Thirdly, school-level studies demonstrated noteworthy differences in teachers' conceptions of mathematics and its teaching owing to nationally situated teaching traditions (Andrews & Hatch, 2000). In my study, no distinctive teaching traditions of technology use at the university-level were identified. This may be due to the fact that the participants of my study constituted an internationally mobile group with many experienced in or aware of international university-level teaching practices and research. In addition, the use of technology in university teaching is a fairly recent endeavour. This result accords with Atweh, Clarkson, and Nebres' (2003) idea that mathematics research and mathematics education have become an international enterprise, particularly at the university level.

For the quantitative phase of the study, I am designing a web-based questionnaire for sending to 3500

45

mathematicians in Hungary, the UK, and the US. In part this will draw on the results of the first phase but will also attempt to uncover additional issues relating to the aims of the study. Therefore, sections of the questionnaire will enquire about:

1. the current use of CAS by selected participants;
2. participants' personal characteristics and institutional settings;

45

This preliminary estimate is based on the estimated population of 35,000 mathematicians in the selected three counties and the desired 20% response rate for the web questionnaire. Detailed sampling strategy is available upon request. 330

3. participants' variety of conceptions of CAS, CAS-assisted teaching, role of CAS in the field of mathematics and mathematics teaching.

It is my expectation that the analysis of the questionnaire data will expose relationships between participants' personal characteristics and institutional settings, their CAS use in teaching and research, their conceptions of mathematics, and their CAS-related conceptions. Furthermore, I plan to exploit factor analytic and structural equation modelling techniques to uncover additional factors that influence CAS integration at universities.

My study will contribute to our knowledge of CAS and its use at the university level by

- providing an overview of CAS use at a large number of universities;
- identifying factors that influence CAS integration at universities and highlight similarities and differences between university- and school-level results;
- allowing insight into mathematicians' understanding of and thinking about CAS and the impact of their teaching/cultural traditions;
- pinpointing some effects of nationally based teaching traditions of CAS use at the university level and mathematicians' conceptions of CAS-assisted teaching.

Results of the study will enable researchers and practitioners to

- pinpoint directions for improvements and show limits of CAS applicability at universities;
- align research into local practices with international trends;
- assist in the possible development of CAS training workshops;
- improve the mathematical preparation of university students.

Once this second aspect of the study has been completed a number of possible research directions present themselves. The study may reveal issues for examination by means of a qualitative study. If, as I hope, the questionnaire proves effective, the study could be replicated in a larger set of countries. In addition, a similar study could be conducted in schools to uncover similarities and differences in university- and school-level use of technology. Furthermore, it would be possible to collaborate with mathematicians as well as school teachers to develop curricula, supporting materials, and a variety of workshops to enhance the use of technology in mathematics education.

If invited to the ICMI-17 conference, I would be able to report on the data collection of both phases of my study and outline the preliminary results of the entire research project. 331

Contributions to the ICMI-17 study

The research reported in this proposal supports the aims of the ICMI-17 study, as set out in the discussion document, in the following ways.

My work aims to identify and analyze aspects of technology integration, primarily in universities (diverse curricular organizations), but also consider connections with pre-university level mathematics education. In addition, my study incorporates and investigates cultural diversity as it takes an international comparative approach to compare the use of technology in a less developed (Hungary) with more developed countries (UK, US) in terms of ICT resources and investment in educational technology . My study addresses well the following aim of the ICMI-17 study:

ICMI Study 17 will also seek to take account of cultural diversity and how issues of culture alongside those related to teacher beliefs and practice all shape the way digital technologies are used and their impact on mathematics and its teaching and learning. (Hoyles & Lagrange, 2005, p.4)

My work is also in line with the following two ICMI-17 study aims:

1) to reflect on actual uses of technology in mathematics education, avoiding mere speculations on hypothetical prospects

2) to address the range of hardware and software with a potential to impact upon or contribute to mathematics teaching and learning. (Hoyles & Lagrange, 2005, p.4)

Although my study concentrates on a particular software package its results should be applicable to a wider range of applications. The examination of CAS is significant for technology-related research because such packages explicitly focus on mathematical activities and do not only reorganize communication in classrooms.

