a numerical answer. This is the socalled lack-of-closure obstacle that was referred to in step 5 of the scheme (Tall & Thomas, 1991).
Teaching experiment phase
By means of practising substitution in the CAS, the students got used to expressions as answers and seemed to consider expressions as sensible results. However, their notion of substitution often was somewhat vague, as the following observation indicates:
Observer: And what happens now for example in V = A•H wherein A = π•R
2
?
Maria: Well that it just makes one formula out of it.
Observer: Yes, and how does it do that then?
Maria: By means of joining them or something?
Later in the teaching experiment, students tried to substitute non-isolated forms, such as for example x
2
+ y
2
= 10 | x + y = a. This error was not only a syntactical matter, but also revealed an imprecise concept of substitution in step 3 of the scheme. In the teaching, a proper view on substitution was supported by means of visualisation:
x
2
+ y
2
= 10 | x = z + 1
The instrumentation of substitution within the computer algebra environment led to an improved conceptual insight on the issues of steps 3 and 5 of the scheme. This was confirmed by data from the post-experiment interviews, during which the computer algebra device was no longer available to the students. Most students showed to be able to substitute y = a - x into the equation x
2
+ y
2
= 10. As fig. # shows, one of them used the vertical bar to indicate the substitution, which clearly was inspired the notation in the computer algebra environment. He wrote down x
2
+ (a - x)
2
= 10 and explained his result by saying: "Here is already a y and here it says what y is, so you just have to replace this with that, I was just thinking too difficultly".
Figure 7. Transfer of notation Design research on IT ORD-2003 14
Retrospective analysis
Looking back at the results of this study, we conclude that the perspective of instrumentation was helpful for understanding the interaction between student and technological tool and for studying the effect of computer algebra use on conceptual development. The question is how these findings link up with theories on symbolising, which stress the signification process in which the student develops his own symbolisations, and improves and uses them in relation to the meaning that he attaches to them (Cobb, Gravemeijer, Yackel, McClain, & Whitenack, 1997; Gravemeijer et al., 2000). Our study did not show much of this bottom-up process, because the computer algebra environment already offers a symbol system and is not very flexible concerning notation and syntax. However, the confrontation with a ready-made symbol system also involves the process of developing meaning while using the system. This links up with the technical and conceptual aspects of instrumentation. In that sense, theories on symbolisation provided a background for understanding the growing sense for the symbols within the computer algebra environment. Furthermore, the use of realistic problem situations such as the cylinder task provided a reference to a meaningful situation for the students. The use of the technological tool did not make such a reference redundant and in the meantime did not hinder generalisation and abstraction.
4. Discussion
In the statistics project, different instances of diagrammatic reasoning have been analysed. It proved useful to let students construct their own diagrams once they had some experience with specially designed software, and reflect on the diagrams they had made in relation to the problem that had to be solved. The alternation of providing carefully designed software and letting students reinvent their own graphs and strategies proved useful. Looking back we notice that the growing samples activity shows a subtle mix of providing and designing (cf. van Dijk et al., 2003). The students had already experience with minitool graphs there were provided, but in the fourth lesson they had to design their own graphs for new situations (very large samples). After the first cycle of growing samples, students received feedback with dot plots. In other words, there was opportunity for a reinvention process, but this was guided carefully. This means that the answer that our design research gives to such questions is subtle and situated, but not easy to generalise.
As intended in the HLT, students did indeed learn to reason about distributions and sampling in a meaningful way in relation to statistical diagrams. This learning process was analysed semiotically and, as expected, the relationship between symbolising and the development of meaning and mathematical objects could be characterised as reflexive.
Also, in the calculus project it appeared that symbols and reasoning could develop in a reflexive process. The IT-tools afforded students many situations with presented representations to analyse. During these analyses the character of the representations changed from situation-close to organising tools for modelling motion. In this way, through emerging models construction and interpretation of graphs and scientific concepts became rooted in the activities of the students. Moreover, we found that classroom discussions where students discuss their solutions and pose new problems to be solved are essential for a learning process during which symbolisations and knowledge of motion co-evolve.
The project on learning algebra in a computer algebra environment showed that the technical skills using the computer algebra device required, were closely related to a conceptual understanding of the mathematics behind the technique. Developing computer algebra techniques and instrumentation schemes proved to be difficult for the students. Overcoming these difficulties often involved a conceptual development that was relevant for the targeted insight. The joint development of technical skills and conceptual understanding is seen as support for the instrumental approach to using IT tools. Design research on IT ORD-2003 15
5. Conclusions
On the issue of the research question from paragraph 1, we notice an agreement on the tension between the bottom-up reinvention process and the top-down character of IT use. Moreover, we notice an agreement on the importance of the perspective of symbolising, though in a different way for each of the studies. On the issue of the methodology, we conclude that the notion of Hypothetical Learning Trajectory was helpful in the preliminary phase of each of the research cycles, and that gathering data

by means of dedicated mini-interviews with students was a fruitful strategy. During the teaching
experiments and retrospective analyses the HLT also served in guiding the observations and analysis.
We now briefly elaborate on each of these conclusions.
In each of the studies we noticed a tension between the targeted bottom-up reinvention process and the
top-down character of IT. The term guided reinvention is used for a process in which students
experience learning mathematics as if they could have invented it themselves, while being supported
by the teacher and instructional materials (including the IT-tools). The IT-tools intrinsically have a
top-down character because they offer a restricted repertoire of representations and. For computer
algebra this top-down character is the strongest, because the large variety of possibilities is combined
with a restricted flexibility in symbols, notation and syntax. Somehow this disadvantage of IT-tools
has to be compensated by instruction; reflection, interaction, carefully designed problems, and so on.
It is important that the teacher not just compares different diagrams and solutions with the students,
but also stimulates students to formulate which problems they solve, why certain solutions work and
in which direction future activities have to take place.
The focus on symbolising proved viable. In the projects on statistics and calculus, using semiotic and
perception theories turned out useful for analysing the relationship between symbolising and
development of meaning. We assume on the basis of these projects and prior research that a carefully
designed trajectory of symbol and meaning development is necessary to give students the
opportunities to learn mathematics. In that process, students need to get ample opportunities for their
own constructions and reflection on them. In the algebra project, this issue was different, because the
computer algebra systems are ready-made symbol systems that are hard to change. As a consequence,
the focus was not on the development of increasingly sophisticated symbols, but on the development
of meaning within an existing symbol system. Realistic contexts proved important in that. The
approach of instrumentation, which considers dealing with a ready-made symbol system in relation to
conceptual development, can be seen as a specification of the symbolising issue in the case of readymade systems.
With respect to the methodology of design research, we consider the Hypothetical Learning
Trajectory a useful instrument in all phases of design research. During the design phase it is the
theoretically grounded vision of the learning process, which is specified for concrete instructional
activities. During the teaching experiments, the HLT guides observations, data collections, which
questions have to be asked during mini-interviews, and offers a framework for educational decisions
during the teaching experiment. The mini-interviews proved useful for getting detailed information
about what symbols meant for students and how they reasoned with these symbols. In the
retrospective analysis phase, the HLT served as a guideline for data selection and offered conjectures
that could be tested during the analysis. Design research on IT ORD-2003 16

How Emergent Models May Foster
the Constitution of Formal Mathematics
Koeno Gravemeijer

Utrecht, The Netherlands and
Department of Teaching and Learning
Vanderbilt University
This article deals with the role that so-called emergent models can play in the process
of constituting formal mathematics. The underlying philosophy is that formal mathematics is something that is, or should be, constituted by the students themselves. In the
instructional design theory for realistic mathematics education, models always have
been employed to foster a process in which formal mathematics is reinvented by the
students themselves. This article describes how the use of models became more and
more explicated over time and developed into the notion of emergent models. The design of an instructional sequence, which deals with flexible mental computation strategies for addition and subtraction up to 100, is taken as an instance for elaborating
what is meant by emergent models and what role they play in fostering the constitution of formal mathematics. The analysis shows that there are 3 interrelated processes.
First. at a more holistic level, there is aglobal transition in which "the model" initially
emerges as a model of informal mathematical activity and then gradually develops
into a model for more formal mathematical reasoning. Second, the transition from
"model of' to "model for" involves the constitution of anew mathematical reality that
can be denoted formal in relation to the original starting points of the students. Third,
in the series of instructional activities, there is not 1 model, but the model actually is
shaped as a series of signs, in which each new sign comes to signify activity with a
previous sign in a chain of signification.
The difficulty of learning mathematics often is attributed to what is perceived as the
gap between everyday life experience and what is colloquially called formal mathematics. In the approach discussed in this article, however, everyday-life experi-

ence and formal mathematics are not seen as two disjunct entities. Instead, what is
aimed for is a process of gradual growth in which formal mathematics comes to the
fore as a natural extension of the student's experiential reality. The focus in this article will be on the role so-called emergent models can play in such a process. The
perspective taken here is that of instructional design. The design of an instructional
sequence that aims at linear measurement and mental arithmetic will be used as an

occasion to elaborate on the role of emergent models.
To provide the necessary background, I start by sketching the context of the instructional design approach, within which the use of emergent models can be depicted as a design heuristic. The instructional design under discussion is a design in the context of developmental or transformational research aiming at the development of a domain-specific instruction theory for realistic mathematics education (RME; Gravemeijer, 1994a; Streefland, 1991; Treffers, 1987). This RME instruction theory is not a fixed, ready-made theory but more a theory that iselaborated and refined continuously. Because of this, I think it is useful to describe the history of the way in which the role of models is conceived in RME. Further, before finally working out the intended exemplary instructional sequence, I sketch the history of that sequence.
I adopt a semihistorical approach in this article. As a consequence, I sometimes use descriptions that may seem unclear or questionable without elaboration, but I do so to do justice to the history.
DEVELOPMENTAL RESEARCH
The design heuristic, which is addressed here, is part of an instructional design approach, which, in turn, is part of a research approach that is known as developmnl research (Cobb, Gravemeijer, Yackel, McClain, & Whitenack, 1997; Freudenthal, 1991; Gravemeijer, 1994b, 1998) or as trar7sformntiotlnl research (National Council of Teachers of Mathematics Research Advisory Committee, 1988). Developmental research is best described as an integration of design and research. That is, the design of instructional sequences serves as research on an instruction theory. This type of research poses the question: What does mathematics education that fulfills certain prechosen points of departure look like?
In the first phase of a developmental research project, a preliminary design of an instructional sequence is constituted. In the second phase, this preliminary design is elaborated and adjusted in a series of cyclic processes of deliberations on and trials of instructional activities. These cycles are to a large extent similar to Simon's (1995) mathematical teaching cycles.
In the last phase of the developmental research project, the knowledge assembled during the experiments with the various instructional activities is used to (re)construct an optimal instructional sequence. A central goal of the research work is to explicate the local instruction theory that underlies this reconstructed in-
Downloaded by [North West University] at 07:05 27 May 2015 EMERGENT MODELS 157
structional sequence and to justify this theory in terms of theoretical deliberations and empirical assessments (see Gravemeijer, 1994a, 1994b, 1998).
This article is limited to the first part of such a developmental research activity. It focuses on the preliminary design of an instructional sequence. It should be noted that such a preliminary design does not necessarily have to be worked out in detailed descriptions of instructional activities because a core element of the developmental research approach is that instructional activities are designed and redesigned during the educational experiment. The experimental phase is not entered with a fixed sequence of instructional activities. Instead, the shape and form of the instructional activities that are actually used in the classroom are decided up on a day-to-day basis while taking into account what is learned from the preceding activities in the classroom.
The preliminary design may consist of a set of instructional activities that are supplemented with guidelines. The guidelines indicate both the order in which the instructional activities are to be enacted and the conjectured learning route in terms of the mental activities the students might engage in as they participate in the instructional activities. In relation to this, we speak of a local instruction theory. The concept of a conjectured local instruction theory is comparable with Simon's (1995) notion of a hypothetical learning trajectory. Such a notion encompasses the "consideration of the learning goal, the learning activities, and the thinking and learning in which the students might engage" (p. 133).
However, there are two differences: (a) The hypothetical learning trajectory deals with a small number of instructional activities, whereas the local instruction theory encompasses a whole instructional sequence; and (b) the hypothetical learning trajectory is tailored to the teacher's own classroom at a given moment in time, whereas the local instruction theory is more general. In my view, the connection between the two is that the local instruction theory entails a framework against which teachers can construe hypothetical learning trajectories that fit the actual situation in their classrooms.
If we return to the three phases of developmental research, we see that a conjectured local instruction theory is construed in the first phase. Subsequently, this conjectured local instruction theory is elaborated, refined, and adjusted in the second phase, the phase of the educational experiment. Then, in the third phase, the improved local instruction theory is reconstructed andjustified. The issue1 deal with in this article is the design of the conjectured local instruction theory in the first phase of adevelopmental research project. The focus is on the use of emergent models as a design heuristic, which can be seen as a constituting element of the RME theory.
The RME theory is not a fixed a priori theory but is a theory that is always "under construction." RME is being developed in an ongoing process of designing,
Downloaded by [North West University] at 07:05 27 May 2015 experimenting, analyzing, and reflecting. Central to this development is the role of developmental research. There is a reflexive relation between RME theory and developmental research. On one hand, RME theory guides the design and research; on the other hand, developmental research serves the elaboration and refinement of the theory. The goal of the RME research program is to determine how mathematics education can be presented to students to facilitate their reinvention of mathematics.
The point of departure is Freudenthal's (1973, 1991) adage of "mathematics as a human activity." For him, mathematics was primarily an activity. Mathematics as a system of organized knowledge was secondary for him. According to Freudenthal, this is how it ought to be for students as well. In his view, students should learn mathematics by mathematizing: both subject matter from reality and their own mathematical activity. Via a process of progressive mathematization, the students should be given the opportunity to reinvent mathematics. In this manner, Freudenthal transcended the apparent dichotomy between mathematics as an activity and mathematics as a body of knowledge.
In fact, the reinvention principle is the first instructional design heuristic in RME. According to the reinvention principle, a learning route has to be mapped out along which the students can find the intended mathematics for themselves (Freudenthal, 1973). To do so, the curriculum developer starts with a thought experiment by imagining a route the students could have invented themselves. Knowledge of the history of mathematics can be used as a heuristic device in this process. Note that the students are not expected to reinvent everything on their own. In relation to this, Freudenthal (1991) noted guided reinvention. For him, the emphasis is on the character of the learning process rather than on inventing as such. The idea is to allow learners to come to regard the knowledge they acquire as their own private knowledge, knowledge for which they themselves are responsible. On the teaching side, students should be given the opportunity to build their own mathematical knowledge store on the basis of such a learning process. In relation to this, it may be noted that the RME theory is primarily a theory about knowledge construction; the idea is not to motivate students with everyday-life contexts but to look for contexts that are experientially real for the students and can be used as starting points for progressive mathematization.
At a closer look, the history of the reinvention heuristic reveals the dynamics of the RME theory. Initially, the reinvention principle was interpreted rather literally, referring to the history of mathematics as a source of inspiration for the design of instructional sequences. Gradually, however, students' informal solution methods have been recognized as a source of inspiration. Sometimes, the informal ways by which students solve applied problems "anticipate" the more formal procedures we are aiming for (Streefland, 1991). For instance, Streefland found that, when solving problems such as dividing three pizzas among four children, students ar-
Downloaded by [North West University] at 07:05 27 May 2015 EMERGENT MODELS 159
rived at solution methods that contained the seeds of more formal procedures for adding and subtracting fractions with unequal denominators. For example, the students came up with solutions that corresponded with 3 divided by 4, 3 times one fourth, one half plus one fourth, or I minus one fourth. Written in a formal notation, one could conclude from this: ¾ = 3 x ¼ = ½ + +, and = 1 - -. In this sense, the informal solution methods of the students anticipated conventional standard procedures (e.g., ¾ + + + - + = x) , and one could think of ways to help students develop procedures similar to the conventional standard procedures.
RME started out as a vision, or as a philosophy of mathematics education that still had to be worked out. This is being done in developmental research projects, in which each time the research question is: What would mathematics education, which fulfills the initial points of departure, look like for a given topic? By reflecting on the yield of these projects, RME theory is developed, new theoretical insights in turn are used in subsequent research projects, and hence RME is developed in an iterative process of elaboration, adjustment, and refinement.
THE ROLE OF MODELS
In recent times, the RME community has expressed increasing interest in the role of models. From early on, it has been clear that models play a different role in RME than in mainstream information-processing approaches or in cultural-historical approaches, as elaborated by Gal'perin (1969).
In the latter approaches, models come to the fore as didactic models that embody the formal mathematics that is to be taught. That is, the formal abstract mathematics is "concretized" to be made accessible for the students. Actually, the students are to discover the mathematics that is concretized by the designer. In the RME approach, the models are not derived from the intended mathematics. Instead, the models are grounded in the contextual problems that are to be solved by the students. The models in RME are related to modeling; the starting point is in the contextual situation of the problem that has to be solved. This problem is modeled by the students who solve it with help of the construed model. The premise here is that students who work with these models will be encouraged to (re)invent the more formal mathematics.
Treffers (1987) discussed "bridging by vertical instruments" (p. 248). Here, vertical instruments also included schemes, diagrams, and symbols, although models were given a central position, and, although other roles of models were mentioned, it was emphasized that models primarily fulfill a bridging function between the phenomenological appearances of mathematics in reality on the one hand and the formal mathematics on the other. Still, models were treated as part of a broader category of instruments with a global function. In later publications, a more specific role of certain models was singled out:
Downloaded by [North West University] at 07:05 27 May 2015 160 GRAVEMEIJER
It is especially by means of strong models that children are given the opportunity to bridge the gap between informal, context-bound work and the formal, standardized manner of operation through the constructive contribution of the chi0ren themselves. They must be "models of' context problems that will serve as "models for" the pure subject restrictedand applied arithmetic in the pertaining area-multifaceted, in other words (Treffers, 199 1, p. 33).
Despite the reference to the constructive contribution of the students, this description may evoke an image of two independent worlds: that of the student and that of the formal mathematics, which have to be brought together. Such an image, however, would not do justice to the RME adage that students have to construct their own mathematics. To put it differently, formal mathematics is not something "out there" with which the student has to connect. Instead, formal mathematics is seen as something that grows out of the students' activity. The students are expected to develop formal mathematics by way of mathematizing their own informal mathematical activities. The notion of two disjunct worlds as it is taken from traditional mathematics education would not fit here.
The objective of the RME approach is that students experience formal mathematics no differently from informal mathematics. Freudenthal (1991) expressed this by speaking of mathematics as starting within common sense and staying within common sense. The premise is that common sense develops as the mathematics-that is, part of this common sense--develops. Within this perspective, we can distinguish between formal and it-form-nl by denoting formal mathematical reasorling as a form of reasoning that builds on arguments that are located in the newly formed mathematical reality. Seen this way, the distinction between informal and formal is a relative distinction-a distinction that is relative to a certain topic and that can be made especially from an observer perspective.
Streefland (1985) argued that models can support the process of mathematical growth: "Reality [is] attenuated into a model, a 'model of,' an after image" (p. 63). The model and the modeling facilitate reflection. Moreover, one may find that the model is also useful in other situations. The model can become exemplary, a "model for mathematical control of new realities" (p. 63). He elaborated: "In the mental shift from after-image to pre-image, realizing and level raising manifest themselves in the learning process. The aforementioned shift in perspective mirrors the new acquired insight in the wider applicability of the model (p. 63)."
In this sense, one can speak of a "model of' informal mathematical activity becoming a "model for" more formal mathematical reasoning. This shift can be exemplified with the fair-sharing situations that Streefland (1991) employed for instruction on fractions. In this setup, problems about sharing pizzas were modeled
'In the translation to English, the Dutch word voorbeeld, literally meaning"example," was translated as prr-image.
Downloaded by [North West University] at 07:05 27 May 2015 EMERGENT MODELS 1 61
by the students by drawing partitioning of circles that signify pizzas (model of). Later, the students used similar drawings to support their reasoning about relations between fractions (model for).
THE EMPTY NUMBER LINE
Thinking about the transition from model of to model for sparked a new impulse, with the research on the empty number line as a means of supporting flexible mental computation strategies for addition and subtraction up to 100.
Inspired by Whitney (1988), Treffers (1991) introduced the use of an empty number line in RME.
An empty number line can be used to describe the solution of (two digit) addition and subtraction problems by marking the numbers involved and drawing the "jumps" that correspond with the partial calculation. Solving 64 - 29 by subtracting 4, 1 0, 1 0, and 5, respectively, would result in the inscription shown in Figure I. Such a solution method, which could be seen as a form of curtailed counting

down, belongs to the most common informal solution methods that students use. Accordingly, we may discern between collection-type solution methods and linear, counting-type solution methods. In the first type, the student partitions each number into a "10s part" and a "1s part" and then adds or subtracts those separately. In the second type of method, the student increments or decrements directly from one number, as in the previous example. The empty number line sequence is especially thought to fit with counting-type rather than collection-type methods. Moreover, the use of the empty number line not only fits these methods but also supports them. The number line supports the execution of counting-type methods by offering a way of scaffolding both partial calculations and partial results. However, the number line has more advantages. One of these advantages is in the flexibility of the empty number line. The students can adapt the model to their thinking. We may contrast this with the common practice with base-10 blocks if we look at the way these blocks typically are used in instructional practices that aim at preparing students for the column algorithm (while acknowledging that these blocks can be used in a variety of other ways).
In this type of instruction, the students are expected to conform their thinking to the regulations that anticipate the written algorithms. When subtracting 37 from 84, the students are expected to start with the 1s to find that you cannot subtract 7 from 4, then exchange one 10 for ten 1s, which makes seven 10s and fourteen 1s.
Downloaded by [North West University] at 07:05 27 May 2015 162 GRAVEMEIJER
Next, the seven 1s can be taken away, followed by the three 10s, which leaves four 10s and seven 1s, equaling 47.
In the approach of Whitney (1988) and Treffers (1991), the model is not employed to steer the student's thinking; instead, the model is meant to be adapted to fit the student's thinking. The student decides what steps to make and marks the number line accordingly. It may be noted that something similar can be done with base-10 blocks, but Whitney and Treffers both chose the number line because of their preference for counting-type solution methods.
Another reason for choosing the empty number line is that it also can be used to depict more sophisticated strategies such as compensating. For example, 95 - 19 can be solved by first subtracting 20 from 95 and then adding 1. The empty number line can be used to explain and justify this strategy (see Figure 2).
Note that here the number line plays a different role than when used to model a context problem. This difference helps us to come to grips with the shift from model of to model for. At first, the focus is on the relation of thecontext problem to the number line; later, the numerical-mathematical relations become more important. At first, we encourage the student to try to mirror the problem situation by the number line representation; later, we encourage the student to use an incongruent representation if that would facilitate the calculation (see Figure 3).
Given the previous characteristics, the empty number line worked as a catalyst for the way the *RME* community was thinking about models. It helped the researchers realize that the shift from model of to model for concurs with a shift in the students' thinking, from thinking about the modeled context situation to a focus on mathematical relations. In the latter phase, number relations dominate the

FIGURE 4 Levels of activity
/ referential
/ task setting
/
use of the number line. Therefore, we can discern two different types of activity (Gravemeijer, 1994a; Gravemeijer, Cobb, Bowers, & Whitenack, in press):
1. Referential activity, in which "models of' refer to activity in the problem setting described in instructional activities.
2. General activity, in which "models for" make possible a focus on interpretations and solutions independently of situation-specific imagery.
These general types of activity can be seen as different levels of activity, which can be completed with (a) a level of activity in the task setting itself and (b) a level of activity in which the student no longer needs a model. Together, these levels can elaborate the distinction between model of and model for by identifying four general types of activity, as shown in Figure 4.
Activity in the task setting involves interpretations and solutions that depend on understanding how to act in the problem setting (often out-of-school settings). Referential activity involves models of that refer to activity in the setting described in instructional activities. General activity involves models for that facilitate a focus on interpretations and solutions independent of situation-specific imagery. The activity of formal matjematical reasoning is no longer dependent on the support of models for to achieve mathematical activity.
Although the four types of activity clearly involve a developmental progression, this does not imply that they involve a strictly ordered hierarchy. In practice, discussions on the level of general activity and of formal mathematical reasoning frequently fold back to referential activity or even to activity in the setting (McClain & Cobb, 1998).
The goal of describing the four levels of activity is to illustrate that models are initially tied to activity in specific settings and involve situation-specific imagery. At the referential level, models are grounded in students' understandings of paradigmatic, experientially real settings. In whole-class discussions, these models are integral to explanations in which students describe how they interpreted and solved tasks centering on the starting-point settings. General activity begins to
Downloaded by [North West University] at 07:05 27 May 2015 emerge as students' reasoning loses its dependency on situation-specific imagery, and the role of models gradually changes as they take on a life of their own. This transition can be seen as a process of reification, wherein the students begin to reflect collectively on their referential activity. In the process, the model becomes an entity in its own right and serves more as a means of mathematical reasoning than as a way to symbolize mathematical activity grounded in particular settings.
Here a connection can be made with the reification processes in mathematics as observed by Sfard (1991). Sfard noted that, in the history of mathematics, repeatedly processes develop into mathematical entities with an object-like character. Examples include the development from counting as a process into numbers as entities, as well as the shift from algebraic functions as recipes for processing an input to obtain an output, to functions as mathematical entities with certain characteristics (e.g., linear functions and quadratic functions).
The analogy with this process of objectivation, or reification, however, begs the question: What is it that is being reified? The analogy with the transition from process to object-like entity, observed by Sfard (1991), illuminates the point that it is not the inscription that is being reified but some activity. To identify the activity, it is necessary to look at the original instructional sequence in which the use of the empty number line is incorporated. In this instructional sequence, the empty number line is preceded by activities with a bead string (Treffers, 1991; Whitney, 1988). Initially, a bead string with 100 beads colored in groups of 1 0 is used for counting games. The beads are counted from left to right, and the number is indicated with a clothes peg that marks the total beads at its left. Students find out that the decimal structure can be used to count efficiently. Using the number line concept, the students solve tasks such as "Count 38 and add 24 more. Which number do you get?" In doing so, they might look for 38 on the bead string (possibly realizing that 38 is 2 less than 40); then, they might add 1 0 beads (knowing that the result will be 48) and another 1 0 beads (arriving at 58); and finally, they might add 4 (possibly as 2 and 2). In this manner, counting games on the bead string anticipate the use of the number line, which is introduced subsequently to model the activities on the bead string.
Initially, in the mode-of phase, the actions on the number line signify actions on the bead string (e.g., actions of counting beads, encompassing resultative counting, counting on, and counting down). It is this activity that is reified. In this manner, acting with the number line functions as an intermediary between counting beads and acting with numbers as elements of a network of number relations. In this sense, the empty number line changes from functioning as a model of acting with the bead string to functioning as a model for reasoning with number relations. Because the beads arecolored in groups of 10, working with the bead string offers the opportunity to develop decuples-referenced solution methods. As a consequence, it may be expected that the students develop a framework of number relations that revolve around the decimal structure of our number system. In conclusion, we could argue
Downloaded by [North West University] at 07:05 27 May 2015 that working with the number line helps students to understand this decimal structure in such a manner that the numbers up to 100 start to derive their meaning from a system of number relations that become meaningful in their own right. In this sense, the goal of the number line sequence corresponds with what Greeno (1991) referred to with his environmental metaphor of number sense.
PROBLEMS OF THE ORIGINAL EMPTY
NUMBER LINE SEQUENCE
Despite all its qualities, however, the empty number line sequence described previously also has some problematic aspects. One drawback concerns the artificial character of the bead string as a sort of tactile microworld. Another drawback is that there is no credible motive. There appears to be no reason for someone to carry out all sorts of counting activities with a bead string. Both points do not sit well with the RME approach, even though it could be argued that the bead string can be seen as a tactile representation of the number sequence that already is grasped by the students.
This critique was the catalyst for efforts to design an instructional sequence that capitalizes on linear measurement as a basis for the introduction of the empty number line (McClain, Cobb, Gravemeijer, & Estes, in press; Stephan, Cobb, Gravemeijer, & McClain, 1998).
To place this effort in the right context, however, I first elaborate on an earlier teaching experiment, in which we tried to circumvent the bead string. In that teaching experiment, we tried to build on activities known under the label "The Candy Shop" (see Cobb et al., 1997). To some extent, this choice was rather accidental. According to the preliminary design, the plan was to introduce the bead string following the candy shop activities. However, the state of affairs in the classroom seemed to justify the introduction of the empty number line as a means of representing the actions that were executed with the candies.
The instructional intent of the candy shop sequence was to support the students' initial coordination of units of 10 and 1. The story revolved around the production and sale of candies that were represented by unifix cubes. Within the scenario of the candy shop, the problem of how to pack the candies was made a topic for discussion. After having discussed the pros and cons of various options, the teacher revealed that the owner of the shop, Mrs. Wright, chose to make rolls of 10. When the students were familiar with packing candies into rolls of 10, other problems were posed within the candy shop scenario. Mathematically, this meant that the students were asked to generate different partitionings of a given collection of candies and to solve problems that involved incrementing and decrementing numbers of candies as required by the packing and unpacking process. The empty number line was introduced in a whole-class mental computation activity called "Target."
Downloaded by [North West University] at 07:05 27 May 2015 In this game-like activity, the task of the students was to determine how much one would have to change a given number to reach a fixed target number. During the Target activity, the ways in which the students solved these problems were symbolized by drawing number lines (see Figure 5).
The empty number line was subsequently extended to 100 during an activity in which it served as a record of simulated transactions in the candy shop. The hypothesis that the empty number line could be grounded in the candy shop activities initially appeared to be confirmed by the facility with which the children, working in pairs, created number lines to tell stories about what happened in the candy shop. However, later events in the classroom led us to revise our view. Problems arose when the teacher posed addition and subtraction tasks by drawing a horizontal empty number line and describing transactions in the candy shop but not acting them out. Here, it showed that the students interpreted the empty number line in a variety of different, yet personally meaningful, ways. The differences in interpretation are illustrated in Figure 6.
One of the tasks posed corresponded to 90 - 8 (i.e., "Mrs. Wright has 90 pieces of candy, and she sells 8 of them"). As part of a counting-back strategy for solving 90 - 8, some of the students interpreted this figure as showing that 3 candies had been subtracted: 89, 88, and 87. Other students argued that 2 candies had been taken away. It further became apparent that, for some students, the 9th decade when counting by 1 0 comprised 80,8 1 , 82, . . . , 89. They appeared to reason that taking away 8 from the 9th decade would leave the candies signified by 80 and 8 1, and so there would be 81 candies left.
In retrospect, we concluded that the students adopted the empty number line primarily as a way of notating and not as a way of modeling a (mental) activity. We inferred that this calculational interpretation is stimulated by the fact that the students conceptualized the candy shop activities from a collection perspective and not from a linear-counting perspective. In the candy shop setting, the students were routinely structuring quantities in 10s and 1s. This split in 10s and 1S then guided their solution methods, whereas the empty number line representation did not lend itself to this type of solution method.

FIGURE 6 Counting down
The original approach aimed to encourage students to model situation-specific solution methods that were situated in the activity of manipulating the bead string. In that situation, we expected the students to develop solution methods of a linear type, such as counting on or counting down in bigger or smaller jumps while using the decuples as reference points. Next, that activity was modeled by the students. Their past experience of working with the bead string provided the necessary imagery behind the increments on the number line.
In the aforementioned teaching experiment, this imagery was lacking. As a consequence, the students had to create a semantic grounding for the empty number line individually and privately by interpreting it in terms of counting activity. They did this in a variety of ways, which made it impossible for them to communicate effectively about what had previously been an unproblematic activity.
MEASUREMENT AS AN ALTERNATIVE

FOR THE BEAD STRING
In the original instructional sequence, the activities with the bead string provided the necessary imagery. Note, however, that the way the bead string has to be interpreted is not self-evident. In this respect, we thought that measuring might offer a better basis for the imagery behind the number line. I explain this by comparing the bead string with measuring.
Just like the empty number line, the bead string can be interpreted in a cardinal or an ordinal manner. This may be illustrated with an incident during an informal empty number line teaching experiment that was carried out in West Lafayette, Indiana, in 1991. During this teaching experiment, we made a transition from working with a bead string to working with activity sheets on which bead strings were depicted. When the students were asked to mark a number (e.g., 53) they began to discuss the positioning of the mark. Should it go on the 53rd bead or next to it? (see Figure 7).
Eventually, this issue was resolved by the realization that the 53 refers to a cardinal number; thus, there were a total of 53 beads. Actually, this would be expressed best by circling all 53 beads or by putting one marker before the first bead and one behind the 53rd bead. Instead, the simpler convention was established that all beads to the left of the mark would count.
Downloaded by [North West University] at 07:05 27 May 2015 FIGURE 7 Different ways of marking 53 on the bead string.
1 1 1 1 1 1 1
FIGURE8 Different ways of mark-
5 3
ing on a ruler.
What is interesting is that the same issue arises in measurement. Applied to a measurement situation, the question might be: How do we mark the ruler? Do we mark the 53rd interval, or do we mark the boundary between the 53rd and the 54th interval? (see Figure 8).
Note that this relates to a conceptual understanding of measurement. Alternatively, from a mathematical point of view, it is not sufficient for the students to learn to measure accurately. Students will have to come to interpret the activity of measuring as the accumulation of distance (cf. Thompson & Thompson, 1994). The latter implies that each number word used in the activity of iterating signifies the total measure of the distance measured until that moment. Another aspect of a conceptual understanding is that the students conceive of the results of measuring as structured quantities. For example, a distance of 20 units can be thought of as being composed of 20 measurement units or as composed of two distances of 10 units or of distances of 5 units and 15 units.
DESIGN HEURISTIC
Given the similarities between the desired quantitative interpretation of the number line and measurement, it seemed sensible to investigate whether linear measurement might provide a sound basis for the introduction of the empty number line. This is where the emergent models design heuristic can show its usefulness. This heuristic can be used to think through a possible sequence. Starting with the hypothesis that such a sequence could be understood as a transition from model of to model for, guiding questions arise. For instance:
Downloaded by [North West University] at 07:05 27 May 2015 What is the model?
What activity is being modeled?
What is the model a model for?
What does the transition from model of to model for entail?
I now endeavor to deconstruct these questions. I start with the observation that there is a strong similarity between the empty number line and a ruler, and we can imagine a sequence in which activities with a number line build on activities with a ruler. However, from an instructional design perspective, the question arises: What do we take as the model? We could construe a conjectured local instruction theory, encompassing a sequence of two models that each pass through a model-of or model-for transition. Reasoning this way, we might find even more model-of or model-for shifts. One could discern various local shifts. The result of such an approach would be thattheemergent models notion loses muchof its meaning. Instead, I prefer to preserve the model-of or model-for language for the description of a more encompassing process that embraces a substantial instructional sequence. To do so, the idea of a model has to be interpreted rather broadly. This is done by interpreting the empty number line as a schematized ruler. In this manner, both the ruler and the empty number line can be seen as two manifestations of the same model.
If we take the ruler as the model, we must identify the activity in which the ruler is the model. Speculating on the genesis of the ruler in history, it makes sense to take the view that the ruler came about as a curtailment of iterating a measurement unit. So the ruler can be seen as a model of iterating some measurement unit. From our earlier reflections on the empty number line, we already know that the empty number line can be seen as a model for mathematical reasoning in the context of mental computation strategies for reasoning with numbers up to 100.
The connection between the two could be in the relation between measurement as accumulating distance and measurement as a cardinal interpretation of distance on the number line. In the context of measurement, distances on a ruler or number line would have the status of magnitudes. As the context of measuring moves becomes less dominant, the interpretation shifts toward numerical quantities in general. Finally, even the direct reference to specified countable objects becomes less prominent as the numbers on the empty number line start to derive their meaning from a framework of number relations.
In conclusion, we can envisage something like the following trajectory that may be embedded in a story line or in a series of stories:
1. The students start with measuring various lengths by iterating some measurement unit. This activity of iterating is modeled with a ruler.
2. The activity of measuring is extended to incrementing, decrementing, and comparing.
Downloaded by [North West University] at 07:05 27 May 2015 3. These activities are represented with the help of arcs on a schematized ruler.
4. This schematized representation is used as a way of scaffolding and as a way of communicating solution methods for all sorts of addition and subtraction problems. (Note that this trajectory is also in agreement with the reinvention heuristic.)
In such a sequence, special attention should be given to the decimal structure of our number system. In the context of measurement, this can be done by curtailing the iterating activity by means of a larger measurement unit, that is, a unit of 10. Measuring with 10s and 1s can form the basis for the development of a ruler that is structured by 10s and 1s. At the same time, it may support the development of strategies that use decuples as reference points.
A feature that may cause problems in such a setup is the rigid character of a ruler on one hand and the more global character of the empty number line on the other. Positions on a ruler have to correspond to exact distances. However, on the number line the distances between the numbers do not have to correspond exactly with their numerical values. The latter is essential because, otherwise, it would be impossible to represent unknown numbers or unknown differences. On reflection, it makes sense to differentiate between measuring and representing solution methods. Incrementing, decrementing, and comparing originate in measuring. However, when solving this type of problem, the opportunity arises to generate solutions by reasoning. For instance, consider the problem: "What is the result of incrementing 64 by 28?A possible line of reasoning could be as follows:
1. You first measure 64.
2. Then add six 1s, which would get you to 70.
3. Then measure 2 times 10, which would get you to 80 and 90, respectively, and finally, add two 1s, which gets you to 92.
When describing this method on an empty number line, it would be sufficient to show that you start at 64, add 6, arrive at 70, and then add 10, arriving at 80, add another 10, arriving at 90, and add 2, arriving at 92. To try to strive for an exact proportional representation of all the jumps would severely hamper a flexible use of the number line. Therefore, we will have to distinguish between the ruler as a measurement instrument and the empty number line as a means of expressing solution methods. This distinction should be drawn both at the preliminary design level and in the enactment in the classroom. In a global sense, we are speaking of one model; in practice, however, this model manifests itself in various symbolic representations.
In an earlier publication on the empty number line (Cobb et al., 1997), we already acknowledged that the model may take various shapes. We differentiated between the model as an overarching concept and the symbolic representations that are used in the instructional sequence. To describe this counterpart, we used