I believe that my research best fits Theme 3 – Teachers and teaching – as it contributes to many of the questions raised in the Study's discussion document. Particularly, it addresses the three questions:

- How are teachers' beliefs, attitudes, mathematical and pedagogical knowledge shaped and shaped by their use of digital technologies in mathematics teaching and how are these issues influenced by access to resources and by differences in culture?
- What can we learn from teachers who use, or who have tried to use, digital

technologies for mathematics teaching?
How can teachers be supported in deciding why, when and how to implement technological resources into their teaching practices? (Hoyles & Lagrange, 2005, p.8) 332

Developing Learning and Assessment Tasks in a Dynamic Geometry Environment
Arthur Man-Sang Lee, Ka-Lok Wong, Allen Yuk-Lun Leung
The University of Hong Kong
amslee@hkucc.hku.hk
This paper presents the development of manipulative tasks in a dynamic geometry environment as a tool for learning and assessment in geometry. In a research study, groups of junior secondary students were asked to manipulate dynamic geometry figures, in the form of Java applets, by dragging movable points to create particular configurations satisfying specified conditions. The tasks are designed in such a way that students are expected to easily make use of learnt knowledge in school geometry to produce the required results. They had to consider real-time measurements provided and constraints on the variation of the figures. As part of design of the tool, students' results of dragging can be recorded as an image and in terms of numerical parameters for later analysis. Students' responses to the tasks were analyzed by first examining quantitatively the variety of configurations produced, followed by clinical interviews probing into the process of students' working on selected tasks. The analysis reveals the complexity of students' interaction with and interpretation of dynamic figures. Based on these results, some major questions are suggested to further explore the nature of dynamic geometry figures and implication of uses of these manipulative tasks in the context of classroom learning and assessment.
Introduction
Dynamic geometry environment is a powerful milieu in which the teaching and learning of plane geometry could be re-conceptualized due to the drag-mode (see for example the discussion in Lopez-Real & Leung, 2004). Indisputably, dragging in dynamic geometry plays a crucial role in the formation of geometrical concepts and conjectures (see for example, Arzarello et al, 2002; Leung and Chan, 2005). In particular, the epistemological values of robust and soft constructions with respect to dragging have been the foci of many studies in dynamic geometry (see for example, Laborde, 2005). Though fruitful insights have been obtained, there is yet a deep understanding on how students perceive the relationship between the spatio-graphical representations (what they actually see on the computer screen) and the theoretical knowledge (the traditional school geometry they learnt). The variation visualized from the drag-mode in dynamic geometry may give students a new reasoning pattern that diverges from the traditional deductive thinking. In particular, the (pseudo) accurate representation of geometrical objects and measurements under dragging offers a confluence of simultaneities that could bring about discernments that might be different from a static paper-pencil environment. Sinclair (2004) concluded in her study on Grade 12 students working on pre-constructed dynamic geometry sketches that "students who focused on visual information and drew conclusions based on the appearance of the onscreen image did not have the tools to develop and communicate a proof based on visual concepts" and this was due to students' unawareness of the 335 accurate representation in dynamic geometry sketches. It would be interesting to probe into the impact of accurate representation and variation under dragging on students' spatio-graphical reasoning that leads to explanations of phenomena in dynamic geometry environments. In this respect, we initiated an experimental instrument to assess students' geometrical understanding in the context of IT activity in a mathematics competition for regional primary schools in Hong Kong (Lee, Wong & Tang, 2004; Wong, Lee & Tang, 2005). The instrument was in the form of dynamic geometry manipulative tasks in which students can vary a point (a dimension of variation) in a geometrical configuration via dragging. Students were asked to drag the point to a position that would satisfy certain required condition. A coded and varying (as the point was dragged) numerical value was associated to the point for the purpose of recording students' answers. This opened up a new arena for quantitative analysis in dynamic geometry research that might yield interesting collective information on students' different ways of interpreting spatio-graphical data in dynamic geometry environment. In this proposal, we continue the quantitative experiment with groups of secondary 1 and 2 (Grade 7 and Grade 8) students in Hong Kong. After patterns are observed in the quantitative analysis, selected students are invited for one-to-one clinical interviews during which they will work on a specific manipulative task while the interviewer will probe them with questions on geometrical understanding of the task.
Design of dynamic geometry manipulative tasks
Each task requires students to manipulate geometric objects on screen by using the mouse to drag around movable points. The dynamic figures are created with the software C.a.R. ("Compass and Ruler" by R. Grothmann, http://mathsrv.kueichstaett.de/MGF/homes/grothmann/java/zirkel/doc_en/) and presented as Java applets so that students can access them through common browsers. These are basically pre-constructed geometric figures in which certain geometric properties are preserved during dragging. Students need not know the hidden construction nor perform additional constructions on the figure. What they observe will be the constrained movement of dependent parts and some displayed real-time measurements (of length, angle size, etc.) as a result of their dragging of movable points. By making use of such observation or information, the students try to turn the figure into a required configuration.
We begin by considering situations in which students may make use of their knowledge and understanding of geometric properties to complete a task. For illustration, let us consider parallelism and angles. In some of the tasks, students are required to make a line parallel to another or to make two lines intersect at a particular angle. In a given figure, students can drag movable points (while the rest are fixed or dependent on others) to re-position lines or segments while seeing measurements of angles continuously updated. Specific solutions, whether there is only one or more, are expected. However, we are not simply interested in the 336 correctness or accuracy of students' solutions, but the variety of results of students' manipulation initiated from the task.
Two of the tasks are explained here to illustrate our considerations.
Task 1
Figure 1a shows the initial configuration of a dynamic figure. The task is to move the point P to make angle a equal to 120°. All the lines are fixed except the one containing P, which will be turned about a fixed point outside the viewing window. Figure 1b shows the result of dragging P to the right and the only position of the variable line that gives the required angle.
Figure 1a Figure 1b Figure 2a Figure 2b
Task 2
This task starts with the figure 2a, in which A, B and C are fixed points while D can be moved freely in any direction. The task is to make a quadrilateral with at least one pair of parallel sides. Figure 2b shows only one among many possible ways fulfilling the requirement.
Collecting and analyzing students' responses
The open source software C.a.R. is modified to allow students to submit electronically the final configuration of their dynamic figures in the browser when a task is finished. We are therefore able to record and retrieve students' responses as an image and numerical values specifying final state of key variable parts. In the examples above, the coordinates of point P (in task 1) and point D (in task 2) will be recorded when students submit their results.
The test was conducted in 9 junior secondary classes from 4 schools with different academic backgrounds in Hong Kong around June 2005. These students had learnt about properties among angles related to parallel lines and transversals, in the same or previous academic year. We first examined distribution of students' responses to individual tasks. By reducing students' submitted configurations into one or two numerical descriptors, we were able to capture the variety of students' results and identify interesting patterns, which provided a useful picture before we probed into individual students' attempts to a task.
For the task 1, we examined students' positioning of the movable point along a horizontal track, which corresponded to different angles formed between the variable transversal and the fixed lines. Nearly half of the students could accurately generate 337 the required angle. Meanwhile, we noticed an unexpected outcome from about one eighth of the students, giving 3 angles in progression, as shown in Figure 3b.
Distribution of x-coordinates of point P in task 1 from 169 students.
Values at about 7 (red column) correspond to result shown in figure 3b.
Figure 3a Figure 3b
Scatter plot of position of point D in task 2 from 162 students.
Positions along the diagonal line (dots in red) give a pair of equal opposite angles, as shown in Figure 4b.
Figure 4a Figure 4b
For the task 2, we considered the scatter plot of all final positions of the vertex D of the quadrilateral. Most students could put the vertex along a line parallel to either fixed side of the quadrilateral, in particular the intersection where the figure resulted in a parallelogram. Among the rest seemingly without pattern, we noticed a special diagonal line attracting some points (about 28 students). Putting the free vertex along this line (near but except the intersection) produced a pair of equal opposite angles