FIGURE 11 Preliminary chain of signification
the notion of a chain of signification (cf. Walkerdine, 1988; Whitson, 1997). The concept of a chain of signification is grounded in the idea that a sign comprises a signified-signifier pair (Lacan, 1977; see Figure9). A chain of signification then is constituted when the activity with one sign comes to signify activity with a previous sign. As the previous sign starts to serve as a signified for a new signifier, a signified-signifier pair is formed. This pair constitutes a link in a more global chain of signification (see Figure 10).
In the measurement-mental-arithmetic sequence in question, the chain of signification basically would look like the one shown in Figure 11. Iterating individual units along the lengths of items that have to be measured would be the starting point. This would come to be curtailed to iterating tens and ones. In this way, sign 1 is formed, of which "iterating individual units" is the signified, and "iterating 10s and 1s" is the signifier. The whole sign 1 (consisting of signified 1 and signifier 1) then becomes the signified (signified 2) for the next signifier: a ruler (signifier 2). These two together shape sign 2, which in turn becomes the signified (signified 3) for the empty number line (signifier 3), and sign 3 is formed.
Based on this preliminary chain of signification, we designed an instructional sequence for a first grade classroom. In elaborating the sequence, the actual chain of signification became more complicated than the one sketched previously (see Stephan et al., 1998). This was because (a) we introduced two different basic measurement units and (b) we inserted the so-called measurement stick to facilitate the transition from the ruler (which we called the measurement strip) to the empty number line.
Downloaded by [North West University] at 07:05 27 May 2015 MEASUREMENT SEQUENCE
The measurement sequence started with measuring by pacing "heel to toe." The idea was that measuring by pacing with your own feet offers a natural situation for iterating. Measuring with centimeters or inches would probably relate to familiarity with the centimeter as a sort of measurement strip and would therefore interfere with the intended buildup. Moreover, measuring with one's feet creates the opportunity to raise awareness for the need of a standardized measurement unit. The initial activities were situated in a scenario in which the king's foot was used as the standard measure.
The instructional intent was that the students came to interpret their pacing activity as an accumulation of distances. This imagery formed the basis for the next step in the sequence: measuring with a larger measurement unit. The scenario of measuring the king was employed to make the students think of more efficient ways of measuring. After a whole-class discussion of alternatives, the teacher told the students how this problem was solved in the kingdom. The solution was to make five footprints of the king's foot and to paste these together. This solution was discussed by the students before they began making their own footstrips. With the help of these footstrips, the students curtailed their counting of individual paces to counting by five paces. The intent was that the footstrips were seen as records of pacing, whereas the placement of one footstrip signified five paced feet.
Next, a shift was made to another measurement unit in the context of a story about Smurfs". The teacher explained that Smurfs are small, dwarf-like people and that one particular Smurf was called on to measure a wall. Because of a lack of measurement tools, he used the food cans he had with him. As a consequence, more Smurfs started measuring with food cans. According to the story, these cans happened to have the size of a unifix cube. This made it possible for the students to act out the measurement activities of the Smurfs. Measuring with unifix cubes was curtailed in the same way as the measurement with the footprints. That is, a "Smurf bar" of 1 0 unifix cubes was constructed to represent 10 cans. Again, the story provided a need for this curtailment, and the students were provided with ample opportunity to invent and discuss solutions before the teacher explained how the problem was solved by the Smurfs. This pattern was repeated in all subsequent steps of the sequence. Let me note, however, that during the teaching experiment, more often than not, at least some of the students came up with suggestions that were similar to the solutions chosen in the story.
Measuring with the cubes and the Smurf bar became a matter of coordinating units of 10 and 1. Measuring started by iterating units of 10, which were then adjusted by adding or subtracting 1s. In this manner, measuring with 10s and 1s helped the students in structuring the number sequence up to 100. At the same time, a basis was being laid for the construction of a measurement strip that comprised 1 0 units of 10, each subdivided into 1 0 units of 1 cube. The idea is that mea-
Downloaded by [North West University] at 07:05 27 May 2015 EMERGENT MODELS 173
suring with the measurement strip is grounded in the imagery of measuring units of 1 0 and I. Thus, for the students, measuring with the strip signified iterating with the Smurf bar and individual cubes. The ultimate aim here was that, in measuring the length of an item and reading off a number, the students would signify the space that extends from the beginning of the measurement strip to the line signifying the end of the item. The students were acting in a spatial environment in which space was already partitioned.
In the following activities, a shift was made from actually measuring items to

reasoning about lengths when solving tasks involving incrementing, decrementing, and comparing lengths of objects that were not physically present (e.g., comparing the measures of the heights of sunflowers in the context of a sunflower contest). These tasks offered opportunities for developing solution methods based on curtailed counting (using the decimal structure as a framework of reference).
The shift away from measuring (as an activity) to reasoning about magnitudes was carried on with the introduction of a measurement stick. The measurement stick was introduced as a yardstick that was attached to a quay wall. The measurement stick had to be used to read the height of the water in the canal. (The context of the canal gives rise to all sorts of problems involving the rise and fall of the water level, the drafts of boats, and shallows in the river.) After discussing the students' suggestions about what a measurement stick would have to look like to make it easy to read, the measurement stick (see Figure 12) was introduced as the solution of the person responsible.
The appearance of the measurement stick was to some extent similar to the original bead string. An important feature was that, although there were no numbers, values were easy to read by counting 10s and 1s. The conjecture was that this feature created opportunities for developing strategies that used the decimal structure. Note that the objective was not that students should acquire particular calculational methods. Instead, the focus was on the students' construction of numerical relations that might give rise to these methods. In this respect, attention was focused on activities that involved reading off numbers, indicating numbers, and analyzing number patterns. Numbers close to a decuple, for instance, could be identified by using that decuple as a referent (e.g., 53 = 50 + 3; 38 = 40 - 2). These relations could be exploited when analyzing patterns that correspond to jumps of 10.
Problems in the context of water heights could be solved in two ways: by counting on the measurement stick or by arithmetical reasoning. The empty number line was introduced as a way of symbolizing the measurement strip arithmetical solu-
FIGURE 12 Measurement stick. Note that here the stick is shown in a horizontal position; in the context of the water heights, the stick has a vertical position.
Downloaded by [North West University] at 07:05 27 May 2015 tion methods that were grounded in reasoning with "10s and 1s." (A jump on the number line described a move on the measurement stick that, in turn, was seen as signifying iterating Smurf bars, unifix cubes, or both.) The empty number line was introduced as a way of communicating solution methods but also functioned as a way of scaffolding. Finally, a generalization was made from magnitudes to numerical quantities in general; the students were asked to solve various addition and subtraction context problems while using the empty number line as a means to record their thinking.
On reflection, it can be argued that the new sequence based on measuring fits better with the RME philosophy than does the original bead-string-based sequence. Actually, the measuring-based sequence can be taken as an exemplary case to illustrate the contrast, mentioned previously, between the use of models that are construed as concretized formal mathematics and models that emerge in the process of modeling. Treffers (1987) elaborated on a distinction of enrhodiment versus embeddedness when he compared Dienes's (1963) teaching-learning theory with the RME instruction theory (which relates to the work of Van Hiele, 1973). Treffers wrote:
Whereas in the first phases of Dienes' learning cycles the children come in touch with concretized mathematical structures, with embodiments of games in artificially created environments, the Van Hiele basic levels entail an exploration of those aspects of reality for which the mathematical concepts and structures (can) serve as means of organization: "embeddedness" versus "embodiment"; the naturally organizable versus the artificially organized matter. (p. 275)
CONCLUSIONS
As our example of the measurement-mental-arithmetic sequence shows, the model in the model-of or model-for metaphor has to be understood as a global overarching concept. In our example, the ruler is the emerging model. The ruler emerges as a model of iterating a measurement unit (or measurement units). In this sense, the ruler is grounded in the activity of measuring. Gradually, however, the ruler changes character as the attention shifts from measuring to reasoning about the results of measuring. Finally, a schematized ruler becomes a model for reasoning about flexible mental-arithmetic strategies for numbers up to 100.
In the concrete elaboration in the sequence, the overarching model assumes various manifestations. The series of manifestations can be described in terms of a chain of signification. The chain of signification is in a sense the counterpart, on a more specific level, of what the model is on a more general level. A chain of signification is constituted as a sign that "slides under" a succeeding signifier (Walkerdine, 1988). That is, on one hand, the new signified encompasses the previous sign, whereas, on the other hand, the meaning of the previous sign changes.
Downloaded by [North West University] at 07:05 27 May 2015 EMERGENT MODELS 175
The latter relates to the constitution of a new sign, in which the signifier and the signified are reflexively related; the signified gives meaning to the signifier, whereas the signifier shapes the signified.
From a mathematics education perspective, the notion of a chain of signification is helpful in that it shows how formal mathematical signs can be rooted in concrete activities of the students. The dynamic character of the chain of signification as such justifies the term emergent models. However, the meaning of the label entergerzt is broader. It refers both to the process by which models emerge within RME and to the process by which these models support the emergence of formal mathematical knowledge.
A crucial aspect of the emergent models heuristic is that the shift from model of to model for is reflexively related to the creation of a new mathematical reality. This can be elucidated by the role of the ruler as a model. What was expected was that, in the course of the sequence, a shift would take place in the student's view of numbers as referents of distances to numbers as mathematical entities. This shift involves a transition from viewing numbers as tied to identifiable objects or units (i.e., numbers as constituents of magnitudes-"37 feet") to viewing numbers as entities on their own ("37"). For the student, a number viewed as a mathematical entity still has quantitative meaning, but this meaning is no longer dependent on its connection with identifiable distances or with specified countable objects. In the students' experienced world, numbers viewed as mathematical entities derive their meaning from their place in a network of number relations. Such a network might include relations such as 37 = 30 + 7, 37 = 3 x 10 + 7, 37 = 20 + 17, and 37 = 40 - 3. The critical aspect of this network is that the students' understanding of these relations transcend individual cases. That is, when students form notions of mathematical entities, they come to view relations like those just noted as holding for any quantity of 37 objects (including a magnitude of 37 units).
This shift from numbers as referents to numbers as mathematical entities is reflexively related to the transition from model of to model for. The students' actions with the model foster the constitution of a framework of number relations. However, through the students' development of this framework of number relations, the model can take its role as a model for mathematical reasoning.
In conclusion, this analysis shows that the emergent models heuristic refers to three interrelated processes. The first process consists of the global transition, in which the model first emerges as a model of informal mathematical activity and then gradually develops into a model for more formal mathematical reasoning. The second process involves the constitution of a new mathematical reality, which emerges as reflexively related to the model-of or model-for transition. The third process concerns the emergence of a chain of signification that can be seen as the concrete manifestation of the model in a series of signs, in which each new sign comes to signify an activity with a previous sign.

Received: date Revised: if applicable
In the Dutch secondary education system, students must carry out at the end of their school career a rather large research or design project to demonstrate their ability to apply acquired knowledge and skills while pursuing a research question or design goal in some depth. They are encouraged to choose the topic themselves and they are to some extent free in setting up their work. Ideally, the students do not only see it as a compulsory subject but also enjoy the stimulating aspects of doing their own research or design. Challenging and authentic projects, which are representative for actual research and design work done by professionals, seem effective in this respect. The focus of this paper is on how the use of ICT can contribute to the realisation of such projects in mathematics and science education and on how it can give students opportunities to take the nature and level of their work close to the characteristics of work of experts in the field. Three examples of students' inquiry work are analysed with regard to ICT usage, authenticity and resemblance with an expert's approach.
1 INTRODUCTION
In the Dutch examination programme of upper secondary education, students are obliged to build up a portfolio consisting of several small practical investigation tasks (4-10 hrs) and one rather large cross-disciplinary research or design project (80 hrs). The main instructional purpose of the small investigation tasks is to give students opportunities to (1) build up general competencies such as research skills, ICT skills, communication skills, and so on; (2) deepen or enlarge existing mathematical and scientific knowledge; and (3) become more proficient in applying knowledge and skills in practice. In the final project, usually done in the last year before the final central examination, students must demonstrate their achieved level of knowledge, skills, and attitude by the creation of a masterpiece of independent work on a topic of their own choice. For example, in a research project students must demonstrate their research abilities, ranging from choosing a manageable problem, formulating a good research question and structuring their work to drawing conclusions and presenting the research results. The final project is part of the examination programme and a sufficient mark is needed for obtaining a secondary school diploma. Notwithstanding that the final project is an assessment, it is seen by many curriculum developers and by many teachers as a chance to expose students to the real world of research and design, and as an opportunity to let students enjoy doing research and development on a subject of their own choice. 'Challenge' and 'authenticity' seem to be useful keywords for describing activities that really turn students on. Because contemporary R&D work makes heavy use of ICT and is often done in multidisciplinary teams, it is natural to raise the following educational research questions: How can the use of ICT contribute to the realisation of challenging cross-disciplinary authentic research projects in mathematics and science education, which are representative for actual research done by real scientists, and how can it give students opportunities to take the nature and level of their work close to the characteristics of work of experts in the field?
In order to be able to answer the above questions, the meaning of the adjectives 'cross-disciplinary' and 'authentic' is first explicated in section 2 in the context of student inquiry work and mathematical modelling. This is especially required because there exist competing views on authentic and realistic student work in research in mathematics and science education. The adjective 'challenging' depends very much on the level of expertise and motivation of the individual student doing his or her research project and is discussed only in an exemplary way. In sections 3 to 5, three illuminating examples of students' inquiry work are analysed with regard to ICT usage, authenticity and resemblance with an expert's approach. Two of these examples are secondary school students' final research projects, one about bungee jumping and another one about gait analysis. A third example, about the chaotic motion of a spring pendulum, comes from a CAS-supported investigation of a first-year university physics student, only three months after entering the university. The analysis of all three projects together leads to conclusions about the use of ICT for realising student research projects that resemble actual research practice.
2 AUTHENTIC INQUIRY BY STUDENTS:
WHAT DOES IT *MEAN*?
Researchers on mathematics and science education use terms like authentic science, authentic practice, authentic learning, authentic inquiry, authentic modelling, and so on (see, for example, Edelson & Reiser, 2006; Palm, 2002, 2006; Roth, 1995; Roth et al., 2008; Schwartz & Crawford, 2004; Vos, 2009; Weiss et al., 2009; Wellington, 1998; Woolnough, 2000). The meaning of the adjective 'authentic' is so diverse, even when connected with a single noun, that it is wise to first explicate the meaning of 'cross-disciplinary authentic student research project' that is used in this paper and to compare it with other uses of this term in inquirybased mathematics and science education.
I refer to an 'authentic student research project' as a students' investigation having the following characteristics:
o Students work on a self-selected, challenging, messy, illdefined, open-ended problem that is rooted in a real life situation instead of a more abstract or ideal situation; [2
André Heck
© 2009 Research Information Ltd. All rights reserved.
o Students do not follow some standard recipes, but they examine their problem from different perspectives, using a variety of resources and high-order skills.
o A broad range of competencies is required to make the project a success, and one of these abilities is making good use of ICT for information gathering, data acquisition, data processing and analysis, problem-solving, reporting, and communication with team members;
o Students' work is open-ended in the sense that there exist multiple methods or approaches to obtain many possible or even competing results and answers. The student researchers actually decide whether the investigation can be finished for whatever reason;
o It offers students the opportunity to be in contact with contemporary, cross-disciplinary research and to learn about the nature of mathematics and science;
o Students disclose their own understanding through a portfolio and/or a more or less polished product like a report, paper, or presentation.
A project is called 'cross-disciplinary' when more than one discipline contributes in an essential way to the process of coming to an understanding of the problem situation. The student research projects presented in this paper are mainly rooted in applied mathematics and physics. The term 'crossdisciplinary' is used, and not a term like 'interdisciplinary,' to emphasise that all disciplines are required to get satisfactory results: The whole is more than the sum of the parts.
In science education literature much has been written about authentic inquiry that gives students the opportunity to learn science by doing science like 'real' scientists, as opposed to carrying out practical work that follows cookbook recipes and has hardly any resemblance with experimental work done in real laboratories (Roth, 1995; Schwartz & Crawford, 2004; Woolnough, 2000). It is noted that an inquiry approach is effective in developing core skills in students, improves their attitudes towards science and technology, and allows students to get an honest picture of the nature of science (Schwartz & Crawford, 2004). Authentic scientific work is linked with the real practice of doing science rather than with the methods narratives of published research that keep up the myth of the 'scientific method.' Educational research literature (cf. Chinn & Malhotra, 2002) often emphasises the differences between the work of experts and novices, and it questions whether authentic science is feasible in educational practice because of its complexity and crossdisciplinary nature, the problems with assessing student work, and its requirements regarding content knowledge, research abilities, engagement, motivation, and time availability. However, according to Roth et al. (2008) the problem of how to organise authentic science lessons does not lie with the level of agreement between school science and laboratory science but rather with the levels of control, authority, mastery, and authorship that students are enabled to exercise.
Following this line of thinking, the emphasis in this paper is on the students' acts, that is, on what the students really did, which decisions they made, how they used ICT to put their ideas into action, and how their work can be characterised as authentic work, rather than on the details of the mathematical and scientific knowledge that the students applied.
In research literature on mathematics education, the adjective 'authentic' is mostly associated with applications of mathematics and with mathematical modelling. Common ground seems to be Lebow's (1993) description of an authentic activity as experiences of personal relevance that permit learners to practise skills in environments that have considerable resemblance to those in which the skills are used. It is derived from socio-constructivist and RME principles of locating learning in the context of reality and of looking upon mathematics as a human activity in which sense making by students through participation in the mathematical representation process is highly valued. For a review of the different meanings attached to a words like '(in)authentic' in mathematics education in general, and in the teaching and learning of mathematical modelling in particular, see for example (Palm, 2002, 2006) and (Vos, 2009), respectively.
3 PHYSICS OF BUNGEE JUMPING
The work of the student researchers who carried out the bungee jumping project resembles the work of 'real' scientists regarding affective and cognitive processes in authentic inquiry. To begin with, there were (1) the students' intrinsic motivation to select the subject of their investigation; and (2) the generation of their own research question(s). The students wrote in their report that they teamed up to investigate the physics of bungee jumping, triggered by their own interest and the article of Menz (1993) on www.bungee.com.
In particular, they were intrigued by the alleged 'greaterthan-g acceleration' of a bungee jumper. The students formulated the following research question: "How large is the acceleration at a bungee jump and to what extent is this acceleration influenced by the relative mass of the rope and the jumper?" They hypothesised that the acceleration would be greater than g and that this effect would be more dramatic in case the rope is relatively heavier compared to the jumper.
In order to find quantitative support for their hypothesis the students designed an experiment in which they recorded with a webcam the motion of dropped wooden blocks of various weight attached to ropes of various stiffness and collected position-time data through video measurements.
The students realised that working with a scale model of a bungee jumper or a wooden block is not the same as investigating real bungee jumping, but that it would provide them with enough information on what happens in reality and could lead to a good understanding. This indicates a research design in which procedures to address a problem are determined, variables to investigate are selected, control of variables is thought of, and measurements are planned. Note that not the measured position is the variable of interest, but a derived quantity, viz., acceleration. The students had learned in previous video analysis activities that adequate numerical derivates could be obtained from measured position data.
After some trials, the students realised that the stiffness of the rope plays only a minor role and that the mass ratio between rope and objects needs to be large enough to notice an outstanding result. Therefore they repeated the experiment with objects of larger mass ratio. This is another aspect of authentic inquiry: Researchers are responsible for 3]
Modelling in Cross-Disciplinary Authentic Student Research Projects
International Journal for Technology in Mathematics Education, Volume 17, No X
detecting flaws in their experimental set-up and must decide how to adjust their original plans. In this case, the students decided to change the mass ratio and to concentrate on the moment when the object has fallen a distance equal to the rest length of the elastic (because they had observed that the acceleration is greatest at this point of the motion). They collected more data and determined the graph of the acceleration at this moment as a function of the mass ratio of elastic and block. They compared their data plot with the graph of a theoretical relationship taken from (Kagan & Kott, 1996).
The students noted that these graphs were alike, with the theoretical values just a bit higher. They attributed the difference mainly to the development of heat during the motion. Again, this indicates a behaviour of the students that resembles the attitude of competent researchers: Comparing own results with work of others and trying to explain differences by scientific reasoning.
The student researchers not only investigated the acceleration of a bungee jumper by quantitative methods, but also tried to explain the greater-than-g acceleration both on qualitative, theory-driven grounds, as well as through a more detailed mathematical model of the phenomenon. The students followed the approach of Kagan and Kott (1996), in which it is noted that here one does not deal with a falling rigid body, but instead with a system consisting of the falling object and the rope. The interested reader is referred to (Heck et al., 2010) for more ICT-supported experimentation and a detailed description of a mathematical model of the system that can be implemented in a modelling and simulation tool to compare experimental results with theory. The main point to make here is that the students' work contains clear signs of their understanding that observation, experiment and theory are related tools for scientific thinking.
The students wrote an article about their work and got it published (Dubbelaar & Brantjes, 2003). This article triggered quite a number of reactions in the journal and for almost a year on Internet. There were complaints about the quality of physics teaching in the Netherlands, arguing that obviously acceleration of a bungee jumper could clearly not exceed the acceleration of gravity and that the students' work

proved that the level of physics education in the Netherlands
had decreased in the last decades. The editorial commentary
on this was subtle, but to the point: “The students who wrote
the paper may consider it a compliment that scepticism overcame professional physicists and physics teachers. That’s
how (or maybe it is just the point that) experienced intuition
can be wrong.” In other words, the students’ work revealed
that in practice, scientists are not as rationally, non-algorithmic thinking and having an open mind as commonly pictured
in literature about science and scientists.
Regarding the use of ICT in this particular student
research project, the following main roles can be identified:
o Internet gave the students access to many of the same resources that professionals use in their research. They
could gather information and get in contact with experts;
o The students used video analysis software, in particular
the video tool of the learning and authoring environment
named Coach (Heck et al., 2009), to collect, visualise,
process, and analyse data. Numerical differentiation,
computing the area under the curve, and function fitting
were the main mathematical tools used in the data processing and data analysis.
o The students used a standard text processor and presentation tool to report their results.
4 GAIT ANALYSIS
In this project, a high school student collected and
analysed gait data in much the same way movement scientists do, namely, via recording and measurement of motions
with a video tool and via electromyography, i.e., measurement of muscle activity. The authenticity of the student project was rooted (1) in the use of inexpensive tools (a webcam, a simple EMG/ECG set and Coach software), which are
on the one hand fit for educational practice and on the other
hand in essence close to the techniques used by biomechanists; and (2) in the student’s use of the theoretical framework,
nomenclature, and research methods of practitioners. That is
to say, the student conducted many aspects of motion analysis herself: She formulated research questions about a selfselected gait pattern; gathered information; designed and carried out experiments; processed, analysed and interpreted data; and finally published results (Heck & van Dongen, 2008).
The main research question in this project was: “How
goes human gait?” It was specialised as follows:
(1) “Which phases are distinguished in the gait cycle?”
(2) “What muscle activity happens during gait?”
(3) “How do bones and joints make gait possible?”
The first and the third sub question were addressed by
video measurement with a webcam of the planar motion of
the leg around the hip and knee joint during normal walk on
a motorised treadmill in a sports centre. The recorded data
were analysed in a knee angle vs. hip angle diagram and the
periodic leg motion was modelled as a force-driven harmonic
oscillator (Holt et al., 1990). The angular motion curve of the
knee joint is described in this model by a sum of two sine
functions, in which one frequency is nearly twice as large as
the other one. This can be verified via a curve stripping regression technique (i.e., repeated sine regression), or via
automated sinusoidal regression based on advanced, highresolution methods. Figure 1 shows the knee joint angle vs.
time point plot for normal walking at a speed of 5 km/h. The
diagram also shows the graph of the best function fit with a
sum of two sine functions. For a description of the experimental setting of the video recording of the normal walk, for
a picture of the measured knee angle vs. hip angle diagram,
and for the connection between points on this parametric
curve and the phases of the gait cycles, the reader is referred
to (Heck & van Dongen, 2008).
Muscle activity is typically studied using dynamic
electromyography (EMG). In case of measurement of activity of superficial muscles, surface electrodes are placed on the
skin surface to detect the electric activity responsible for contraction of muscles (Kamen & Gabriel, 2010). EMG recording is rather difficult because correct placement of electrodes
is critical. Processing and interpreting an EMG for a muscle
is also not easy. This research project offered the student the [4
André Heck
© 2009 Research Information Ltd. All rights reserved.
opportunity to personally experience such challenges faced
in gait analysis. She not only learned science content by
doing science, but also got a valid picture of how scientific
knowledge is obtained and what the nature and status of scientific knowledge is. These are in fact commonly identified
aims of practical work (‘knowing that,’ ‘knowing how,’ and
‘knowing about;’ cf. Wellington, 1998; Woolnough, 2000).
Although the student found it difficult to process and
interpret the recorded EMG data, she managed to read off
from the EMG signal when muscle activity was on and off in
normal walking and to interpret the EMG signal in terms of
phases and events in the gait cycle. Essential for successful
analysis is that the data acquisition system allows simultaneous measurement with sensors and video capture. In Coach,
the video clip and the measured data are synchronised: This
means that clicking with the mouse on a point on the graph
automatically shows the corresponding video frame and that
selecting a particular frame highlights the corresponding
points in diagrams, when scanning mode is on. Scrubbing,
i.e., advancing or reversing the video clip manually and
simultaneously watching the points in the data graphs that
correspond with the video frame in view, is then an effective
means to reveal that maxima and minima in the clearly periodic, raw and processed EMG signal are consistently linked to
certain gait events. The lower diagram in Figure 2 shows the
graph of the processed EMG signal during one gait cycle:
‘Processing’ means here that the absolute value of the raw
signal is taken with respect to the zero level of the signal (socalled full-wave rectification) and that the rectified signal is
smoothed via a moving average. These techniques exemplify
the use of basic mathematics in biomechanical practice.
Peaks in the diagram correspond with muscle activity and
corresponding gait events have been marked in the diagram.
The most general conclusion of the student, based on the
processed EMG diagram, was that the gastrocnemius is predominantly active during stance phase.
The role of ICT in the gait analysis project did not differ much from that in the bungee jumping project, except that
the hardware and software offered the student here the
opportunity to collect and work with high-quality, real-time
data about human gait in much the same way movement
scientists do. Regarding mathematical content, emphasis was
put in the project on data processing, regression, visualisation
and interpretation of graphs in a real world context.
Figure 1 Knee joint angle vs. time:
collected data and a regression curve.

muscle for normal walking at low speed
5 MOTION OF THE SPRING PENDULUM
A learning activity can also make use of authentic
software tools, i.e., computer environments that are used by
professional mathematicians and scientists on the workplace.
Computer algebra systems belong to this category of tools. A
popular system, Mathematica (www.wolfram.com), is advertised as “an environment for doing anything technical, that is,
not for computing only, but also for modelling, simulation,
visualisation, development, documentation, and deployment.” All of these purposes are relevant for doing research
and hardly anyone ignores the advantages of using ICT for
this type of work. At the Science Faculty of the University of
Amsterdam freshmen get the opportunity to experience this
in a short (10 hrs) CAS-supported investigation. Students can
choose a project out of a given list, work it out in groups of
two, and finally report on it through a Mathematica notebook. Other aims of the student projects are to motivate the
freshmen in their first steps in the discipline and to let them
experience that their present knowledge of mathematics and
science, empowered by a computer algebra system, already
suffices for investigating a phenomenon at a rather deep level. The authentic nature of the activity also lies in ample
choice of exploratory pathways: the students themselves select the research methodology and the level of complexity to
which they feel themselves challenged; a general research
question is already given to direct the research. The fact that
all projects concern well-known, solved problems does not
matter much: the students are unfamiliar with the problems,
they get the opportunity to explore and solve them in their
own way, or they can follow in the footsteps of researchers.
I discuss the work of a physics student who chose to
study the motion of a spring pendulum, for which the given
research question was: “Is the orbit of a given spring pendulum predictable and to what extent is the motion influenced by small changes in initial conditions?” The spring
pendulum is an understandable and yet intriguing example of 5]
Modelling in Cross-Disciplinary Authentic Student Research Projects
International Journal for Technology in Mathematics Education, Volume 17, No X
a nonlinear physics problem that shows chaotic behaviour
(van der Weele & de Kleine, 1996). Although its mathematical modelling is often used in mechanics courses to exemplify the Euler-Lagrange formalism, the model can also be
derived from first principles of Newton mechanics. Figure 3
shows the Cartesian and polar coordinate systems used in
studying the motion of the pendulum bob with mass m that is
attached to a massless spring of rest length l. The spring can
make on its turn a two-dimensional pendular motion around
a fixed point that is taken as origin of the coordinate system.
Figure 3 The spring pendulum configuration
There are two basic forces in the problem when dissipation is not taken into account: a constant gravity force
(where g denotes the acceleration of gravity), and a spring
force that is assumed to obey Hooke’s law, which means that
the spring force is proportional to the extension of the spring
(the proportionality constant is denoted by k). In Cartesian
coordinates, Newton’s second law of motion and decomposition of the forces acting on the mass in the coordinate directions leads to the following system of differential equations:
2 2 2 2
1 , 1
kx l ky l
x y g
m m x y x y
□ □ □ □
= – – = – – – □ □ □ □
+ +
□ □ □ □
JJ JJ
In order to increase the authenticity of the research project,
the student must derive the equations of motion. This is uncommon in secondary school practice: There, mathematical
equations are often given without much explanation.
Hereafter, the student determined the equilibrium positions: there are a stable equilibrium point below the origin
and an unstable point above the origin under reasonable conditions. The student implemented the equations of motion in
Mathematica and verified that the numerical solution of the
differential equations with the spring pendulum bob initially
at rest in one of the equilibrium points remains constant. He
chose for this and for further computations the following
rational parameter values (which we take as well):
2 2
m g k g = = = = 1 20kg, 981/100 m s , 1kg s , 981/1000 m
He motivated his choice of fractions instead of floating-point
number by the intention to work as much as possible in exact
arithmetic, trying to avoid in this way problems with numerical precision and reducing errors introduced by numerical
computation. The noticeable point here is that the student apparently realised that he should distinguish between phenomena that inevitably occur in reality and those that are caused
by inexact, numerical computations. This is a good sign of
reflection about the quality of research. The student’s choice
of parameter values actually implies that a remarkable behaviour of the spring pendulum can be found, ranging from periodic to chaotic motion (cf., van der Weele & de Kleine,
1996). Figure 4 shows rather stable oscillatory movements in
case the bob starts at position (1.45, -1.45) and (0.4, 0.4),
respectively, with zero speed. Figure 5 shows the periodic
orbit of the bob when it starts at (0.1, 0.281058) without
speed and at a point nearby, viz., (0.1, 0.281058). This figure
illustrates what is meant by chaos: A small change in the
initial condition can lead to a dramatic change in behaviour
of the solution. This is not a consequence of numerical computations in a given working precision, but a fundamental
property of the dynamical system.
Being confronted with regular and chaotic behaviour
of solutions of the motion of a spring pendulum, the student
set himself the task to systematically analyse in what regions
chaos occurs. For example, he looked at various starting
points on the x-axis. Figure 6 shows how close periodic and
chaotic motions can be: The starting points for the orbits are
(1.496, 0) and (1.495, 0), respectively.
Figure 4 Two oscillatory motions of a spring pendulum
Figure 5 Motions starting at nearby points close to origin
Figure 6 Motions starting at nearby points along the x-axis
The student explored the motion systematically and
discovered that small deviations from the stable equilibrium
point and large extensions of the spring pendulum do not
lead to chaotic behaviour. He also concluded that there are
regions in space where chaos occurs and where chaos hardly
occurs. Of course he did not have the background knowledge
to get advanced results. But this was not the aim of the
project and lab assistants better make not many suggestions
in such directions. Instead, they should give students ample
opportunity and encourage them to discover things on their
own, explore ideas, and enjoy doing investigations. [6

6 CONCLUSION
The educational issue in the described students’ investigative work is the ICT-supported interaction between experimental work and mathematical modelling, in which the obtainment and interpretation of results is based on methods
from mathematics and science. The fact that students must
apply their mathematical and scientific knowledge in a meaningful way in a concrete context leads at the same time to
consolidation and deepening of this knowledge. The examples in this paper show that ICT can contribute to the realisation of authentic inquiry and raise its level by allowing students to gather information about the subject and be in contact with experts; to collect real-time data of good quality; to
process, analyse and visualise data; to do computations that

are otherwise impossible; to build and use computer models
of dynamic systems in much the same way as professionals
do; to compare results from experiments, models, and theory;
and to report results. Besides, students can develop, practise
and demonstrate the following research abilities:
o formulate good research questions that guide the work;
o design and implement an experiment for collection of
relevant data;
o apply mathematical knowledge and techniques, and science concepts in new situations;
o effectively use a computer in research work;
o construct, test, evaluate, and improve computer models,
and have insight in their role in science;
o interpret, theoretically underpin and reflect on results;
o collaborate with others in an investigation task.
The student-driven experimental design, the modelling process, the underlying thinking processes, the discussions with
peers, the effective use of ICT, and the improvement of students' mathematical and scientific literacy in the research are
considered more important than the obtained results.

Applets for learning school algebra and calculus
Experiences from secondary school practice with an
integrated learning environment for mathematics

Abstract. In recent years, the use of ICT tools for learning of mathematics received a lot of attention. New computer programs include digital
chapters for existing schoolbooks, Java applets, dynamic software for geometry and statistics, computer algebra systems, computer aided testing
and assessment systems, and many more. In this paper we will focus on
the development and use of Java applets for learning and practising algebra and calculus at secondary school level. We have explored in what
ways applets can help student to develop algebraic understanding and
algebraic skills. Especially applets that provide feedback with scoring
facilities and that are fully integrated in a learning environment with
which students and teachers are familiar have great potential. Of course,
teachers should be able to create exercises and tests based on their own
ideas: the customizable SCORM compliant Java applet generator makes
this possible. We will discuss our experiences from development work
and classroom tests during the GALOIS project.
1 The GALOIS project
Since December 2004 the GALOIS project aims to realize an integrated learning
environment for learning and doing mathematics in which
- students can practise mathematics anytime and anywhere;
- mathematical assignments can be generated 'at random', so that the amount
of exercise material becomes unlimited;
- activities and answers of students are stored;
- "intelligent" feedback on students' work is given automatically.
We wish to reach these goals by using open source technologies and open standards. We try to translate and extend existing technologies into concepts that
work in the practice of school mathematics. We also make ICT-rich learning
materials and try them out in the classroom. In this paper we describe our
classroom experiences with exercise material at secondary school level. We discuss the following topics in the given order:
- the design and use of mathematical Java applets from the Freudenthal
Institute, called WisWeb applets [1],2
- the use of the 'Digitale Wiskunde Oefenomgeving' [Digital Mathematical
Exercise Environment] developed at the Freudenthal Institute [2];
- the use of the SCORM standard [3] to make teaching and learning with
WisWeb applets fully operational in an existing virtual learning environment,
in this case the open source system Moodle [4];
- intelligent feedback in the JavaScript-based testing and assignment environment DITwis [5], which is also integrated in an existing VLE, in this case
Moodle again, via the SCORM standard;
- the design and use of a customizable SCORM compliant applet generator
for learning school algebra and calculus.
By the way, GALOIS is a Dutch acronym for Ge¨integreerde Algebra¨ische LeerOmgeving In School [Integrated Algebraic Learning Environment in School].
The Dutch Ministry of Education, Culture and Science financially supports this
innovation project in the Vooruit! framework until 2007. For more information we
refer to the website www.stmichaelcollege.nl/galois/index.php?lang=en.
2 Design and use of WisWeb applets
In the framework of the projects WisWeb and Welp [1] a large number of Java
applets for learning mathematics have been developed by a team of researchers
and curriculum developers at the Freudenthal Institute in collaboration with
teachers at secondary schools. The last three authors of this paper were involved from early days, tried out prototypes of these little computer programs
in the classroom, and improved the software and accompanying instructional
materials. Knowledge on how to use the software to enrich the learning was
built up in this way. The use of applets for learning mathematics was expected
to contribute to visualization of mathematical concepts, exploration of context
situations (including purely mathematical contexts), and to bridging the gap between informal knowledge and formal mathematics. The Realistic Mathematics
Education (RME [6]) approach was the key theoretical framework for the design
of the software and of the instructional material, and for the flanking educational
research. Considerable eijort was put into the design and field testing of applets
for students to develop algebraic understanding and skills, because this topic is
for ages an important topic in mathematics education, but at the same time it
is an obstacle for many a student. This kind of applets were used and further
developed in the GALOIS project.
Two kinds of applets can be distinguished: model applets, which help to develop mathematical understanding (concepts), and exercise applets, which support the development of mathematical skills. In model applets visual representations are used as models for mathematical concepts. Within these representations
students can work on the basis of their own ideas and experiment freely. An example of a model applet is the 'Geometric Algebra 2D' applet shown in Figure 1.
It allows adding and multiplying numbers and variables by combining line segments to new line segments and rectangles. The lengths of the line segments and3
the areas of the rectangles are displayed as expressions. By splitting and joining
rectangles students can develop insight in equivalence of various expressions.
Fig. 1. The 'Geometric Algebra 2D' applet.
A model applet such as the 'Geometric Algebra 2D' applet has an open
nature: it allows students to work with it on the basis of their own constructions
and productions. The ICT tool is only expected to help students to mathematise
the situation on the basis of their activities. Activity sheets may guide students
in making progress from informal to more formal mathematical activity. We refer
to [7, 8] for further reading about the concept of the emergent-modeling design
heuristic, in which the objective is to help students model their own informal
mathematics activity and gradually develop this model into a model for more
formal mathematical reasoning.
In the second class of Java applets that have been developed, the exercise
applets, this open structure is replaced by a more closed structure. In exercise
applets, a number of tasks of certain type are given to the students, their work is
checked and feedback is provided. Figure 2 illustrates the 'Area Algebra' applet,
in which the area model is used to verify equivalence of algebraic expressions.
The main task is to find the correct expressions for areas and edges of rectangles.
The applet is an interactive version of the well-known geometrical representation
of the distributive law of algebra. A formula like 3(y+2) is treated as the area of
a rectangle with length 3 and width y+2. This results in a stepwise formula with
a part equal to 3y and a part equal to 6. Students intuitively learn and see that
3(y + 2) is equivalent to 3y + 6. Of course, this model has some limitations when
it comes to negative numbers, but then it can easily be replaced with a simple
table. Feedback in this applet is direct: green symbols indicate which part of
the answer is correct, and red, orange and green circles around the assignment4
numbers indicate wrong, incomplete and correct answers. This stimulates the
students to go on and try another one, and to get as many correct answers as
possible. Also very important, the stored feedback provides both the student and
the teacher detailed information about where and what kind of mistakes have
been made. The screen shot shows an example: maybe the student had simply
forgotten to fill out a text box in the rectangle; maybe he or she had worked in
a too formal manner and written 32 with 3 · 2 in mind, just as one writes 3y
when the product is actually meant.
Fig. 2. The 'Area Algebra' applet with immediate feedback.
The method of completing squares for solving quadratic equations links up
well with the above area model. It is supported in the exercise applet 'Quadratic
Equations' shown in Figure 3. The applet presents a quadratic equation that is
to be solved step by step. With the red buttons on top, the student can select an
operation that is to be performed on both sides of the equation. The goal is to
simplify the equation and eventually end with x = solutions. With this applet,
a student has to think and decide what operation to perform. Two versions of
the applets are available: one in which the computer performs the calculation
at each step, thus allowing the student to concentrate on the solution strategy,
and one in which the student has to do the calculation himself and the program
only verifies whether intermediate expressions are still equivalent. A 'gaming'
feature can be added to the second version by letting students earn points for
entering correct intermediate results. Using help or letting the computer perform
an intermediate step costs points. The idea is that changing a set of mathematical
exercises into a game with various levels motivates students to work hard.5
Fig. 3. The 'Quadratic Equations' applet, using the completed squares method and