but no parallel sides.
After this preliminary quantitative analysis, we proceeded to interview individual students and observe their processes of working on selected tasks from the test. We 338 interviewed 24 students from 4 schools with similar background but had not done the test in the first stage. Even from such a small sample, we realized the complexity of students' processes of working with the dynamic figures despite overall fairly good results from the test. Even though some students did eventually come to a correct result, the process could be far from a straightforward application of their knowledge of school geometry on the manipulation of the dynamic figures. Students' explanation of their work reflected their incomplete or conflicting conceptions regarding basic geometric notions such as parallel lines and angle relation. This may be due to their inexperience in articulating their geometric thoughts, or unfamiliarity with behavior of dynamic figures and interpretation of real measurements.
A student working on task 1 started with a slow and careful dragging of point P across the screen. He stopped at the position in fig. 3b and declared that it was the required angle. He explicitly pointed out that the "angles differ by 2˚ and then 2˚", leading to his belief that angle a was 120˚ at that position. (Note that the given angles made by the transversal on the right kept differing by 2˚ as P varied.) Yet he also noticed by himself the given angles on the left (84˚, 86˚, 84˚) were not "considered". He started to wonder if the lines were parallel, partly based on their appearance and partly based on their angles between the transversal. He tried to relate the "imbalance" of the lines to the difference in the angles. He finally chose to ignore the middle line, which "deviates from the other two". He proceeded to adjust his answer to that of fig. 1b, where the angles on the upper and lower lines "look symmetric". At the end he was sure that the upper and lower lines were parallel, following his previous inspection of the angles and inclination of the lines. Yet this was not a simple deduction of the angle properties from relevant geometrical theorems, which we may assume from students giving a correct result. On the other hand, we also noticed how the student tried hard to make sense of the real representation and varying measurement during the process.
The results of Task 2 as mentioned above reveal an interesting fact that students attend to a pair of equal opposite angles rather than a pair of angles associated directly with one pair of parallel lines. Some students in our interviews on this task made explicit attempts at making BAD equal to BCD (Figure 4b). We find this point even more intriguing when we look at students' responses to another similar task but with different given conditions. On the one hand, similar responses along a diagonal (as in Figure 4a) are observed. On the other hand, interviews on this task show clearly this undue attention to the opposite angles. Suffice to mention one telling example. A few students first came to a parallelogram (Figure 5a) but provided with a strong reason that each opposite angle gives the same sum of 99˚. When a student was prompted by the interviewer to produce another answer – i.e. a quadrilateral with at least one pair of parallel lines, she managed to produce one with an equal pair of alternate angles (Figure 5b). But she failed to recognize it as an answer and explained that the sum of angles at one corner (33˚ + 66˚ = 99˚
) was not equal to the other
(66˚ + 36˚ =102˚
). 339
Figure 5a Figure 5b
Questions for Investigation
Through the design of the DG manipulative tasks and analysis of students' responses in both quantitative and qualitative manner, we attempt to develop new perspectives on the role of DG in the classroom learning and assessment. We start with a fundamental question.
• How do students understand the dynamic figures presented in this kind of manipulative tasks? In particular, when they drag a figure, how do they interpret the given measurements together with the varying shapes? And, when they want to achieve a certain target diagram, how do they decide on the pertinence of various geometric properties?
We go on to elaborate this question in the context of teaching and learning and then assessment.
• How will this kind of DG manipulative tasks be useful in learning and teaching?
Usually, when setting a mathematics question for students, a teacher has a good idea of what knowledge (e.g. a geometric property in its precise expression) is to be applied. This kind of conception leaves little room for exploration in the student's problem-solving process and thus does not appear to be consonant with the potential benefits granted by the DG environment. Nevertheless, a manipulative task of this kind has a very precise goal but leaves a reasonable scope of exploration (by very limited number of movable points or constrained movements). On a task with such reduced complexity, we seek to understand how students perceive the spatiographical representations presented and what geometric knowledge (from the formal curriculum) is to be enacted. The collective quantitative information from a large number of students and the qualitative data from the interviews should provide us with evidence.
Inspired by the distinction between soft and robust construction and also the benefits of the former in teaching (Laborde, 2005), we consider this kind of manipulative tasks more like the "soft" ones in the sense that a manipulative task of this kind 340 requires a student to attain a figure that meets a certain condition by dragging a preconstructed figure. The important point is that the pre-constructed figure does not have all the necessary invariant properties that lead to the target condition – otherwise it is already a robust construction. By a careful design of what is allowed to vary and what is kept invariant in the background, the student would be helped to visualize how a particular property emerges from a varying figure and to realize the interdependency between the geometric properties. Collection of all students' responses on the other hand can help teachers or researchers to visualize the 'locus' of the points resulted from students' examples chosen to satisfy some particular conditions. Interview data in the current research project would help us understand better how students perceive a geometric figure and, in particular, what geometric features of it are taken into consideration when they are trying to make it satisfy a certain geometric condition. Understanding on this aspect will guide us on another path of developing the tasks for classroom use in the process of learning and teaching.
Can students' performance in this kind of DG manipulative tasks be assessed with the aid of the quantitative measures? If yes, what are we assessing and what can we tell out of the quantitative results?
Traditional paper-and-pencil assessment used to test whether a student can make use of basic geometric properties to find an unknown geometric measure or to produce a written proof of an unfamiliar property. This accounts at least partly for the concern of most teachers with what students know (a product-oriented curriculum) rather than how they come to know (a process-oriented curriculum). Just as DG and the research thereof seem to have suggested more on the latter but not the former, many teachers are hesitant to bring DG into the curriculum.
This new type of DG manipulative tasks suggests a potential use for assessment (Lee, Wong & Tang, 2004). With a parameter assigned to describe the relevant geometric feature(s) of the DG figure, a numerical value as a result of a student's manipulation is obtainable. The value in turn reflects, to a certain extent, how well a student has fulfilled the requirement of a certain manipulative task. Despite various difficulties pertaining to the design of the task as well as the designation of an appropriate parameter, this quantification of student performance in the dynamic geometry environment offers a possibility for assessment. Apart from a numerical score given to individual students, collective information from a large group of students may also reveal common mistakes and help serving the diagnostic purpose of the assessment (Lee, Wong & Tang, 2004). Numerical data collected also allows various quantitative analysis. Wong, Lee & Tang (2005) has attempted Factor Analysis and, in their interpretation and characterization of the factors, the authors start to be convinced of a distinctive element of exploratory interaction as opposed to working with formulas and computation in accounting for student performance. If successful in this integration of DG in assessment, we would be in a better position to materialize such new learning objective (e.g. in the curricular context of Hong Kong) as "to explore 341 and visualize geometric properties." Analysis of the data in the current research project will shed more light on this aspect.

Using technology in the teaching of mathematics at Lesotho National University
Moneoang Leshota National University of Lesotho, Lesotho,
mjmakcele@nul.ls
Introduction
In 1993 while I was studying for my Masters degree in the UK, I came across the book "Computers in the Mathematics Curriculum" by the Mathematical Association. After reading through this book, I felt an uplifting in spirits which had not happened in a long time. How wonderful it would be to get into my Pre-entry programme class back in Lesotho and draw all these different graphs (linear, quadratic) using excel spreadsheet instead of pencil and a graph sheet. I recalled how it used to be: The pencil should have a very sharp tip, and should actually be "HP" so that it does not a make a mess on the graph sheet when one rubs it off. To draw the quadratic graph, one should not move their hand as the graph might have bumps.
This happened around the time when I was about to finish my dissertation "Discontinuities in Mathematics Education between High School and University in Lesotho: Bridging the Gap". I had learned most profoundly how technologies could aid in the teaching and learning of mathematics, and had experimented with "Derive" and "Cabri-Geometre".
My view was that, the usage of computers and other technologies was quite a breakthrough in my teaching of mathematics, and for my students as, whom the biggest concern at the time for them was their poor and seemingly deteriorating performance in mathematics at o' level and beyond.
I returned home in 1993 and was about to experiment with my new-found knowledge on using technology to teach the Pre-Entry Science class just about to enter into first year of their BSc degree. Then reality hit home.
Socio-Economic factors in Lesotho
Lesotho is a country of approximately 30000 km
2
in area, with a population of just
over two million people. According to the Human Development Report 2005, Lesotho is ranked 149
th
out of 177 countries on the Human Development Index with a HDI value of 0.497. It is one of the low human development countries with GNP per capita (PPP US$) of 2561, and 49.2% of the population living below the income poverty line, therefore, quite a poor country.
In terms of technology and technology development, Lesotho has 16 telephone mainlines per 1000 people, 47 cellular subscribers per 1000 people, 14 internet users per 1000 people, and 42 researchers per 1000 000 people (HDR, 2005). Therefore, for most of the population of Lesotho acquiring a computer would be quite impossible, so that the usage of computers is done mostly from the work-place by adults instead of school children.
Political factors
At the National University of Lesotho (NUL), in 1993 when I got back from my studies, there were about one hundred and twenty students joining the faculty of 343 science and technology at first year level. The computer laboratories available in the university were stocked with about fifty (50) machines which were used exclusively by students at second year level and above, who measured in computer science.
In recent years, the university has introduced a computer literacy course for all students of the university making it compulsory for each student to have done at least this computer literacy course by the time they graduate. To this effect, the university introduced a few computer laboratories stocked with computers to serve this purpose. All first year students in all faculties of the university excluding the faculty of science do the computer literacy course.
The faculty of science and technology has two streams of first year students. The first stream, the "specialized programme" has about one hundred and twenty students majoring in Computer Science, Information Technology and Statistics. The second stream is the BSc general stream of some four hundred students following common first year programme. Both streams follow a similar curriculum for mathematics in the first year, namely, "M1501 – Algebra, Trigonometry and Analytical Geometry", and "M1502 – Calculus I". The implications here are that for the specialized programme, one can introduce the usage of computers in the teaching, but not for the general stream, as this stream would only have access to computers in their second year.
The National University of Lesotho is mostly funded by government for its activities. At present, top on government agenda are issues of HIV and AIDS which is 30% prevalent in Lesotho, and issues of poverty reduction. Hence, the need for acquisition of more computers would have to be prioritised with all these other national programmes. Since the acquisition would be just for supplementing the teaching of