the balance strategy for solving equations.
As was noted before, the Java applets have been published on the WisWebsite (www.wisweb.nl) and have been field tested extensively at secondary schools in collaboration with teachers and educational researchers [9-11]. We quote some findings on the use of school algebra applets [11]:
"It was found that the use of applets has add-on value: they are fun and motivate students; they allow students to work at their own level of thinking and thus better address individual dijerence between students; the visual, interactive and dynamic features of applets makes the mathematics more easy to understand; thanks to the calculation power of the applets one can focus on the mathematical concepts and models; students are more creative and get more self esteem; the applets form a model students can fall back on; the practice and feedback features are much more powerful than pencil-and-paper exercises. However, to take fully advantage of these opportunities of applets, applets should be integrated in the daily mathematics class routine. Using the computer should not be a voluntary thing that is extra beyond regular math class."
The last issue played an important role in the GALOIS project. The successes with mathematical applets and other ICT tools actually lead to higher expectations. For a teacher it would be nice if he or she could review after a computer aided lesson what the students actually did, what progress they made, which problems arose during learning and to which mathematical subjects attention must be paid in the next lessons. Also, if assignments were given outside of class, this mechanism of 'student tracking' would aid a teacher in determining student ability. An even more basic advantage would be the possibility of checking whether a student has actually done his or her homework. At secondary school level -- with students at age between 12 and 18 years -- this added bonus is often overlooked.
All this would enable teachers to use their actual 'contact time' more ejj-ciently. On the other hand, students also benefit from monitoring student performance: a digital archive of computer based activities gives these activities a6 firm place in the curriculum and improves the learning process while it enables students to review mistakes made and it stores feedback. This systematic approach within one learning environment enhances the already positive ejects of direct, instantaneous feedback.
Many Virtual Learning Environments (VLE) store student work, and it seems that the use of VLEs in secondary education in the Netherlands is on the rise. Nonetheless, with these environments, schools still have to add their own educational tools and lecture notes. Reuse ofICT-components and exchange of learning materials with colleagues without conversion problems promotes this. One could even argue that a VLE only deserves its name when one can actually learn within the system, which implies that an integrated learning environment actually has content. A logical next step in creating an integrated learning environment for mathematics is to see whether mathematics programs can communicate with standard VLEs to store user feedback and aid sharing of content. For this we used in the GALOIS project the SCORM standard.
3 The DWO math environment
The DWO math environment [2] is a web-based application in which a student logs in on a central server, works with an applet, and automatically receives feedback from this applet. Student results are stored so that students can stop working in the DWO and return later, without loosing any results. Teachers can monitor the progress of individual students, but also of entire classes (Figures 4 and 5 show examples).
At the secondary school St. Micha¨el College, the DWO math environment was used for example in the second grade (12 to 14 year olds) in combination with written material, replacing two chapters on algebra. This first learning unit gave students a first acquaintance with mathematical expressions and above all the important mathematical concept of 'variable'. It also aimed to instil some 'symbol sense' and the ability to rewrite mathematical formulas. One of the applets used was the 'Area Algebra', which we described in the previous section (Figure 2). Students were given the opportunity to go through the instructional materials at their own pace, not only at school but also at home. Because the DWO math environment stores the results and feedback of the exercises of all students, the teachers could not only see which assignments students answered incorrectly, but also watch the mistakes in detail.
As a matter of fact, just the knowledge that most pupils did not have any problems with certain subjects was valuable information in practice, too: the teachers could pay more attention to the things the students did not know or had not mastered well enough, instead of teaching about things the students already knew. Of course, in the classes there were dijerences in the progress that students made because they had dijerent levels of 'talent' for the subject. Individual results from students in one class (Figure 4) and in other classes (Figure 5) helped with tracking student performance individually as well as globally, and at a more detailed level than in traditional classroom instruction.7
To correctly interpret the results shown in Figures 4 and 5, it is important to know that in this case teachers had given the students homework to make the first two parts of the applet, resulting in the highest attainable score of 42%. In this case five out of seven classes score higher than the expected percentage. Upon even closer inspection 25% of all students correctly made more than two thirds of all assignments, and 5% of all students even scored 100%. This is a clear sign that the applets highly motivated the students, even beyond the requested activity level.
Fig. 4. The results of all students in one class using the 'Area Algebra' Applet.
Fig. 5. The results of all 2nd grade classes using the 'Area Algebra' Applet.8
In summary, use of the DWO helps the teacher to get good insight into the learning processes of pupils and to make grounded choices in the construction of his or her lessons. With the possibilities of such an interactive environment the polarity between classroom and individual teaching has to be reconsidered. Teaching can shift from a classroom approach, with instruction and discussion, to a more individualistic approach with custom feedback. To students and teachers alike, the DWO is seen as a clear and intuitive environment with not too many options and features. Administration of the DWO is in the hands of an external organization (in this case the Freudenthal Institute) and teachers do not have to concern themselves with the technical side of things.
It also is possible to construct new assignments within a couple of Java applets. This feature aids a teacher in making custom made assignments for every school level within a given subject. To evaluate the performance of students it is also possible to give an exam within the DWO environment. A teacher makes a new module that can be accessed during a limited time span. In this module buttons for feedback and marking have been removed, so now a student has to do everything himself. A teacher does have access to the marking button to facilitate the marking of these assignments.
There are some disadvantages, too. When a school already uses a VLE, with all kinds of communication facilities such as email and bulletin board available, it could be considered cumbersome that yet another environment is added to the already long list. Especially when more and more persons start learning and teaching with the aid of computers, the necessity of an integrated and uniform learning environment, becomes more and more apparent. In some cases it is preferable that administration of the system lies with the own organization (for example when one wants to indicate whether parts of a learning module belong to a basic or an advanced track). These pros and cons of the DWO environment were also mentioned during interviews with teachers and students. We refer to [12] for details about practical problems, user wishes and other remarks that came up on usage of the DWO math environment in classroom experiments.
4 Using SCORM to monitor student performance with applets in an existing VLE
A big advantage of using an existing virtual learning environment with which students and teachers are familiar is that many things run very smoothly: the users know how to log in on the system, how to send emails to groups of student or to individuals, how to work with other built-in communication tools, and how to inspect students' results and export them into the school administrative system. There are a couple of requirements when aiming to integrate applets into an existing learning environment:
- An applet and the VLE have to be able to communicate with each other;
- It should be possible to share the content in various VLEs, for it could very well be that existing programs and learning environments change over the years at school;9
- It should be possible to use this mechanism for other applets or computer programs.
The use of existing standards seems to be the best method to reach these goals, with a clear distinction between the role a VLE plays and the role the program plays. This distinction also means that suppliers of learning environments can operate independently from the suppliers of educational programs, but with the certainty that both work well together. A well-known and often used model is the Sharable Content Object Reference Model, abbreviated as SCORM [3]. It aims to integrate several specifications into one standard describing technical requirements for storing digital learning materials and the interaction between VLE and these materials. SCORM 2004 consists of seven dijerent standards, including requirements for
- metadata (What type of material? What is the target audience? Who has made this material? How can use this material? etc);
- constructing SCORM packages;
- for navigation through the package;
- for 'running' the package in a particular VLE.
Many system suppliers already support the SCORM model, e.g., Moodle [4] and Blackboard [13]. Within the GALOIS project we adapted applets and exercise programs so that they would be SCORM compliant. We intended to use SCORM compliant packages in Moodle, which is called MichelangElo at the St. Micha¨el College, but by using a standard we wanted to ensure that our results could be used in any SCORM compliant learning environment.
Fig. 6. The 'Herleiden' [Rewriting] applet in Moodle.10
One of the applets that we made SCORM compliant is the 'Herleiden' applet, shown in Figure 6. This applet was actually used in a fourth grade class to practise rewriting of given expressions and to reinforce symbol sense. Examples of given assignments concern expanding and rewriting mathematical expressions like 2·3(2a+2b)-2c+a·(a+2), (a+b)(b+c)-2ac, and (2x+y)
2 -(2x-y)
2
. Many
students had problems with this type of assignments, despite the attention given to formula manipulation in the years before and the successes at that time. A common mistake in teaching and learning: not only does one have to teach a certain mathematical skill or ability, it also has to be maintained. Practice makes perfect, but in this case it would be helpful if students could practise a lot without giving the teacher an unnecessary extra workload. A web-based exercise program makes this possible. In our school situation, students could practise rewriting formulas during computer workshops at school as well as at home. Students' scores and results were stored in the system, which enabled the teacher to see whether students have a good command of the algebraic skill of removing brackets and combining like term.
Within MichelangElo it is also possible to export results to text and spreadsheet format. With slight modifications they can even be exported into existing school administration systems. When giving assignments, there naturally are students who do not do their homework. Low scores easily reveal this. Moodle's internal messenger can be used to address these students. Problems are also discovered easily, especially because 'the road to an answer' is also stored in the VLE [14]. For example, some students still made the common mistake to rewrite
(2a + b)
2
as 4a
2 + b
2
. This misconception was addressed in the next lesson by using the area model to explain why this equivalence doesn't hold. We noticed in practice that the students -- at the dijicult age of 16 -- were highly motivated by this novel way of practising an otherwise dijicult and boring subject; they found the applets attractive and motivating. The short-term eject of using the applets in the VLE was that students seemed to get a better understanding of the structure of formulas and that the teachers could monitor student performances and address common mistakes more easily. All this happened within a VLE that was already in use at school and that both teachers and students were familiar with.
5 Intelligent feedback
A teacher must be all ears and have eyes in the back of one's head during classroom work when he or she puts ejort in interactive education that takes individual dijerences of students into account. Occasionally -- mostly when working with small groups or in a face-to-face situation -- one gets the feeling of having realized 'customized education' in which dijerentiation based on the needs of the students came into being. Normally, a teacher is forced to aim at the average student or the interaction is merely a random check. Issues like a large number of students in a class, a limited number of contact hours, time pressure, and so on, often make things more complicated.11
Whether ICT can make the dijerence here is not clear yet. Of course, a modern teacher benefits nowadays from all kinds of computer programs and Internet (for lesson material and communication), but the optimism that ICT can contribute to ejective teaching and learning is not shared by everybody.
It is tempting to state that an online exercise environment enables students to practise mathematics independently and as much as needed, without increasing the work load of a teacher. But often the interaction is rather primitive and limited: answers are marked correct or incorrect without any explanation or further information. The student is left with questions like "What's wrong? Should I type a comma or a decimal point (or the other way around)?", "Is my answer not accurate enough (or too accurate)?", and "Did I make a mistake and, if so, what kind of error: a careless mistake, a reading error, or a conceptual misunderstanding?" When they call in a teacher he or she may hope to find out quickly where the shoe pinches.
An interesting question is to what extent the expertise of a mathematics teacher, i.e., the knowledge about mathematics, teaching and learning, and about the students, can be built into an exercise environment in a such that student receive useful feedback when they make a mistake. We refer to this as 'intelligent feedback' and 'tailored feedback'.

In education, feedback is inextricably bound up with learning processes [15]:
It is usually meant to give students insight in their own learning process or
functioning, to confirm, strengthen or transform their knowledge, and to give
teachers insight in the competencies of their students so that they can make their
teaching more ejective. In this paper we restrict ourselves to 'local feedback', i.e.,
to feedback that is based on the typed answer or another interaction provoked
by a question or task. Dijerent forms of local feedback can be distinguished
and often more than one of these forms is present in a single reaction. Some
examples:
- conceptual: explanation or elucidation of a particular reaction (comments on
the accuracy ofthe given response, instructions of how to input mathematical
expressions, etc.);
- clarifying: supportive remarks concerning content (hints, references to learning materials, etc.);
- evaluative: information about total score, time spent on the task, and so on;
- ajective: for example, an encouragement or a indication of correctness of
intermediate results;
- advisory: think of suggestions for further practice.
We speak about intelligent feedback when it is based on an analysis of the
student's answer or action and when it goes beyond a simple correct/incorrect
sign or a mark. For example, an incorrect answer is annotated with a short
explanation of what might have gone wrong. Also, a hint might be given or a
student gets a second chance. Another example is the highlighting of a correct,
but mathematically inferior answer (e.g.,
2
4 and
2
50 are usually simplified to
2 and 5
2
2, respectively). Intelligent feedback is a detailed reaction based on the
following.12
1. expert knowledge about the mathematical content;
2. a model in which common mistakes and actions are rubricated;
3. knowledge about learning and instruction so that the most suitable feedback
can be chosen.
In the GALOIS project we have experimented with tailored feedback for
exercises in algebra and arithmetic. For an algebraic example we refer to [16].
Table 1 shows various forms of feedback on typical answers to an arithmetic
question.
Question: Your bicycle tyre has a puncture. Each minute 8% of air escapes. What
percentage has escaped after 11 minutes? Round your answer to the nearest integer.
Response Feedback Explanation
60 Excellent! correct answer
60.04 Fine, but too accurate too accurate answer
60.04 Your answer cannot be
interpreted; use the decimal point
not recognized by parser
59 or 61 Close to the correct answer. A
round-oj error?
probably a round-oj error
40 This amount of air is left well-known mistake
133 Confusing addition of 8% ? 1.08
11
= 2.33; well-known mistake
88 No, this is not the way it goes. Use
the growth factor.
notorious mistake (8 times 11)
other Wrong answer; have again a close
look at the section on exponential
decay
God knows what went wrong.
Table 1. Example of tailored feedback on students' responses.
This form of feedback is not in the future. Tailored feedback exists in the
computer algebra based testing and assignment environment STACK [17] and
in the custom-made JavaScript-based testing and assignment environment called
DITwis [5]. At first, DITwis was developed as an independent means to practice
and test certain concepts without teacher's intervention. However, we thought
it would be useful to see whether integration of DITwis into an existing VLE
would be beneficial. Again we made this program SCORM compliant. We used
the system in a third grade (trigonometry) and a fourth grade (combinatorics
and probability) class. The advantages of integration soon became apparent, as
well as (temporarily) some disadvantages. Many of these findings overlap with
the aforementioned ones, with a positive emphasis on: better insight in student
work and problems that students face; the possibility of practising anytime,
anywhere; the added bonus in the communication facilities of a standard VLE.
6 Design and use of a customizable SCORM compliant
applet generator
It would be even better if an applet could be configured within the learning
environment in such a way that custom assignments could be made. This pos-13
sibility has been successfully explored in the last phase of the GALOIS project
in 2006-2007. In this section we discuss a prototype of a customizable SCORM
compliant applet generator for learning school algebra and calculus.
The primary design goal was to enable teachers to create exercises and tests
for their students similar to the existing WisWeb applets, but set up according
to their own ideas. WisWeb applets dealing with the same mathematical topic
vary with respect to feedback, ranging from marking correct/incorrect only to
symbols indicating (in)correctness of intermediate results, and with respect to
marking of answers (e.g., dijerent marks for fully simplified answers and correct,
but not completely worked out responses). We wanted to leave the decision on
the level of feedback and the marking system to the teacher who creates algebraic exercises and tests. Furthermore, teachers should be able to create SCORM
compliant applets so that they can use them in any virtual learning environment
that supports this standard. In this way, teachers could exchange their materials
more easily. Since teachers are not computer programmers, the process of creating SCORM packages containing Java based exercises should be as simple as
possible. Teachers should be able to concentrate on the mathematical contents
and instructional design instead of spending time and ejort on technicalities. A
teacher should also be able to look at the end result through the eyes of students. Keeping in mind that most teachers have no programming experience, the
process of creating randomized questions should be kept simple, too.
Let us first look at a real example of an exercise on computing derivatives,
which was used in a test for 4th grade pre-university students. Figure 7 is a screen
shot of a prototype of the customizable SCORM compliant applet generator.
Fig. 7. Creating an exercise with the applet generator.14
When this exercise together with all the other exercises in the test is saved,
the program generates a SCORM package that can be uploaded into a VLE that
supports this standard. That's all! In such a learning environment, marking of
the students' work is automatically dealt with. Slight modification of the Moodle
environment [14] and other VLEs allowed us to save and reuse the state in which
a student leaves the applet. The advantage of this in school practice was that
a student could temporarily stop working at the computer and return later to
the tasks, that a student could go back to an earlier task and improve his or her
work, and that a teacher could not only see the marks of the students, but also
inspect their work and see how they had done the exercises. Figure 8 shows a
screen shot of how the applet generated looks like when used in Blackboard. The
example shows that the randomly generated exercise was not completed yet, but
was already marked with 6 points; combination of like terms would lead to the
full score of 10 points.
Fig. 8. Use of the generated applet in Blackboard.
Let us examine in more detail the implementation of the question shown in
Figure 8. It naturally includes more than just the question posed to the student.
The minimum information which needs to be entered to create a viable question
is the text of the question, the teacher's provided answer, and the marking. For
simple questions this is entirely straightforward. Having mastered this, a teacher
can seek to include randomly generated parameters, a more complicated expression generation, a tool menu, and more sophisticated marking of (intermediate)
expressions entered by a student. We detail the fields in the applet generator in
this section to illustrate the authoring of questions.
Question variables are of the form parameter = value, separated by a semicolon when they are specified in one line. The value can be a sequence of integers
separated by comma's or a range of values (denoted as a starting value and an15
end value, separated by the ellipsis operator ..). When a question is instantiated, a random choice from possible integer values will be made. It is possible to
use previously defined question variables when making a new one. For example,
i=1..5; j=i^2 will lead to a random choice of i and j such that j = i
2
and
i=1..5; j=1..i will lead to a random choice of i and j such that i ≥ j;
Initial formula is the expression or equation posed to the student in the
work area. You use this field for example, when you do not want the formula in
the question text. In the given example, the function whose derivative must be
calculated is specified in the question text.
Question text is the actual question or exercise posed to the student. It is
more or less a compulsory field which the teacher must enter for a valid question.
It may contain text and formulas. In Figure 7 you see that the formula (invoked
by pressing the F button) is a mathematical expression surrounded by hash
signs (#). When the question is instantiated, all parameter values are randomly
chosen, their values are substituted in the parts that are between hash signs,
and basic simplifications (e.g., combining like powers, adding numbers, removal
of superfluous zeros and ones in expressions — think of replacements such as
x + 0 → x, 1x → x, x
1 → x, and so on →) are automatically carried out.
Apparently, the following values were chosen for the parameter in the given
example: a = 4, b = 2, q = 2, and d = 4. More than one pair of hash signs may
be present in a formula to allow maximal flexibility in the formula generated. An
example says more than words. Assume that a, b and n are question variables
leading to nonzero natural numbers. In Table 2 are listed formulas with 1, 2,
and 4 pairs of hash signs leading to dijerent formula types (a concrete example
is given for a = 4, b = 6, and n = 12).

Table 2. Example of the use of hash signs in formula generation.
Correct answer is another compulsory field that the teacher must enter; a
checkbox is used to indicate that the answer is an equation instead of an algebraic
expression. By using pairs of hash signs, the type of answer that is considered
as correct in a randomized question may be specified (as we have seen before).
But there exist other ways of specifying the level of correctness. When the box
Equivalence is checked, any student answer that is equivalent to the teacher's
answer is marked as correct and a number of points is scored. When the box
Rewriting is checked, additional points can be earned by the student when
he or she has simplified an intermediate result. In the given example, extra
points are given when the answer is a polynomial in expanded form, i.e., without
brackets. Special forms that have been implemented in the prototype of the
applet generator are expressions in which16
- no brackets are left in polynomial expressions (e.g., (x + 1)
2 → x
2 + 2x + 1);
- powers with the same base have been combined into one power (x
2
x
3 → x
5
);
- a formula has been rewritten such that no powers with fractional or negative
exponents occur (x
−2 → 1
x2 and x
5
2 → x
2/
x);
- a rational expression has been rewritten into a single fraction (
1
2 +
1
3 → 5
6
);
- logarithms have been combined as much as possible into a single logarithm
(2 ln 3 + ln 8 → ln 72);
- only simple logarithms appear in a formula (ln 72 → 2 ln 3 + 3 ln 2).
When the box Exact has been checked, a student can score extra points when
he or she enters exactly the answer that the teacher had in mind . When the box
Steps enabled has been checked, a student can enter intermediate expressions
in the work field, gets feedback on correctness, and may even score points for
correct intermediate expressions.

Levels of sets of exercises can be specified in the left bottom corner of the user
interface of the applet generator. In the example shown in Figure 7, the dijerent
levels have been named after the dijerentiation rule that must be applied. But
one can also divide the exercises in a test into sets of easy and dijcult exercises.
The number of levels and the number of questions at each level can be set by
pressing the up/down and left/right arrows, respectively.
Title of the exercise is optional. It can only contain plain text and no formulas. Like in the question field, you can only use alphabetic characters and digits.
Use of accents and HTML coding is not provided (yet).
Fig. 9. Creating an exercise about addition of two fractions.17
The dedicated use of hash signs in randomized questions and the sophisticated processing of (intermediate) student's answers are very convenient for
intelligent marking of responses. Such intelligent question generation and marking of answers is not easily implemented in computer algebra based systems like
STACK [17] or Maple T.A. [18]. Making an exercise in steps is not possible in
these systems either, unless it has been explicitly implemented by the author of
the exercise. The following example shows how easy it is to implement an addition of two randomly generated fractions and to give dijerent marking when a
student is able to
– write the fractions such that they have a common denominator (2 points);
- rewrite the sum correctly as a single fraction, but not with the smallest
possible denominator (5 points);
– find the exact teacher's answer (10 points).
Figure 9 shows the applet generator in action. Figure 10 shows a correct answer
to the question. The marking changed in the intermediate steps from 2 points
to 5 points, and finally to the full score of 10 points.
Fig. 10. Creating an exercise about addition of two fractions.
The main drawback of the generated Java applets is that there is no computer
algebra system behind it (yet). Thus, equivalence testing is done numerically.
Although this may lead to erroneous results – after all, inequivalent algebraic
expressions may evaluate to the same numerical result – in practice it works
quite satisfactory.18
7 Conclusion
Existing mathematical tools become even more powerful and useful when results
and performance of students can be tracked online. Use of a common standard,
in this case SCORM, enables the sharing of content, but also of storing student performance. Students know that they can be and are monitored by their
teacher. Together with other features in virtual learning environments, especially for communication, students are stimulated to do their homework, or even
more than that. Students do not seem to mind this 'big brother is watching
you' concept. On the contrary, they seem to appreciate the fact that a teacher
has good insight into common mistakes and can use this knowledge to address
certain problems more ejectively. They also seem to find that computer practice
prepares them better for written exams than making assignments from a book.
Computer aided learning is also seen as a more 'fun' way of practising otherwise
boring subjects. Direct feedback adds to this appreciation as well as the fact that
small mistakes can easily be corrected. Using direct feedback, giving students
hints and enabling a 'trial and error' approach makes it possible for students
to explore dijerent strategies for solving a given problem. But exercise applets
without these facilities have also been developed.
In our opinion, digital assignments and diagnostic testing add to the motivation and performance of students in mathematics education. By making use
of computers, the extra time involved for teachers is acceptable. Contact time
can ejectively be reorganized because students that need extra attention are
signalled earlier. One of the success factors of the use of ICT would be that
all teachers in an organization agree on the vision they have on mathematics
education. Ideally, less experienced teachers would be supported by experienced
teachers and experiences are shared alike to evaluate and improve the use of ICT
in the classroom. From technological point of view, SCORM contributes to the
realization of meaningful ICT-rich education. The customizable SCORM compliant Java applet generator allows teachers to create exercises and tests for their
students in an easy way and based on their own ideas. These tests can be exchanged with fellow teachers because of the use of a widely used standard. Field
tests at school confirm that all works well in practice, although many wishes for
improvement of the software arise at this stage of the development work. Linking
the applets to a backbone computer algebra system and having more question
types at one's disposal are two of the envisioned extensions. The developed ICT
tools have a surplus value for mathematics education at secondary school, and
probably as well for other educational levels: experiments at the University of
Amsterdam in remedial math for freshmen and in math intensive courses for
first year chemistry students take place at this moment.

We describe the development and use of Mathematica empowered
applets for learning and practising algebra and calculus at secondary
school level. We discuss how Mathematica can be used as back engine
to evaluate students' answers and provide appropriate feedback. These
applets provide scoring facilities, are fully integrated in a virtual learning environment in which answers are stored, and can be edited by
teachers to create their own exercises and tests. Students benefit from
the applets because the exercises help them to develop mathematical
understanding and skills more thoroughly than is possible with pencil
and paper. Using the applets, a teacher can review after a computer
aided lesson what the students actually did, what progress they made,
which problems arose during learning and to which mathematical
subjects attention must be paid in the next lessons. In other words, the
applets help the teacher to get insight into the learning process of
students and to make grounded choices in the construction of his or
her lessons.

Many students at secondary school level and beyond have difficulties in
mastering algebraic skills. Often the algebraic manipulations are carried out in
a superficial way, using rules that are not meaningfully connected with the
underlying concepts. To help secondary school students to develop real algebraic understanding (insights and concepts) and to learn and practice algebraic skills in sense-making ways, designers of the Freudenthal Institute have
developed several sequences of programs, Java applets, that (1) enable
students to connect the formal mathematical activities in a meaningful way
with the underlying concepts and (2) provide exercises with feedback and
have scoring facilities in a game-like setting. Later these applets were integrated in a virtual learning environment, in which information on the results
and the learning could be captured. At the moment the Freudenthal Institute
is extending this learning environment with authoring facilities, to create new
applets without the need for specialized programming knowledge. This
enables teachers to design their own interactive activities and tests on their
own ideas.
Many of the interactive exercises are using build-in computer algebra alike
facilities for evaluating students' answers and be for generating proper feedback. The evaluation of an answer can be the verification of the correctness
of the final answer to a question, but it may also be the verification of the
correctness of an intermediate computational step entered by a student. For
the more advanced mathematical topics, the need for a professional
computer algebra system like Mathematica to do this job is felt more and
more. As a proof of concept, some of the developed applets are redesigned
for using Mathematica as back engine to evaluate students' answers. The
screen shot in Figure 1 gives an impression of the user interface for the case
of exercising integration by parts.
Mathematica Empowered Applets 3
IMS08_paper_Heck_Boon_vanVelthoven.nb 4/15/08 The Mathematica Journal volume:issue © year Wolfram Media, Inc.Figure 1. The 'Integrating by Parts' applet with immediate feedback
In this paper we will discuss our experiences from development work and
classroom tests. We will pay special attention to the way Mathematica is used
as back engine. We will also exemplify this use of Mathematica in the context
of geometry education. The article is organized as follows. First we discuss
the theoretical framework for the design and use of the educational applets,
their use in the classroom via a virtual learning environment, the feedback
provided in the applets, and the authoring of the applets. Hereafter we
discuss in detail the use of Mathematica as back engine to evaluate students'
answers on the basis of the exercise applet for integrating by parts. Finally we
give a short example of the use of Mathematica in geometric theorem proving
when using a dynamic geometry applet. We conclude with our ideas for future
development resulting from our experience with the prototypical Mathematica
empowered Java applets that have been developed so far.

4 Heck, Boon, van Velthoven
The Mathematica Journal volume:issue © year Wolfram Media, Inc. IMS08_paper_Heck_Boon_vanVelthoven.nb 4/15/08â Design and Use of Applets for Learning Mathematics
â Theoretical Framework
In the last decade, a team of researchers, curriculum developers and software designers at the Freudenthal Institute have developed in collaboration
with secondary school teachers various applets for learning mathematics.
This development effort was made with the expectation that use of such mathematical applets would contribute to visualization of mathematical concepts,
exploration of context situations (including purely mathematical contexts), and
to bridging the gap between informal knowledge and formal mathematics.
The Realistic Mathematics Education (RME, [1]) approach was the key theoretical framework for the design of the computer programs and the accompanying lesson material, and for the flanking educational research. The key
element of the RME approach for the design and use of the applets is that the
problems that they present are real and meaningful to the students and worth
the effort of solving. Considerable work was put into the design and field
testing of applets for students to develop algebraic understanding and skills,
to introduce and strengthen the notion of function, and to develop geometrical
insight and spatial abilities.
Two kinds of applets can be distinguished:
è model applets, which help to develop mathematical understanding;
è exercise applets, which help to develop mathematical skills.
In model applets visual representations are used as models for mathematical
concepts. Within these representations students can work on the basis of
their own ideas and experiment freely. An example of a model applet is the
"Geometric Algebra 2D" applet shown in Figure 2. It allows adding and multiplying numbers and variables by combining line segments to new line
segments and rectangles. The lengths of the line segments and the areas of
the rectangles are displayed as expressions. By splitting and joining rectangles students can develop insight in equivalence of various algebraic
expressions.
Mathematica Empowered Applets 5
IMS08_paper_Heck_Boon_vanVelthoven.nb 4/15/08 The Mathematica Journal volume:issue © year Wolfram Media, Inc.Figure 2. The 'Geometric Algebra 2D' applet.
A model applet such as the 'Geometric Algebra 2D' applet has an open
nature: it allows students to work with it on the basis of their own constructions and productions. The ICT tool is only expected to help students to mathematise the situation on the basis of their activities. Activity sheets may guide
students in making progress from informal to more formal mathematical
activity.
Exercise applets have a more closed structure: a number of tasks of certain
type are given to the students, their work is checked and feedback is
provided. Figure 3 illustrates the 'Area Algebra' applet, in which the area
model is used to verify equivalence of algebraic expressions. The main task
is to find the correct expressions for areas and edges of rectangles. The
applet is an interactive version of the well-known geometrical representation
of the distributive law of algebra. A formula like 3 Hy + 2L is treated as the area
of a rectangle with length 3 and width Hy + 2L. This results in a stepwise
formula with a part equal to 3 y and a part equal to 6. Students intuitively learn
and see that 3 Hy + 2L is equivalent to H3 y + 6L.
Feedback in this applet is direct: green symbols in the work area indicate
which part of the answer is correct, and red, orange and green circles around
the assignment numbers indicate wrong, incomplete and correct answers.
This stimulates the students to go on and try another one, and to get as many
correct answers as possible. And what is also very important, the stored feedback provides both the student and the teacher detailed information about
where and what kind of mistakes have been made. The screen shot shows
an example: maybe the student had simplify forgotten to fill out a text box in
the rectangle; maybe (s)he had worked in a too formal manner and written 32
6 Heck, Boon, van Velthoven
The Mathematica Journal volume:issue © year Wolfram Media, Inc. IMS08_paper_Heck_Boon_vanVelthoven.nb 4/15/08the rectangle; maybe (s)he had worked in a too formal manner and written 32
with 3 y2 in mind, just as one writes 3 y when the product is meant.
Figure 3. The 'Area' applet with immediate feedback.
The method of completing squares for solving quadratic equations links up
well with the above area model. It is supported in the exercise applet 'Quadratic Equations' shown in Figure 4. The applet presents a quadratic equation
that is to be solved step by step. With the red buttons on top, the student can
select an operation that is to be performed on both sides of the equation. The
goal is to simplify the equation and eventually end with x = … solutions. With
this applet, a student has to think and decide what operation to perform. Two
versions of the applets are available:
è one in which the computer performs the calculation at each step,
thus allowing the student to concentrate on the solution strategy;
è one in which the student has to do the calculation himself and the
program only verifies whether intermediate expressions are still
equivalent.
Mathematica Empowered Applets 7
IMS08_paper_Heck_Boon_vanVelthoven.nb 4/15/08 The Mathematica Journal volume:issue © year Wolfram Media, Inc.Figure 4. The 'Quadratic Equations' applet, using the completed squares method and the
balance strategy for solving equations.
A gaming feature can be added to the second version by letting students earn
points for entering correct intermediate results. Using help or letting the
computer perform an intermediate step cost points. The idea, proven to be
true in field tests, is that changing a set of mathematical exercises into a
game with various levels motivates students to work hard.
One of the other exercise applets is the applet called 'Herleiden' (Dutch for
"rewriting") and shown in Figure 5. This applet presents mathematical expressions that are to be simplified step by step, where a student gets in each step
feedback in the from of a cross or checkmark whether he or she is still on the
right track or not. The purpose of this applet is to practise rewriting of given
algebraic expressions and to reinforce students' symbol sense.
8 Heck, Boon, van Velthoven
The Mathematica Journal volume:issue © year Wolfram Media, Inc. IMS08_paper_Heck_Boon_vanVelthoven.nb 4/15/08Figure 5. The 'Herleiden' applet with intermediate feedback.
While a student works with an applet (s) he receives instantaneous local feedback, i.e., feedback that is based on the typed answer or another interaction
provoked by a question or task. Different forms of local feedback can be distinguished and often more than one of these forms is present in a single reaction. In Figures 1, 3, 4, and 5 green marks and red crosses indicate which
part of the answer is correct and incorrect, respectively. In addition, red,
orange and green circles around the assignment numbers indicate wrong,
incomplete and correct answers. Another form of feedback in the applets are
messages informing the student that "the notion used is invalid" or that
"superfluous solutions are present in the answer". Via such intelligent, tailored
feedback that goes beyond a simple correct/incorrect sign or a mark a
student gets the impression that a teacher is looking over his/her shoulder to
make useful remarks, to warn for common mistakes, and to give hints if
needed.
Mathematica Empowered Applets 9
IMS08_paper_Heck_Boon_vanVelthoven.nb 4/15/08 The Mathematica Journal volume:issue © year Wolfram Media, Inc.â The Digital Mathematics Environment
The applets can be embedded in a simple electronic learning environment,
which is called the Digital Mathematics Environment (DME [2]; in Dutch called
the "Digitale Wiskunde Oefenomgeving", DWO). The DME is an answer to the
fleeting character of the work with applets, which both students and teachers
often experience. In the DME, a student logs in on a central server, works
with an applet, and automatically receives feedback from the applet.
Students' results are stored on a central server. This allows the student to
review his/her work, correct it, and continue it in any location with Internet
access, particularly at home. The teacher can check and grade the students'
work and (s)he can monitor the learning process of individual students and of
entire classes. An example of an overview of students' results is shown in
Figure 6.
Figure 6. The results of all students in one class using the "Area Algebra" applet.
10 Heck, Boon, van Velthoven
The Mathematica Journal volume:issue © year Wolfram Media, Inc. IMS08_paper_Heck_Boon_vanVelthoven.nb 4/15/08â User-Friendly Authoring Facilities for Teachers
A promising new feature of the DME is the authoring tool for designing new
exercise applets. A prototype of this tool was developed in the Galois project
[3]. Lately much effort is put in the further development. The editor of the
authoring tool enables teachers to create exercises and tests for their
students similar to the existing applets, but set up according to their own
ideas. The decision on the level of feedback and the marking system is left to
the teacher who creates exercises and tests. Since teachers are not
computer programmers, the process of creating the interactive exercises is
kept as simple as possible. Teachers should be able to concentrate on the
mathematical contents and instructional design instead of spending time and
effort on technicalities. A teacher or author is able to look at the final result of
the applet creation through the eyes of students. Keeping in mind that most
teachers have no programming experience, the process of creating randomized questions should be kept simple too. Although designed for teachers, at
the moment textbook authors use this authoring tool as well to design the
accompanying ICT-materials for students.
â Interoperability
The two functionalities of the DME (learning environment and authoring environment) can be separated. As an authoring environment, the DME can, on
the one hand, package the designed activities in so-called SCORM-compliant
learning objects [4] that can be used in other learning environments, for
example Moodle or other SCORM-compliant environments. On the other
hand, as a learning environment, the DME can also embed other (SCORMcompliant) learning objects that are not designed and produced with the DME.
This possibility, especially the adoption of the SCORM-standard, facilitates
the collaboration with other systems and designers.
â Description of the Authoring Tool
Figure 7 is a screen shot of the editor of the authoring tool.
Mathematica Empowered Applets 11
IMS08_paper_Heck_Boon_vanVelthoven.nb 4/15/08 The Mathematica Journal volume:issue © year Wolfram Media, Inc.Figure 7. Creation of an exercise with (the prototype of) the applet generator.
We describe the fields in the above editor to illustrate the authoring of questions; more details can be found in [5].
Question variables are of the form parameter = value, separated by a semicolon when they are specified in one line. The value can be a sequence of integers separated by comma's or a range of values (denoted as a starting value
and an end value, separated by the ellipsis (..). When a question is instantiated, a random choice from possible integer values will be made.
Initial formula is the expression or equation posed to the student in the work
area. You use this field for example, when you do not want the formula in the
question text. In the given example, the function whose derivative must be
calculated is specified in the question text.
Question text is the actual question or exercise posed to the student. It is
more or less a compulsory field that the teacher must enter for a valid question. It may contain text and formulas. In Figure 7 you see that the formula
(invoked by pressing the F button) is a mathematical expression surrounded
by hash signs (#). When the question is instantiated, all parameter values are
randomly chosen, their values are substituted in the parts that are between
hash signs, and basic simplifications (e.g., combining like terms, adding
numbers, removal of superfluous zeros and ones in expressions) are automatically carried out.
Correct answer is another compulsory field that the teacher must enter; a
checkbox is used to indicate that the answer is an equation instead of an algebraic expression. By using pairs of hash signs, the type of answer that is
considered as correct in a randomized question may be specified (as we have
seen before). But there exist other ways of specifying the level of correctness.
12 Heck, Boon, van Velthoven
The Mathematica Journal volume:issue © year Wolfram Media, Inc. IMS08_paper_Heck_Boon_vanVelthoven.nb 4/15/08seen before). But there exist other ways of specifying the level of correctness.
When the box 'Equivalence' is checked, any student answer that is equivalent
to the teacher's answer is marked as correct and a number of points is
scored. When the box 'Rewriting' is checked, additional points can be earned
by the student when he or she has simplified an intermediate result. In the
given example, extra points are given when the answer is a polynomial in
expanded form, i.e., without brackets. Other special forms have been implemented in the editor.
Levels of sets of exercises can be specified in the left bottom corner of the
user interface of the applet generator. In the example shown in Figure 7, the
different levels have been named after the differentiation rule that must be
applied. But one can also divide the exercises in a test into sets of easy and
difficult exercises. The number of levels and the number of questions at each
level can be set by pressing the up/down and left/right arrows, respectively.
Title of the exercise is optional. It can only contain plain text and no formulas.
Like in the question field, you can only use alphabetic characters and digits.
Use of accents and HTML coding is not provided (yet).
â Mathematica Empowerment of the Applets
The main drawback of the generated Java applets is that there is no real
computer algebra system behind it yet. Some limited computer algebra facilities are embedded, like expanding polynomials, simplifying a limited number
of expression types and performing substitutions. But most of the equivalence
testing is done numerically via a randomized process: random values are
repeatedly substituted for the variables in the expressions under consideration and only when the results are notably different from each other, nonequivalence of the expressions is proven. If the tests are passed for enough
substitutions it is assumed that equivalence holds. In a few cases, formal
equivalence is tested, e.g., in case of arithmetic tasks and when removal of
brackets in polynomial expression is applied. Although this numerical equivalence testing may lead to erroneous results — after all, nonequivalent algebraic expressions may evaluate to the same numerical result — in practice it
works quite satisfactory for simple algebraic expressions like polynomials.
However, when more complicated expressions or mathematical functions
come into play, the need for algebraic equivalence testing is felt more and
more. A modern computer algebra system can do the work in the background. In the implementation of the prototypical Mathematica empowered
Java applets we use the Simplify command to this end.
â A Problematic Example: Integration by Parts
Let us have a look again at the example of the Mathematica empowered Java
applet in Figure 1. The task is to compute the definite integral
∫ (1)
1
2
x
3
ln x „x .
Mathematica Empowered Applets 13
IMS08_paper_Heck_Boon_vanVelthoven.nb 4/15/08 The Mathematica Journal volume:issue © year Wolfram Media, Inc.Integrating by parts leads to the following equivalent expression:
Hln xL (2)
x
4
4
1
2
-∫
1
2 1
x
x
4
4
„x ,
which can be worked out into
4 ln 2 - ∫ (3)
1

2 x
3
4
„x
But how can we easily check equivalence of expressions (1), (2) and (3)?
Randomized equivalence testing is not possible and numerical integration
does not seem appropriate either! Only use of a computer algebra system
can really solve this equivalence problem, which is transformed into a zero
test problem (also referred to as the problem of normal form simplification)
that is in general more easily solved than the problem of bringing expressions
to their canonical form.
á Example of a Mathematica empowered Java Applet: Integration
by Parts
Verification of the final answer and the intermediate results in the 'Integration
by Parts' example shown in Figure 1 is carried out as follows. Whenever the
user enters an expression, the parser checks whether the computer algebra
system is really necessary for equivalence testing. For example, when the
mathematical notation for integration is encountered, the decision is made
that Mathematica is indeed needed and the whole expression that was
entered by the user is translated toward a Mathematica expression. This translated expression is send to a Mathematica server accessible to the user and
running in the background together with the previous expression (translated
as well according to the syntax of the Mathematica language). The computer
algebra system uses the Simplify command to verify whether the difference
between these two Mathematica expressions is equal to zero. If so, the two
expressions in the applet are equivalent and a checkmark indicating the
student that (s)he may be on the right track can be set. If a non-zero difference was obtained by the Mathematica zero test, the two expressions in the
Java applet are most probably not equivalent and appropriate feedback can
be provided. You may be worried that failure of the Mathematica zero test
does not guarantee that the expressions are non-equivalent – after all, you
may write zero in such a complicated way that even the Mathematica
command Simplify or FullSimplify cannot recognize it as zero – but it is
our experience that this does not happen for mathematical expressions at the
difficulty level of secondary school.
14 Heck, Boon, van Velthoven
The Mathematica Journal volume:issue © year Wolfram Media, Inc. IMS08_paper_Heck_Boon_vanVelthoven.nb 4/15/08á Implementation Details
Our approach is similar to WebMathematica: the student interacts via a
browser with a Java applet (entering expression, dragging objects, etc.) and
this interaction leads to one or more Mathematica expressions that are then
carried out by a Mathematica program run on a server that is accessible to
the user. The main difference is that we do not use the computer algebra
system for evaluation of each and every mathematical expression. Our
approach is simple: after the Mathematica command is carried out, the Mathematica session is 'cleaned' in that the user can no longer refer to the previous
command or result.
All communication tools are based on Java Technology: Servlet technology,
Java technology and special purpose Java technology developed for example
in the OpenMath project [6]. The Java tools govern the interaction with the
mathematical service offered by Mathematica. They make it possible to
contact the computational back engine, submit queries to the service, and
also take care of handling the responses obtained from this back engine. The
browser-webserver based architecture used for supporting the exercise
applets is shown in Figure 8.
Figure 8. The general scheme of the Mathematica empowered architecture
We explain in some detail the main components shown in this picture.
A web browser with Java support represents the client. It will present views of
the Java applets on an external server to the user, interact with the user, and
communicate user interaction (mainly mathematical expressions entered) to
the server. The responsibility for interaction is mostly on the server side.
The Java applet, which is a either a model applet or an exercise applet,
caters to presentation, communication, and context. It supports a wide range
of actions ranging from entry and handling mathematical expressions to
providing hints and offering graph tools to support the students in doing their
tasks.
The Mathematica web service serves as an interface to the computer algebra
system. We have made use of standard protocols, among which those developed by RIACA at the University of Eindhoven [7]. In short, it is sockets-based
technology that allows a Mathematica service to run the Mathematica
package across the web and that relies on a dedicated program to handle the
actual connection to/from a Mathematica engine. In order to run a Mathematica web service, a web server (e.g., Apache Tomcat) must have been set
up. A main difference with other approaches such as MathDox [8] is that in
our prototypical examples we have not yet used OpenMath technology [6] in
most applets: input to and from the Mathematica engine goes via strings in
Mathematica Empowered Applets 15
IMS08_paper_Heck_Boon_vanVelthoven.nb 4/15/08 The Mathematica Journal volume:issue © year Wolfram Media, Inc.most applets: input to and from the Mathematica engine goes via strings in
the syntax of the Mathematica language.
á Another Example of Mathematica Empowerment: Geometric
Reasoning with a Dynamic Geometry Applet
A dynamic geometry applet lets students build geometric constructions with a
digital ruler and compass. The students can test whether certain assertions
hold in their configuration. The applet is able to verify numerically these assertions for the displayed construction. The students can move the free points of
the construction to other positions and the program will automatically test the
assertions again. In popular packages like Cabri Geometry and Cinderella, a
probabilistic prover is used to verify assertions [9].
A very simple example is the midpoint theorem:
The midpoint theorem.
Let ABC be a triangle and let D and E be the midpoints of AC and BC, respectively.Then the line DE is parallel to the base AB.
Figure 9. Snapshot of the dynamic geometry applet about the midpoint theorem.
A snapshot of the dynamic geometry applet is shown in Figure 9. When
students make the construction, they may quickly conjecture the parallelism
of the two lines drawn. The system offers tools to check such facts and here
the text label in the middle of the screen informs the students that the system
agrees with the assertion of parallelism of the lines. Dragging one of the free
points A, B, or C, may convince the students about correctness of the statement.
The next step is that the students are able to verify their assertions in the
general case. This is where Mathematica comes in. The applet replaces coordinates of the free points with variables and redoes the construction symbolically. Below we discuss the approach that applies for our concrete example.
We may choose a coordinate system such that the coordinates of the five
points A, B, C, D, and E are as follows:
16 Heck, Boon, van Velthoven
The Mathematica Journal volume:issue © year Wolfram Media, Inc. IMS08_paper_Heck_Boon_vanVelthoven.nb 4/15/08AH0, 0L
è BH1, 0L
è CHx, yL
è DI
x
2
,
y
2
M
è EI
1+x
2
,
y
2
M
The statement that the line AB is parallel to DE means in algebraic form that
HxA - xBLHyD - yEL - HyA - yBLHxD - xEL = 0 . (4)
Expression (4) is fed to Mathematica.
H0 - 1L+ Iyë2 - yë2M - H0 - 0L +Ixë2 - H1 + xL ë2M 0
True
Because of our smart choice of the coordinate system, the formulas became
very simple and Mathematica could perform the above zero testing by simply
evaluating the expression entered. In general the mathematical formulas
won't be that simple and the use of a computer algebra system is needed.
Suppose that we do not make any assumption on the coordinate system, i.e.,
suppose that the coordinates of the five points are as follows:
è AHxA, yAL
è BHxB, yBL
è CHxC, yCL
è DI
xA+xC
2
,
yA+yC
2
M
è EI
xB+xC
2
,
yB+yC
2
M
In this case we must rely on the Simplify command of Mathematica.
HxA - xBL+IHyA + yCL ë2 - HyB + yCL ë2M -
HyA - yBL+IHxA + xCL ë2 - HxB + xCL ë2M 0
-
1
2
H-xB - xCL +
1
2
HxA + xCL HyA - yBL +
HxA - xBL
1
2
H-yB - yCL +
1
2
HyA + yCL 0
Simplify@%D
True
The boolean value proves that the assertion holds. Especially when intersection points or points that are constrained to a particular line or circle come into
play, one may easily get a full page formula, which Mathematica will happily
simplify to True.
Mathematica Empowered Applets 17
IMS08_paper_Heck_Boon_vanVelthoven.nb 4/15/08 The Mathematica Journal volume:issue © year Wolfram Media, Inc.Alternatively, the constraints for the points D and E can be formulated as polynomial equations.
2 xD - HxA + xCL = 0
2 yD - HyA + yCL = 0
2 xE - HxB + xCL = 0
2 yE - HyA + yCL = 0
Then the GroebnerBasis method can be applied to prove the geometric
theorem (see [10] for a short gentle introduction to the theory): Use the PolynomialReduce command on a GroebnerBasis of the constraints.
polys =
82 xD - HxA + xCL, 2 yD - HyA + yCL, 2 xE - HxB + xCL, 2 yE - HyB + yCL<;
vars = 8xA, xB, xC, xD, xE, yA, yB, yC, yD, yE<;
gb = GroebnerBasis@polys, varsD;
Last@PolynomialReduce@
HxA - xBL HyD - yEL - HyA - yBL HxD - xEL, gb, varsDD 0
True
We end this section with a few remarks on the implementation of Mathematica support in geometric theorem proving. The approach is similar to the
architecture in Figure 8. However this time the OpenMath [6] technology is
used. The Java applet will contact a servlet, sending it the configuration and
assertion in OpenMath style. This servlet then reformulates the assertion in
an algebraic expression also in OpenMath style. With this formula the servlet
will call a Mathematica service as developed by RIACA [7] after converting the
OpenMath expressions to the Mathematica syntax and vice versa.
á Conclusion
We conclude with a summary of our experiences with web-based mathematical tools for learning and practising algebra and with our ideas for future development resulting from our experience with the prototypical Mathematica
empowered Java applets that have been developed so far.
First we quote some findings on the use of school algebra applets [11]:
"It was found that the use of applets has add-on value: they are fun and motivate students; they allow students to work at their own level of thinking and
thus better address individual difference between students; the visual, interactive and dynamic features of applets makes the mathematics more easy to
understand; thanks to the calculation power of the applets one can focus on
the mathematical concepts and models; students are more creative and get
more self esteem; the applets form a model students can fall back on; the practice and feedback features are much more powerful than pencil-and-paper
exercises. However, to take fully advantage of these opportunities of applets,
applets should be integrated in the daily mathematics class routine. Using the
computed should not be a voluntary thing that is extra beyond regular math
class."
18 Heck, Boon, van Velthoven
The Mathematica Journal volume:issue © year Wolfram Media, Inc. IMS08_paper_Heck_Boon_vanVelthoven.nb 4/15/08The last issue played an important role in the GALOIS project that took place
in the period 2005-2007 [3]. This project aimed to realize an integrated
learning environment for learning and doing mathematics in which
è students can practise mathematics anytime and anywhere;
è mathematical assignments can be generated 'at random', so that the
amount of exercise material becomes unlimited; mathematical
assignments can be generated 'at random', so that the amount of
exercise material becomes unlimited;
è activities and answers of students are stored;
è intelligent feedback on students' work is given automatically.
This project and its one-year extension project SAGE led much to the work
presented in this article. We quote the conclusion drawn in [3]:
"Existing mathematical tools become even more powerful and useful when

results and performance of students can be tracked online in a virtual learning
environment with which teachers and students are familiar. Use of a common
standard, in this case SCORM, enables the sharing of content, but also of
storing student performance. Students know that they can be and are monitored by their teacher. Together with other features in virtual learning environments, especially for communication, students are stimulated to do their homework, or even more than that. Students do not seem to mind this 'big brother
is watching you' concept. On the contrary, they seem to appreciate the fact
that a teacher has good insight into common mistakes and can use this knowledge to address certain problems more effectively. They also seem to find
that computer practice prepares them better for written exams than making
assignments from a book. Computer aided learning is also seen as a more
'fun' way of practicing otherwise 'boring' subjects. Using direct feedback,
giving students hints and enabling a 'trial and error' approach makes it
possible for students to explore different strategies for solving a given
problem.
In our opinion, digital assignments and diagnostic testing add to the motivation and performance of students in mathematics education. By making use of
computers, the extra time involved for teachers is acceptable. Contact time
can effectively be reorganized because students that need extra attention are
signaled earlier."
In field tests at schools during the past projects it was found that all works
well in practice, although many wishes for improvement of the software arose
at these staged of the development work. Linking the applets to a backbone
computer algebra system and having more question types at one's disposal
were two of the envisioned extensions. The first steps to meet the first wish
have been made with the Mathematica empowered Java applets.