mathematics there would have to be a major political support on the side of the university to place its demand on computer acquisition to government.
Lesotho and the Republic of South Africa
Lesotho has an unusually distinct feature of being completely landlocked by another country, the Republic of South Africa. This makes South Africa Lesotho's immediate neighbour at all points. This is one rich neighbour ranking 120
th
on HDI scale, with
GNP per capita (PPP US$) of 10346 and 192 researchers per 1million people,
features which cannot be compared at all with those of Lesotho.
Due to this proximity and South Africa's international position academically, most of the students from Lesotho attend school in South Africa, from primary level up to university level. It is obvious that those students who start schooling in South Africa and are able to continue throughout university there would have better access to computers.
On the other hand, most of the students only manage to get to South Africa at tertiary level. These students would have to work extremely hard to compete with the best of South African students who have had access to computers from early schooling.
Mathematics education in Lesotho 344
It is my opinion that mathematics education in Lesotho has not transformed in any major way in the last two decades or so. Factors affecting student performance in mathematics at high school and university were grouped into three categories way back in 1993 (Makoele: M.Sc Dissertation), namely:
Teaching Methods used in the schools
There was evident lack of teaching approaches such as investigation and problemsolving. It was believed by both students and lecturers interviewed at the time that the teaching was not geared to understanding due to pressures of examinations at the end of three years and five years respectively for the Lesotho schools, so that the teaching was seen to encourage rote learning.
I have not found reason to believe that things have changed for the better in recent years as I teach more new students at university coming directly from the schools.
Mathematics at University
On this particular issue, important factors were:
i. The method of lecturing, which is traditionally followed at university requires some adjustment in the learning habits of students.
Big classes at university of about 400 students taught together as opposed to classes of 40 to 50 students at school. The syllabus which in other countries would be covered over a period of two years at A'level, is done over nine months at the NUL.
ii. Textbooks.
Due to foreign exchange rates, the cost of textbooks is very high, hence there would be not much variety in the books for reference purposes. It has been the case that at NUL for some years there had not been prescribed books and students depend entirely on lecture notes.
iii. Research.
In my opinion, research in mathematics education is virtually non-existent. Where there has been some research done, it would be uncoordinated, and hence unavailable to the public. In particular, at NUL, the departments of mathematics education and mathematics fall under two different faculties, their only interaction being of students in mathematics education taking mathematics courses in the department of mathematics. The department of mathematics education main focus is on the teaching of mathematics at school level, so that it does not work on research issues in undergraduate teaching of mathematics.
On the other hand, there is a feeling among the members of the department of mathematics that issues of undergraduate teaching of mathematics fall under education and therefore have no place really in the department of mathematics. This has caused a major neglect of this important sector in the teaching of mathematics, so that at NUL there is no study or research whatsoever about the teaching of mathematics at undergraduate level, let alone the usage of digital technologies in the teaching of undergraduate mathematics.
Mathematics Education in the World 345
The Lecturers at NUL are expected to be conversant with the stuff that they teach to students like everyone else. In the light of unavailability of textbooks as mentioned earlier, they depend largely on the wide world web for reference. Here one finds lecture notes of other lecturers teaching the same subject in their own universities, research on current issues on specific subject matters, and innovations in the development of mathematics teaching. In as much as the stuff from the internet is fascinating, it is also very intimidating to some extent. For example, in teaching a topic in complex functions, I was distraught when introducing the concept of "complex maps", until I discovered a web page where someone did the very mapping using computer technology. This was so helpful to me that I conducted the next lecture to some 30 students in my office showing them how the functions map. And the next thought was, if only I could do that for all the courses and to all students that I teach. The possibilities created by technology in the teaching of undergraduate mathematics cannot be overemphasized, but the challenges posed by inaccessibility to these technologies and to be part of the "global village" that researches first hand on issues of using these technologies in the teaching of mathematics are similarly devastating to those interested in the technologies.
Conclusion
I believe that for many of us in the developing countries, the possibility of using digital technologies in the teaching of mathematics would be a great advantage. It is true that these technologies do not come cheap, but if they could be available, then a lot of work done in specialised programmes such as "bridging and remedial" programmes instituted for the science students entering tertiary education would be minimised, and there would be better results from these remedial and bridging programmes observed than without the technologies.
Despite all these, I agree with Harold Wenglinsky who says that "Computers can raise student achievement and even improve a school's climate. But they have to be placed in the right hands and used in the right ways".(Education Week).
What is needed is research on the aspects of the teaching of mathematics at all sectors of education, that is, from primary throughout to tertiary level so that individual efforts made could be adequately monitored and publicised. The research would help in giving guidance for educators to know exactly where and how to use the digital technologies.

Instrumental Genesis in Dynamic Geometry Environments
Allen Leung, Yip-cheung Chan, Francis Lopez-Real
Faculty of Education, The University of Hong Kong
ayleung@hkucc.hku.hk
Over the past decade, much research has been done on dynamic geometry software investigating how this virtual environment can change our perception of mathematics and doing mathematics (in particular geometry), in the hope of enriching the pedagogical practices of mathematics teaching/learning. This proposal attempts to employ Vérillon and Rabardel's theoretical construct – instrumental genesis – to study the evolution of utilization schemes by persons engaging in dynamic geometry explorative tasks; a first step in a programme to probe deeper into how geometry is conceptualized and learnt in dynamic geometry environments (DGE). In this study, the theory of variation in the phenomenographic research approach is used as an interpretive tool. In particular, the drag-mode in dynamic geometry is perceived as an artifact, hence an instrument. Consequently, instrumentation/instrumentalization of dragging via functions of variation (contrast, separation, generalization, fusion) and dragging modalities will be a main focus of DGE instrumental genesis. In the proposal, a pair of Hong Kong pre-service mathematics student-teachers' DGE exploration episode is presented and briefly analysed. A possible variational dragging scheme is then proposed for their process of discovery. The studying of the conversation between the two student-teachers during their collaboration in the DGE task further identified a few DGE utterances which illuminate ways to conceptualize discourses in DGE.
The proposal
Over the past decade, much research has been done on dynamic geometry software investigating how this virtual environment can change our perception of mathematics and doing mathematics (in particular geometry), in the hope of enriching the pedagogical practices of mathematics teaching/learning (see for examples, Educational Studies in Mathematics 44:1-161, 2000; International Journal of Computers for Mathematical Learning 6:229-333, 2001; Math ZDM 34(3), 2002; Leung and Lopez-Real, 2002; Lopez-Real and Leung, 2004). Dynamic Geometry Environments (DGEs) opened up a milieu for the integration of experimental mathematics into classroom didactic and consequently brought forth the role of ICT as a key contributor to mathematical discourse. A key feature of DGE is its ability to visually represent geometrical invariants amidst simultaneous variations induced by dragging activities. This dynamic tool – dragging – induces potential dialectic between the conceptual realm (abstraction) of mathematical entities and the world of virtual empirical objects. Because of this possibility, dragging has been a major focus of research in DGE resulting in fruitful discussions on promising dragging modalities and strategies that seem to be conducive to knowledge construction (see for 347
examples, Hölzl, 1996; Arzarello et al, 2002). Indeed, when the drag mode "acts" on a virtual empirical object in DGE, the object undergoes transformations in a domain in which the dual nature of mathematical object (Sfard, 1991) can be "lived out". This domain is a complex network that covers various aspects of DGE and human behaviours (physical, psychological and cognitive) where artifacts/tools could be turned into instruments/psychological tools. It thus provides an integrated environment (DGE plus human) where situated (mathematical) abstraction (Noss and Hoyles, 1996) could be constructed and "behaviour of mathematics" could be studied. The transition from concrete to abstract (epistemic transformation), or vice versa (pragmatic transformation), in this integrated environment spans a zone where creativity resides. This zone is the object of study for most of the DGE research. It is where experiences and "imagination" in DGE meet, merging to shape geometrical concepts. The idea of instrumental genesis proposed by Vérillon and Rabardel (1995) is a suitable framework to begin the exploration in this transition zone.
Instrumental genesis differentiates an artifact (a man-made object/tool) from an instrument (a psychological construct) by defining the latter as formed by an artifact together with one or more associated utilization schemes that emerge from SIA (Situated Instrumented Activity). SIA (Vérillon, 2000) is an inter-activities web formed by a triad that consists of a subject (as user), an instrument (as tool) and an object (as epistemic transformation, e.g. geometrical knowledge). Tools are artifacts that can amplify or modify our abilities to transform the world around us. They are shaped and fashioned in ways that contain the potential to reify human imagination. Hence, the value of a tool is inseparable from the one who uses it, in particular, how one uses it. We learn mathematics with tools. A pair of compasses gives us a vision of the ideal circle, a ruler is a representation of straightness, a calculator enables us to see patterns behind the complexity of routine calculations, and the list goes on. A user turns a tool into an instrument for a specific mathematical task by associating with it a scheme of use. A scheme is a systematic procedure on how to use a certain tool to achieve a certain purpose. Thus, an instrument is a psychological construct in the cognitive ergonomic domain (Vérillon and Rabardel, 1995). This is the useroriented micro-genetic process of instrumentation in instrumental genesis. At the same time, specific functionalities, even purposes, are attributed by the user to the tool (not necessarily intended by the designer of the tool) in the instrumental genesis process. Rabardel (1995) called this instrumentalization of the artifact. Hence, an instrument is a dual entity – artifactual and psychological.
A user-oriented utilization scheme is somewhat reminiscent of Kant's schema – "representation of a universal procedure of imagination in providing an image of a concept" (Kant, as cited in Tasi, 2001, p.11). In a sense, a utilization scheme in instrumentation can be thought of as a local realization of a schema; however, this raises the important question of whether different utilization schemes would converge to the same concept object. Mariotti contended 348
"The artifact, although incorporating mathematical knowledge and integrated by appropriate utilization schemes, might not function in generating mathematical meaning; its user might not access the meaning incorporated in the artifact."
(Mariotti, 2002, p.704)
Hence a utilization scheme can be just a routine procedure for a particular task and remains a situated abstraction that might not explicitly harvest the universal mathematical meaning behind it. Instead of artifact and instrument, Mariotti favoured the Vygotskian distinction between the mediating functions of technical tools and psychological tools (or signs: a mental construct) and preferred using semiotic mediation as an umbrella over instrumental genesis. Instead of focusing on the evolution of a utilization scheme in instrumental genesis, meaning construction becomes the core activity in a process of internalization where technical tools are being transformed into psychological tools for the purpose of shaping new meanings. In semiotic mediation, the focus is not on distinction between artifact and instrument; rather it is on the externally or internally oriented usage of the tool that could bring about the construal of mathematical meanings.
How do we gain geometrical knowledge in DGE? This is the ultimate question that we seek to answer. Instrumental genesis and semiotic mediation are promising theoretical frameworks that could pave a path to start the journey. Any path to knowledge construction should be an experiential one. How a person experiences the world of DGE will determine the kind of knowledge that he/she gains in DGE. The utilization schemes in instrumental genesis are schemes on how to experience the potentiality of a tool/artifact. This somewhat echoes to Vergnaud's notions of scheme and operational invariant (Vergnaud, 1999). In semiotic mediation, the process of internalization concerns the transformation of experiences; a change in the way of seeing something via a change in the nature (pragmatic, epistemic) of the tools.
Experiences, discernment, variation and simultaneity are the central concepts in the phenomenographic research approach in which learning and awareness are interpreted under a theoretical framework of variation.
"The unit of phenomenographic research is a way of experiencing something, ..., and the object of the research is the variation in ways of experiencing phenomena."