About the Authors
André Heck earned MSc degrees in mathematics and chemistry. He is project manager at the
Faculty of Science of the University of Amsterdam. His research area is the application of ICT
in mathematics and science education.
Peter Boon is developer of educational software at the Freudenthal Institute for Science and
Mathematics Education and the principal architect of the applets for learning mathematics and
the digital mathematics environment.
Wim van Velthoven has degrees in physics and education. He is software developer at the
Freudenthal Institute for Science and Mathematics Education, mostly developing applets for
primary and secondary education.

Research on e-Learning and ICT in Education
Information and Communication Technologies (ICT) have had a huge impact on
contemporary society, fundamentally changing the way that we communicate,
work, and entertain. Education is one of the fi elds where ICT applications have
been used extensively over the years.
In the early days of computers, educators saw the potential of digital material to
improve education, at least from a management and economic point of view: digital
content can be easily managed and distributed to large groups of learners. With the
rapid evolution of computers (with increased processing power, screen displays, and
usability) digital learning materials offered additional affordances over "traditional"
print materials that can signifi cantly improve the quality of education such as
multimedia (i.e., multiple representations of the learning material), hypermedia
(i.e., non-serial access to the learning material), and interactivity (i.e., active engagement with the learning material). This gave birth to a whole new series of initiatives
around the world from ministries, educational organizations, companies, etc., who
developed digital learning resources and educational software.
With the advent of the Internet and the web, educators realized the tremendous
potential for distributing the digital learning materials and for supporting new forms
of web-based learning. This resulted in the development of e-Learning systems, which
mainly support the sharing of digital learning material and facilitate the communication between learners and educators. At the same time, lifelong learning emerged
as a vital necessity since all citizens need to be educated throughout their lives in
order to remain competitive in the knowledge-based economy. To meet these needs
of supporting access to education and training to anyone, anytime, anyplace, the
e-Learning industry has experienced rapid growth over the past decade becoming
the second largest industry evolving around the Internet and the web (second only
to the e-Health industry).
In this context, the fi eld of ICT in Education and e-Learning in particular has
attracted increasing research interest worldwide during the past decades. This
research is constantly evolving, especially since technology itself is also evolving at
rapid pace and new devices, solutions, and practices are becoming increasingly vi
available. This extensive research interest in the potential of technology to support
learning has led to a considerable body of knowledge. Still, many issues remain
open such as:
• How can ICT improve learning in preschool and primary education settings?
• How can it improve teaching of programming?
• How can the new Web 2.0 tools support learning in different educational settings?
• How can technology be used to support learning in museums and other cultural
institutions?
• How can teachers use ICT to improve teaching and learning practices?
This volume aims to contribute to the literature in ICT in Education and
e- Learning by addressing several core issues. The Volume includes 19 chapters
which cover a wide variety of topics.
• The fi rst part includes three chapters which attempt to situate ICT in the broader
educational context. Underwood questions why digital technology has penetrated our lives so much, but has failed to make an impact in the classroom.
Mikropoulos , Sampson , Nikopoulos , and Pintelas explore the evolution of educational
technology through a bibliometric study. Apostolopoulou , Panagiotakopoulos ,
and Karatrantou conclude this part through an investigation of the learning theories underlying the development of educational applications for supporting
teaching and learning of Mathematics, Physics, and Chemistry in Secondary
Education.
• The second part includes three chapters which focus on ICT use in preschool and
primary school settings. Nikolopoulou investigates how educational software is
used in kindergartens. Zaranis examines how ICT can facilitate fi rst graders'
Geometry concepts. Halki and Politis investigate how educational software
affects the learning outcomes of primary school students in high level skills of
critical thinking and programming.
• The third part includes two chapters which address the teaching of programming
concepts through ICT. Malliarakis , Satratzemi , and Xinogalos investigate teaching
of programming through educational games. Misirli and Komis also target programming through robotics in the context of early childhood education.
• The fourth part includes three chapters which investigate how Web 2.0 technologies can affect education. Eteokleous - Grigoriou and Photiou investigate how
blogs can be integrated in primary education. Altanopoulou , Katsanos , and
Tselios investigate the effectiveness of Wikis in undergraduate education.
Kazanidis , Valsamidis , Kontogiannis , and Karakos address the evaluation of
courseware at the exams, usage, and content level.
• The fi fth part includes two chapters which explore technology-based learning in
museums and cultural institutions. Yiannoutsou and Avouris propose the use of
digital games as a means to actively involve museum visitors to participate in the
process of culture creation. Nikonanou and Bounia discuss digital applications
created by museums and other cultural institutions.
• The sixth part includes three chapters which investigate how ICT affects Pre- and
In-service teachers and their practices. Karasavvidis and Kollias examine the
Research on e-Learning and ICT in Educationvii
ways in-service teachers integrate technology in their designs after an extensive
Professional Development Training program. Khaneboubi and Beauné investigate the effect of ICT in French middle schools involved in a national endowment program on digital textbooks. Vekiri investigates the challenges and needs
that should be addressed in teacher preparation for educational technology.
• Finally, the seventh part includes three chapters which address specialized topics
in ICT in Education. Tegos , Karakostas , and Demetriadis address conversational
pedagogical agents in individual and collaborative learning settings. Apostolidis
and Tsiatsos present a prototype device that measures the anxiety level of a person
by collecting bio-signals. Chatzara , Karagiannidis , Mavropoulou , and Stamatis
discuss the potential value of using Digital Storytelling for teaching social skills
to children with Autism Spectrum Disorders.
The following sections describe the parts and chapters in detail.
Part I: Situating ICT in Education
Underwood questions why digital technology is a ubiquitous tool outside of the
classroom but is less well received within the classroom. She addresses the questions

of what happens if we—the educators—fail to embrace technology, and if technology
could take education out of the classroom and the hands of educators themselves. The
chapter proposes that digital technologies can act as a change agent, a galvanizing
force in a way that other previous innovations have failed to do. In doing so, we may
need to "merge and evolve," i.e., educators allow ourselves to adapt and respond to
the possibilities afforded by the technology and embrace innovation.
Mikropoulos , Sampson , Nikopoulos , and Pintelas explore the evolution of educational technology through a bibliometric study. They analyze the 849 papers presented
in a specifi c series of educational technology conferences (HCICTE from 2000 to
2012), in order to study the e-Learning scientifi c community in Greece, to identify the
evolution of salient topics, and the emergence of the trends in the fi eld. Their analysis
reveals that there is a wide involvement of researchers in e-Learning innovations at
schools and less basic and applied technological research, indicating the need for a
more balanced research in both theoretical issues and technological aspects.
Apostolopoulou , Panagiotakopoulos , and Karatrantou investigate the learning
theories underlying the development of educational applications for supporting
teaching and learning of Mathematics, Physics, and Chemistry in Secondary
Education. They argue that it is important for teachers to be able to recognize the
theories behind these educational applications, in order to utilize them in the
most effective way. Their study involved 50 in-service teachers who answered a
questionnaire, and 3 teacher trainers who were interviewed. The results showed that
there is an increasing tendency towards the utilization of the Theories of Construction
of knowledge, and that the perceptions of the in-service teachers are in agreement
with the aims of the developers of the applications.
Research on e-Learning and ICT in Educationviii
Part II: ICT in Preschool and Primary Education
Nikolopoulou investigates educational software use in kindergartens. She interviews
25 teachers from 17 Greek kindergartens to identify the educational software commonly used by children in the classes, how this software is used, and the main diffi -
culties children face in the use of this educational software. Her analysis reveals that
a variety of educational software is used in these classes, most of them being
open-ended software aiming to advance language, reading, and writing skills. The
main diffi culties that children face with the use of this software are related to the
requisite motor skills and the language readiness required for their operation.
Zaranis investigates how ICT can improve fi rst grade students' basic geometry achievement, especially regarding circles and triangles. He employs the
Realistic Mathematics Education (RME) and the van Hiele models, and compares it against the "traditional" teaching methodology. He experiments with two
student groups involving 234 fi rst graders, and concludes that teaching and learning through ICT is an interactive process for students at the fi rst grade level and
has a positive effect for learning Geometric concepts when employing RME and
the van Hiele model.
Halki and Politis investigate the use of ICT for improving critical thinking and
programming skills of primary school children. They experiment with two student
groups, one using the Scratch educational programming language and the other
educational games and experiential learning. They conclude that the two groups
presented almost same results in most learning outcomes they examined. The differentiation referred only to debugging skills (which were higher for the group
using the Scratch), and to cooperativeness and teamwork skills (which were higher
for the group without ICT support).
Part III: ICT and Teaching Programming
Malliarakis , Satratzemi , and Xinogalos examine the teaching of programming
through educational games. They offer a critical review of the most well-known
educational games for teaching programming, which can guide the development of
future applications. Their analysis is based on a framework which summarizes the
functionality that should be supported by educational games for teaching programming. The proposed framework has been based on an analysis of 70 papers from the
related literature.
Misirli and Komis address the teaching of programming for early childhood education through robotics. They propose a conceptual framework for designing educational scenarios that integrate programmable toys as a guide to teaching programming
concepts. Their framework involves seven phases for designing educational scenarios, including identifi cation of the teaching subject, identifi cation of children's
prior knowledge, determination of scenario goals, selection of ICT teaching materials,
Research on e-Learning and ICT in Educationix
design of scenario activities, scenario assessment, and scenario documentation.
Their framework has been tested and verifi ed by 46 educators on 864 children
between the ages of 4-6.
Part IV: Web 2.0 Tools and Learning
Eteokleous - Grigoriou and Photiou investigate the integration of Blogs as tools in
primary education, and describe the development of a Community of Inquiry (CoI)
within a blended learning environment developed through hybrid learning. They
analyze the social, cognitive, and teaching presence within a CoI in a specifi c class,
where students use a blog to achieve specifi c learning objectives. The results of the
study reveal the development of a CoI through a blended learning environment and
the potential of using blogs as tools to achieve specifi c learning objectives, and
highlight the important role of the educator and lesson's design.
Altanopoulou , Katsanos , and Tselios investigate the effectiveness of a framed
wiki-based learning activity. They report a study which involve 139 fi rst year undergraduates who used Wikis to learn about Web 2.0 and its applications in the
context of an introductory course. The study demonstrated signifi cant improvement
in learning outcomes, both for students with low and high initial performance.
In addition, it was found that students benefi ted from the activity regardless of their
role in the Wiki project. Furthermore, results showed that students with a higher
number of logged Wiki actions had a signifi cantly higher learning gain compared to
those that were less active.
Kazanidis , Valsamidis , Kontogiannis , and Karakos propose a method which
evaluates courseware at the exams, usage, and content level. It defi nes different
measures and metrics for each level, and it uses data mining techniques, such as
classifi cation, clustering, association rule mining, and regression analysis, in order
to discover possible dependencies of the e-learning data. The proposed method was
successfully tested to e-learning data from a Greek University, and the results con-
fi rmed the validity of the approach and showed a relationship among the components of the proposed three-level schema.
Part V: ICT for Learning in Museums
Yiannoutsou and Avouris analyze two different trends that have informed technology
for learning in cultural institutions during recent years. The fi rst one supports the
information consumption metaphor where museums produce "information" in digital
or other form for the visitor to consume, while the second one invites visitors to participate in the process of culture creation. They then discuss game design as an example of participatory activity and they identify its learning dimensions. They analyze
the role of technology in providing a scaffold that can help museum audience to
Research on e-Learning and ICT in Educationx
construct games which can function as "public artifacts" and can be added to the
museum's assets, enhancing audience engagement and community building.
Nikonanou and Bounia present a qualitative evaluation study of digital applications created by Greek museums and other cultural institutions during the past
few years. The study is based on contemporary theoretical approaches in the fi eld
of museum education and aims to explore the extent to which these approaches
are taken into account when designing a digital application for museum education use. The research highlights that there is a growing interest in developing
ICT applications on the part of the museums, but also that there are many possibilities regarding interactivity, active involvement, collaboration, and creative
expression that are still open for consideration and exploitation by cultural
institutions.
Part VI: ICT and Pre- and In-service Teacher Practices
Karasavvidis and Kollias aimed to bridge the knowledge gap of how specifi c teacher
groups respond to in-service Professional Development Training (PDT) on ICT
pedagogy. They examined how teachers' backgrounds infl uence their responses to
an extensive PDT program. They report data from a multiple case study involving
three in-service teachers who had constructivist teaching philosophies and high academic qualifi cations. The study inquired whether the teachers integrated technology
in ways that supported or transformed their existing practices. The fi rst study fi nding is that the teachers integrated technology in their designs in ways that supported
their existing practices, closely following the dominant science education paradigm
in Greece. The second study fi nding is that the teacher participants were very reluctant
to consider other types of technology integration that would lead to more transformative teaching practices. The authors conclude that their results cast serious doubts
on the potential of contemporary PDT programs to transform teaching practices
through technology and discuss the implications of their work for future conceptualizations of PDT.
Khaneboubi and Beauné investigate the effect of ICT in four French middle
schools involved in a national endowment program on digital textbooks. The analysis of two datasets collected in 2010 and 2012, involving 89 teachers, provides useful insights into the school dynamics in this context. The use of technologies by
teachers in the classrooms seems to be determined by the quality of infrastructure
and equipment reliability. Gender and seniority appear as discriminating factors in
the perception of technologies' availability. And teachers in charge of pedagogical
uses of ICT in each school are almost exclusively sought for technical support.
Vekiri investigates the challenges and needs that should be addressed in teacher
preparation for educational technology. She presents a study which analyzed 30 pre-
service elementary school teachers' lesson plans, representing their fi rst attempts to
Research on e-Learning and ICT in Educationxi
design a web-based lesson. The analysis focused on the types of activities they had
designed, the characteristics of the web resources they had selected, and the scaffolding techniques they had planned to use to support their students. Study fi ndings
highlight that, in order to use the Internet productively and creatively, teachers need
to develop complex forms of knowledge that require the integration of knowledge
about technology, pedagogy, and content.
Part VII: ICT for Specialized Uses
Tegos , Karakostas , and Demetriadis address conversational pedagogical agents
which can guide and scaffold student dialogue using natural language in both individual and collaborative learning settings. They present the results of an experimental collaborative learning activity exploring whether the different agent roles (peer
or tutor) may affect the students' perceptions of the agent or their conversational
style in their responses to it. The study fi ndings provide valuable insights into how
the different agent' appearance and communication styles can have an impact on the
degree of formality in students' utterances.
Apostolidis and Tsiatsos present a prototype device that measures the anxiety
level of a person by collecting bio-signals, namely Galvanic Skin Response and
Photoplethysmography. They pilot-tested their device with 13 students, who suggested that the anxiety measurement may be useful to learning activities such as
examinations and workshops, that they are willing to reuse these sensors in other
academic activities, and that stress level awareness can motivate students to
regulate themselves.
Chatzara , Karagiannidis , Mavropoulou , and Stamatis discuss the potential value
of using Digital Storytelling for teaching social skills to children with Autism
Spectrum Disorders. They present the DiSSA (Digital Structured Storytelling for
Autism) tool, a software application for creating digital stories following a structured approach. The system is aimed to cater for the needs of students in the autistic
spectrum, taking advantage of structured teaching in the design of the application.
It accommodates user's performance data towards the learning outcomes and
thereby provides feedback to other users (such as, teachers or parents) about children's
progress. DiSSA has been pilot-tested with four pupils (7-11 years) with a formal
diagnosis of mild autism, and has demonstrated to be successful in terms of user
satisfaction and user task accomplishment.
We would like to express our deepest appreciation to a large number of people
who helped us towards the publication of this Volume. First of all to the Hellenic
ICT in Education Society who entrusted us with the organization of the HCICTE
2012 Conference and the editing of this volume. We would like to thank all the book
contributors for submitting their work and for collaborating closely with us during
Research on e-Learning and ICT in Educationxii
the course of a very long reviewing and revision process. We extend our gratitude to
all the colleagues who have signifi cantly assisted in evaluating and improving the
chapters featured in the present volume through their review comments. Finally,
many thanks to Melissa James and Joseph Quatela from Springer US for their help
and excellent collaboration.

Naturally Resistant

Although many in education would argue that we are in a constant state of fl ux the changes, irritating though they may be, are often superfi cial. As Papert (1993) has argued the education system is highly resistant to change. The proposition explored in this chapter is that digital technologies can act as a change agent, a galvanising force in a way that other previous innovations have failed to do so. This places high expectations on the use of the technology but can it deliver? There are still many who doubt the usefulness of such technologies in the classroom, yet we are very accepting of digital tools in our daily life. Why is this the case? While plotting a timeline of technological development, and even projecting into the future, is a relatively simple task, assessing the impact of those technological developments on teaching and learning is far more problematic. The underlying ambivalence to the educational use of technology makes future projections diffi cult, and at fi rst sight the prospects are not encouraging.

A Brief History of Digital Technology

Learning technologies are not a recent idea although it is no easy matter to identify their inception; they are as old as written language itself (Westera, 2010). For a long time the slate and the chalkboard were the dominant educational technologies, but the twentieth century proved to be a century of rapid technological advance inside and outside of the classroom. First technologies such as fi lm and radio were added

Digital Technologies: An Effective Educational
Change Agent?

e-mail: jean.underwood@ntu.ac.uk4

to the teacher's toolbox, and then, towards the end of the last century, digital technologies fi rst crept and then thrust themselves onto the educational scene. Digital technologies are different from previous technologies in a number of ways not least because they are in a constant state of rapid evolution. This is clearly illustrated by Apple's i-Phone. Just a few years ago Apple released this touchscreen 2G (second generation, that is, digital) mobile phone, which I purchased with pride. It was not just a phone of course; it came with Internet access, a camera, note pad and much more. It was a communication system and mini-offi ce all rolled into one. Four years on and my i-Phone became a poor relation of its 3G cousin the i-Phone 3. As is the way of each new generation of such technologies, the i-Phone 3 was of course faster and had greater memory capacity and enhanced functionalities such video capture and streaming alongside the still image camera. However it too has been superceded by new generations of i-Phones. My fi rst-generation i-Phone is not able to play the cult game "Angry Birds" nor does it allow me to access You-Tube clips or have face-to-face real-time conversations.

That such an iconic object as the original i-Phone became effectively obsolete in less than 4 years, and its successor in even less time than that, graphically illustrates the speed and nature of technology development, which, on the whole, have improved what already exists and also added new functionalities. These new functionalities have resulted in a rapid move towards the personalisation of content, where every user has his or her own custom distribution channel. However, although the technology has become more powerful, that is, it has more on-board memory, a more powerful central processing units (CPU), and most signifi cantly wireless network access, we fi nd activities such as playing "Angry Birds" or sending short video clips absorb all the additional power. This has resulted in a new industry supplying digital storage space in the "clouds". Large clusters of networked servers supply vast processing power and storage capacity at low cost removing the need for large personal data stores for your personal images or music fi les (Johnson, Levine, & Smith, 2009).

So the technology is faster, more powerful and has greater functionality at a reduced cost, and yet it still disappoints because we want more.

And the Impact of That Technology Is?

As technology has spread through our society new behaviours and new ways of working have emerged; for instance mobile phones have become indispensable to the operation of small independent businesses. This is how we now contact our local plumber or electrician (Crabtree & Roberts, 2003). Further it has become a ubiquitous tool of the young. In the UK over 90 % of all 11-21-year-olds had access to a mobile phone (Haste, 2005), and by 2006 49 % of 8-11-year-olds and 82 % of 12-15-yearolds had their own phones (OfCom, 2006). Moreover, 82 % of 8-11-year-olds and 93 % of 12-15-year-olds spent time texting. Texting has become such a widespread and valued activity among many young learners (c.f., Plester & Wood, 2009).

J. Underwood5

Typically 16-24-year-olds spend more time on their mobile phones and social networking sites than watching television (OfCom, 2010).

Other changes have been seismic shifts rather than modifi cations of behaviour. For example, few would have predicted the impact of technology on news reporting, an impact that has led to the rise of the citizen reporter. Armed with a camera phone anyone can be both reporter and editor of current events. What was once hidden is now exposed across the world on You-Tube, often before the offi cial news networks. Such changes necessarily affect the structures of a society. The result is that institutions fi nd themselves unable to handle key changes in the rhythms and patterns of emerging human behaviours, and so new or transformed institutions emerge. Thus the Iranian Government made a huge effort to block images and news reports of the violence following the 2009 elections, but there was still leakage of news (Palser, 2009). However in the USA political structure was transformed post the 2008 presidential elections, which were won and lost in cyberspace. The now US President Obama had three times as many supporters signed up on Facebook than his republican rival John McCain, and 500 million blog posts mentioned Obama compared to 150 mentioning McCain (Aronson, 2012). Obama managed to do what many politicians in the West have failed to, that is, engage a new generation in politics by using their preferred communication tools.

And the Impact on Education Is?

Learners of all ages are exhibiting new behaviours as a result of these ubiquitous high-functioning technologies. Changes may be relatively mundane, such as replacing the school satchel with a memory stick, or profound, as when learners seek out expertise beyond the traditional classroom or move from text to more visual modes of representation. For example we reported on two primary schools, both of which were linked to the same theatre group in order to write a play as part of the web play

project (Underwood et al., 2005). While signifi cant, these changes are not necessarily transformational, but it could be argued that given the formal framework of education such transformation may not be possible. Lowendahl (2009) argues that the education system has a history of resistance to change, a resistance born out of disappointment when the "hype cycle" of technology in education fails to deliver. This cycle which starts with a techno-romantic phase often leads to disillusionment when the technology fails to deliver nirvana. There is then a need to pass through to a slope of enlightenment, that is, to make a realistic assessment of what technology can and cannot do, before reaching a plateau of productivity when the technology actually delivers to realistic goals.
Both students and tutors have been shown to underuse many high-level functions such as the communication tools (Sclater, 2010), and teachers often fi nd the more advanced functionalities diffi cult to customise (Severance, Hardin & Whyte, 2008). Our own research has shown that while there have been signifi cant advances in educational technology they have not always brought about measurable shifts in

user behaviour. A study of learning platform use in eight technically savvy English secondary schools (Underwood & Stiller, 2014) showed that while teachers' intentions to use the range of functions available to them on the learning platform varied from extensive to as little as possible, those expressing a desire to use the system creatively found themselves held back by mundane barriers associated with time, personal skills and curriculum demands. Innovative uses of blogs, wikis, and other tools remained aspirational at best even in these schools where technology innovation, at a surface level at least, was actively encouraged.
So while Lowendahl calls for more realism and less hype in technology innovation and acceptance, Westera (2010) argues that the main barrier to effective embedding of technology is a little too much realism. The computer has been used as a sensible teaching aid, quite useful for a specifi c subset of learning activities, but it has never challenged the educational system as a whole. Resnick (2006) picks up this argument by raising the following question: "'Which is the odd one out: the television, the computer or the paintbrush?'" He argues that the potential of digital technologies will not be realised until we think of them as modern equivalents of the paintbrush and not as televisions. That is, we need to start seeing computers not simply as information machines but also as a new medium for creative design and expression.
Although those of us who teach see ourselves as innovators, the truth is that change in education is very slow. Seymour Papert (1993) graphically depicted the immovability of education in his story about surgeons and teachers. He argued that a surgeon from a century ago would not recognise a modern operating room but while a teacher might be puzzled by some of the resources in the new classroom, he or she would nevertheless feel at home. Papert posed the question as to why, when so much has changed over the last century, there has not been a comparable change in the way we educate our children. It is not because new tools, the equivalent of the surgeon's heart monitor machine, do not exist. So is it because teachers are inherently resistant to change? While we are cautious professionals we are not Luddites,
1
entrenched
opponents of change. The slow pace of change is more to do with need. Medical practice needed to change because people were dying, but traditional methods of teaching do result in children learning, so why are we in such a hurry to change?
So Why Change?
From Aviram and Talmi's (2005) point of view, the centrality of digital technologies in education is both assured and inevitable. That perceived inevitability is built on the assumption of the omnipresence of ICT in our everyday lives and the rise of the generation of digital natives (Prensky, 2001). Indeed Prensky argues that today's students are no longer the people our educational system was designed to teach.
1
Luddites: Workers who violently resisted the introduction of new machinery into the textile industry in nineteenth-century England.

Teachers are told that they have to attract students' interest and attention (Simplicio, 2000), recognising that learners are growing up surrounded by video games, mobile phones and other digital media, all of which are leading to new learner expectations of an acceptable educational environment (Pedró, 2006). However, Watson (2001) queries the automatic link made between the everyday and educational uses of technology, as it does not take into account the fact that technology often fi ts uncomfortably with teachers' professional judgments. In support of Watson's analysis, the evidence shows that technologies that move teachers outside their comfort zone tend to have a slower take-up and high rejection rates. The conclusion from our own work is that positive impacts are more likely when linked to a teacher's existing pedagogical philosophy, hence the rapid acceptance of interactive whiteboards (IWB) compared to virtual learning (Underwood et al., 2010). Indeed half of the teachers we interviewed identifi ed the IWB as their "must-have" technology. However, some teachers expressed unease with this position, for example stating "IWB and PowerPoint, sadly ...", acknowledging that there were other more exciting ways of using technology although they were not exploiting these opportunities themselves. The discontinuity between teachers and technology may be more deep-seated than a clash with professional practice though. It may lie in the nature of those who choose to teach. For example, it is not age or sex but membership of the teaching profession that is the defi ning characteristic of low involvement with video games (Sandford, Ulksak, Facer & Rudd, 2006). Books are the preferred tool of this group as a whole. If teachers, as a group, are inherently low technology users compared to the general population, does this mean that there is a natural resistance to the embedding of technology into the educational processes and practices? While this rather negative portrayal of the teaching profession may be valid in some cases, our evidence of a decade of national research projects presents a more positive picture of a profession that is cautious but constructive in its approach to innovation.
Three Possible Ways Forward
It has long been argued that any good teaching system aligns the teaching method and assessment to the stated learning objectives (Lebrun, 2007). How do we achieve this alignment? There are broadly three strategic responses to the demands to go digital (Underwood & Dillon, 2011).
1. Minimise the use of technology : This approach minimises the demands on teachers and maintains the status quo. However, such a strategy raises very real issues of equality. Those learners with access to technology outside of the school will be advantaged, leaving a digital underclass of learners who lack either the economic or the cultural support that would make these technology tools available to them.
2. Use technology to support current practice : Accept technology where it fi ts current educational structures and practices. This approach recognises technology as a useful tool in the right place but removes the role of catalyst for change. So we fi nd that some innovations are more readily assimilated into the classroom than

others; for example digital whiteboards is a case in point. However other ubiquitous technologies such as 3G phones have minimal impact (Wang, Shen, Novak, & Pan, 2009) and are resisted by teacher unions (Robinson, 2010). This way forward feels comfortable and of course is in widespread use. However, there is an inherent risk that such use will lead to learner disaffection and rejection of the educational process, particularly in the case of the digitally savvy learner.
3. Merge and evolve : Here, we educators allow ourselves to adapt and respond to the possibilities afforded by the technology and embrace innovation. The approach recognises that digital technologies necessarily require us to reassess how learners learn and teachers teach. From this perspective we need to think about how schools or learning ecologies are organised, including the role of technology, to support meaningful student achievement. Schools will move to be more open educational institutions that "dramatically change their views on knowledge, assessment and the teacher, student and information relationships" (Hernandez & Goodison, 2004 , p. xvi). One such example is the emergence of the personal web that will allow learners and teachers to customise the web to their own needs and interests using a range of data management and tracking tools. A second example would be the simulated contexts provided by virtual environments in which participants interact with digital objects and tools, such as historical photographs or virtual microscopes (Clarke-Midura & Dede, 2010).
But Even If We Decide to Merge and Evolve?
The Perils of Joining the Net Generation
In 2009 a comparison of faculty and student responses indicates that students were much more likely than faculty to use Facebook and were signifi cantly more open to the possibility of using Facebook and similar technologies to support classroom work. Faculty members were predisposed to use more "traditional" technologies such as email (Roblyer et al., 2010). However, there are tutors who have joined the Facebook generation, and in doing so they have taken the decision to merge and evolve. However, this brings its own perils. Just as we, the tutors, begin to feel in charge of the technology we are reminded that the potential risks of the digital world are not just for learners but for tutors as well.
A study by Sleigh, Smith, and Laboe (2013) of students' responses to tutors' Facebook pages is illuminating. They examined whether the specifi c type of self-disclosure on a tutor's profi le would affect students' perceptions of the tutor including their expectations of the tutor's classroom practice. Students reported being most interested in professional information on a tutor's Facebook profi le, yet they reported being least infl uenced by that professional profi le. They found that tutors who were seen as social individuals had high popularity ratings but the sting in the tail was that, although their profi les were viewed as entertaining, they were judged as inappropriate for a professional. This perception resulted in such tutors

being assessed as less skilled professionally. It would appear that students form perceptions about the classroom environment and about their tutors based on the specifi c details disclosed in tutors' Facebook profi les.
So while tapping into students' interest SNSs may be an effective way for tutors and institutions to communicate and stimulate their students (Junco, 2011), the technology can be revealing and the students' developing perceptions and expectations may not always be what we intended or desired.
And Then There Are MOOCs
Massive open online courses (MOOCs) may seem somewhat tangential to what has gone before in this short piece, but they raise considerable issues for educators and possibly learners too. They are the dream scenario:
Nothing has more potential to unlock a billion more brains to solve the world's biggest problems. And nothing has more potential to enable us to reimagine higher education than the massive open online course, or MOOC, platforms that are being developed by the likes of Stanford and the Massachusetts Institute of Technology and companies like Coursera and Udacity. (Friedman, 2013 , page SR1)
So what are MOOCs, and why are they arousing such interest? MOOCs have been developed to support large-scale, open-access participation that includes varying levels of interaction. While such systems can appear prosaic at fi rst sight, delivering traditional course materials such as videos, readings and exercises through the web, it is the use of interactive user forums designed to build a community of learners and tutors that elevates the MOOC from a delivery system to a new approach to knowledge and learning. Such knowledge, according to Downes (2005), is created by interaction and is not simply a relationship or a distributive pattern between one fact or idea and another. In essence connective knowledge is knowledge of the connection.
For a connectivist dynamic system to exist, Downes (2005) argues that there must be learner autonomy, group diversity, openness and interactivity and connectedness defi ned as follows:
1. Autonomy—The level of learner autonomy must be high, and the learners must be more than simply managed participants who receive rather than create of knowledge.
2. Diversity—The community will have a diverse membership and not be a self-perpetuating in-group maintaining the status quo and stifl ing new ideas and connections.
3. Openness—This will support free-fl owing communication at various levels of activities with easy access for participants with no clear boundaries between membership and non-membership.
4. Interactivity and connectedness will produce knowledge that is unique within the community. Such knowledge will very likely be complex, representing not simple statements of fact or principle, but rather refl ecting a community response to complex phenomena.

However, this utopian dream often falls short even in networks that are open and allow autonomy as only certain perspectives of those of participants occupying the highly connected nodes tend to be circulated to the network as a whole for consideration.
The University of Manitoba delivered an early interpretation of the MOOC principles in the autumn term of 2008. Predicated on this new perception of knowledge and way of learning "connectionism" (Downes, 2005 ; Siemens, 2004), CCK08 was designed to enable participants to engage with the theory and practice of connectivism. Over 2,000 participants signed up for the course, including Mackness, Mak and Williams (2010) who were keen to explore the Downes's model of learning in practice. They found that all four characteristics of a MOOC, autonomy, diversity, openness and connectedness/interactivity, were present in the MOOC, but that they did not necessarily lead to an effective learning experience. The more autonomous, diverse and open the course, and the more connected the learners, the more the potential for their learning to be limited by the lack of structure, support and moderation normally associated with an online course. These students fell back engaging in traditional groups as opposed to the open network. The fi nding that there can be too much autonomy has already established in other learning situations (Underwood et al., 2010). These responses constrain the possibility of having the positive experiences of autonomy, diversity, openness and connectedness/interactivity normally expected of an online network. The research suggests that the question of whether a large open online network can be fused with a course has yet to be resolved. Further research studies with larger samples are needed, as is an investigation into the ethical considerations that may need to be taken into account when testing new theory and practice on course participants.
However, the nightmare scenario would see MOOCs as leading to the demise of universities, colleges and even upper secondary or high school education
I believe that online education will be an important building block of teaching in the future…I see great potential in having the opportunity to learn no matter where you are. You don't need to be in school or in a lecture hall of a university anymore, and therefore I believe that this will dramatically change our lives.
(Dr. Angela Merkel, Chancellor of the Federal Republic of Germany (https://moocfellowship.org/ 2013, no page)
One cannot deny the size of the MOOC impact on higher education, for example:
Mitch Duneier, a Princeton sociology professor, wrote an essay in The Chronicle of Higher Education in the fall about his experience teaching a class through Coursera: "A few months ago, just as the campus of Princeton University had grown nearly silent after commencement, 40,000 students from 113 countries arrived here via the Internet to take a free course in introductory sociology. (Friedman, 2013 , no page)
Further the fi rst UK-based MOOC platform, FutureLearn, is intended to go live in autumn 2013. It will be populated by MOOC courses designed by its 21 member institutions. It is estimated that it will cost about £30,000 (35,000 euros) to develop a MOOC for this platform (Parr, 2013a). While MOOCs can be linked to other tools such as Facebook such linkage can result in negative consequences. For example,

Kop, Fournier and Mak (2011) found that students had privacy and security concerns about Facebook. It would appear that the level of trust, feelings of confi dence and the sense of presence and community are crucial to students engaging with the system, and Facebook leaves them uneasy.
But There Is a Twist in the Tail
Completion rates for MOOC courses, defi ned by the number of students being awarded some form of certifi cate, are alarmingly low. The Times Higher Education quotes an average fi gure of 7 %, that is, 93 % of students failing to complete such courses (Parr, 2013b). There is signifi cant variation in these rates as is shown by the following three courses, all mounted on Coursera (Jordan, 2013). A History of the World course at Princeton University which ran 2012-2013 is recorded as having the poorest completion rate at 0.7 % of students enrolled; that is, 581 of the 83,00

who enrolled were certifi cated. However the University of Edinburgh had a completion rate of 2.3 % for its Artifi cial Intelligence Planning in 2013, that is, 660 students out of 28,689 students enrolled on the course. The most successful course in terms of completion rates according to Jordan was a course in Functional Programming Principles from the Ecole Polytechnique Fédérale de Lausanne from 2012-09 to 2012-11. Here 19.2 % completed the course, that is, 9,600 students out of the 50,000 who enrolled.
The headline fi ndings from Jordan's (2013) data are encouraging for those who would hold back the march of online teaching and learning. However, look deeper and you will see that the World History course made assignment completion optional. This suggests that the course was designed with more than one audience in mind. Yes there were students of history seeking qualifi cation, but there were also those who were simply interested in the topic, many of whom I would surmise are learners of the third age, that is, retirees coming back to a subject that interested them in the past but was not seen as providing job skills when younger. How many students are enrolling on these courses as top-up, tasters or as a hobby is yet to be established. The fi ndings from the Edinburgh and Lausanne courses might be of greater concern, as these are not "hobby" subjects for most people. However, even here the numbers passing the course are not insignifi cant; 9,600 completions in the case of the Lausanne course should not be viewed as an inconsequential with the potential to impact on more traditionally provided courses. That really is cost- effective education.
Where Do You Stand?
Attempts to bed in new technologies necessarily involve some level of disturbance to the educational system. The degree to which these perturbations are tolerated will affect technology acceptance. This raises the question of whether the educational
Digital Technologies: An Effective Educational Change Agent?12
system will allow itself to be transformed or not although the rise of MOOCs may take these decisions out of the hands of educational establishment at least at the university level even if schools are more future proof.
Of course there is always that cynical old "truism". In the UK education circles it has long been the belief that universities will survive all educational revolutions because in the end the middle classes have to send their children somewhere to fi nd suitable husbands and wives. With the advent of social networking and online dating even this role is now under threat.
The equally cynical view of schools as state-provided babysitting services has yet to be questioned although one can see the rise of plugged-in children. In the end if we do not adapt then for some learners the educational system will become increasingly irrelevant and they will carve out a learning environment for themselves, dipping into the formal system only when they see the need. As Prensky (2001) points out we ignore the fundamental fact that in a digital world the students themselves have changed. Will we as educators change with them or will the majority of us become increasingly less relevant?

Introduction
During the past years, the increased interest for applying technology to improve learning and teaching (Spector, 2012) has led to the evolution of this discipline from educational technology (ET) defi ned as "the study and ethical practice of facilitating learning and improving performance by creating, using, and managing appropriate technological processes and resources" (Januszewski & Molenda, 2008) to technology-enhanced learning (TeL) referring to a transformative movement in learning and teaching that exploits technological advances for offering learning experiences not possible to be organized in current formal educational settings (Haythornthwaite & Andrews, 2011). Educational technology and TeL are now mature interdisciplinary research areas, and there are already literature studies aiming at the study of scientifi c communities, the identifi cation and evolution of salient topics, and the emergence of the trends in the fi eld (Cho, Park, Jo, & Suh, 2013 ; Kinshuk, Huang, Sampson, & Chen, 2013 ; Masood, 2004 ; Pham, Derntl, & Klamma, 2012). Such studies are important since they can provide insights into the

development of a particular research area. Typically, social network analysis and bibliometric approaches using co-word, performance analysis, and science mapping have been exploited for this purpose (Cobo, López-Herrera, Herrera-Viedma, & Herrera, 2011 ; Masood, 2004 ; Muñoz-Leiva, Sánchez-Fernández, Liébana-Cabanillas, & Martínez-Fiestas, 2013).
In educational technology and TeL, there are some efforts to analyze research trends and scientifi c communities using as sources articles published in journals (Cho et al., 2013 ; Klein, 1997 ; LeBaron & McDonough, 2009 ; Masood, 2004). On the other hand, Randolph, Julnes, Bednarik, and Sutinen have indicated that "there were no practically or statistically signifi cant differences between the articles published in journals and those published in conference proceedings on any of the indicators of methodological quality" (2007). As a result, there have been similar studies where the sources were articles published in international conference such as the IEEE International Conference on Advanced Learning Technologies (ICALT) (Pham et al., 2012 ; Randolph et al., 2005) and the Artifi cial Intelligence in Education conference organized by the International Artifi cial Intelligence in Education (AIED) Society (Rourke, Anerson, Garrison, & Archer, 2001).
In this work, we aim to investigate the evolution of the educational technology fi eld in a European Union member state, namely, Greece, through the analysis of the category of targeted research outcomes and the key topics of interest that have been emerged in all papers presented at the main national scientifi c conference of this fi eld between 2000 and 2012. More specifi cally, we analyzed papers presented in the biannual conference of the Hellenic Scientifi c Association for ICT in Education, a nonprofi t scientifi c association founded in 2000 with the aim to promote research and development in the fi eld of educational technology. Through this analysis, we aim to identify trends between three different categories of targeted research outcomes (theory, technology, practice) and the evolution of different key topics of interest over a period of 12 years. We then discuss these trends in relation to educational technology policies and programs that have stimulated both research and development activities as well as mainstreaming activities aiming to widespread adoption of educational technologies in school education.
Method
Sample
The sample of this study consists of the population, namely, all the articles published in the proceedings of all seven biannual national conferences organized by the Hellenic Scientifi c Association for ICT in Education between 2000 and 2012.
The association is the only scientifi c, on behalf of membership criteria, body in the fi eld in Greece and represents almost the entire research community in Greece, and its conferences are the biggest in Greece. Thus, it can be considered that a

bibliometric analysis based on the association's proceedings covers the Greek community of ICT in education in Greece. The number of articles presented and published in both printed and electronic form is 849 which constitutes a signifi cant number of articles from which we can extract meaningful conclusions. Figure 1 shows the distribution of all articles in the seven biannual conferences from 2000 to 2012. It can be seen that there is a reasonably balanced distribution with peaks during 2002-2006 due to the implementation of a large-scale public-funded program for introducing ICT in school education which stimulated interest from both educational practitioners and researchers.
Bibliometric Approach
For the purposes of the present study, the co-word analysis, as a powerful quantitative content analysis technique "in mapping the strength of association between information items in textual data" (Cobo et al., 2011), is applied. Moreover, co- word analysis is used for temporal analysis and "develops a performance analysis of specifi c themes using a series of basic bibliometric indicators" (Muñoz-Leiva et al., 2013).
The key topics of interest are formed by studying the common keywords from

the corpus of the articles. The keywords used are retrieved from the conference
index, author's keywords, and their combinations. Moreover, two different coders
studied a specifi c number of articles and found common keywords at a level of 80 %
that is usually characterized as standard (Rourke et al., 2001). Based on the common
keywords, clusters of keywords are formed, thus creating the key topics of interest.

Results
First, we have identifi ed three different categories of targeted research outcomes,
namely, theory, technology, and practice. The fi rst category concerns with theoretical issues of educational technology such as "pedagogy in TeL" and "learning
design: theoretical aspects." Thus, we refer to this category as "theory." The second
category concerns with a variety of learning technologies, from "authoring tools for
educational content and learning designs" and "course management systems" to
"wireless, mobile, and ubiquitous technologies" and "Web 2.0 and social computing technologies," and involves articles that emphasize on learning systems based
on these technologies. We refer to this category as "technology." The third category
concerns with those topics of interest that relate to the practical pedagogical exploitation of ICT in formal and informal learning settings, including ICT in teaching
various subject domains, and other implementation issues of ICT in education.
Thus, we refer to this category as "practice."
Table 1 presents the categories of targeted research outcomes (level 1) and their
corresponding key topics of interest per category of research that have arisen from
the co-word analysis (level 2), together with their frequencies (%) and absolute
frequencies for the entire 12-year period. It can be noticed that the balance between
the three different categories of targeted research (theory—5.18 %, technology—10.95 %, and practice—83.86 %) indicates that the vast majority of conducted
research concerns with the practical use of existing theories and technologies in
school education.
Figure 2 illustrates how these trends are evolved over time during the 12-year
period. It can be noticed that basic research ("theory") tends to be reduced and
applied technological research ("technology") has a constant increase (mainly due
to the continuing development of new technologies), but still the core bulk of
research concerns "practice."
This is consistent with our hypothesis that the community considers that the fi eld
of educational technology has matured enough to mainly concern mainstreaming
(that is, large-scale implementation of technology-supported educational innovations in formal setting, like schools), rather than basic research or even applied
technological research. This is consistent with current European Union policies and
trends in TeL.
Figures 3 , 4 , and 5 illustrate the time evolution of key topics of interest in each
category of targeted research outcomes during the 12-year period.
From Fig. 3 it can be noticed that in category "theory" the main topics of interest
have been "learning design: theoretical aspects" and "pedagogy in TeL," whereas
there are some sporadic contribution in "learning theories in TeL" and "e- assessment:
theory and methods." Even so, the topic with a consistent interest over time has been
the "pedagogy in TeL," which is reasonable since the implementation of large-scale
ICT in school education programs stimulates interest in basic research related with
the rethinking of pedagogy in TeL.

Table 1 Key topics of interest in national conferences

Level 1: Category of targeted research outcomes	Level 2: Key topics of interest	Frequencies (%) of level 1 categories over 2000-2012	Absolute frequencies of level 1 categories over 2000-2012 N (= 849)	Frequencies (%) of level 2 topics over 2000-2012	Absolute frequencies of level 2 topics over 2000-2012 (N = 849)
Theory	Pedagogy in technology- enhanced learning	5.18	44	2.00	17
	Learning theories in technology - enhanced learning	0.35	3		
	Learning design: Theoretical aspects	2.71	23

directly useful in the implementation of large-scale ICT in school education programs,
whereas collaborative technologies are attracting practical interest since collaborative learning aspects are considered a major educational innovation that can be
supported by technology. On the other hand, applied technological research on topics
such as digital games and educational robotics, as well as wireless, mobile, and
ubiquitous technologies, appears not to be supported by the Greek research
community, mainly due to the lack of national industry that develops such
technologies.
From Fig. 5 it can be noticed that in category "practice" the main topics of interest have been "ICT in science education," "ICT in computer science education," and
"distance learning: implementation issues." This is reasonable because science,

technology, engineering, and mathematics (STEM) are the key school curriculum
subject domain topics that can benefi t the most from innovative technology-
supported teaching and learning strategies (Rocard et al., 2007). This is consistent
with fi nding in other member states of the European Union and all over the world
(Rocard et al., 2007).
Conclusions
Educational technology and TeL are now mature interdisciplinary research areas,
and there are already literature studies aiming at the study of scientifi c communities,
the identifi cation and evolution of salient topics, and the emergence of the trends in
the fi eld. Such studies are important since they can provide insights into the development of a particular research area.
In this work, we investigated the evolution of the educational technology fi eld in
a European Union member state, namely, Greece, through the analysis of trends
between three different categories of targeted research outcomes (theory, technology, practice) and the corresponding key topics of interest that have been emerged
in all 849 papers presented at the main national scientifi c conference of this fi eld
between 2000 and 2012.
Some interesting conclusions can be drawn for the discussion of the obtained
results. It appears that the educational technology community, at least in Greece,
considers that the fi eld has matured enough to mainly concern mainstreaming (that
is, large-scale implementation of technology-supported educational innovations in
formal setting, like schools), rather than basic research or even applied technological research. This can be a misleading route which can result to disappointments,
since using existing technologies, mainly developed out of the context of learning
and education, simply used as a facilitator for implementing incremental innovations in school education has potential risks of failure. In our view, the truly transformative value of educational technologies in formal and informal learning requires
disruptive innovations that question the why-what-how-where of learning and
teaching in the digital era. To this end, basic and applied technological and pedagogical interdisciplinary research is needed more than any other time in the past.

Introduction
In the history of pedagogical thought and psychology, every defi nition of learning
is supported by an entire world view, a sequence of ontological assumptions concerning nature, man, and the relation between them. In parallel, the phenomenon
of learning is approached by distinct disciplines in a different way (Bigge &
Shermis, 1999). The variety of Learning Theories has led us to the conclusion that
the phenomenon of learning constitutes a complex and composite fact, of various
dimensions, since no theory on its own is able to describe and interpret the whole
range of learning and its dimensions. The ideological currents and the theories of
learning, as well as the methods via which the latter contribute to the shaping of
teaching, are various. Among the most widespread schools of thought are those
which consider learning as (Ertmer & Newby, 1993 ; Nagowah & Nagowah, 2009):
a change in the observable behavior (Theories of Behavior – Behaviorism), an
internal mental process of the learner (Cognitive Theories – Cognitivism), or an
adjustment of mental models to accommodate new experiences (Theories of
Construction of Knowledge– Constructivism). Teaching with or without the
implementation of ICT tools is every time based on certain acceptances regarding
what learners have to learn and which way of learning is the best. These arguments
are substantially connected directly to a certain learning theory. Thus, the educational software, as well, as a means of learning, is always based on a certain or
certain theories of learning, incorporated in it by its creators (Mcleod, 2003 ;
Roblyer, 2006).
Theories of Learning in Math and Science
Educational Software

Today it is commonly accepted that ICT integration in the educational process is
able to support educational activities in a rich educational environment in which
learners can have multiple representations of complex phenomena and even be individually supported in the construction of knowledge in an authentic learning environment (Cooper & Brna, 2002). Worldwide research, though, has shown that
teachers take advantage of capabilities of this kind in a restricted manner, using
ICTs mainly for supporting traditional teaching practices and not for designing and
implementing educational activities which involve learners actively in the learning
process (Sang, Valcke, van Braak, & Tondeur, 2010 ; Tondeur, van Keer, van Braak,
& Valcke, 2008).
In the present research paper an attempt is being made to study teachers' perceptions about applications of educational software which deal with the syllabus of
Mathematics, Physics, and Chemistry of Secondary Education regarding the embedded learning theories. The main research question was to identify which groups of
theories of learning are embedded in certain applications , and to what extent ,
according to in - service teachers ' perceptions . These perceptions were correlated
with the ones of experienced teachers in the use of ICT in the classroom and the
statements of the developers of the applications under study as they described in the
supporting material of each application.
Theories of Learning and Educational Software
Each one of the three groups of learning theories can be used in the educational
software (Mcleod, 2003 ; Roblyer, 2006). Which one precisely and at which point of
the software it will be applied depends on the users' background knowledge and
their characteristics, as well as the discipline presented via the educational software.
A suffi cient condition for this to happen is that the design and production team be
aware of both the positive and negative elements of each theory, in order for the team
to utilize them appropriately (Panagiotakopoulos, Pierrakeas, & Pintelas, 2003).
Theories of Behavior
Learning is defi ned as a change in learner's behavior arising from experiences, as
well as the tasks set by the teacher. Learning occurs through the reinforcement of
the desired behavior either through its reward (positive reinforcement) or through
punishment (negative reinforcement) (Nagowah & Nagowah, 2009). The teacher
plays a central role as a transmitter of knowledge to learners and as a basic factor in
the educational process which reinforces the desired behavior .
A learning environment designed in the context of the Theories of Behavior must
have specifi c characteristics concerning the structure of the curriculum in short
units, gradual progress of the syllabus according to the learner's learning pace,

exposition of the syllabus in increasing order of diffi culty, and direct verifi cation of
the learner's response (Ertmer & Newby, 1993).
Theories of Behavior constitute the fi rst Learning Theories, which were utilized
for the theoretical support of technology application in education. Educational
applications integrating the aforementioned theories are mostly of the type of tutorials and drill and practice, and are judged effi cient at providing supervisory teaching
as well as at consolidating a low level of knowledge and skills (Nagowah &
Nagowah, 2009 ; Panagiotakopoulos, Pierrakeas, & Pintelas, 2003).
Cognitive Theories
Cognitive Learning Theories have ensued from a reaction to Theories of Behavior,
since researchers considered that the emphasis laid by the latter theories on the connection of stimulus-response was not effi cient enough to interpret human activity
during the learning process. They focus on the mental processes put into motion on
the basis of the stimuli presented in the human perceptual and cognitive systems.
That is, they probe into the functions of the cerebral mechanisms which are related
to learning and describe their relations so as for them to be better understood. To the
researchers of Cognitive Theories learning is a change in behavior, in thought, in
understanding, and in feelings (McLeod, 2003 ; Porpodas, 2000).
These new models focused on the processes of codifi cation, knowledge representation, on information storage, and on the retrieval and integration of new knowledge into the preceding pieces of information. The aim is still knowledge transfer in
the most effective and effi cient way. Cognitive Theories have imposed on education
metaphors, the analysis of complex concepts into simpler ones and the scrupulous
organization of the educational material from the simple to the complicated
(McLeod, 2003 ; Panagiotakopoulos, Pierrakeas, & Pintelas, 2003).
As far as the interaction between the learner and the software is concerned, there
is no strictly predetermined sequence in which the learner has to "learn by heart" the
subtopics of the syllabus, but he can study any of its subsections and test his knowledge wherever he considers (Anderson, Redder, & Simon, 1998).
Theories of Construction of Knowledge
Learning is a subjective and internal process of concept construction and is deemed
to be the result of organizing and adjusting new pieces of information to already
existing knowledge. That is, learning demands the rearrangement and reconstruction of the individual's mental structures, so that they adjust to new knowledge, and
also "adapt" new knowledge to the subordinate mental structures (Shunk, 2004).
A central role is played by the learner, who assumes an active role in the construction of his knowledge, by the preexisting knowledge of the learner, which has to be

modifi ed and expanded as a result of learning and by the teacher, who assumes a
supportive-consultative role in learners' activity (McLeod, 2003).
The researchers have adopted in their studies several approaches of constructivism, from the view of the theory, which supports that learning is simply the process
of adjusting our mental models to accommodate new experiences and involves constructing one's own knowledge from one's own experiences, to sociocultural
approach, which emphasizes learning from experience and discourse in authentic
learning environments, through collaboration and social interactions (Jonassen,
1999 ; Mahoney & Granvold, 2005).
A learning environment which is designed to comply with the Theories of
Construction of Knowledge, according to Boyle (1997), must have specifi c features
which aim at constructing knowledge, such as providing the learner with experiences, integrating knowledge in a realistic environment directly related to the real
world, encouraging the affi rmation and expression of perceptions in the learning
process, consolidating knowledge via social experience, encouraging the use of
multiple forms of knowledge representation, and encouraging self-awareness in the
process of constructing knowledge. Educational applications, which are designed to
take the aforementioned theories into consideration, should encourage a series of
procedures and support the creation of such teaching contexts which would advocate the idea of Knowledge Construction by the learner himself/herself while trying
to solve problems and interacting with the environment in this attempt. They should
also encourage learners' self-expression and provide authentic learning activities
(Edgar, 2012 ; Jonassen, 1999).
Educational Software for Maths and Science
Until today, there have been many studies about the potential of the educational
software to contribute positively to the learning process. These studies have concluded that the use of educational software as an educational tool under certain
conditions can be extended to all educational sectors (Bowman, Hodges, Allison, &
Wineman, 1999 ; Vanucci & Colla, 2010).
In the fi eld of mathematics education student's active involvement in their learning has the main role to their engaging with mathematical ideas as it is very important to them to participate in forming and testing hypotheses, trying out models, and
developing reasoned solutions to authentic problems. The use of software applications such as dynamic geometry, graphing and data-modeling packages, databases,
interactive games, simulations, and programming tools enables students to reach
accurate feedback and gain positive motivation (Barzel, Drijvers, Maschietto, &
Trouche, 2005). The use of such applications also allows students to focus on strategies and interpretations and not on complex computational calculations. In this way
the use of ICT in mathematics education supports constructivist pedagogy and supports students to explore mathematical concepts, relations and procedures, promoting higher order thinking and problem-solving strategies which are in line with the

new trends in mathematics education (Ruthven and Hennessy, 2002).
D. Apostolopoulou et al. 29
In the fi eld of Science, tools such as the ones used for collecting, processing, and
interpreting data, databases and spreadsheets, graphic tools, modeling environments, multimedia software intended for simulating processes and phenomena and
for conducting "virtual" experiments, publication and presentation tools and, fi nally,
computer-controlled apparatuses can offer prospects for interactive educational
activities (Osborne & Hennessy, 2003).
By utilizing such tools appropriately learners are given the opportunity of working in an environment adapted to specialized educational needs, of comprehending
natural phenomena and natural laws by using hypotheses and trial and error methods, and of experimenting in a structured way by exploring a model and discovering
the elements of the simulation environment. Furthermore, learners are enabled to
use a variety of representations (images, graphs, data tables etc.), which are useful
in comprehending concepts and their interrelation. Finally, learners are given the
opportunity of expressing concept representation and cognitive models of the
surrounding natural world (Osborne & Hennessy, 2003 ; Velázquez-Marcano,
Williamson, Ashkenazi, Tasker, & Williamson, 2004).
Today innovative educational activities, which contribute to the interconnection
of concepts and, by extension, highlight the homogeneity of Sciences, are of special
interest in the educational process. The contribution of new technologies towards
that direction seems to be quite signifi cant, due to the fact that they provide the
opportunity to highlight the modern way in which Science and Maths are taught.
These technologies also create new prospects in the context of knowledge exploration and collaborative learning as the Theories of Construction of Knowledge
prescribe.
Studies have shown that teaching which takes advantage of ICT applications
proves to be much more effective, regarding the comprehension of Science-related
concepts, processes, and phenomena, than activities designed in a traditional way
(Redish, Saul, & Steinberg, 1997), since learners are given the possibility of a direct
visualization of natural or/and chemical phenomena (Bowman et al., 1999).
Methodology
For the needs of our research a sample was used which is, to a great extent, a
"convenience sample" (Bryman, 1995). To achieve greater reliability and control of
internal validity, the collection of data was done by using two research tools: a
questionnaire—as the main research tool—and a semi-structured interview (Cohen,
Manion, & Morisson, 2007). The questionnaire was addressed to teachers of Science
and Maths in Secondary Education, who participated in a national in-service training course. The objective of this course was to educate 28,100 teachers of primary
and secondary education, concerning the utilization and application of ICTs in the
teaching practice (http://b-epipedo2.cti.gr/en). Participants, after the training course,
expressed their perceptions on the educational software applications under investigation, by answering to specifi c questions related to the Learning Theory or Theories
which the applications utilize.
Theories of Learning in Math and Science Educational Software30
The questionnaire consisted of 50 questions which were divided into two parts,
one for collecting demographic data and the other for investigating the main research
question. The fi rst part included questions about the teachers' personal profi le with
special emphasis on their dealing with applications of educational software and on
their getting accustomed to using it. The second part (main part) of the questionnaire consisted of 40 questions related to the features of Learning Theories. Fifteen
out of the questions posed concerned the Theories of Behavior, seven of them the
Cognitive Theories, and eighteen of them the Theories of Construction of
Knowledge. The questions lent themselves to two types of answer, the Yes-No type
and the 5-grade Likert-type Scale (1 = Never, 2 = Rarely, 3 = Sometimes, 4 = Often,
5 = Always). According to the existing research on the features of learning theories
when apply to learning environments, a set of questions was formulated, which fall
into the following axes (Anderson, Reder, & Simon, 1998 ; Atkins, 1993 ; Edgar,
2012 ; Ertmer & Newby, 1993 ; Nagowah & Nagowah, 2009):
• The transparency of the aim and the learning objectives to be achieved
• The existence of a logical distinction and cohesion of the instructional units
• The way in which the syllabus is presented in the software
• The relation between the learner's prior knowledge and the content to be studied
• The cultivating of student's ability to interpret facts and phenomena
• The way a learner can be evaluated/self-evaluated
• Whether the educational activities are able to connect real-life situations based
on learners' experiences with representations of the real world and daily life
• Whether they cultivate the use of critical thinking methods allowing for the
learner's autonomous course in constructing knowledge
• Whether learners' active participation is promoted and in what way
• Whether the collaborative approach to knowledge and problem-solving is
encouraged by cultivating learners' creativity and imagination at the same time
The software applications chosen to be studied are the ones suggested by the
Hellenic Ministry of Education and the Pedagogical Institute to be used at schools
and which are used at the abovementioned in-service training course (3 closed type
and 2 open type ones, 4 regarding Science and 1 regarding Mathematics) out of
those most implemented in class.
Thirty-two (32) teachers of Science completed the questionnaire for each one of
the four software applications for science, and eighteen (18) teachers of Mathematics
completed the questionnaire for the application of mathematics. In order for the data
to be processed, the answers to the questionnaires were input to statistical data analysis software. At fi rst, the reliability coeffi cient α (Chronbach's alpha) of the questionnaire responses, regarding every group of the participants (Science teachers,
Mathematics teachers), was estimated. In order for the teachers' descriptive answers
to questions to be classifi ed, a content analysis of the responses was conducted
(Bogdan & Bilken, 1982).
The interviews conducted with participants who were in key positions in the
abovementioned in-service training course (Cohen et al., 2007). Interviewees were
D. Apostolopoulou et al. 31
three teacher trainers specializing on the utilization and application of ICTs in the
teaching practice, who had great training and research experience on issues regarding the utilization of ICTs in the teaching practice. These trainers were educators in
the aforementioned in-service teachers' training course. Interviews aimed to provide qualitative data from the view of the trainer-expert, complementary or explanatory to the quantitative data provided by the questionnaires. The interview consisted
of 23 questions which were divided into two parts. In the fi rst part demographic data
were recorded while in the second part an attempt was made to collect data via
open-ended questions related to the research issues. A content analysis to the interviewees' responses was conducted.
Findings and Analysis
The values for the coeffi cient of internal consistency (Chronbach's alpha) of the
questionnaire responses were 0.842 for Science teachers and 0.853 for Mathematics
teachers. This fact shows strong reliability of the answers. The sample's characteristics are presented in Table 1 .
Twenty-seven (27) of the Science teachers answered that they use general purpose software for the needs of their lesson very often, whereas fi ve (5) of them use
it rarely. Twelve (12) of the Mathematics teachers also use general purpose software
often, while six (6) of them use it rarely.
The main criteria for the selection of the 3 teacher trainers who participated in
the interview were their involvement in the teacher's training courses and their
experience in using educational software applications in the classroom. They all had
a teaching experience of more than 15 years, great experience in training and
research, as well as in using educational software in class.
The following paragraphs present the results of the quantitative (Table 2) as well
as the qualitative research of the fi ve (5) characteristic software applications studied. The presentation of the quantitative results is made in relation to the number of
questions (related to every Learning Theory), which the teachers estimated that the
software fulfi lls to a "Full" (grade 4 and 5 of the scale) or "Partly" (grade 3 and 2 of
the scale) extent.

Theories of Learning in Math and Science Educational Software32
More specifi cally:
A Wonderful Journey in the World of Physics
The "A Wonderful Journey in the World of Physics" software fully satisfi es six (6)
questions about the Theories of Behavior, three (3) questions about the Cognitive
Theories and eleven (11) questions about the Theories of Construction of Knowledge.
It also partly satisfi es nine (9) questions about the Theories of Behavior, two (2)
questions about Cognitive Theories, and fi ve (5) questions about the Theories of
Construction of Knowledge.
The same fi ndings also emerged from the teacher trainers' interviews, who
responded that although the specifi c software is suitable for being utilized in class
through activities aiming at Knowledge Construction by learners, it also includes
elements of the Theories of Behavior. More specifi cally, there seemed to be a distinction between instructional units and a representation of the syllabus in various
ways. The examples, simulations and videos provided allow and promote the connection between the learner's prior knowledge and the content to be studied. Thus,
the learner's skill to interpret phenomena is cultivated and, simultaneously, a connection is being realized between the learner's experience and the representation of
his/her daily life.
Interactive Physics
Regarding the "Interactive Physics" software, due to the fact that it is a type of open
software, the teachers who participated in the research chose not to answer to all of
the questions in the Likert Scale or in the nominal Yes/No scale, but to answer periphrastically to some of them by making a comment. Based on the questions answered,
in the scales, this software fully satisfi es seven (7) questions about the Theories
of Construction of Knowledge and one (1) question about Cognitive Theories.
Table 2 Frequencies of answers per learning theories and software
Software/learning theory
Behaviorism
(15 criteria)
Cognitivism
(7 criteria)
Constructivism
(18 criteria)
Full Partly Full Partly Full Partly
A wonderful journey in the world of Physics 6 9 3 2 11 5
Interactive Physics 0 0 1 0 7 0
Composite Laboratory Environment—C.L.E. 0 3 2 1 11 4
The Wonderful World of Chemistry 7 8 4 3 9 7
The Geometer's Sketchpad 0 0 1 0 7 0
D. Apostolopoulou et al. 33
In the rest of the questions, it becomes evident from the teachers' comments that this
software provides the user-teacher with the ability to design and support educational
activities aiming at his/her learners' Construction of Knowledge by planning and
utilizing appropriate educational scenarios and worksheets in the classroom.
On the basis of the aforementioned data, the descriptive answers of the participants to the rest of the questions and the teacher trainers' answers in the interviews
it could be concluded that this software distinctly applies the Theories of Construction
of Knowledge. Teacher trainers agree that, during the utilization of the software, the
teacher plays an especially active role. The teacher should, every time, design and
create a simulation which provides his/her learners the opportunity to work on powerfully exploratory learning activities via appropriately designed educational scenarios and specifi c worksheets.
Composite Laboratory Environment (C.L.E.)
The "Composite Laboratory Environment—C.L.E." software fully satisfi es eleven
(11) questions about the Theories of Construction of Knowledge and two (2) questions about Cognitive Theory. It also partly fulfi lls three (3) questions about the
Theories of Behavior, one (1) question about the Cognitive Theories and four (4)
questions about the Theories of Construction of Knowledge. Based on the aforementioned results, it would be concluded that the software orientates towards those
which mainly integrate the Theories of Construction of Knowledge.
The interviews lead to the same conclusions, as well. Due to the virtual experiments it provides, this type of software encourages the learner's ability to interpret
facts and phenomena. The virtual experiments and the videos included in the software are realistic to a great extent, a fact which facilitates the connection between
real-life situations from the learner's experiences and what is being studied through
the representation of the real world and everyday life.
The Wonderful World of Chemistry
The "The Wonderful World of Chemistry" software fully satisfi es seven (7) questions about the Theories of Behavior, four (4) questions about Cognitive Theories,
and nine (9) questions about the Theories of Construction of Knowledge. It also
partly satisfi es eight (8) questions about the Theories of Behavior, three (3) about
Cognitive Theories, and seven (7) questions about the Theories of Construction of
Knowledge.
The teacher trainers agree that this type of software is mainly utilized in activities
based on the Theories of Construction of Knowledge. However, it includes elements
from the Theories of Behavior, as well. The software includes distinct instructional
units. The syllabus presentation is carried out through defi nitions, examples, rules,
Theories of Learning in Math and Science Educational Software34
and simulation examples. The possibility of learner evaluation is provided. The
learner is informed on his/her answer correctness through positive or negative feedback. Moreover, via examples, simulations, and videos, the learner's skill to interpret facts and phenomena is cultivated.
The Geometer's Sketchpad
As far as "The Geometer's Sketchpad" is concerned, since it constitutes open software, the teachers participating in the research chose not to answer to all the questions in the Likert Scale or in the nominal Yes/No scale. They also answered
periphrastically to some of them by providing a comment. Based on the questions
answered in the scales, this type of software fully satisfi es seven (7) questions about
the Theories of Construction of Knowledge and very much one (1) question about
the Cognitive Learning Theories. Thus, this software could be classifi ed as one of
the types integrating the Theories of Construction of Knowledge.
On the basis of the aforementioned data, the descriptive answers of the participants to the rest of the questions and the teacher trainer's answers in the interviews
it could be concluded that the specifi c software application is placed among those
applications which clearly serves the purpose of the Theories of Construction of
Knowledge, since the learner is evidently involved in the construction and structuring of his/her knowledge. It constitutes interactive software, which enables the
learner to be actively involved in geometrical design and construction activities,
which strongly promote learner autonomy.
All fi ndings are in agreement with the objectives of the developers of the fi ve
applications studied, as reported in the supporting material of each application.
Discussion and Conclusions
In the present research paper the dominating Learning Theories were studied in
terms of their existence in applications of Educational Software for Science and
Mathematics, according to the perceptions of a sample of in-service teachers. These
perceptions resulted from the participants' responses on questions concerning the
characteristics of fi ve specifi c educational applications.
According to the sample's perceptions, the results of the fi ve applications presented allow us to conclude that open type applications (Interactive Physics, The
Geometer's Sketchpad) serve the Theories of Construction of Knowledge, since
through them the teacher is able not only to create new interactional applications
according to his/her learners' educational needs, but also to encourage learners in
creating by themselves their own simulations and models of interpreting processes
and phenomena. These fi ndings are in agreement also with the three expert teachers'
responses.
D. Apostolopoulou et al. 35
The fi ndings from both the answers of the sample and the three expert teachers

interviewed about the close type applications showed that these applications incorporate characteristics of both Theories of Behavior and Theories of Construction of
Knowledge. All these fi ndings fall in with the statements of the developers of the
fi ve applications studied, as reported in the supporting material of each application.
Taking under consideration that the dominating theories of learning are the Theories
of Construction of Knowledge, as they can broaden the students' skills better than
others (Malabar & Pountney, 2002), it is obvious that the fi ve applications which
were studied and are proposed for use in the Greek schools incorporate these theories in whole or in part.
Moreover, it is important for a teacher to be able to recognize specifi c characteristics of an educational application concerning the embedded learning theories in
order to utilize the application in the most proper way in the educational process.
Teachers should be supported via suitable training courses towards this direction.
However, studies have shown that many factors affect, eventually, the way of integrating ICTs in the educational process. Such factors may be related, except for
teacher training, to the technological infrastructure of school units, to both technological and pedagogical support in applying educational activities in class, and to
teachers' beliefs about teaching and learning, their attitudes towards ICTs in the
fi eld of education, and towards life in general, skills of using ICTs, etc. (Sang et al.,
2010). All the aforementioned factors should be studied, taken into account and
dealt with in order for ICTs to be fully integrated into school class and practice.

Introduction
Although Information and Communication Technology (ICT) use and particularly
computer use in early childhood educational settings is under-examined in comparison to other educational levels (e.g., primary and secondary education), the debate
is no longer one of should we or should not we use computers in early childhood
settings. Electronic culture is already an integral part of early childhood experience
for many youngsters (Parette & Blum, 2013). Research studies (Clements & Sarama,
2003 ; Haugland, 2005 ; McCarrick & Li, 2007 ; McKenney & Voogt, 2012 ; Siraj-
Blatchford & Siraj-Blatchford, 2006 ; Stephen & Plowman, 2003 , 2008 ; Yelland,
2005) reported that computer can be used as a tool to support learning, and assist
communication, collaboration, creativity, and language development in young children. Judge, Puckett, and Cabuk (2004) reported that it is increasingly important for
early childhood educators to introduce and use computers in their settings, particularly for those children who do not have access at home. They assert that offering
access to computers in early childhood settings helps to reduce the digital divide.
The essential role of early childhood teachers in the improvement of children's
computer/ICT related experiences has also been reported (Stephen & Plowman,
2008). Kindergarten teachers are, for example, responsible for selecting educational
software and deciding on the ways of its use. The aim of this research study was to
investigate educational software use by young children in kindergarten classes.
For the purpose of this paper, specifi c terms used are briefl y explained. Initially,
the term computers is used as synonymous and as more preferable to the terms ICT
(Information and Communication Technology) and technology . Apart from computer
software, a number of products that incorporate some aspects of ICT are available to
Educational Software Use in Kindergarten

young children such as electronic-musical keyboards, programmable interactive
toys, and digital cameras. However, practitioners defi ne ICT more narrowly as computers and printers and this view is very infl uential (Stephen & Plowman, 2008) till
now. Moreover, this study focuses on computers and software that runs on computers as, for the present, this is the predominant technological device for those kindergarten classrooms in Greece that have access to technology. The term educational
software use refers to children's computer related activities, as well as the observation of such activities. The term early childhood settings is used as synonymous to
the terms kindergartens and preschools . This term refers to kindergarten classrooms
(formal educational settings) that attend children above 3 years old.
Theoretical Background
Educational Software Usage in Early Childhood Settings
Regarding educational software usage in kindergarten classes, different software
programs/applications have been used such as interactive multimedia environments,
games, painting/drawing programs, Word processing, and Logo programming
(Chera & Wood, 2003 ; Clements, 2000 ; Labbo, Sprague, Montero, & Font, 2000 ;
Sung, Chang, & Lee, 2008). The boundaries between different software applications produced for young children are not necessarily fi xed, as different applications
are presented in a form of play designed to attract and sustain children's attention.
For example, both commercial and educational CD-ROMs incorporate the play
component, which should not be seen solely for recreation or fun purposes
(Verenikina, Herrington, Peterson, & Mantei, 2010). Early childhood educational
software contains activities which quite frequently focus on early development
skills such as sorting-classifying, matching, following instructions, and spatial reasoning (Stephen & Plowman, 2003). Regarding its usage in early childhood educational settings, McKenney's and Voogt's study (2010) showed that children 4-7
year old reported playing games, practicing words/maths, and drawing as the most
frequently activities done in kindergarten classrooms. Marsh et al. (2005) reported
frequent use of painting/drawing packages and rare use of the Internet.
Although there are a variety of educational software programs used by children
in kindergarten classes, there is limited empirical evidence on how educational software is used in classrooms. For example, Ljung-Djärf, Åberg-Bengtsson, and
Ottosson (2005) reported that computer can be used, among others, as an available
option or as an essential activity. Computer use is often something that may be
allowed between planned or adult-led activities, which means that it is typically
used during the time that is organized as free play (Howard, Miles, & Rees-Davies,
2012 ; Ljung-Djärf, 2008). In America, the National Association for the Education
of Young Children and Fred Rogers Center for early learning and children's media
(NAEYC - FRC 2012), in their position statement regarding the role of technology
in preschool classrooms, state that (a) technology and interactive media tools must
K. Nikolopoulou41
be used appropriately, and (b) technology integration is effective when integrated
into the environment, curriculum, and daily routines. When computer use takes
place within kindergarten classes, the role of teacher/adult intervention in supporting and extending children's experiences has been emphasized (Nir-Gal & Klein,
2004 ; Stephen & Plowman, 2003). For example, McKenney and Voogt (2009)
found that teacher intervention elicited young children's engagement with literacy
concepts and that children were able to work independently with the computer program after a few instruction sessions. Other studies have shown that children are
largely left alone at the computer with the teachers seldom to participate in what
goes on there (Plowman & Stephen, 2005) and, in particular, when children played
computer games there was lack of teacher intervention (Ljung-Djärf et al., 2005 ;
Vangsnes, Økland, & Krumsvik, 2012).
In Greece there are a few empirical studies regarding educational software or
Internet usage in kindergarten classes (Chronaki & Stergiou, 2005 ; Fesakis,
Sofroniou, & Mavroudi, 2011). For example, Chronaki and Stergiou (2005) compared computer use in two kindergartens, carrying out interviews with teachers and
children. This paper presents research fi ndings regarding educational software use
in kindergarten classes in Athens, Greece. Fesakis et al. (2011) carried out an experimental case study of a learning activity meant for teaching preschoolers geometric
concepts, via the use of communication tools from the Internet. The results of this
study constitute part of a research project regarding ICT use-integration in kindergarten classes in Greece. Thus, some information about ICT in early childhood
education in Greece is provided below.
ICT in Early Childhood Education in Greece
The Greek educational system is centrally organized and the main bodies of educational policy and planning are the Ministry of Education (YPEPTH) and the
Pedagogical Institute (PI). Until recently, there was a lack of a central plan for
the introduction of ICT. The Pedagogical Institute has published a framework for the
introduction of ICT in teaching and learning, the so-called "Cross-Thematic
Curriculum Framework for ICTs." For early childhood education, it sets directions
for programs regarding planning and development of activities in the context of the
following subjects: language, mathematics, environmental studies, creation/expression, and computer science (YPEPTH - PI 2003). These programs are not considered as independent subjects, but it is suggested to be taken into account when
planning and implementing meaningful and purposeful activities for the children.
Among the essential prerequisites for computer integration in early childhood
education are the placement of the computer/ICT in class (i.e., the so called "computer corner") and its inclusion in kindergarten's daily teaching practice (Komis,
2004). In order to successfully implement the curriculum, it is essential for teachers
to be provided with the appropriate training and for early childhood classrooms with
the appropriate resources. Regarding resources, many kindergartens have lately
Educational Software Use in Kindergarten42
acquired computers for use by the children. However, those kindergartens with a
computer in their classrooms have, more or less, similar technology facilities (i.e.,
predominantly one or two computers). There are no computer labs in kindergartens.
Regarding teachers, they are responsible for translating into practice the expectations/visions of curricula planners. The "Teachers' training on ICT in Education"
program (YPEPTH - PI 2009), which is the most widespread in Greece, included
the training of early childhood teachers as well. The fi rst phase of the program
included training in technical skills and has been attended by the majority of early
childhood teachers. The second phase of the program which is dedicated to providing teachers with the pedagogical skills for ICT integration in the classrooms has
been attended and is currently being attended by a number of teachers (the actual
number is not known yet, as it forms part of internal evaluation of the program which
still takes place). This large scale inservice training aims, among others, to familiarize teachers with appropriate educational software and the skills to adopt-integrate
ICT in their everyday teaching practices. Within the Greek context, there is currently
poor uptake of computers in early childhood settings (Nikolopoulou, 2009).
Method
Objectives of the Study
As stated earlier, the aim of this research study was to investigate the use of educational software in kindergarten classes. Three basic parameters of the study were as
follows: (1) the presence of at least one computer in the kindergarten classroom and
its use by preschool children, (2) the voluntary participation of kindergarten teachers, and (3) the study to be carried out without artifi cial intervention by the researcher
(i.e., into the "natural" classroom environment). For the purpose of this research,
offi cial permission was provided by the research department of the Greek
Pedagogical Institute and all kindergarten schools and their participants were treated
anonymously. The objectives of this study were:
1. To identify the educational software commonly used by children in kindergarten
classes.
2. To investigate how educational software is used in kindergarten classes.
3. To fi nd out possible diffi culties children face in the use of educational software.
Sample
Seventeen state kindergartens from Athens, in Greece, participated in this study and
their teachers agreed to voluntarily participate in the research project. All kindergarten teachers were women (age range: 26-55), most of whom had attended the fi rst
phase of the "Teachers' training on ICT in Education" program (i.e., introductory
K. Nikolopoulou43
training in ICT skills). However, none of them had attended the second phase of this
program which regards pedagogical training in the use of ICT in classes (this phase
has started only recently, see YPEPTH 2012). All schools were committed to the
same National Curriculum guidelines. The ages of the children ranged from 4 to
6.5 years. However, over 88 % of the children were aged 5-6.5 years old, as kindergarten attendance in Greece is now obligatory for this age group (i.e., the age group
that will attend primary school during the next academic year). Table 1 shows the characteristics of kindergartens, as derived from interviews/discussions with the teachers

and observations made in classes. In order to maintain the anonymity, the codes
N1-N17 (N1: kindergarten 1, N2: kindergarten 2, etc.) were used. Each kindergarten participated in the research with one or more classes (full-day and/or classic
class, as shown in the second column of Table 1). Classes held between 13 and 26
children, except those serving children with special needs. Table 1 also shows the
number of teachers interviewed, the total number and ages of children, the number
of computers, as well as the frequency and the duration of computer use (per child).
One or two computers were available in 15 (out of the 17) kindergartens and this
refl ects the typical situation in Greek kindergartens. The computer(s) were located
in the classroom, they were set up on a table at the computer corner, while each
computer had two kindergarten-sized chairs placed before it: to facilitate collaboration and to provide a place for children to sit and watch their peers if they are waiting to use the computer on their own (according to teachers' explanations). In only
one school (N9), the teacher had her desk in the classroom and as a result it was the
same computer (located on teacher's desk) being used by both the children and the
class teacher (for administrative purposes etc.). Computer use appeared to be an
established practice during the last 3 years.
Almost all schools (except N17) were located in central semi-urban areas of the
Greek capital, in medium (neither high nor low) socioeconomic areas, without variation in ethnic background. Only the school N17 was located in a working class
socioeconomic area, around 17 km away from the city center. Around 90 % of the
children of the sample spoke Greek as a fi rst language.
Data Collection Process and Research Instruments
The data were collected between January 2009 and June 2010 and consisted of interviews and informal discussions with the kindergarten teachers, observations and
fi eld notes of class activities. All data were collected by the researcher and author of
this paper. Qualitative approaches seem practical and valuable for early childhood
settings, although they include small samples and are not easily generalizable
(Nikolopoulou, 2010). The interviews with the teachers were conducted before the
observation sessions, they took place in the classroom (after the preschool day
ended) and they were recorded digitally and transcribed. Approximately 8 h of interview recordings was collected and transcribed. The semi-structured interviews were
based on specifi c axes related to the research objectives. The following questions
were used: What educational software programs are used by children in the class?

a
Full-day class: children attend kindergarten from 8:30 a.m. to 4 p.m.
b
Classic class: children attend kindergarten from 8:30 a.m.to 12:30 p.m.

How are these programs being used? Do children face diffi culties when using
specifi c software programs? All teachers were confronted with the same set of core
questions, while follow-up questions were formulated in order to offer teachers the
opportunity to introduce unexpected ideas and thoughts. The interviews also
addressed areas such as demographics and computer availability/access.
In parallel with the interviews, in each kindergarten were conducted two or three
observations of computer use (i.e., two or three sessions, each one in a different
day), of total duration of 1.6-3 h. All observations took place from January (2009 or
2010) onwards, after negotiation with class teachers. This time period, being
3 months after the commencement of the academic year, was proposed by the teachers because they wanted their children to be initially acquainted to the new kindergarten environment before any research took place. The observations were
naturalistic observations of the children's and teachers' activity in the classroom. As
the researcher was also an observer, she sat close to the computer corner and she
needed to be mindful of her position in the classroom (e.g., as a researcher observing children using computers there was a challenge of supporting their engagement). During the observations, a small number of children (two or three) sat at the
computer corner, while the rest of the class was engaged in other free play activities.
Children did engage with the computer activities in ways that suggested that they
were comfortable with the researcher's presence. The observations involved the
writing of detailed fi eld notes (what took place around the computer etc.) during and
immediately after the observations. As fi eld notes were reviewed memos were
recorded to document emerging thoughts, feelings and questions regarding the
observations. Informal discussions with the teachers took place during and mainly
immediately after the observations (e.g., for clarifi cations on various actions).
In order to investigate the fi rst research objective, the data were collected via
interviews with the teachers. For the investigation of the second and third objectives, interviews and observations/fi eld notes were used. As a main parameter of the
study was to be carried out without an imposed intervention by the researcher (i.e.,
in the natural environment of the everyday practice), it was the teachers who decided
on the timing of the observations, as well as on the software used. There was also
negotiation with the teachers with regard to the number of sessions observed (i.e.,
two or three sessions).
Data Analysis
The qualitative data gathered (from interviews, observations, fi eld notes) were each
analyzed using classical content analysis. All the data sources were analyzed to fi nd
codes that could be organized into categories. The codes were produced deductively
and then included as descriptive information about the data (Leech & Onwuegbuzie,
2007). Results derived from one source of data were supported by other data
sources. Some of the interview statements most strongly supporting the categories
are presented.

Ethical Considerations
Regarding ethical considerations, kindergarten teachers were informed about the
nature, duration, and the aim of the research study. Ethical issues arise when investigating dependent, vulnerable members of society such as young children in early
childhood education settings (Morgan, 2010). Gaining informed consent from
research participants is widely regarded as central to ethical research practice and in
institutional settings such as schools, access tends to be mediated by teachers, managers, etc. (Heath, Charles, Crow, & Wiles, 2007). Issues of anonymity and confi -
dentiality are also included in ethical considerations, thus the above parameters
were assured in this study (i.e., all kindergartens and participants were replaced
with codes). Additionally, initial and ongoing consent with teachers was negotiated
and participants were informed about research outcomes.
Results and Discussion
This section describes and discusses the results in three subsections, according to
the research objectives, with parallel presentation of indicative excerpts from the
interviews. This is done because direct quotes from the interviews can help readers
to acquire a more complete view of the events and situations (Forman & Hall, 2005).
The fi ndings are presented for all schools, descriptively.
Educational Software Commonly Used by Children
in Kindergarten Classes
Table 2 shows the educational software/programs most commonly used by young
children in classes, as reported by kindergarten teachers: the MS Paint, the commercial series Ram Kid/Kide Pedia (which include many games), followed by the use of

educational CD-ROMs (e.g., "My class," "Salto and Zelia," "On the road safely")
and the MS Word. The programs "MS Paint" and "MS Word" are included in every
computer as parts of the Microsoft Offi ce, and thus, there is no extra cost for the
kindergartens. Taken into account the limited school budgets, such open ended software is suggested to be embraced in kindergarten classrooms (and as a consequence,
it is interesting to investigate examples of good practice and what actually children
learn). Additionally, the educational software "Explorer of the computer–Electronic
Postman" (contains language and mathematics learning activities) has been distributed recently, during the academic year 2008-2009, by the Greek Ministry of
Education in most full-day kindergarten classes without any cost. Some kindergarten teachers use this software in their class and characterized it as particularly interesting. For example, in N4 (full-day class) it is used as a supporting tool for language
and mathematics, while the teachers in N7 (classic and full- day classes) use it systematically during the hour of free play activities. However, other teachers (in N1,
N2) who have this software in the kindergarten, do not use it in their class because
they do not consider it as appropriate for the children. For example, "I do not consider it (the software) appropriate as to its design-placement of specifi c buttons on
screen–because the children can be easily lost" (teacher in N1), or "It has a long
introduction and the kids get bored…" (teacher in N2).
Some programs (especially the commercial series Ram Kid/Kide Pedia and the
educational CD-ROMs) are frequently brought in classes either by the teachers (e.g.,
in kindergartens N2, N10, N11, N12, N14) or by the parents (e.g., in N3, N9, N10,
N11, N12). Table 2 reveals a limited range of programs used in classes and this may
be attributed to the tight school fi nances. The fi ndings are in some agreement with
earlier research. For example, Marsh et al. (2005) reported frequent use of painting/
drawing programs and rare use of the Internet, while others (Lee & O'Rourke, 2006)
found frequent use of CD-ROMs (e.g., games, talking books). In Greece, Chronaki
and Stergiou (2005) found that children carried out educational activities (writing
words and numbers, painting), aiming at children's familiarization with the computer. The reasons for using computers with children in kindergarten classes (discussed in another paper) were the development of language and fi ne motor skills,
and the computer's contribution as an incentive in the learning process. In particular,
the MS Word was mainly used for the development of language, reading, and writing skills, for emergent literacy skills and in order to support curriculum learning
objectives in language–as well as for providing practice in the recognition of the
alphabet letters. The Internet (in those kindergartens which had a connection) was
reported to be mainly used for downloading/playing games, for carrying out project
work and for downloading educational material and photographs.
Independently of the programs used and the tight budgets, the role of the
kindergarten teachers was essential because they decided on the program(s) used by
their children. An example of an interview excerpt was: "We have some of the Ram
Kid series, we intend to buy them with our money. A mother has brought the program 'On the road safely' and when we talk about traffi c education we use this very
much… We fi rst look at the software, i.e., we see whether the activities included are
appropriate for our children. We have found some (programs) that were very nice

but they did not correspond to our children's level and interests" (teacher in N11).
Different decisions made by the teachers are mentioned in the following sections of
the paper. The crucial role of the kindergarten teachers in the computer environment
has been reported in literature (Keengwe & Onchwari, 2009 ; Nir-Gal & Klein,
2004). The essential role of the teachers in this study is also highlighted in the subsequent sections of this paper.
How Educational Software Is Used in Kindergarten Classes
This section discusses how educational software was used in the classes, and it also
includes fi ndings regarding when the software was used. Computer use took place,
mainly, during the hour of free activities/play at the computer corner. As most teachers stated, one hour every morning or every afternoon is devoted to computer use.
These fi ndings are in agreement with the relevant literature which refers to computer
use in kindergarten's daily practice so that children can understand its contribution
towards teaching and learning (Plowman & Stephen, 2003), and to that computer use
took place during the free play activities (Ljung-Djärf, 2008 ; Ljung- Djärf et al.,
2005). In this study, the frequency of computer use, per child, was found to vary
between 2 and 3 times per week and once per month (see Table 1). In most kindergartens, teachers reported that every child was entitled to work on the computer (if
s/he wanted) once per week with an average time of 10-20 min. In about half of the
kindergartens there was a sort of a systematic way for the children to have access to
the computer, such as a reference plan. In cases of a lack of a reference plan, children's use of the computer was not recorded, but some teachers said they did remember which children passed from the computer corner. Educational software was often
reported to be used in the context of a project in combination with other non-computer based activities (e.g., in N1, N2, N3, N5), or for producing the class' newspaper (in N1). Computer use is suggested to be combined with off- computer classroom
activities, as relevant literature has shown that this way can lead to better learning
effects (Haugland, 2000 ; McKenney & Voogt, 2009). Parette and Blum (2013)
discussed elements of technology integration and identifi ed key activities in which
technologies can be used across preschool settings. Such activities may embrace the
use of educational software in order to support and enhance children's leaning.
Class organization in computer environment was found to, mainly, take place in
small groups because as two teachers explained: "It works very well as a group
because the other child sits next to it and says 'you haven't seen this!' or 'no, we must
not do this', i.e., they discuss, they help each other, the child waits his/her turn"
(teachers in N11). An exception to group work constituted the kindergarten N17,
which serves children with special needs. In this case, each child works with the
teacher's help in order to achieve specifi c objectives: "The autistic child, who can not
interact simultaneously with the screen and the teacher, focuses on the screen… It is
important for children with special needs to acquire fi ne motor skills and to understand the cause-effect relationship. There are diffi culties depending on the child, for

example with the mouse. I do help them… Two objectives can be pursued in parallel,
for example, development of fi ne motor and cognitive skills" (teacher in N17).

Class observations revealed that, in most cases, when children were using different programs there was some type of teacher intervention and guidance. For example, when they were using the program MS Word there was an initial guidance from the teachers and afterwards an intervention-assistance when children did not know specifi c functions (transition to the next line, error erasing, etc.). The class observations (in kindergartens N1, N3, N4, N6, N7, N9, N10) revealed that children, with the help of their teachers, used successfully different functions of the MS Word such as "delete an error" (button "Backspace"), "transfer to the next line" (button "Enter"), "select a color," "drag and drop," and "save a fi le." Children were happy to write their name, to select-change a color and to change the size of the letters of their name (as well as of other words). It was also observed that children cooperated and helped each other for the successful outcome of a learning activity. In any case, it was the teacher who knew her children in the class and she decided on the type of intervention needed. For example, an interview excerpt was: "Children sit (on the computer) several times on their own and seek help from other children—they believe they know—rather than from myself... I consider it important to sit next to very young children because when they cannot fi nd something they get bored and leave the computer" (teacher in N7). Teacher's guidance/mediation could be broadly divided into three categories, which were also observed to take place in combination: (a) step-by-step guidance for teaching new concepts/skills, (b) initial explanations (e.g., function of specifi c buttons) provided by the teachers and then independent work by the children, and (c) teacher guidance/assistance whenever children asked for it. These types of teacher guidance are discussed among the recommendations made by researchers (Plowman & Stephen, 2005 ; Stephen & Plowman, 2008) for more effective computer integration in early childhood settings. Regarding teacher guidance, the use of computer games (the series Ram Kid, Kide Pedia, etc.) constituted an exception, as children played on their own (without asking for help), they often chose activities they had played before and knew in advance the correct answers (they did not even wait to listen to the instructions), and they never asked for teacher's help. Regarding this point, there is an agreement with other research studies (Ljung-Djärf et al., 2005 ; Vangsnes et al., 2012) which reported lack of teacher intervention when children played computer games. As evidence-based guidelines for computer use in preschool education are limited (Siraj-Blatchford & Siraj-Blatchford, 2006), it is rather uncertain for teachers on how to achieve the visions-claims reported in literature. The issue of teacher guidance when children use different educational software programs in kindergarten classes is suggested for further investigation.

Teachers reported that children's computer work is often displayed in the classroom. For example, children's drawings made with the program MS Paint alternate as a background on the class computer (in N2), children's printed work is displayed at the end of the year (in N9), while all children's computer work is copied onto a CD for the parents (in N10). For example, "There is a computer folder which is given to parents at the end of the year...it includes all work the child has done on

the computer (printouts with names, pictures on Paint etc)" (teacher in N10). In such a way, computer use is considered as an activity carried out in kindergarten's daily practice, an activity like other school activities that may foster the links between school and parents. Additionally, several teachers noted examples of children's evident pleasure during their engagement with ICT (i.e., an aspect of children's preschool experiences that is valued, as promoting a positive disposition towards learning): "After help as to where to click, she was happy to print, a short phrase she wrote using MS Word, independently" (teacher in N4).

The interviews with the teachers also revealed the time period (timing) during which some of the programs are being used in classes. It was shown that computer games are mainly used at the beginning of the academic year, while the word processor is used by the end of the year. Indicative quotes from interviews were: "Computer games are mainly used at the beginning of the year, so that children become acquainted with the use of the mouse, while the word processor is used by the end of the year" (teacher in N3), "Children, especially by the end of the year, recognize the letters of the alphabet, they can make the transfer between lowercase and uppercase letters... thus the word processor is used by the end of the year" (in N7), and "The letters on keyboard are uppercase, while the children in kindergarten learn initially the lowercase letter... the (program) Word is used in spring" (in N9). In another kindergarten where the uppercase letters are being taught fi rst, "Every child who enters the class in the morning is encouraged to sit on the computer to write her /his name on a separate line. They have been taught the uppercase letters and now (month May) we are in the process of teaching the lowercase letters. After March they started to write their name in the Word every morning, as a kind of register -till then they wrote it on a paper" (teacher in N6). It appears that some teachers decide on the learning goals to be achieved in their class before they decide on the type of software, and this decision/sequence is in agreement with earlier research (Haugland, 2005 ; Lin, 2012). For example, Lin (2012) suggests that teachers can choose the learning objectives and design a series of activities (software use could be among them) in order to accomplish learning goals.

Diffi culties Children Face in the Use of Educational Software

The interviews with the teachers in combination with class observations revealed some diffi culties children encountered when using the programs MS Paint and MS Word. Interestingly, although the use of MS Paint was most commonly reported (as shown in Table 2), in almost one third of the kindergartens (in N7, N9, N10, N11, and N16) children faced some sort of diffi culties. Examples of excerpts from the interviews were: "The children initially preferred games but now they are also using MS Paint with my help, because they have diffi culties" (teacher in N10) and "The MS Paint is not used because i fi nd it diffi cult... in order to get a quality result - painting—it needs time for training" (teacher in N7). One factor that makes the program MS Paint diffi cult is that some children have not developed the necessary fi ne motor skills: for example, they have got used to draw a house much easier by

hand using traditional materials, rather than by using the Paint program. Drawing with pencils and other traditional materials is an essential traditional activity and the use of the software does not come to replace it but to support and extend children's experiences. Guided interaction (e.g., demonstrating how to use the eraser/paintbrush, or providing feedback so as to encourage the child's efforts) is a way for helping the children overcome some diffi culties. Overall, the role of learning in the use of software programs is important and (as a teacher mentioned) time is needed for children's training and practice.

Regarding the use of MS Word, almost in every class where its use was observed, children faced diffi culties in identifying specifi c alphabet letters on the keyboard—because the Greek and the English characters were both present on some buttons. This diffi culty could be overcome by placing on the keyboard, stickers with the Greek uppercase letters, a procedure which was successfully followed in kindergarten N6. Furthermore, another diffi culty was that children pressed continually one button, with the consequent need to delete several characters (i.e., by using the Backspace button). In order for the MS Word to be used in class, it is suggested for children to have an initial acquaintance with the alphabet letters: this helps children to identify/recognize the relevant letters on the keyboard. Thus, the time period the Word is introduced in class is very important. It has been mentioned that teachers chose to introduce the program in spring, towards the end of the academic year. The role of learning in the use of MS Word is important. For example, as two teachers reported informally, children are sometimes given text to copy and as their skill and accuracy develop, they are expected to type and print short sentences.

Aspects of observations together with the interviews revealed that some children haven't developed the necessary fi ne motor skills for the use of the software. At the beginning of the academic year some problems appear mainly with those children who do not have a computer at home, but afterwards all children seem to become accustomed to computer use. Diffi culties with the mouse seem to be easily overcome, through practice. Examples from interview excerpts were: "Some children need physical guidance to support their development of mouse control. However, after few attempts they get mouse control and become more confi dent" (teacher in N8), "Children are more familiar with the mouse—because they play games—rather than with the keyboard. They often press continually the keyboard buttons... I've noticed differences in children's fi ne motor skills due to computer use at home" (teacher in N7), "We found out that some children do not have computer at home and at the beginning they face diffi culties. The computer helps in the development of fi ne motor skills -the mouse helps a lot...In general, when computer games are carefully selected they help a lot" (teacher in N11) and "Gender differences are not intense, the differences appear due to different access to computer at home and due to the frequency of choosing the computer at school...sometimes, children 4 years old handle the mouse much better than older children who rarely choose to use the computer at school" (teacher in N6). Additionally, in a class with children with special needs there were present some initial diffi culties, which were then overcome: "We started with the painting program where children struggled a bit because it did not come out—what they wanted—i.e., what comes out with the hand. They faced diffi culties with the use of the mouse...Later on, we put children's names on

the computer and they were encouraged to write them with different characters" (teacher in N16). The interview excerpts reveal the role of learning/practice as well as the crucial role of the kindergarten teachers in the study. Computers have the potential to support young children's classroom experiences, but for this to happen "it is necessary for teachers to carefully plan for, and articulate to children, suitable classroom tasks" (Kervin & Mantei, 2009 , p. 30).

Some of the interview excerpts presented in this paper, as well as others not shown here, revealed issues related (a) to the use of computer by children at home and (b) to children's gender. The already developed children's fi ne motor skills were often attributed to the use of computer at home. Recent research (McKenney & Voogt, 2010 ; Plowman, McPake, & Stephen, 2008) reported that young children have access to and use the computer/ICT at home and many children had acquired the basic computer skills already from home (before they entered kindergarten). As there are differences regarding the skills children bring to classroom use of computers, it is suggested for teachers to be aware of these skills (in order, for example, to provide support for those children without previous technological experience).

Regarding children's gender, the results appeared contradictory. In some kindergartens (in N9, N10, N12), children's gender appears to be related to the frequency of computer use (is higher for boys) or to children's preferences to different types of software. Some teachers reported that boys were more interested in using the computer because they chose it more frequently during the hours of free activities, while the girls preferred to be engaged in other activities. Two interview excerpts regarding children's preferences were: "Girls prefer activities with puzzles, painting" (in N9) and "Boys prefer action games, games that provide scores" (in N9, N12).

However, in other kindergartens (e.g., in N6 and N7) no gender differences were reported, as "When it comes their turn to work on the computer all children want – it did not happen a child not to want (the computer) and to choose another activity" (teacher in N7). In literature, gender differences regarded children's preferences towards interface design (Passig & Levin, 2000) and software's characters (Littleton, Light, Joiner, Messer, & Barnes, 1992). In particular, young boys seem to be attracted by movement, "male" characters and action games, while young girls seem to prefer the colorful buttons of a program and "female" characters. However, other studies did not report on signifi cant gender differences when children use computers in class (Hatzigianni & Margetts, 2012 ; Shawareb, 2011). As a consequence, the issue of gender can be further investigated.

Concluding Comments and Recommendations for Future Research

The research described in this paper provides some useful insight for researchers and teachers about educational software usage in kindergarten classes. The class observations and the interviews with the teachers revealed some issues diffi cult to be explored through large-scale quantitative surveys. The data derived from the 17

kindergartens cannot be generalized due to the small sample and its origin from one region. However, taken into account that in Greece (as well as in other countries) there is limited empirical research, this study contributes to our understanding of computer use and classroom practices with young children. Concluding comments are presented below.

The most commonly used programs were painting programs (especially the MS Paint), the commercial series Ram Kid/Kide Pedia (which include many games), educational CD-ROMs and the MS Word, while the use of the Internet was rare. For early childhood settings with tight budgets, the use of software programs that are free, low cost or downloadable seems a good choice. In parallel, researchers have emphasized the issue of using developmentally appropriate software, in appropriate ways (Parette & Blum, 2013). Classroom activities designed using appropriate technologies and NAEYC principles (e.g., the technologies should align with the curriculum, the choice of technology should be based on how it serves classroom learning, see NAEYC – FRC 2012) support the developmental learning needs of young learners. It is the case that not all commercial computer games are developmentally appropriate for use by young children. As a starting point, software/games need to be carefully evaluated by teachers (a process facilitated when teachers have attended appropriate training) before any usage in the classroom.

This study found that computer use took place, mainly, during the hour of free activities at the computer corner. "Playing with the computer" designates a series of qualitatively different activities in which children can, for example, engage in drawing, writing or play (Plowman & Stephen, 2005), and computer use in the hour of free play activities is linked to literacy and pedagogy. For example, the manipulation of symbols and images on computer screen represents a new form of symbolic play, and there is potential in the development of children's higher order thinking (Verenikina et al., 2010 ; Yelland, 2005). Wohlwend (2009) demonstrated that 5-7-year-old children were accessing new literacies through pretend play—to explore iPods and video games— while Morgan (2010) indicated that teachers value and promote "playful" and interactive technology experiences as vehicles for 3-7-year-old children's learning. Appropriate ways for computer/technology integration could include technology-supported learning experiences during the hour of free activities: for example, instances where children are provided with technology support that help them complete tasks in classroom activities. With regard to the third objective, children encountered some diffi culties in using the programs MS Paint and MS Word. Some diffi culties with the MS Paint were mainly attributed to children's underdeveloped fi ne motor skills. The role of learning in the use of such programs is important, because these programs support and extend children's experiences.

The crucial role of early childhood teachers, in the whole process of computer use in kindergarten classes, has emerged. Initially, teachers' participation in this project was voluntary and they suggested the timing for the observations, while later they decided on the program(s) used in their classes and on class organization. The essential role of kindergarten teachers in ICT environments, for supporting and extending children's experiences, has been extensively discussed in relevant literature (Kervin & Mantei, 2009 ; Stephen & Plowman, 2008). Selwyn (2011) proposed the cultivation

of a critical digital literacy approach: for example, the development of creative spaces utilizing digital technologies that bridge formal/informal divide. As young children are entering early childhood settings with dispositions that may not have been part of their repertoire of skills in past decades, early childhood educators need to be aware of this and to develop new learning experiences for young children (Zevenbergen & Logan, 2008). The teachers are the designers and implementers of learning activities for children. The role of the teachers is related to and has implications for teacher training. Teachers' skills, views, and classroom practices have all implications for inservice training in the pedagogical uses of ICT. According to Parette, Quesenberry, and Blum (2010), both preservice education and in-service professional development are important so that early childhood teachers develop and apply skills in integrating and using ICT in classroom settings.

The limitations of this study included the limited amount of time and the limited fi nancial resources. For example, if video recordings were used during class observations, this could have highlighted the interactions between young children and software, as well as the interactions among children (their gestures, dialogues, etc.). It is noted that this study did not investigate the acquisition/development of skills and knowledge through the use of educational software, and this will constitute the focus of another paper.

As there is little empirical evidence on the use of computers in early childhood

settings, the following issues are suggested for future research. Investigation of the
activities children do on the class computer and the development of specifi c skills.
The research has now moved on from questions about whether ICT can help children learn (Stephen & Plowman, 2008), with the need to investigate further how and
whether it makes a difference in young children's learning and development. For
example, Haugland (2000) discussed for developmentally appropriate activities,
while Yelland and Kilderry (2010) reported that ICT as a resource is being
underutilized and children are being denied access to learning opportunities that
promote open-ended applications, problem solving situations/tasks that result in
varied learning outcomes. The link between early childhood pedagogy and ICT
could also be further explored. It is a fact that software and hardware are constantly
changing. Whilst this does not necessarily mean that the pedagogical issues of using
ICT in early childhood settings automatically change as well, it cannot be assumed
that they remain constant either. There is a need, for example, to identify quality
practices and appropriate types of teacher intervention. As Parette and Blum (2013)
reported, the key challenge for today's teachers is how to use technologies effectively and effi ciently in order to support learning experiences for young children in
the classroom. Future research could also investigate to what extent the factors
"children's use of computer/ICT at home" and "children's gender" impact on children's use of ICT in early childhood settings. Finally, some other broader fi elds that
might be of interest to educators/researchers include teachers' attitudes and motivations to use ICT in kindergartens. Provided that today's children are surrounded by
different technological tools, it is worth investigating how teachers embrace and
utilize a broader range of technologies, apart from computers, to support young
children's learning in classrooms.

Introduction
Nowadays, it is becoming increasingly accepted that various ICT applications are
developmentally appropriate technological resources for children of primary and
secondary school age (Druin & Fast, 2002 ; Passey, 2006 ; Plowman & Stephen,
2003 ; Zaranis, 2011). It is obvious now that the original "aphorism" and the ignoring of ICT are no longer effective strategies and are gradually replaced by more
realistic solutions as infl uenced by related research (Remtulla, 2010).
Technology, in this enlarged view, acts as a catalyst in their social interaction and
moreover provides additional opportunities for a rich learning environment that is
consistent with the modern era. International research confi rms that the implementation of computers in education can have positive results in different subjects (Chou
& Liu, 2005 ; Finegan & Austin, 2002 ; Livingstone, 2012). These technologies can
therefore play an essential role in achieving the objectives of the primary curriculum
in all sectors and subjects if supported by developmentally appropriate software
applications embedded in appropriate educational scenarios (Dwyer, 2007 ; Fisher,
Denning, Higgins, & Loveless, 2012 ; Lee, 2009 ; Zaranis & Oikonomidis 2009).
ICT and Mathematics
In the most ideal setting, information communication technologies are treated as a
tool for teaching and learning (Burnett, 2009 ; Sife, Lwoga, & Sanga, 2007 ;
Sutherland et al., 2004). They are used as a tool for the students to become more

familiar with new technology and to integrate investigation, communication, and
understanding across the full range of the curriculum. Particularly, in the cognitive
fi eld of mathematics an evaluation of learning outcomes regarding computer based
mathematical teaching in students showed that computer-assisted learning can signifi cantly help in developing proper mathematical skills and the cultivation of deeper
conceptual thinking in comparison to the traditional mathematical teaching method
(Dimakos & Zaranis 2010 ; Hardman, 2005 ; Keong, Horani, & Daniel, 2005).
Researchers suggest that the mathematical diffi culties students encounter later
are correlated with insuffi cient development of mathematical thinking in their early
years (Bobis et al., 2005 ; Gersten, Jordan, & Flojo, 2005). Various researches'
results relate the appropriate use of computers with the ability of students to more
effi ciently understand the different mathematical notions (Howie & Blignaut, 2009 ;
Trouche & Drijvers, 2010). Thus, it becomes obvious that in the primary school
level a very attractive environment of investigating the computer use in mathematics
education emerges. Indeed, a vast number of studies show a positive interrelation
between the use of computers and the development of mathematical thinking in
school (Clements, 2002 ; Vale & Leder, 2004). Nonetheless, computer based activities should refl ect the theoretical ideas behind them (Clements & Sarama, 2004 ;
Disanayake, Karunananda, & Lekamge, 2007).
Following this principle, the software designed and the students' activities developed and examined for the purposes of the current study were inspired by the framework of Realistic Mathematics Education (RME) and the van Hiele model. RME
was based and developed principally upon Freudenthal's (1968) view of mathematics
as a "human activity." According to his perspective, in order for mathematics to be
of human value, it has to be taught so as to be useful, it has to be closely related to
reality, close to children and relevant to the society (Freudenthal, 1968 ; Van den
Heuvel-Panhuizen & Wijers, 2005). RME is an active and constantly evolving theory of teaching and learning mathematics (Van den Heuvel-Panhuizen, 2001).
Indicative of this, the learning and teaching trajectories with intermediate attainment targets were fi rst conducted for the subject of mathematical calculation at the
primary school level and extended to the subject of geometry (Van den Heuvel-
Panhuizen & Buys, 2008).
In the whole trajectory of the RME teaching theory, fi ve main characteristics of
understanding geometry concepts are involved: (a) introducing a problem using a
realistic context; (b) identifying the main objects of the problem; (c) using appropriate social interaction and teacher intervention to refi ne the models of the problem;
(d) encouraging the process of reinvention with the development of the problem;
and (e) focusing on the connections and aspects of mathematics in general (Van den
Heuvel-Panhuizen, 2001). These should be the main focuses of the learning and
teaching procedure concerning geometry in primary school.
Moreover, the theory of the van Hiele model deals specifi cally with geometric
thought as it develops through several levels of sophistication under the infl uence of
a school curriculum (Clements & Battista, 1992). The van Hiele model uses fi ve
levels, however, for the fi rst grade students only the fi rst two levels were used. In the
Visual Level, students were able to identify fi gures such as circles and triangles as
visual gestalts. Conceptualization at this level includes being able to name, reproduce
N. Zaranis61
and group similar geometric objects by visual recognition. For instance, they might
say that a fi gure is a rectangle because it looks like a door. In the Descriptive/
Analytic Level, students were able to identify shapes from their properties.
Conceptualization at this level includes identifying geometric objects according to
their properties. For example, a student sees a rhombus as a fi gure with four equal
sides (Zaranis, 2012). Following the theoretical framework that blends together
Realistic Mathematics Education (RME), the van Hiele model of geometric thinking and the use of ICT in primary school, we designed a new model referred to as

the First Class Primary Shape Model (FCPSM) which consisted of fi ve levels.
The majority of previous studies aggregately examined the effects of various
teaching on the geometric shapes. However, a small number of studies have found
that in the fi rst levels of primary school, various shapes are understood differently
by students (Walcott et al., 2009 ; Wong et al., 2007). These studies examined the
impact of various teaching interventions on each shape distinctively. Specifi cally, in
the case of circles, only the thickness and size may be varied. Rectangles and triangles may also share differences in characteristics of thickness and size with the
addition of other variable characteristics such as length of sides and orientation.
Moreover, triangles may vary in the degree of their angles, resulting in a greater
variety of shapes. Thus, from the perspective of characteristic features, circles are
the simplest. On the contrary, triangles are the most complex, and rectangles are of
intermediate diffi culty (Satlow & Newcombe, 1998 ; Wong et al., 2011).
Our study was based on the above mentioned international literature; we set out
to investigate the following research question: Is the concept of triangles more dif-
fi cult to understand than circles for the fi rst grade students?
In addition, based on the previous studies, we set out to investigate the following
hypotheses:
1. The students who will be taught circles with educational intervention based on
FCPSM will have a signifi cant improvement in comparison to those taught using
the traditional teaching method according to the fi rst grade curriculum.
2. The students who will be taught triangles with educational intervention based on
FCPSM will have a signifi cant improvement in comparison to those taught using
the traditional teaching method according to the fi rst grade curriculum.
The present study makes an important contribution to the literature; we examined and compared the effects of a new model which combines computer and non-
computer activities for teaching circles and triangles separately.
Methodology
Subjects
The study was carried out during the 2011-2012 school year in ten public primary
schools located in the cities of Rethymno in Crete (two classes) and Athens (eight
classes). It was an experimental research which compared the FCPSM teaching

process to traditional teaching based on fi rst grade curriculum. The sample included
234 fi rst graders consisting of 123 girls and 111 boys age 6-7 years old. There were
two groups in the study, one control (n = 121) and one experimental (n = 113). In the
control group there was not a computer available for the students' use. The classes
in the experimental group, in order to participate, were required to have a laptop
computer and a video projector available for use by children as part of the teaching
procedure. For the uniformity of the survey, instructions were given to the teachers
who taught in the experimental or control groups. Teachers who participated in the
study had university degrees in education. The teachers in the experimental group
ranged from 40 to 50-year-olds with in-service teaching experience ranging from 18
to 28 years. The teachers in the control group were of ages 38-48 years with in-
service teaching experience ranging from 15 to 25 years.
Instructional Intervention
In the second phase the control group taught with traditional teaching according to
kindergarten curriculum. Group and individual activities were given to children
every day. The experimental group covered the same material at roughly the same
time according to the FCPSM teaching. The content of the 4-week syllabus of the
FCPSM divided in fi ve levels. It comprised of shapes including a variety of topics
concerning fundamental geometry concepts and focus on circles and triangles.
The fi rst level of the teaching intervention was according to the fi rst characteristic of the teaching theory of RME which introduces a problem using a realistic
context. In this level a story called "The Family of Shapes" was presented to the
students. Various geometrical shapes including circles and triangles are presented in
this story in a fi ctional family setting where each member of the family represents a
particular shape. This story was designed using Flash CS3 Professional Edition and
presented with the video projector in the classroom. In this story Mrs. Square and
Mr. Triangle (Fig. 1 -left) had a daughter Miss Circle. Later in the story, Miss Circle
met Mr. Rectangle, got married, and had many children that looked like their parents and grandparents.
The second level started with an activity which identifi es the main objects of the
problem as underlined by the RME theory. According to the fi rst level of the van
Hiele model and the second characteristics of the RME theory, the students (a) identifi ed various geometrical shapes by examining objects in their classrooms, (b) drew
certain geometrical shapes (Fig. 1 -right), and (c) named the shape of a set of various
objects presented to them by the teacher.
The third level of the teaching procedure included activities using appropriate
social interaction to refi ne the models of the problem. Firstly, a child had to draw a
shape from a bag and to fi nd out the name of the shape without seeing it. Then, the
students split into groups and each group had to construct a dog or a man using a set
of shapes. The fi nal part of this level involved a computer-based group activity in
which the student had to recognize and choose the correct shape among other shapes
(Fig. 2 -left) as implied by the fi rst van Hiele level.

In the fourth level of the teaching procedure, according to the second level of the
van Hiele model and the RME theory, we implemented a process of reinvention
with the development of the shapes in a higher cognitive level where the properties
of an object were presented in a software activity (Fig. 2 -right). Next, the children
were separated into groups and cooperated with one another to make a shape with
their bodies on the fl oor (Fig. 3 -left). Then, they divided into groups and each group
was assigned a specifi c shape. Each of these groups was instructed to make fake
cookies from plasticine in the form of the groups' assigned shape. At the end of this
activity, the students in each group shared their cookies with the other groups.
In the last level of the teaching process, as the second level of van Hiele theory
implied, the students played card games with the properties of shapes. The goal
of this card game is to focus on the connections and aspects of the properties of
circles and triangles as implied by the fi fth characteristic of the RME theory.
There were two kinds of card games: the white cards with shapes and their properties of sides and the yellow cards with shapes and their properties of angles. The
students are separated into groups and each student in a group starts with a number
of cards in their hand. Each student takes his/her turn throwing a card on the table.
Fig. 1 Students watched the story "The Family of Shapes" (left —fi rst level) and did a drawing
activity (right —second level)
Fig. 2 The student had to recognize shapes (left —third level) and students viewed the properties
of a triangle on the computer (right —fourth level)

The purpose of the game is to match cards with identical properties and to collect
those cards. At the end of the game the child who had the majority of cards was the
winner. Afterwards, there were computer activities where the children had to recognize the shapes from using only the properties of the shapes. The computer presents
a picture as a puzzle. The students then must drag and drop the corresponding shape,
based the geometrical property displayed on the screen, into the box (Fig. 3 -right).
In the software represented above, once an activity is selected, a problem is
announced verbally and directions are given to the user through a recorded message.
The feedback users get after following these directions is represented by two different screens, one positive and one negative. This feedback is accompanied with the
corresponding audio messages. In the fi rst case, the user receives a "well-done"
message and in the second case the user gets a "try it again" message. In both cases,
though, an effort was made to keep these messages to be as little emphatic as possible. This way, the children's' interest is focused more on the mathematical procedure of the application rather than their result or the competition.
Educational Measures
The present research was conducted in three phases. In the fi rst phase, the pretest
was given to the classes of the experimental and control groups during the beginning of December 2011 to isolate the effects of the treatment by looking for inherent
inequities in the geometry achievement potential of the two groups. The pretest was
referred to as First Class Primary Shape Test (FCPST) and it contained thirty tasks
in total. The fi rst twenty tasks of the FCPST were based on the fi rst level of the Van
Hiele model and the last ten were from the test that was used in the research by
Clements, Swaminathan, Zeitler-Hannibal, and Sarama (1999) based on the second
van Hiele level. Due to the young age of the students, the pretests were administrated in the class with explicit and detailed instructions of the teacher. These were
pencil-and-paper tasks in which the children were asked to select shapes including
Fig. 3 Students made a shape with their bodies on the fl oor (left —fourth level) and completed a
software activity (right —fi fth level)

rectangles, squares, triangles, and circles on a page with various geometric fi gures
(Fig. 4). Each task had a weighted grade that was computed from the student's
answers. Particularly, for each correct answer the student was given one grade and
lost one grade for each incorrect. Scores were computed for each of the individual
geometrical tasks of the FCPST. Since the numbers of problems varied across tasks,
a mean proportion of correct responses for each of the thirty tasks were produced by
dividing the number of correct responses by the total number of problems on that
task (possible range of standardized scores, 0-1.00). Moreover, for the purposes of
the present study, we measured the score of circles and the score of the triangles
separately. The scale used to measure the unstandardized scores for circles is based
on a scale from 0 to 69. The scale used to measure the unstandardized scores for
triangles is based on a scale from 0 to 40.
Similarly, during the third and fi nal phase of the study, after the teaching intervention, the same test (FCPST) was given to all students in both the experimental
and control groups as a posttest at the beginning of March 2012 to measure their
improvement on circles and triangles separately.
Research Design
The present study was a quasi-experimental design with one experimental and one
control groups. Eight fi rst grade classes from Athens and two from Rethymno participated in this study. From the eight classes located in Athens, we randomly
assigned four classes to the control group and the remaining four classes were
Fig. 4 Student marks circles

assigned to the experimental group. We then randomly assigned one of the two
classes from Rethymno to the control group and the other class to the experimental
group. Therefore, fi ve classes were in the control group (n = 121) and the remaining
fi ve classes were in the experimental group (n = 113).
Results
A set of analyses was conducted to determine the effects of the mathematics intervention on fi rst grade students' geometry knowledge for circles and triangles. The
pretest and posttest were taken by 234 students. Analysis of the data was carried out
using the SPSS (ver. 19) statistical analysis computer program. The independent
variables were the group (experimental group and control group) and the shape (circles or triangles). The dependent variable was the students' FCPST posttest score.
Comparing the Diffi culty Between Understanding
Circles and Triangles
The fi rst analysis was a paired t -test among the students' FCPST pretest scores of
circles and triangles in order to examine whether the concept of triangles is more
diffi cult to understand than circles. There was a signifi cant difference in the students' FCPST pretest scores for circles (M = 0.94, SD = 0.04) and triangles (M = 0.83,
SD = 0.07); t (233) = 25.93, p <0.001.
The descriptive statistics for students' scores for circles and triangles are presented in Table 1 . Observing the standardized values, students scored higher for
circles and triangles after receiving the intervention than before receiving it.
Moreover, the score of the students in triangles was lower than those in circles after
the teaching intervention (Table 1).
Evaluate the Effectiveness of FCPSM for Circles
Before conducting the analysis of ANCOVA on the students' FCPST posttest scores
for circles to evaluate the effectiveness of the intervention, checks were performed
to confi rm that there were no violations of the assumptions of homogeneity of
Table 1 Descriptive statistics for students' standardized scores of experimental and control groups
Circles Triangles
Pretest Posttest Pretest Posttest
Group M SD M SD M SD M SD
Control 0.94 0.04 0.95 0.03 0.82 0.05 0.85 0.06
Experimental 0.95 0.04 0.97 0.03 0.83 0.08 0.91 0.06

variances and homogeneity of regression slopes (Pallant, 2001). The result of
Levene's test when pretest for circles was included in the model as a covariate was
not signifi cant, indicating that the group variances were equal, F (1, 232) = 0.476,
p = 0.491; hence, the assumption of homogeneity of variance was not been violated.
The value of the covariance by dependent variable interaction (group × score for
circles) was not signifi cant, F (1, 230) = 2.042, p = 0.154, η^2 = 0.009; therefore, the
assumption homogeneity of regression slopes was tenable. After adjusting for
FCPST scores for circles in the pretest (covariate), the following results were
obtained from the analysis of covariance (ANCOVA). A statistically signifi cant main
effect was found for type of intervention on the FCPST posttest scores for circles,
F (1, 231) = 46.513, p < 0.001, η^2 = 0.168 (Table 2); thus, the experimental group performed signifi cantly higher in the FCPST posttest for circles than the control group.
Evaluate the Effectiveness of FCPSM for Triangles
Then, the analysis of ANCOVA on the students' FCPST posttest scores for triangles
was performed to evaluate the effectiveness of the intervention. The result of Levene's
test when pretest for triangles was included in the model as a covariate was not signifi cant, indicating that the group variances were equal, F (1, 232) = 0.044, p = 0.834;
hence, the assumption of homogeneity of variance was not been violated.
The value of the covariance by dependent variable interaction (group × score for
triangles) was not signifi cant, F (1, 230) = 0.214, p = 0.644, η^2 = 0.001; therefore, the
assumption homogeneity of regression slopes was tenable. After adjusting for
FCPST scores for triangles in the pretest (covariate), the following results were
obtained from the analysis of covariance (ANCOVA). A statistically signifi cant
main effect was found for type of intervention on the FCPST posttest scores for
triangles, F (1, 231) = 69.715, p < 0.001, η^2 = 0.232 (Table 3); thus, the experimental
group performed signifi cantly higher in the FCPST posttest for triangles than the
control group.

Results of this study expand the research on the effects of appropriate software

embedded in a computerized environment as a tool for visualization and mathematical reasoning used alongside with specially designed activities (Bobis et al., 2005 ; Dimakos & Zaranis, 2010 ; Dissanayake et al., 2007 ; Gersten et al., 2005 ; Howie & Blignaut, 2009 ; Starkey, Klein, & Wakeley, 2004 ; Trouche & Drijvers, 2010 ; Wong et al., 2007 , 2011 ; Zaranis, 2012). Also, the outcomes of the present study create a new teaching model with computer and non-computer activities based on the theoretical framework that blends together Realistic Mathematics Education and the van Hiele model of geometric thinking in primary school.

Discussion

The overall purpose of the study was to investigate the impact of instructional intervention using the First Class Primary Shape Model (specially designed mathematics activities and software based on Realistic Mathematics Education and the van Hiele model) for the purpose of teaching the basic geometrical concepts of circles and triangles in regard to the geometry competence of the fi rst grade students of primary school. In this research, we found that it is more diffi cult for fi rst grade students to understand the concept of triangles than circles. These students carried a relatively great amount of geometric knowledge from kindergarten and as a result, it is possible that the students understand circles and their properties better than triangles because triangles are more complex shapes than circles (Bobis et al., 2005 ; Clements & Sarama, 2004). Our fi ndings agree with similar researches (Satlow & Newcombe, 1998 ; Walcott et al., 2009 ; Wong et al., 2007 , 2011) which implied that circles are simpler and triangles are most complex. As a result, the research question answered positively.

Moreover, we found that the students that were taught circles with educational intervention based on FCPSM had a signifi cant improvement compared to those taught using the traditional teaching method according to the fi rst grade curriculum (hypothesis 1). Our results overlap with the results of other analogous studies which indicate the positive effects of a computer based-model of teaching geometry (Bobis et al., 2005 ; Dissanayake et al., 2007 ; Wong et al., 2007 ; Zaranis, 2012). Therefore, the fi rst hypothesis was confi rmed.

Also, our fi ndings suggest that the students were taught triangles with educational intervention based on FCPSM had a signifi cant improvement compared to those taught using the traditional teaching method (hypothesis 2). Our outcomes overlie the results of other similar studies which indicate the positive effects of a computer based teaching model for geometric shapes (Dimakos & Zaranis, 2010 ; Howie & Blignaut, 2009 ; Starkey et al., 2004 ; Trouche & Drijvers, 2010 ; Wong et al., 2011). Thus, the second hypothesis was answered positively. In addition, as it mentioned in the results section, students in both the experimental and the control groups scored higher for shapes of circles or triangles after receiving the teaching intervention than before the teaching process.

N. Zaranis69

Moreover, an important statistical outcome of the present study was that the partial eta squared for triangles (η
2
= 0.232, Table 3) is higher than it was for circles
(η
2
= 0.168, Table 2). This outcomes supports that, our teaching intervention had a somewhat greater impact in learning triangles than of learning circles for fi rst grade students. Also, the present study demonstrates that our fi rst grade teaching process, the non-computer based mathematics activities and the computer based mathematics activities, may support the learning of both diffi cult and simple mathematics in the primary school level. Our fi ndings agree with other similar researches supporting the effective role of ICT in education and more specifi cally in mathematical reasoning (Clements & Sarama, 2004 ; Dimakos and Zaranis 2010 ; Furner & Marinas, 2007 ; Hardman, 2005 ; Howie & Blignaut, 2009 ; Keong et al., 2005 ; Vale & Leder, 2004).

The above discussion should be referenced in light of some of the limitations of this study. The fi rst limitation of the study is that the data collected was from the participants residing the cities of Athens and Rethymno. The second limitation was the generalizability of this study which was limited to participants attending public schools. Therefore, the results from this research can be generalized only to similar groups of students. The results may not adequately describe students from other regions of Greece. However, as the study was of small scale and context specifi c, any application of the fi ndings should be done with caution.

Furthermore, the undertaken computer assisted educational procedure revealed an extended interest for the tasks involved from the part of the students. It is an ongoing challenge for the refl ective teacher to decide how this technology can be best utilized in education; especially in light of the current researches on the effects of such an implementation. This study is one small piece in the puzzle of geometry education in primary schools.

Introduction

A series of studies suggest that learning programming languages affects the development of critical and structured thinking and the acquiring of higher thinking skills, while at the same time programming languages support learning in other areas (Mikropoulos, 2004). From 1970 and for almost 2 decades Informatics was taught mainly in secondary education and focused mainly on learning some programming language (Komis, 2004). At the same time there has been research on the didactics of programming. It focused on charting the relevant students' initial misconceptions so as to develop standards, both for the teaching materials and for the teaching methods that were in agreement with constructivism (Jimoyiannis, 2005).

The need for constructivist and exploratory approaches in teaching Informatics become even more relevant with the introduction of Programming, as part of the module "Programming the computer" of the Cross-thematic Curriculum Framework (CCF), in the 5th and 6th grades of Primary education in Greece a few years ago, specifi cally in 2011 (CCF, 2011).

Research Questions

In order to address the research question, the following points were taking into consideration.

• There are no textbooks available for teaching Programming in the Primary School (Pedagogical Institute, 2013) and the teaching material presently offered is limited and often has not been previously implemented and assessed (Ministry of Education, 2013).

• Results of a series of studies focused on the experiential teaching of computer science without any use of computers show that the experiential learning of programming promotes collaboration and teamwork (Bell, 2000 ; Bell, Alexander, Freema, & Grimley, 2009 ; Curzon & McOwan, 2008 ; Taub, Ben-Ari, & Armoni, 2009).

• In the CCF for ICT teaching in primary education, the initial students' misconceptions have not been taken into account. However, available research points out that students assume that the computer has "anthropomorphic characteristics" and that it has a "hidden intelligence" (Pea, 1986 ; Taylor, 1990),

Through these three points the parameters of the research question were determined.

The purpose of this study is to assess the learning outcomes of teaching scenarios, designed by our team, for the module "Programming the computer" of the CCF for teaching Informatics in the 5th Grade. These teaching scenarios promoted problem solving and the development of critical thinking and included exploratory, constructive and collaborative activities (CCF, 2011). Moreover, the initial students' misconceptions and students' specifi c cognitive diffi culties related to learning computer programming were taken into account.

The following research questions were addressed:

1. What is the improvement in critical thinking skills (Matsagouras, 2000 , 2005 ,

2007) that is achieved through the teaching of the designed module "Programming the computer" in a programming environment?
2. What is the improvement in critical thinking skills (Matsagouras, 2000 , 2005 , 2007) that is achieved through the teaching of the designed module "Programming the computer" without computer usage, namely experientially?
3. Does the teaching of the designed module whether in a programming environment or without the use of computer (experientially) promote collaboration, inquiry, critical thinking and development of problem solving skills, in accordance with the general purpose of ICT integration in the Primary School (CCF, 2011)?
Theoretical Framework
Since the design of the module followed the constructivist approach, it took into account the students' initial misconceptions and the cognitive diffi culties that they face (Skoumios, 2011). Summarising the studies on the cognitive
P. Halki and P. Politis75
diffi culties and the students' initial misconceptions on Programming leads to the following conclusions:
• Students need to not only understand the syntax and the specifi c semantics of a programming language, but also to use properly and in a structurally coherent way these programming language tools, which are not related to their prior practical- experiential knowledge (Jimoyiannis, 2005).
• The concept of some terms, already known to the students, such as "equal", "data", found in other cognitive areas (mathematics, science) are not identical to that in the fi eld of Programming. This differentiated concept creates diffi culties for students in understanding and writing in a programming environment (Jimoyiannis, 2005).
• In any programming environment, students face diffi culties in writing commands following the correct syntax, since this is the fi rst time they come in contact with the syntax and semantics of the specifi c programming language commands. With no exception, programming languages require a rigorous design in the syntax and structure of their own commands (Jimoyiannis, 2005).
• Students cannot understand the role of the computational machine during the execution of program. Students have diffi culty in understanding the data fl ow in a computer system (Jimoyiannis, 2005). They also have diffi culty to develop effective models for the computer and its operation during the execution of a program (Bonar & Soloway, 1985 ; Rogalski & Vergnaud, 1987). Students perceive hardware as a "black box" and attribute to it several anthropomorphic characteristics as if it is a "mental giant" or has "hidden intelligence" (Pea, 1986 ; Taylor, 1990). Moreover, students create their own model based on their initial perceptions about computer operation.
• Students face diffi culties to learn how to use the available tools of a programming environment, prior to begin learning the main programming concepts of the programming language itself (Du Boulay, 1989).
The main objectives set by the CCF for teaching the module "Programming the computer" are introducing to and familiarising students with:
• The concept of algorithms.
• The use of strict syntax and interpretation of basic commands solving a concrete problem, through their implementation in a visual programming environment.
• The breaking up of problems into simpler ones.
• The composition of a task from individual components.
• The use of debugging techniques (CCF, 2011).
The computational fl ow of data directly related to a program's execution is not among the objectives that students have to achieve, nor is the interpretation of a program written in any programming language into the language "understood" by the computer.
As mentioned above, the main purpose of this study is to assess learning outcomes of teaching scenarios that were created on the basis of the CCF guidelines taking into account the students' misconceptions regarding the computational fl ow
Teaching Informatics in Primary School…76
of data. However, the teaching scenarios had objectives that promoted the development of critical thinking and followed the learning levels of critical thinking delineated by Matsagouras. Matsagouras (2000 , 2005 , 2007) schema of learning levels of critical thinking was affected by Bloom's taxonomy of learning domains' and was further developed in a more constructivist point of view (Table 1).
Data Collection
This is the recall and reproduction level of information, where students were asked to retrieve knowledge referring to terminology, specifi c clues, events, etc. (Matsagouras, 2007 ; Oosterhof, 2010 ; Sofos, 2012).
Data Management
This is the skills and concepts level, where the main focus is on procedural knowledge specifi ed by differentiation, concepts and rules. With respect to differentiation what matters is that students differentiate or fi nd similarities among individual stimuli received from the environment. With respect to concepts, what matters is that students perceive the characteristics that can be leveraged so that materials, phenomena, situations, etc. can be classifi ed (Sofos, 2012).
Table 1 Learning levels of critical thinking (Matsagouras 2000 , 2005 , 2007)

Learning levels	Skills	Learning outcomes
First level		
Informational learning (best learning outcome is the completeness of information)		
Data collection		
	1. Observation	
	2. Identifi cation	
	3. Recall	
Information		
Second level		
Organisational learning (best learning outcome is the ability on building concepts)		
Data management		
	1. Comparison	
	2. Categorisation	
	3. Regularisation	
	4. Classifi cation	
Concepts, simple correlations		
Third level		
Analytical learning (best learning outcome is the ability on formulating generalisations)		
Data analysis		
	1. Structural elements analysis	
	2. Relations differentiation	
	3. Pattern differentiation	
	4. Distinguishes facts from opinions/estimations	
	5. Clarifi cation	
Generalisations—principles- schemes		
Fourth level		
Productive learning (best learning outcome is the ability on problem solving)		
Going beyond the data		
	1. Explanation	
	2. Prediction—Hypothesis	
	3. Confi rmation—Inference	
	4. Organisation	
Problem solving		
Theory/prototype generation of cognitive/cultural products		

P. Halki and P. Politis77
Data Analysis
This is the level of generalisation and strategic thinking. This level's main characteristics are the representation of the problem, the classifi cation of the problem, the selection of strategy, the solving method (Sofos, 2012).
Going Beyond the Data
This is the level of extended operation, thought and research, which refers to going beyond the data. The main characteristic of this level is the scientifi c approach adopted using various points of view, leading to hypotheses formulation, disciplined inquiry, stating of explanations and decisions, extracting conclusions, etc. These skills are based on the types of learning that are relevant to forming composite rules and to problem solving (Sofos, 2012).
Methodology
The sample consisted of 35 5th grade students, of a primary school located in the capital of one of the largest Greek islands. The students were divided into two groups. The fi rst, the experimental group (EG) consisting of 16 people, used the educational programming environment Scratch to elaborate the teaching scenarios. The second, the control group (CG) consisting of 19 people, used no technological support, elaborated the didactic scenarios through playing games and so achieving experiential learning.
Scratch is an educational programming language and multimedia authoring tool allowing users to use event driven programming. Scratch can be used by students for a range of educational constructivist purposes from math and science projects, including simulations and visualisations of experiments.
Description of the Educational Factors
Four teaching scenarios were developed for the research needs of this study. Each scenario comprised some educational activities and each student group elaborated them for approximately 2 teaching hours. The EG accomplished the activities by using Scratch. The necessary feedback provided to the students was coming mainly from the educational programming environment and the teacher acted as an auxiliary partner. In contrast, the CG accomplished the activities in question through the use of play, where experiential learning was taking place, whilst the feedback was provided publicly in the classroom mainly by the teacher, who acted also as an organiser. Titles, objectives and duration of teaching scenarios (Table 2) were identical for both groups of students.
Teaching Informatics in Primary School…78
The phases of the teaching scenarios as well as the types of teaching techniques according Matsagouras (Matsagouras, 2005) used overall in all units are presented in Table 3 .
The 1st Section, "What language does the computer 'speak'?" (based on the scenario developed in the context of the web site Computer Science Unplugged: csunplugged.org) dealt with the computer's binary numbering system, i.e. how the data registered by the man in a PC can be converted by the PC in a language that the computer can process (Fig. 1).
In the 2nd Section, teaching focused on the strict syntax of commands. The students took the roles of the computer and the programmer, of robots and their operators so as to conclude that a computer, unlike men, understands only certain and strictly indexed commands (Fig. 2).
Table 2 Titles and duration of didactic scenarios

Section/issue	Teaching hours (approximately)
1. What language does the computer "speak"?	2
2. I articulate the commands and move the robot	2
3. I build scenarios by using orders	2
4. I execute and correct fi nal scenarios	2

Table 3 Phases and teaching styles/techniques on teaching scenarios

S/n	Teaching phases	Teaching styles/techniques
1	Presentation geared to problematic situations	Discussion among students and between students and teacher Questions-answers, thought disclosure
2	Highlighting and clarifying initial perceptions	Discussion among students and between students and teacher Plan design for the emergence of students' initial perceptions
3	Constructive processing	Practice, discussion among students and between students and teacher Discussion on everyday life similar cases, trial implementation of proposed decisions
4	Application to new situations, feedback	Discussion among students and between students and teacher, role play, practice, challenge, personal support (experimental group), feedback at the class level (control group)
5	Refl ection	Discussion among students and between students and teacher
6	Evaluation	Written tests

Fig. 1 Worksheet (on the left) that CG students were asked to fi ll with the help of their classmates (on the centre) and the EG students to fi ll with the help of Scratch (on the right)
P. Halki and P. Politis79
In the 3rd Section, teaching concerned the creation of sequences of a set of commands in order to create a desired image. Students were asked to create sequences that were syntactically and semantically correct (Fig. 3).
The 4th Section dealt with the execution of a sequence of commands that was provided to them and they were asked to analyse its structural elements in order to predict the result of the scenario and debug possible errors inside the code (Fig. 4).
Fig. 2 On the left shows the CG students who are trying to fi nd the right commands so as to move their classmate-robot to the desired position. On the right shows the corresponding setting in Scratch for EG students
Fig. 3 Tasks: (1) send the cat to eat the fi sh, (2) make minnow build the cage to protect the starfi sh from the shark
Fig. 4 Task (on the left): a kitty must save her friend whose house is burned and a solution by EG student (on the centre) and CG student (on the right)
Teaching Informatics in Primary School…80
Data Collection and Analysis
The data collection and analysis of the study was based on:
1. Students' answers in Worksheets and Evaluation Sheets that they were given during teaching. Each question in the Worksheets and Evaluation Sheets related to a specifi c skill according to the levels of critical thinking presented in the theory part of this paper and the analysis was based on counting the frequency of correct answers, indicating the mastering (or not) of the relevant skills (e.g. confi rmation, error fi nding, extract conclusions, etc.).
An example of evaluation questions is presented below:
Given the two scenarios of commands below please answer the questions: (1) Write the numbers of the commands that cause movement in the kitty; (skill:

recognition). (2) Are commands 7 and 9 the same? Justify your answer; (skill: distinction). (3) What is the difference between the two scenarios shown below? What different would happen if the kitty was performing scenario 3 instead of scenario 2; (skill: comparison). (4) Which set of commands is repeated in Scenario 1; (skill: pattern recognition).
2. The observation sheet. The observation sheet was containing general observations about students' behaviour and attitudes, namely: children's participation in the learning process, their learning interoperability, their tensions, their assistance from other peers or the teacher, etc. Four sheets were complemented in each teaching module, while the fi nal observation sheet was the result of the averaging responses from each individual sheet (low—1, moderate—2, or high—3 level).
P. Haliki and P. Politis81
Results
Results are classifi ed into four categories according to levels of critical thinking: data collection, organisation, analysis and going beyond. Each fi gure compares the learning outcomes as produced by the EG and the CG. The experimental group presented slightly better results with regard to data collection and organisation (Figs. 5 and 6). In data analysis, in contrast, the CG has showed slightly better results (Fig. 7) while in going beyond the data the EG displays higher rates in the
Fig. 5 Learning outcomes and data collection skills
Fig. 6 Learning outcomes and data organisation skills
Fig. 7 Learning outcomes and data analysis skills
Teaching Informatics in Primary School…82
responses with fewer errors (Fig. 8). This difference in rates, is mainly due to the error correction skills developed more by the students in the EG because of the immediate and individualised feedback offered by the Scratch, unlike the CG were feedback was neither direct nor individualised, as it was offered at the class level.
This is confi rmed by the application of the statistical criterion t which shows a statistically signifi cant difference between the two research groups as far as the debugging is concerned. Most likely, there is no such statistically signifi cant difference as far as the problem solution is concerned (Fig. 9).

Fig. 9 T -Test statistics
P. Haliki and P. Politis83
From the results taken from the observation sheet, students both in the EG and the CG collaborated highly with each other, except that in the CG there was both intra and inter group cooperation. In addition, in the CG students were more enthusiastic in expressing their views. This was in agreement with the teaching method, which in the case of the CG was always collective (solving the exercise, experiential activities, etc.) and was perceived as a play by the students.
Conclusions
Both problem-solving and critical thinking, characteristics that were directly related to the skills that correspond to higher levels of critical thinking (see Table 1), showed equal level in both groups. The two groups were different in that the students without PC usage had a greater diffi culty to correct errors than the students with PC usage due to the lack of immediate and individualised feedback. On the other hand, with regard to cooperativeness, the results of our study agree with those of respective investigations which support that teaching without PC enhances the interest and teamwork of students (Bell, 2000 ; Bell et al., 2009 ; Curzon & McOwan, 2008 ; Taub et al., 2009).
The survey results taken from the observation sheet showed that by implementing those specifi c teaching scenarios, the cooperativity was promoted to a higher degree in CG students. Although the role of the software in developing the "going beyond the data skills" dimension should not be underestimated, the positive results offered by experiential learning relative to the promotion of collaboration and teamwork amongst students are also important.
We are therefore led to the suggestion of devising didactic scenarios that could combine both software and experiential learning process. Such a didactic proposal could be developed with virtual reality software, whose results would be of particular interest.
Moreover, the didactic scenarios that were designed for the section "What language does the computer 'speak'" dealt with the computer's binary numbering system and turned out to be effective in both conditions. The learning results show that students at this age are able to understand this particular section. By applying the same methodology there could be developed didactic scenarios for other modules (e.g. the development of a microworld simulating the computational data fl ow, the formation of an image on a computer screen etc.) and assessed in the process of curricula teaching transformation for ICT teaching in primary education (Sofos & Kron, 2010).

Introduction
Students of the twenty-fi rst century have been growing up in a highly digital world, where they learn and react very differently during the learning process in comparison to students not familiarised with technology. This is also due to the fact that computer games invade students' lives from a very early age, making them signifi - cantly accustomed to many of the computer's functionalities.
At the same time, students continue to face diffi culties in computer science courses such as computer programming, even though their familiarisation with computers would suggest their learning of programming would become easier nowadays. The extended research studies carried out the last two decades state that these diffi culties are still present and students seem to be even less interested in programming (Lahtinen, Ala-Mutka, & Jarvinen, 2005).
The hindering of these diffi culties is important, as successful teaching and learning of computer programming can be extremely benefi cial for twenty-fi rst century generation students. It enables the development of various competences such as critical thinking, by allowing students to create their own programs, and of concept analysis and problem solving, as they are usually required to decipher a given scenario and interpret it into lines of code. Moreover, students learn to work in groups and collaborate with each other in their effort to develop executable programs while exercising in exchanging expertise and communicating ideas. Thus,
Educational Games for Teaching Computer Programming

overall computer programming empowers students to become lifelong learners, a very important benefi t for this ever-growing world of knowledge since they can

transfer their skills to a number of future work domains (engineering, computer
science, etc.) (Law, Lee, & Yu, 2010).
An interesting proposal for alleviating the problems faced is the incorporation of
educational games or serious games within computer programming courses. The
term educational games is commonly used to describe computer games that are used
as educational tools and provide interactive and appealing activities that attract students' interest for learning (Gunter, Kenny, & Vick, 2008). These games reinforce
students' intrinsic motivation through the sense of challenge; they pique their curiosity, enforce a sense of security as well as stimulate their imagination (Ho, Chung,
& Tsai, 2006). Also, students are able to achieve specifi c goals and view the success
results immediately, not only when they complete the game but also when they pass
the game's stages, a process that increases their self-confi dence and helps them trust
their decision making skills. Hence, there is a need to readjust currently followed
learning techniques according to these newly emerged technological trends that can
more easily and effi ciently pull the new generation of students towards computer
programming education.
The main purpose of this paper is to review existing educational games that aim
to teach computer programming and correspondingly review how effectively they
support students in achieving the educational goals that teachers set in each case.
The rest of the paper is organised as follows: the next section provides information
regarding the requirements that have been identifi ed in the literature regarding the
development of educational games. The following section presents a review and
comparative analysis of educational games for teaching computer programming
elements, giving emphasis in features that correspond to the requirements identifi ed
in the previous section. Finally, the paper concludes with an overview of the work
done in the fi eld in terms of how well and to what extend the studied educational
games cover the identifi ed requirements and suggests future work.
Educational Games Requirements Specifi cation
Our work was carried out following a rigorous review methodology, where we
searched a variety of academic databases (e.g. Web of Science, Scopus, CiteSeer
and Google Scholar) for identifying relevant papers. During this search, we used
keywords such as: educational games, computer programming, requirements, facilitating tools, etc., in various combinations. Over 70 papers were originally identifi ed
and in the end 20 were used for our review after thorough fi ltering as the most relevant to our scope of interest.
We have studied thoroughly case studies that have proposed and developed frameworks for educational games (Becker, 2010 ; De Freitas, & Jarvis, 2006 ; Salen &
Zimmerman, 2004 ; Yusoff, Crowder, Gilbert, & Wills, 2009 ; Zualkernan, 2006).
According to these works, the development of an educational game should be carried
out after the examination of a number of aspects, where each aspect determines the

features that should be supported in an educational game. All frameworks include
similar requirements as concepts that are considered important. In this work, we
choose to follow the one suggested by Becker (2010), because its concepts encompass
all the ones included in previous frameworks. Thus, we consider it to be a more
abstract superset of features that should be supported by all educational games.
Initially, it is suggested that the educational goals should be investigated across
two axes by using a different viewpoint, so that their specifi cation will be complete.
These axes are:
• Cognitive axis , relating to mental competencies (Knowledge). Educational goals
should make sure that the information received by the students begin from the
fi rst category in the Bloom's taxonomy (Knowledge) and end in the fi nal and
most complex category (Evaluation) successfully.
• Emotional axis , relating to emotions or emotional areas (Attitude). Educational
goals should enable students to handle given situations through the enticement of
their emotions. For example, the need and thus the desire to free a prisoner during a game motivates students to solve the assigned task faster and correctly so
that they can experience the emotions followed by accomplishing the goal.
Additionally, it is important to select a proper framework that will guide the
learning experience with the incorporation of educational games. The construction
of a development framework requires the determination of various elements that
together structure the framework's components. For example, the processes of the
real world that will need to be simulated into the game (which movements will be
allowed, how will the virtual world be constructed, how will the players be represented, etc.) need to be clearly identifi ed. This is a very important step as it determines the educational scenarios that can be supported by the game's environment
and thus affects the entire learning process.
Following the framework's specifi cation, an architecture will be constructed
based on the components identifi ed that will have to be available in an authentic
game environment. These components include:
• The scenario ' s space . Students are introduced to the game's storyline once they
logon to the environment with a short description of the plot as well as a brief
overview of the basic activities they will have to execute.
• Relevant cases . Students are provided with a set of pre-solved similar cases from
which they can get a better insight of the game's knowledge and skills requirements and thus be better prepared for when it is their turn to solve assigned tasks.
• Information resources . Students can access information relevant to the task at
hand whenever they are in need of assistance.
• Facilitating tools . A set of tools is included that students can use when they are trying to execute a task and that help them build new knowledge. Additionally, the
game provides tools that underpin student communication as well as discussion with
the teachers regarding any questions, thoughts or refl ection on the virtual world.
Also, it is essential to distinguish information regarding the student, such as
learning goals, learning style (holistic, analytical, etc.) as well cognitive limitations
(e.g. behavioural competences that can affect their learning).

Teachers should also be able to set educational goals that will have to be accomplished by the students during the game by assigning specifi c activities for them to
participate in. This way, students achieve interim goals by successfully completing
tasks that will lead them to absorbing the fi nal learning outcomes set by the teachers.
The above features will underpin the selection of an authentic scenario that will
provide an attractive story to go along with the game's virtual world. To this end,
students should be presented with an interesting and motivating problem that needs
solving and it is best if the plot is similar to the ones available in existing computer
games. This way, students will be already familiar with the overall concept and the
activities they will engage in will seem more like games than teaching exercises.
Similarly, the individual problems that students will be called to solve during the
game should be consistent with the educational goals as well as with any cognitive
limitations that may be apparent to the teachers. This is one more reason why both
these features are required to be supported in an educational game.
Another important feature is the constant and explanatory feedback provided to
the students during their navigation through the game's levels. This feedback should
be represented in a form of messages that guide students towards understanding
what they did right, what they did wrong and how they can achieve their goals, even
through the mistakes they have made. This scaffolding technique ensures that students realise why their actions did not lead to successful task execution and thus
they will be able to perform better in their next endeavour.
Finally, a number of generic conditions need to be taken into consideration while
designing and developing an educational game. Such is the location and type of the
education to take place (e.g. offl ine, online, blended learning). For example, if the
learning process will be realised entirely online, then the game requires all the educational material to be uploaded within the environment and communication tools
should be very well supported and plentiful. Moreover, the course's duration will
determine how many hours students will spend on the game and how many scenarios need to be constructed according to the elements that need to be taught in this
duration. All of the above require adequate preparation from the teacher and proper
confi guration of the environment so as to exploit all of the game's benefi ts and foster knowledge and skills development by the students.
Educational Games for Computer Programming Education
This section presents a series of games that have been developed specifi cally for
computer programming courses. The review of these games was carried out based on
the specifi cations identifi ed and described in the previous section, in the cases where
they were explicitly identifi ed by the relevant literature. Moreover, all chosen games
have addressed both the cognitive axis and the emotional axis during their development. Thus, in each game students start out by receiving pieces of information, and
through their engagement with the game, they move on up the Bloom's taxonomy
to the evaluation step by refl ecting on their progress and fi nalising assignments.
Also, the emotional axis is addressed via the game scenarios. All scenarios stimulate
emotions that motivate students to go through all tasks in order to win.

Two major categories could be distinguished during the research, which sort
educational games based on the educational goals they aim to support. The fi rst
category includes games that focus on teaching specifi c computer programming units
while the second category represents games that cover multiple educational goals
and thus computer programming material. A review for each category is presented
in the next two subsections, followed by a comparative analysis presented in Table 1 .
Educational Games Focused on Teaching
a Specifi c Unit of Learning
Catacombs . It is a three-dimensional multiplayer game that aims to teach students
how to declare variables and use simple and nested if statements and loops. According
to the game's scenario, each player represents a wizard that has to rescue two children trapped within catacombs. Towards this goal, the wizards have to answer multiple choice questions trying to solve a given programming code that will help them
complete their quests. The answers to the given questions automatically create executable lines of code in a micro-language. If the answers are correct, the wizards
progress through the game's levels; otherwise they are given corresponding feedback
as to what they answered wrong and are prompted to try again. The game records
experience scores for each student and provides explanatory messages as a scaffolding mechanism (Barnes, Chaffi n, Powell, & Lipford, 2008 ; Barnes et al., 2007).
Saving Princess Sera . It is a two-dimensional game that enables students' scaffolding through explanatory messages directed to the player. Each player has to try and
save a princess named Sera who has been abducted by a monster named Gargamel,
on her sixteenth birthday. Students are required to complete a number of quests in
order to progress in the plot of the game. Towards this goal, they complete lines of
code that will result to an executable program or they have to correctly map existing
lines of code to their proper position or order within a program employing a drag
and drop functionality. This way, students learn the quick-sort algorithm along with
simple and nested loops with the usage of a micro-language (Barnes et al., 2007 ;
Barnes et al., 2008).
EleMental : The Recurrence . It is a three-dimensional game that aims to teach students how to execute recursion and depth-fi rst search transversal using the C# programming language. The player has to navigate across a virtual binary tree by
employing the depth-fi rst transversal and complete three quests by applying
recursion. Two avatars named Ele and Cera help students during the game in various
ways. For example, once the code is written, Ele crosses the binary tree according
to how the written code is deployed, while Cera explains exactly what the code is
producing at a specifi c moment (Chaffi n, Doran, Hicks, & Barnes, 2009).
Wu ' s Castle . It is a two-dimensional role playing game that aims to teach students
loops and arrays through interactive activities. Each player is a wizard that can control an army of snowmen. Players recognise logical errors at lines of code written in
the C++ programming language. The game allows arrays management through

changing the parameters inside the loops and movement of the characters through
the execution of nested loops (Eagle & Barnes, 2009).
Robozzle . It is an online puzzle game that provides a series of predefi ned commands
ready for use and does not show any actual code. According to the game's scenario,
users have to build functions that will help them achieve each given task in a grid
and tiles virtual world. Users can run their functions and see how their hero will
move across the world and can therefore easily detect what mistakes they have made
and reprogram accordingly (Li & Watson, 2011).
LightBot . LightBot (Piteira & Haddad, 2011) is an online puzzle game similar to
Robozzle. It includes a series of predefi ned commands and no actual code or programming language. Additionally, users have to complete given tasks by building
their own functions and moving the hero across a grid and tiles environment and
light all the blue tiles. Once a task is completed, the user can move to the next level,
which requires the construction of more complex functions.
TALENT . TALENT (Maragos & Grigoriadou, 2011) focuses on teaching if statements and loops in the forms of algorithms by using a micro-language. Each player
is an archaeologist that has to navigate across the virtual environment by completing
a series of tasks and collect objects that are available at specifi c locations for their
future exhibition at a museum. Towards this goal, students can drag and drop lines
of code as well as write them in an editor whenever requested. As a scaffolding
mechanism, TALENT provides an agent that acts as a mentor and helps students
when needed as well as suggest what their next mission should be.
Educational Games Focused on Teaching Multiple Units
of Learning
Robocode . It is a two-dimensional environment that aims to teach computer programming using the Java language. The game comprises of a programming editor,
robots and a virtual arena, and students are required to program a robot that will
compete against one another in the arena. Students familiarise themselves with the
basic commands of structured computer programming and object-oriented programming (e.g. inheritance, polymorphism) while they try to build a robot ready for
combat. During its construction, the robot inherits basic methods that can later be
extended by students according to the behaviour they want their robots to have
inside the arena (O'Kelly & Gibson, 2006).
M.U.P.P.E.T.S . It is a three-dimensional, Web-based and collaborative game that aims
to teach object building and in general to familiarise students with the basic concepts
of object-oriented programming using the Java language. Students create a robot that
has to fi ght another robot inside a virtual arena, interact with the objects they build
and write and compile their lines of code within the embedded development environment that includes a commands console (Phelps, Bierre, & Parks, 2003).

Table 1 Overview of the educational games for computer programming courses
Game Programming elements Programming language Programming activities Special characteristics
Catacombs Variables; simple and nested if
statements; loops
Micro- language Multiple choice questions; fi lling
out lines of code
Three dimensional; multiplayer;
success scores; scaffolding
with explanatory messages
from the hero
Saving Sera If statements; recursion Micro- language Filling out lines of code; mapping
parts of code in corresponding
locations; multiple choice questions
Two dimensional; scaffolding
EleMental Recursion; depth-fi rst search (DFS)
algorithm
C# Depth-fi rst search algorithm; moving
the hero on a fantastical binary tree
Three dimensional; scaffolding
ProgBPlay Structured computer programming,
if-statements, loops
Ada, C, Java, OCaml,
Scratch, Compalgo
Completing eight missions Multiplayer; infi nite scenarios;
available
Wu's Castle Loops; arrays C++ Arrays management; movement
of the hero; identifi cation
of logical mistakes in code
Interaction; role playing

Robozzle Functions No code used Creating functions through the hero's movement
Interactive; available
LightBot Functions No code used Creating functions through the hero's movement
Web based; available
TALENT If statements; loops Micro- language drag and drop lines of code; writing lines of code in an editor
Explanatory messages
Robocode Structured computer programming; object- oriented programming
Java Writing lines of code Every robot stores data of past activities; available
M.U.P.P.E.T.S. Three- dimensional objects; object- oriented programming
Java Interaction with the developed objects; writing lines of code; compile
Collaborative; three dimensional; commands panel; embedded development environment
PlayLogo 3D Basic concepts and commands of structured programming
Logo Creation of heroes; navigation across the "galaxy" by writing commands
Interaction; multiplayer; three dimensional; available
Gidget Analysis and design of basic algorithms
Micro- language Fixing problems and programs; interaction with a personalised robot
Web based; explanatory messages

Educational Games for Teaching Computer Programming94

ProgßPlay . It is a library currently integrated in the Web-based, real-time multi-player strategy game Kernel Panic, which enables constant interaction amongst users. Students can program their own heroes and form alliances with each other aiming to prevail in the game. ProgßPlay allows students to choose the language in which they prefer to code their programs amongst programming languages such as Ada, C, Java, OCaml, Scratch and Compalgo (Muratet, Torguet, Viallet, & Jessel, 2011).

PlayLogo 3D . It is a three-dimensional, role playing game that allows interaction amongst multiple users and aims to teach basic concepts of structured computer programming. Users are required to program their heroes by writing the corresponding lines of code in the LOGO language, and navigate them across the environment. More specifi cally, the virtual world consists of the spaceship X-15 located on a constellation of the Andromeda galaxy, where a contest is held each year amongst pilot-robots (Paliokas, Arapidis, & Mpimpitsos, 2011).

Gidget . It is a Web-based game where students can program using a simplifi ed programming language created specifi cally for the game in order to learn how to design and analyse basic algorithms. A robot named Gidget has problems with a part of his software and thus cannot complete its tasks. Therefore, students are called in to help Gidget by either fi xing wrong lines of code, or by completing missing code within given programs. During these processes, students receive constant feedback of their progress (Lee & Ko, 2011).

The above table presents the study with a structured representation of features supported by the most commonly known educational games for computer programming. The programming elements, characteristics as well programming activities identifi ed can be considered as concepts that describe the fi eld. Thus, future researchers and game developers should take them into consideration when designing a new and advanced educational game for computer programming.

Discussion

In this section we provide an overview of the development of existing educational games for computer programming, and their limitations. The results are categorised based on the features identifi ed that should be taken into consideration during the design and development of an educational game for computer programming.

Educational goals . The educational goals seem to cover both the cognitive and emotional axes . Within the games, these goals are clearly focused in the computer programming concepts that each game aims to teach. This is especially the case in the educational games that cover specifi c units of learning, and thus the desired learning outcomes are more clearly identifi ed. The emotional goals seem to be accomplished through the numerous attractive scenarios available in each game.

The problems students are required to solve are consistent with the set educational goals and their cognitive limitations. In the educational games focused in specifi c units of learning, students execute and complete quests that teach them knowledge that is relevant to the programming concepts set in the goals. As an

C. Malliarakis et al.95

example, the simple and nested loops in Catacombs are taught through the completion of lines of code, and their correct syntax allows students to pass to the next level, while the same concepts are taught in Wu's Castle when students move their characters across the world and recognise logical errors. On the other hand, the second category of educational games (e.g. Robocode, M.U.P.P.E.T.S, PlayLogo 3D) employs problems that allow students to interact with each other and execute multiple tasks that will teach them all the basic concepts of computer programming.

Framework . Educational games that focus on specifi c units of learning seem to have properly defi ned a framework for their employment in educational contexts. However, games that teach multiple and more complex units of learning, and thus cover multiple educational goals usually set several frameworks. It should be noted that the games Lightbot and Robozzle do not defi ne any framework.

Scenario ' s space . All educational games present and work based on a scenario in order to attract and motivate students. In some cases introductory information is provided to the players in regard to the virtual world (e.g. PlayLogo 3D, Wu's Castle).

Information resources . Most educational games provide explanatory messages . The games where this feature is more fully supported are Catacombs, Saving Sera, EleMental: The Recurrence and Wu's Castle. Moreover, scaffolding techniques are provided through these explanatory messages that appear while students are trying to solve their quests (e.g. Catacombs, Saving Sera, EleMental).

Facilitating tools . Tools where students can write requested lines of code exist in the Catacombs, Saving Sera, EleMental, Robocode and M.U.P.P.E.T.S games. In addition, multiplayer games (e.g. PlayLogo 3D, M.U.P.P.E.T.S., ProgßPlay, Catacombs) include features where students can communicate and interact with one another.

Generic conditions . The generic conditions have been taken into consideration. This has been carried out more effi ciently in the educational games that cover specifi c units of learning rather than in the ones that teach multiple and complex computer programming concepts. On the other hand, they have not been considered at all during the design of the Robozzle and Lightbot games.

It should be noted that none of the studied games provides relevant cases that can prepare students for the activities they will be required to execute. The existence of this feature would signifi cantly increase the quality of the games, since it would provide useful tutorials and guidelines for learners.

We also have to mention that many of the aforementioned information regarding these games derive exclusively from the relevant literature, since they are not available for access. This fact also results in our inability to exploit them in the learning process and actually test them against set educational goals in computer programming courses. Summing up, it seems that all studied games include scenarios that motivate learners, clearly indicate the educational goals that need to be reached and include problems that are set up as specifi ed above. Other features, such as facilitating tools, information resources, one or several frameworks and taking into consideration generic conditions are supported by the majority of the studied games. However, none of the games appear to support relevant cases to prepare learners before engaging with the environments or to act as manuals for when learners require guidance.

Educational Games for Teaching Computer Programming96

Conclusions

The main implications derived from the analysis include that most games have been developed to cover programming concepts (such as variables, simple and nested if statements, loops, arrays, functions) with the exception of M.U.P.P.E.T.S. and Robocode that cover more complex concepts such as object-oriented programming. We do not consider the fact that the games do not tackle all programming concepts as a disadvantage, since they seem to successfully fulfi l the educational goals they set regarding the group of concepts they aim to teach.

Also, the study elaborated on the added values of using educational games in computer programming. Our research revealed a number of interesting principles that can help us understand why educational games can improve teaching and learning of computer programming. For example, games seem to have a facilitating role in the learning process during the teaching of specifi ed concepts and could play a small or a big part in the entire course's implementation process, depending on the generic conditions. More specifi cally, depending on the nature of the course (online, offl ine, blended), materials, communications, exams, etc. could be supported on different levels by the games' environments. To this end, educational games can provide a number of characteristics, such as storytelling, scaffolding and interactivity, which increase motivation for participation in class as well as attract students to complete their tasks through interesting scenarios.

We examined the educational games in terms of the educational value that they bring, and we derived that they can provide students with:

• Clear educational goals and learning outputs, ensuring that they know what they have to do to achieve the required knowledge and skills.
• A familiar and immersive environment that attracts students' attention facilitates their active participation and increases their motivation.
• Interesting scenarios with comprehensive problems they have to solve, which enable them to learn in a contextual manner (learning specifi c units of learning periodically).
• Tools that help them communicate and collaborate with their classmates, improving their group work skills and guiding them through the learning process by explaining the possible mistakes they make. These tools can be applied either with chat functionalities or with different types of interactions between the learners and the game while trying to achieve and fulfi l common goals.

Furthermore, the study's fi ndings have implications regarding the design of future educational games focused on computer programming, listing and elaborating on the requirements educational game designers and developers should strive to support and thus setting the foundations for future holistic environments.

Educational games can also assist teachers teach programming in their courses by designing the game and setting up its parameters. For example, teachers can use educational games to plan their courses and monitor students' interactions, progress and evaluation through their activities in the game. The establishment of the educational goals, learning outcomes and the setting up of a scenario that will

C. Malliarakis et al.97

delineate the curriculum into units of learning also enables teachers to be better prepared and have a deeper knowledge of the materials they teach and get more skilled in course planning.

On the other hand, a signifi cant limitation identifi ed in the existing educational games focused on computer programming courses is the ability of the teacher to confi gure the environment according to the pedagogical goals related to the respective unit of learning. Additionally, the collaboration concept could be reinforced and better supported within multiplayer educational games so that they can teach more complex programming concepts that will be more effi ciently understood through team-based learning activities.

The evaluations carried out during the pilots studies, showed that the majority of learners expressed positive attitudes towards the examined environments. Thus, this enables the initial implications of our research to exploit the features considered important by the literature and presented throughout the paper during future design and development of educational games.

Such games will fully support all identifi ed specifi cations and features and will aim to teach in-depth more complex concepts, such as object-oriented programming.

Introduction
The term "Educational Robotics" refers to the teaching practice during which the
students use the robots to construct knowledge with the help of or for the robots
themselves. The term appeared in the 1960s through the educational approach of the
Logo programming language. Within this context educational robotics consists of
an educational approach which recruits programmable devices to improve the learning process through project-based learning. It is defi ned by the use of Information
and Communication Technologies (ICT) in its own affordances for observation,
analysis, modelling and control of various physical procedures (Depover, Karsenti,
& Komis, 2007). It concerns an approach which allows the learner to familiarise
himself with the Information and Communication Technologies and use them to
defi ne a plan, to organise and fi nd a specifi c solution to the given problem exchanging his opinion with those of others (Denis & Baron, 1993 ; Leroux, Nonnon, &
Ginestié, 2005). The cognitive abilities that develop in early childhood with the use
of robotics have been studied since the introduction of the Logo educational
approach. A distinct category of educational robotics is the Logo-like programmable toys which are appropriate in early childhood and primary education. These
programmable toys are programmable robots which are controlled by the user for
the respective movement or path they are ordered to execute. In some cases the connection with the computing environment may be used. The child conceives and
defi nes the commands which are introduced into the robot following the principles
of the Logo programming language. This robotics subcategory is inscribed in the
Robotics and Programming Concepts
in Early Childhood Education: A Conceptual
Framework for Designing Educational
Scenarios

psychopedagogical approach of the Logo language, supporting the development of
the metacognitive ability, with which the children refl ect on the cognitive process
adopted, improving the ability of problem-solving and promoting the ability of spatial orientation (Clements & Nastasi, 1999 ; Clements & Sarama, 2002).
An Overview of Programmable Toys in Early Childhood
The Logo programming language developed in the mid-1960s at the M.I.T.
(Massachusetts Institute of Technology). At the same time various types of fl oor-
robots which are programmed with the Logo language make their appearance to aid
the implementation of the new programming language in educational contexts after
further research activity. Since then a series of robots featuring a common Logo
programming language implementation have been used for educational purposes.
A literature review of the integration of robotics in education allows us to distinguish two approaches: (a) the use of educational kits for the construction and function of the robotic system using the appropriate programming language and (b) the
use of educational kits with pre-constructed robotic systems using the appropriate
programming language.
The fi rst category includes kits like LEGO ®
-WeDo™ and LEGO ®
-Mindstorms™.
The second category includes the robotic programmable toys such as the Roamer,
the Bee-Bot, the Pro-Bot and the Constructa-Bot. The latter require the user to
design and compose a program and execute it in order to achieve a goal, thereby
solving a problem. Their characteristic is that they are programmed by novice users
either through the use of a computer or through the device itself. Most of the programmable toys use the ideas of the initial Logo fl oor robot—the Logo turtle—and
have similar functional and operational characteristics.
Table 1 presents an overview of early childhood and primary education robotic
devices (Table 1). It is clear that the majority of the robotic systems refers mainly to
pre-constructed robotic devices the so-called "programmable toys" (Hirst, Johnson,
Petre, Price, & Richards, 2003). Some have a more attractive appearance and function due to the production of sensory stimuli one of which is the Bee-Bot programmable toy while some others are less complex and are more of a machine such as
the PIXIE. In any case, the child designs and defi nes the total amount of commands
which are introduced into the robot following the principles of the Logo programming language. The added value of this specifi c programming language is the fact
that it is appropriate for early childhood development and support abilities such as
problem-solving, metacognitive thought as well as skills such as counting, spatial
orientation and measurement (Bers, 2008 ; Highfi eld, 2010 ; Highfi eld & Mulligan,
2008 ; Highfi eld, Mulligan, & Hedberg, 2008 ; Papert, 1980).
Two interesting conclusions can be drawn from this table. First, programmable
toys have been under development for the last 40 years within the context of Logo
language paradigm. These toys have a Logo-like robust interface and are technological devices using this specifi c language.

Second they are supported by appropriate educational material and are, apart
from the LEGO ®
robotics kits (LEGO ®
Mindstorms™ & LEGO ®
WeDo™), pre-
constructed systems requiring no construction. Their manipulation focuses on
developing the user programming abilities rather than engineering/technology ones.
Their educational applications focus on STEM whereas those which are addressed
to younger children such as the Bee-Bot may cover other cognitive areas as well
(Language, Arts). Most of the recent toys (Bee-Bot and Pro-Bot) have more user
friendly (robust) interface and a more playful appearance.
Educational Robotics in Early Childhood Education
The implementation of educational robotics in early childhood education is seen as
a way of introducing various concepts and developing different abilities.
Robotics is an interesting cognitive domain because it is a tool through which
children have the opportunity to approach mathematical concepts, applying strategies such as problem-solving, inquiry and experimentation (Rogers & Portsmore,
2004). It is worth mentioning that robotics is an educational approach with a variable dimension, which it can be easily integrated in various educational settings
(Bers & Horn, 2010). Furthermore, teaching about and through computer programming and robotics using developmentally appropriate approaches increases children's sequencing abilities (Kazakoff, Sullivan, & Bers, 2013). During the planning
and constructing procedure of a robotic model children of early childhood put into
action cognitive abilities which are under development (Papert, 1980). Programming
concepts which may be developed within computing environments are not always
developed for children of this age range. There are usually environments which
require users to develop the ability of abstract thought.
Hirst et al. (2003) dealt with the review, the description and the presentation of
robotic environments which are based on the technology of the LEGO ®
Mindstorms™ robotics systems. They propose that these specifi c systems bridge
the gap between how the user acts concerning more abstract computing systems and
specifi c conventional tools. They also propose that the creation of a more individualised system of a graphic microworld for novice users must be created so that they
are progressively drawn towards a more advanced programming environment.
Therefore, educational robotics in early childhood education uses appropriate
cognitive tools, emphasising on tangible use. The use of such tools which is the case
of programmable toys is a factor of motivation infusing the interest in children and
their actions towards learning. Those tools are developmentally appropriate as they
are based on playing and consisting of meaningful action and reaction (Highfi eld,
2010 ; Highfi eld et al., 2008 ; Highfi eld & Mulligan, 2008).
Some researchers suggest that learning through interaction with a programmable
toy, the construction of more abstract cognitive structures and the development of
social skills is reinforced (Bers & Horn, 2010 ; Yelland, 2007).

However researchers such as Greff (1998 , 2001) attempted to reinforce the learning context and developed appropriate teaching materials based on a language of
graphic representation of the commands for the approach of algorithmic concepts.
A positive aspect of this language was that it offered the user directness because of the
appropriateness of its structure and planning during the creation of a program. Thus,
algorithms were planned in order to direct the fl oor-robot to complete a specifi c path.
Other researchers used the programmable toy fl oor-robot Roamer in their study.
João-Monteiro, Cristóvão-Morgado, Bulas-Cruz, and Morgado (2003) report the
results of their teaching intervention within the context of the ICEI programme in
preschool settings in Portugal. The fl oor-robot Roamer was used to support teachers
in using the ICT as a cognitive tool. The added value of this particular robot lies in
its potential to develop mathematical concepts in children in early childhood.
A look at the studies published in the last decade shows that the use of Logo-like
programmable toy Bee-Bot lies in the centre of the scientifi c interest for this specifi c
age group.
Beraza, Pina, and Demo (2010) in their study presented teacher-orientated robotics activities in order to support teachers in their practice. They claim that the programmable toy Bee-Bot is suitable for early childhood and primary education but
provides limited programming opportunities. For this reason and for encouraging
teachers in designing suitable educational scenarios with programmable toys robots
they proposed the use of the Arduino platform.
In the study by Highfi led (2010) 33 children of early childhood and their teachers
chose the Bee-Bots and Pro-Bots from a range of robotic toys. Through a learning
process of a combination of robotic toys and engaging tasks mathematical thinking
and sustained engagement was promoted.
Pekarova (2008) studied the development of effective teaching practices and
attractive activities for children through digital technologies in early childhood education. Her results show the need of an organised context for teaching programming
concepts with the use of the Bee-Bot. However, since this procedure is not suffi cient
enough for activating children's inner motives, the formation and the organisation
of appropriate problem-solving tasks as well as the development of teaching materials are required.
Highfi eld and Mulligan (2008) describe various instances where early childhood
and primary school children interacted with the programmable Bee-Bot toys. The

desired outcome came through the experimentation with the programmable toy as
children applied different strategies in order to discover its functions and features.
Especially the experimentation gave children the opportunity to discover the feature
of programmable toy to rotate rather than move aside. Similar outcomes have also
been stated by Highfi eld et al. (2008) for the development of mathematical concepts
in children of early childhood when using the Bee-Bot programmable toy. This toy
facilitates children's learning and in particular the way to approach topics such as
measurement and geometrical transformations as opposed to traditional teacher-
orientated teaching.
Similar conclusions are drawn by De Michele, Demo, and Siega (2008) where
children from primary education used the programmable toy Bee-Bot to program
through mathematical concepts of multiplication and addition in typical classroom
teaching practices.
A. Misirli and V. Komis105
Overall, research has shown that there is no systematic and principle-based framework for teaching educational robotics concepts in early childhood settings. What
appears to be missing is a developmentally appropriate educational context for developing programming abilities and reinforcing inner motives of children in early childhood. This is important because integration and use of a programmable toy within an
appropriate teaching and learning context may infuse cognitive development (Depover
et al., 2007) such as mathematical skills and problem-solving abilities in children.
Furthermore, Csink and Farkas (2010) gave emphasis to the use of fl oor-robot
Roamer to teach programming concepts integrated within the curriculum and the
additional methodology. They also propose teaching programming that should be in
a context with role-playing and 3D games instead of using computer software. The
same point of view for integration of programming concepts within the offi cial curriculum is shared by De Michele et al. (2008). Scientifi c activity in the fi eld of
educational robotics and especially in the fi eld of programmable toys seems to infl uence the curriculum of various countries such as those of England, Australia,
Croatia, Estonia and Hungary (Csink & Farkas, 2010) as well as that of Greece in
which a clearly distinct thematic approach has been integrated for the teaching of
programming. In some cases like England, Australia, Scotland and Greece there is
an explicit reference to the use of programmable toys. In England specifi cally programmable toys have been integrated in the mathematical learning area and children
learn to program by designing paths, a procedure through which they develop abilities such as spatial orientation. In Australia the Ministry of Education introduced a
teaching guide concerning the integration and use of the Bee-Bot programmable toy
in early childhood education (Kopelke, 2007). In Greece a new curriculum proposal
announced in 2011 (The Greek Institute of Educational Policy, 2011) is currently
being piloted and includes the integration and use of programmable toys in early
childhood and primary education. In addition, in Malta since 2011 and Scotland
since 2013 educational programmes targeting the use of the Bee-Bot programmable
toy have been launched. In these countries, the Bee-Bot programmable toy is being
used as a teaching and learning tool in several academic subjects (ICT, Mathematics,
Language, Social Studies, and Physical Education).
A Methodology Framework for Educational Scenarios
in Programming and Robotics in Early Childhood
As the preceding literature review of educational robotics in early childhood education clearly shows, the relative research is limited in references of implemented
teaching activities without systematic educational design or organization. In some
cases the researchers have tried to gather students' representations concerning the
content of the robot (through the use of a single question) as well as try to record and
present students' programming strategies during free experimentation of the children
with the Bee-Bot (Pekarova, 2008). In other cases an attempt to trace children's initial
representations and their manipulation of the Bee-Bot is recorded. However, there is
still lack of systematic observation and recording of children's learning processes
(Highfi eld, 2010 ; Highfi eld et al., 2008 ; Highfi eld & Mulligan, 2008).
Robotics and Programming Concepts in Early Childhood Education…106
In the above studies we can additionally observe that there is no specifi c or organised meaningful context. In other words, they lack in presenting a context suitable for
teaching programming as well as for problem-solving situations. Especially the more
recent studies use the researcher's demonstration of a particular path and the aim is
that children reproduce the same path (Highfi eld et al., 2008 ; Highfi eld & Mulligan,
2008). On the contrary it is Pekarova (2008) who claims that the programmable toy
has attractive features and functions for children of this age but these elements are
not effi cient enough. There is a need for a clear and appropriate planning program
construction orientated for the reinforcement and the function of teamwork.
Greff (1998) shows that the creation of a pseudo-language through the graphic
representation of the commands of the Roamer programmable toy is an appropriate
teaching strategy for the visualization of the programming procedure. This procedure provides user with the opportunity to not only visualize a program but also
refl ect on and correct its content. This visualisation technique was evaluated by
other researchers using a different methodology. In the study of João-Monteiro et al.
(2003), the users were asked to programme the toy to reach a desired position or
goal as it is represented on a coloured patterned command on a card.
It is worth mentioning the fact that most studies which used the Bee-Bot programmable toy were not integrated in typical classroom teaching practices. They
appear to be more focused on free experimentation with the tool and orientated
towards the implementation form the scientists themselves who act either as facilitators of the research or are supported by the classroom teacher (Highfi eld et al.,
2008 ; Highfi eld & Mulligan, 2008 ; Pekarova, 2008). On the other hand, Greff
(1996) reports the implementation of a teaching intervention towards the development of a programming ability while placing the children either in the position of
the robot or in the position of the user under real classroom conditions. Moreover,
Greff (2001) and João-Monteiro et al. (2003) describe cases of use of the Roamer
robot in typical classroom conditions for the development of programming and
mathematical concepts.
As far as the cognitive context is concerned, concepts referring to either premature programming structures (the sequence of commands) or belonging to mathematical learning areas (counting, shapes) were approached. João-Monteiro et al.
(2003) in their study implemented the cross-curricular approach in order for children to construct programming concepts.
The primary aim of this study is to propose an appropriate educational framework for organising the teaching process, one that emphasises the understanding,
design and implementation of robotics and programming concepts. The study is
situated in the wider scientifi c research context of robotics use in early childhood
education. It follows the design based research mixed research model and uses
the method of multiple case studies for collecting qualitative and quantitative developmental data (Kelly, Lesh, & Baek, 2008). This kind of research deals with the
design, development and evaluation of educational programmes or constructions
as part of the teaching practice in such a way that the most effi cient conditions
for teaching and learning are assured for the benefi t of everyone involved
(Depover et al., 2007).
A. Misirli and V. Komis107
Since there is no existing framework for teaching programming in early childhood the approach proposed below is an innovative, new tool for educators. This
framework is based on a conceptualization where methodological and pedagogical
issues are suitably integrated to facilitate the teaching and learning process, thereby
addressing the defi ciencies of former studies identifi ed above. Such defi ciencies
have resulted in unsystematic and unstructured educational interventions, which
failed to address issues related to the teaching of programming, educational practices and pedagogical principles. The teaching of programming includes concepts
such as algorithms, programs, memory and debugging. Moreover, a structured and
systematic educational intervention should give emphasis on and carefully select
the appropriate teaching approaches. Such issues refer to defi ning an objective and
the goals which meet early childhood children's needs, to using additional teaching
strategies, to comprising didactic transposition on programming concepts and to
developing appropriate teaching material. These teaching practices are based on
pedagogical principles such as project-based learning, child-centred learning, collaborative learning, and well-organised learning environments.
The proposed educational and methodological framework includes seven (7) distinct phases (Fig. 1) for designing an educational scenario. The importance of designing an educational scenario is to include issues of programming concepts, educational
practices and pedagogical principles to lead the teaching process. Therefore the
selection of a specifi c subject orients teaching to set an objective, as well as the goals
for delivering its content through seven (7) distinct phases, which in fact present different instances of the planning and the implementation process. These phases are
found in the core part of the whole design are closely interrelated and interact at the
same time (Komis, 2010 ; Komis, Tzavara, Kansenti, Collin, & Simard, 2013).
From an educator's point of view designing an educational scenario is very
important as it addresses issues such as the integration of ICT at least in some of the
phases using a computer or robotic device during its implementation and application. The structure of current methodology describes the method with which the
participants (in our case early childhood educators) are asked to use ICT in a suitable planned and well-organised context. Thus, the educational scenarios used
within this study adopt concepts and themes of computer science and mathematics
curricula expecting children to construct programming concepts by using the Bee-
Bot programmable toy.
Based on the above conceptualization, a teaching model was developed for educational robotics which was structured after appropriate adaptations as those which
emerged by analysing former studies. So a conceptual model was created of an
educational scenario appropriately structured and adapted to the cognitive early
childhood children's needs. Anticipations and adaptations that took place aspired to
minimise methodological faults with the aim of maximising the validity of research
fi ndings. Pekarova (2008) mentioned that emphasis on teaching programming in
early childhood children should be given to plan a well-organised and systematic
teaching intervention. Particularly, all the adaptations that were taken into account
were divided into two categories concerning different approaches such as (a) methodological and (b) pedagogical.
Robotics and Programming Concepts in Early Childhood Education…108
Methodological Approaches
The methodological approaches include: (a) the organisation of the educational scenario, (b) the introduction and the integration of didactic transposition of programming and informatics concepts, (c) the development of instructional design, (d) the
integration of inherent teaching strategies in pedagogical and informatics design, (e)
the use of explicitly stated teaching contracts and (f) the development of research
protocols (instruments gathering data) for each individual.
Educational Scenario
The organisation of the educational scenario (structure and content) followed a spiral
developmental procedure, comprising the six (6) following steps: (1) Design, (2)
Implementation, (3) Evaluation, (4) Modifi cation, (5) Re-implementation and (6)
Re-evaluation with the aim of potentially adapting it in every different educational
context or group of children. The interventions which used the programmable toy
Bee-Bot do not explicitly mention a systematic implementation to gather data for
evaluation and feedback for modifi cation (De Michele et al., 2008 ; Highfi eld, 2010 ;
Fig. 1 The phases in designing educational scenarios for robotics
A. Misirli and V. Komis109
Highfi eld et al., 2008 ; Highfi eld & Mulligan, 2008 ; João-Monteiro et al., 2003 ;
Pekarova, 2008). Every educational scenario we designed was pilot tested in a typical
classroom setting, before being formally implemented by the in-service teachers.
Didactic Transposition of Programming and Informatics Concept
Moreover, in the published literature there is no illustrated integration of didactic
transposition of programming and informatics concepts. All of them are giving
more emphasis on the development of abilities concerning mathematical concepts,
rather than programming and informatics ones. In our case, the integration of programming and informatics concepts created a more explicit context not only for the
children but also for the teachers. For children it is self-evident to deliver the epistemological knowledge under appropriate transposition, while for the teachers it
was necessary since they had no previous experience on robotics.
Instructional Design
A development of instructional design underlined the teaching of programming and
informatics concepts by increasing the level of cognitive diffi culty. This meant that
each educational scenario had been designed by increasing the diffi culty level in its
goals and activities. Researchers, using interventions focused on curricular subjects
may have used similar adaptations, however this is not clearly stated (De Michele
et al., 2008 ; João-Monteiro et al., 2003).
Teaching Strategies
Being a more structured and theory-based educational scenario, this has integrated
inherent teaching strategies such as problem-solving, cognitive confl ict and inquiring. Especially in pedagogical and informatics educational design these strategies
provide an ascending engagement and learning process.
Teaching Contract
Furthermore, the use of an explicitly stated teaching contract, customised for each
activity was clearly defi ned, in order to arrange the class' settlement and to motivate
the self-regulation of group members, as well as that of the whole class.
Research Protocols
To trace pre and evaluate post-intervention children's ideas, conceptions and representations using Bee-Bot and its functions, research protocols were developed and
fi lled for each individual. Additionally, this process includes children's personal
Robotics and Programming Concepts in Early Childhood Education…110
graphic representations (pre and post drawings) showing their ideas about the
Bee- Bot. These two different protocols provide the educator with the opportunity to
verify early childhood children's verbal representations, since at this age different
approaches are required to facilitate verbal communication.
Pedagogical Approaches
The pedagogical approaches include: (a) the development of a pseudo-language, (b)
the development of additional teaching materials, (c) the initiation/organisation of
an appropriate learning context and (d) the appropriate adaptation for implementation by in-service teachers in typical classrooms settings, taking the role of facilitators and co-researchers.
Pseudo-Language
The development of a pseudo-language, through a series of graphical representation
of commands on cards—based on Greff's study (1998), who had argued that developing such language is developmentally and pedagogical appropriate for the visualization of programming procedures for children in early childhood. This procedure
provides the user with the opportunity to not only visualize a program but also
refl ect on and correct its content. In particular, every command of Bee-Bot's interface has been represented on a card containing three different semiotic systems.
Those are: (1) the image or representation of the real object/button, (2) the image of
Bee-Bot's interface with the additional button highlighted and (3) the word corresponding to the additional command (Fig. 2).
Every synthesis of card-commands constitutes a full program, which could be
executed by the Bee-Bot (Fig. 3). It is also structured according to the program's
syntax process (CLEAR-COMMAND OF DIRECTION/ORIENTATION-GO) and
placed vertically following of the principles of the Logo language. Each card is
15 cm wide, the same as the Bee-Bot's step length, facilitating children to develop
learning strategies for the interrelation between cards, the Bee-Bot's step and the
squares of gridded mats.
Fig. 2 Graphical representation of Bee-Bot's commands on cards
A. Misirli and V. Komis111
Teaching Materials
Alongside the previous pseudo-language teaching material was developed to support and facilitate the teaching process. Gridded mats of 15 cm each square (the
Bee-Bot's step length) on A3 laminated papers were created. This kind of material
enabled children to consider the sequence of commands of an algorithm. The child/
user is supported and reinforced to fi nd the appropriate commands/cards of orientation and direction, visualizing the program, matching each command/card to a
square. Moreover, a series of additional pictures or 3D objects (animals, toys, sticks/
ribbons for measuring, adhesive bookmarks), were customised for each educational
scenario depending on the learning context they were integrated to.
Learning Context
For each educational scenario an adequate learning context was designed, so as to
introduce problem-solving situations as well as to support the educator's teaching
practices concerning programming concepts. The so-called learning context initiated an inquiry/problem-solving situation with a developmentally appropriate way,
taking into account the children's prior knowledge and experience on programmable toys, as well as programming and mathematical concepts. Through this context
open questions (questions stimulating productive activity) were set up for each goal
to lead inquiry and problem-solving activities. The learning context takes advantage
Fig. 3 Examples of programs developed by a team while working on a teaching activity on orientation concepts
Robotics and Programming Concepts in Early Childhood Education…112
of the Bee-Bot's animated and playful appearance, enabling children to inquire.
In that way the programmable toy is integrated as a member of the team, enabling
children to relate to its action and see themselves as co-researchers.
The previous adaptations are based on Papert's ideas about creating a developmentally appropriate constructivist programming environment where concrete material facilitates the construction of abstract ideas and refl ection on them (Papert, 1980).
Role of Teachers

Last but not least, an appropriate adaptation for implementation by in-service teachers in typical classrooms, taking the role of facilitators and co-researchers was taken into account. This approach is implied by the broader context of educational robotics thus is the constructionism (Papert, 1980) and the social-constructivism (Vygotsky, 1978). Each teaching activity provided teachers with the knowledge of the learning process they should have, in order for children to construct knowledge. Each activity is comprised of: the learning goal, the question to be explored (inquiry question), one or more teaching strategies, the additional teaching material, the class organisation, the description of the process and fi nally the conclusion--reference to the prospected learning outcome. Moreover, the scenario documentation (phase 7) comprised of useful references (scientifi c knowledge) on the children's cognitive development on each teaching subject, additional appropriate vocabulary on programming concepts and guidelines on how to assess and implement the interviews with each child.
Therefore the idea was to divide each educational scenario in two distinct sections. The fi rst section (shared across all scenarios) introduces programming concepts and provides children with basic skills/knowledge to understand the functions and the use of the programmable toy. Within that section a transition from exploration and investigation to more structured activities is applied. Respectively those skills were delivered and extended in the second section where children were engaged in more open-ended activities focused on inquiry and experimentation of mathematical and programming concepts. Mathematical concepts such as spatial awareness are aside to programming concepts due to the Logo-language structure.
For example in one educational scenario children applied the robot step as a unit of measure to extend their understanding on length concepts.
The conception and design of educational scenarios of robotics and programming in early childhood education adopt concepts from the cognitive fi elds of computer science and mathematics. The scientifi c fi eld of educational robotics concerning the use of the programmable toys is part of the learning theories of constructionism and social constructivism (Bers, 2008 ; Depover et al., 2007 ; Papert, 1980 ; Resnick, 2006). Both these theoretical models lead to the development of abilities of a cognitive style such as inquiry, experimentation, observation, and recording as well as of a social context such as cooperation and discussion with others, refl ection on fi nal conclusions and share the results.
A. Misirli and V. Komis113
An Empirical Investigation of the Framework
Subjects and Setting
The framework outlined above has been implemented for 3 years (2010-2013) through the scientifi c European project Fibonacci by 46 educators and 864 children between the ages of 4-6. Eventually valuable data was gathered from 38 educators and 674 children. It follows the design based research mixed research model and uses the method of multiple case studies for collecting qualitative and quantitative developmental data (Kelly et al., 2008). A concurrent triangulation approach was applied which "provides quantitative statistical results followed by qualitative quotes that support or disconfi rm the quantitative results" (Creswell, 2009). The quantitative analysis of the data has not yet been completed; however initial results provide interesting details about the proposed framework.
Measures and Data Collection
Concerning the techniques gathering the quantitative data; different research protocols (instruments) were developed and introduced to the distinct phases of an educational scenario (Fig. 1). All these instruments were tools for educators for recording and evaluating the learning process. A structured interview was introduced at the phase where children's prior representations and knowledge about the programmable toy Bee-Bot were to be identifi ed. It comprised of eleven (11) open-ended questions and was used to assess pre and to evaluate post-intervention children's ideas. These questions formed the categorical variables. The results from the post-intervention interview are embedded in the phase where the scenario activities are designed and particular to the sub-category of subject evaluation process. In the same sub-category three more instruments have been applied. After the fi rst section of teaching activities (function and use of programmable toy), an instrument for assessing every child's prior knowledge on the mathematical concepts was introduced. Another instrument was used to record each child's evaluation on the programming and maths concepts. Its structure provided us with more categorical variables. Moreover, every child was accessed for his refl ection on the programmable toy. All these instruments shared the same technique of a structured interview.
Data Analysis
As far as the qualitative analysis is concerned, data from records and videos has been collected but not yet completed. In particular, records are written notes kept by teachers on a daily basis during the implementation of an educational scenario along with notes regarding each child's evaluation on programming and maths.
Robotics and Programming Concepts in Early Childhood Education…114
The data gathered from several case studies (92 children) on the fi rst year of the implementation, indicated that children were having diffi culties understanding orientation concepts (Komis & Misirli, 2011). This educational scenario was focused on measurement, enabling children to use the robot step as a unit of measure. The fi ndings indicated the need to engage children with spatial concepts and especially directionality. Therefore an appropriate educational scenario was implemented. In the third year, one more scenario was developed. It was aimed to develop concepts of iteration and sequencing of patterns as those could be initiated through the concept of a program and its structure.
The analysis clearly shows the development of algorithmic thought and programmable abilities as well as the evolution of abilities in diverse mathematical structures. The development and the evolution of these specifi c cognitive abilities is facilitated through designing and implementing developmentally appropriate educational scenarios which in turn lead to the creation of relative cognitive representations on the function and the use of the Bee-Bot programmable toy (Komis & Misirli, 2011 , 2012 ; Misirli & Komis, 2012).
Data gathered through structured interviews and drawings from ninety two (92) children show a signifi cant shift to more qualitative representations in the post tests. This became apparent by the fact that more explanations was provided (by the children) about the programmable toy's functions and controls (Misirli & Komis, 2012).
The interpretation of these preliminary fi ndings attributed to the conception of appropriate teaching activities illustrating and highlighting programmable toy's functions and controls (Greff, 2005).
Concerning the development of algorithmic thought, this was formed through the cognitive process of problem-solving which in our case demanded from each child to plan a spatial path. Thus, a spatial path is suffi ciently abstract for this age group, the pseudo-language--a series of card commands--alongside the developed teaching material engaged children in tasks were algorithms were visualised (Komis & Misirli, 2011). The same study showed that a small group of children tried to plan a path mentally without visualizing it. Moreover, gender differences were not signifi cant but differences among different age groups were. The pre and post assessment showed that children aged fi ve and six understand programming concepts more easily.
A very interesting fi nding is the design and the programming of algorithms by early childhood children (Komis & Misirli, 2013 ; Misirli & Komis, 2013). During this cognitive construction of an algorithm the children follow two (2) steps: (a) initially they verbalise the abstract conception of the algorithm and (b) they proceed to the syntax of the algorithm by implementing the programming stages respectively. While the syntax procedure takes place, a variance of the amount of commands which are used and rate between three (3) cards-commands and twelve (12) cards-commands for direction and orientation, is observed. On the whole the design of scenario activities (phase 5), were structured and organised to initially familiarise children with the abstract process of conceiving an algorithm. According to Vygotsky (1978) thought is considered as "inner speech" and is the result of language. The "inner speech" was in educational scenario the time when children verbalised (thinking aloud) an algorithm and thus planned their program and
A. Misirli and V. Komis115
consequently organised a strategy to process. This cognitive construction leads children to modelling the solution of a problem as they form it verbally and consequently indicate it by their fi nger or the programmable toy itself. Moreover, all the activities of a scenario (phase 5) had a teaching contract placed from the very beginning when children were introduced to the activities of cognitive and psychological preparation. It is worth mentioning that all children for the 3 years intervention proceeded to verbalizing an algorithm having the programmable toy as system of reference and not their body as it was proposed from the studies of Greff (1998) and De Michele et al. (2008).
Discussion
The preliminary fi ndings drawn from the present conceptualization and its implementation show that although the programmable toy Bee-Bot has a limited command set (Beraza et al., 2010 ; Kazakoff et al., 2013) it may be a cognitive tool for children if a systematic, structured, principled and theory-based framework is used.
The application of the educational scenarios in typical classrooms in early childhood education, showed that preliminary concepts of programming could be developed through the use of programmable toys. Thus the cognitive potential (Depover et al., 2007) applies not only to the development of mathematical abilities but also to the development of programming abilities and problem-solving situations.
Our proposed framework is validated by quantitative and qualitative data gathered from cases where in-service teachers integrated the educational scenarios in their teaching, without having prior knowledge neither on robotics nor on educational scenarios. This implementation in typical classroom contexts also distinguishes our approach from other researches on programmable toys, which were conducted mostly by researchers and in some cases they have demonstrated to children how to input a program (Beraza et al., 2010 ; Highfi eld, 2010 ; Highfi eld et al., 2008 ; Highfi eld & Mulligan, 2008 ; Pekarova, 2008). Furthermore, our work demonstrates that the methodological and pedagogical approaches we used to underline this conceptualization, were effi ciently addressing the defi ciencies of previous studies. Our fi ndings show that although children had no prior experience with programmable toys they fi nally achieved the cognitive objectives set through inquiry-based activities. They were able to build sequential programs based on graphical representations and transfer them to the programmable toy's tangible interface in a learning context, underlined by appropriate methodological and pedagogical approaches.
It seems that the development of programming skills (algorithmic thinking, concept of memory, debugging, structure of sequence, and inputting strategies) requires an appropriate conceptualization to effi ciently motivate young children. Based on these preliminary fi ndings, we reach the same conclusion as Highfi eld et al. (2008): "the Bee-Bot has the potential to enhance children's development of mathematical concepts, particularly … measurement processes much earlier that traditionally expected." On the top of that we also found spatial orientation (Misirli & Komis, 2013) and sequencing skills.
Robotics and Programming Concepts in Early Childhood Education…116
The present study has drawn conclusions from a specifi c educational context, but the fi ndings need to be validated in other educational contexts. Several questions such as the role of the teacher in the learning process, the potential differences if the educational scenario is applied it a digital rather than a physical environment, the transfer of programming concepts to other learning areas and metacognitive processes remain open. Our study could be extended and expanded in the future allowing for the above questions to be answered.
In conclusion, the conceptual framework proposed above consists a tool with cognitive potential for early childhood children to develop initial programming concepts via a developmentally appropriate and supportive learning environment. It allows each child to create his/her personal learning "trajectory," one that fulfi ls his/her own learning needs. There is evidence to suggest that this conceptual model can be integrated into everyday teaching practices and into the everyday processes. In addition, it does not necessarily require educators to be specialized in educational robotics and programming.
Acknowledgements This research was integrated within the context of the European Fibonacci Project. The authors would like to thank the local coordinator Pr. V. Zogza at the Department of Educational Science and Early Childhood Education, University of Patras, participating schools, teachers and children. The authors would like to thank the anonymous reviewers for their constructive comments, which helped us to improve the manuscript.

Introduction
With the rapid diffusion of the Internet; new approaches to learning were created
(Crosta, 2004). As a result, the interest in the development and use of online learning has been steadily increasing (Dabbagh & Kitsantas, 2004) providing "anytime,
anywhere learning." More specifi cally, the technological advancement in information technology and telecommunications resulted in the development of the Web 2.0
and created the appropriate framework for user participation. The traditional one-
way communication is transformed into a two-way communication, and process of
information. In Web 2.0 users are Contributing, Collaborating, Creating—the 3C's
(Ala-Mutka, Punie, & Ferrari, 2009). Various online tools have emerged such as
blogs, wikis, discussion forums, online collaborative documents, online sharing of
documents, pictures and videos, podcasts, RSS feed, etc. Millions of people use
various social and professional networks, such as Facebook, MySpace, Twitter,
Delicious, Flickr, LinkedIn, and Live Journal. Nowadays, with the advent of Web
2.0, the Internet has become truly interactive. The aforementioned tools and networks are excellent examples of how defi nitions, ideas, photographs, videos, and
voice can be shared over a powerful Web 2.0 Internet. Technology provides a realistic, visually compelling, and motivating interactive environment for developing
the life skills and knowledge needed for today's globalized, hi-tech environment
(Goddard, 2002). The Web 2.0 technologies became an essential tool of daily life
and a crucial part of students' personal knowledge tools (Lee, Miller, & Newnham,
2008). Consequently, the Web 2.0 tools can be educationally exploited for teaching
and learning purposes towards achieving educational objectives, thus transforming
social to educational networking.
Integrating Blogs in Primary Education
Nikleia Eteokleous-Grigoriou and Stella Photiou
N. Eteokleous-Grigoriou (*) • S. Photiou

e-mail: n.eteokleous@frederick.ac.cy; stellaphot@hotmail.com122
Blogs are one of the most popular Web 2.0 tools. In 2009, 133 million blogs were
online and two new blogs are created every second! It is supported that blogs have
educational value given their characteristics and the opportunities provided to users
(Davis, 2005 ; Eid Neurolearning, 2005 ; Richardson, 2010). Even though they were
around for years, they recently emerged as a popular means of communication,
discussion, collaboration, and information sharing. Blogs are Web publishing tools
which provide teachers and students an interactive platform where text, images, and
links to other blogs, Web pages, are posted mostly focusing on a particular subject.
It is supported that blogs have educational value given their characteristics and the
opportunities provided to users (Richardson, 2010). Blogs are most popular among
students since they are virtual and can be worked at any time and place (Richardson,
2010). It is extremely benefi cial to integrate Web 2.0 tools; in this case blogs, as
learning-cognitive tools, to add educational value and enhance the teaching and
learning process and promote the development of higher-order thinking skills, such
as application, synthesis, evaluation, creation (Anderson & Krathwohl, 2001). It can
be also suggested that by default blogs facilitate and promote the development of a
community. The members of the community are the bloggers, since bloggers share
a common interest (a specifi c subject under "investigation"); connecting to each
other by posting comments and discussing. Students extensive use of technology is
possible to facilitate the integration of blogs (and technology overall) as tools in the
teaching and learning process. Being part of our students' digital world might be
more possible to raise their interest, motivate them, transform the classroom environment, and properly prepare them for the rapidly changing information society's
needs and demands.
Main Aim of the Study
The current study evaluates blog integration as an educational tool within the teaching and learning process and specifi cally within the Language and Linguistics
course in fi fth grade (Subject examined: The time machine) and its role in developing a Community of Inquiry (CoI). The research objectives that guided the current
study are the following:
- To investigate the effectiveness and role of blog in achieving specifi c learning
objectives when it is integrated as an educational tool within the teaching and
learning process,
- To examine the development of a blended learning environment with the use of
blog in relation to in-classroom activity,
- To identify how the role of educator and students differentiate within a blended
learning environment,
- To investigate the development of a Community of Inquiry (CoI), by identifying
the existence of the three parameters that characterizes a CoI: cognitive, social,
and teaching presence.
N. Eteokleous-Grigoriou and S. Photiou123
Theoretical Background
Blogs
Blog is considered an important tool of the Web 2.0 toolbox (Richardson, 2009) and
blogging has become one of the most popular Web 2.0 activities. The origins of the
blog emerged from the short term of "web log" (Bauer, 2011); an online chronological collection of personal commentary and links that was fi rst used by Barger (1997).
A blog is a Web site that is maintained by an individual or a group where readers can
comment on blog posts to supply more information and discuss various issues (Allen,
2011). A person that owns a blog and/or posts messages on blogs is called a blogger
and the actions within its environment are known as blogging (Hill, 2004). Blogs
contain text, graphics, images, videos, and hyperlinks to other Web sites. Bloggers
comment on the posts, discuss, argue, and provide their opinions. Blogs create conditions for interaction, refl ection, ideas' synthesis, exchange and discussion,
self-evaluation, and feedback (Petko, 2011 ; Sim & Hew, 2010 ; Zawilinski, 2009).
Blogs and Education
Given the great educational blogging potential, numerous educators have already
started using blogs in the classroom. Blogs can be integrated as educational tools
across the curriculum, from primary to higher education, achieving collaboration
among students and educators even in different schools and countries. Many studies
explored the features and educational benefi ts that blogging offers to students, and
discussed the major blog uses in education (Churchill, 2009 , Downes, 2004 ,
Richardson, 2009 ; Richardson, 2010 ; Siemens, 2005). Specifi cally, studies integrated blogs into their teaching exploring the learning value of blogging (Chen,
Cannon, Gabrio, & Leifer, 2005 , Makri & Kynigos, 2007), i.e., for group teaching,
collaborative learning, and Web-based collaboration (Grassley & Bartoletti, 2009).
Educational blogs provide a practical online platform for discussions that hastens
the acquisition of knowledge and learning (Liu & Chang, 2010). Additionally,
blogs provide space for the students to refl ect and publish their thoughts and understandings, and opportunities for feedback, scaffolding of new ideas, as well as collaborative learning. Blogs also promote the development of higher-order thinking