(Marton and Booth, 1997, p.111).

Phenomenography literally can mean the act of representing an object of study as qualitatively distinct phenomena. In particular, it concerns the second-order nondualistic (neither internal/mental nor external/physical) categories of description 349 of the variation in ways of experiencing something (phenomena), and is about categorizing the limited number of qualitatively different ways of seeing, or experiencing, a phenomenon in a hierarchical fashion. DGE is rooted in variation in its design. It is a milieu where mathematical concepts can be given visual dynamic forms subject to our actions, powerful or not and mathematical concepts can be developed through experiencing invariance under different dimensions of variation mediated by the tool/artifact in DGE. DGE is a natural experimental ground to experience variation since it has the built-in mechanism that enables the generation (via intelligent construction and dragging by us) of various qualitatively different ways of literally seeing a geometrical phenomenon in action. In this respect, Leung (2003) and Leung and Chan (2005) made initial attempts to discuss how functions of variation (specifically contrast, separation, generalization and fusion) in the phenomenographic research approach could be realized under different DGE dragging strategies in problem-solving and conjecturing episodes. It seems to be a worthwhile research to consider the functions of variation as functions of dragging and investigate how these functions can be realized through different dragging modalities in different DGE contexts (for examples, construction, problem solving, conjecturing, proving), or vice versa. That is, how to use which dragging modalities for different functions of dragging in different DGE contexts; in other words, an instrumentation of dragging in DGE via functions of variation and dragging modalities. Hence, the overarching question is how to integrate the theory of variation in the phenomenographic research approach into instrumental genesis and semiotic mediation in the study of how geometry is learnt (experienced) in DGE, which might lead to sound pedagogical content knowledge in DGE. In particular, here are a few possible (inter-related) research questions:

1. Explore how the functions of variation interact with features (e.g. dragging modalities/strategies) in DGE and investigate how this interaction contributes to the formation of utilization schemes in the process of instrumental genesis.
2. Can ways of experiencing geometry in DGE be categorized in some sort of hierarchical schematic fashion? If yes, how does this hierarchy contribute to the conceptualization of geometrical knowledge?
3. DGE is somewhere between physical and psychological, hence may be regarded as a kind of non-dualistic field of experience, a natural niche for the phenomenographic assumption. Does the idea of non-dualistic tool for semiotic mediation in DGE make any sense? If so, in what ways?

These are questions that need in-depth research to reach some sort of answers.

Extensive research has been done on instrumental genesis in Computer Algebra System (see for examples, Artigue, 2002; Guin and Trouche, 2002, Trouche, 2004; Guin, Ruthven and Trouche, 2005); however, there seems to be a gap in the literature on instrumental genesis in DGE. In the following, we describe a portion of an episode 350 in which two pre-service mathematics student-teachers studying at the University of Hong Kong for the Postgraduate Diploma in Education (PGDE) were taking part in a conjecture making activity in DGE. The DGE they used was C.a.R. (Compass and Ruler, a DGS developed by R. Grothmann, http://mathsrv.ku-eichstaett.de/MGF/homes/grothmann/java/zirkel/doc_en/). During their exploration, an implicit dragging
scheme was evolved for the problem they were
working on that eventually led them to the
discovery of a (correct) conjecture. This
dragging scheme composed of (a) key
functions of variation mentioned in the
discussion above and (b) dragging modalities
that have been identified in research and
practices (the student-teachers were not aware
of these). The problem they were working on was finding a relation that was essentially the necessary condition in Ceva's Theorem. In particular, they were given a C.a.R file (see figure on the right) in which A, B, C and P are independent draggable points while X, Y and Z are points dependent on P. The task was to find a relation connecting the lengths of the segments BX, XC, CY, YA, AZ and ZB. These two student-teachers had undergraduate degrees in mathematics-related subject areas but they didn't know Ceva's Theorem. They were introduced to C.a.R. in a two-hour session in the PGDE programme and they had no knowledge of the above mentioned functions of variation. At the beginning of the exploration, they spent a few minutes familiarizing themselves with the C.a.R environment and they measured the length of all the segments in question. The following is a brief outline and description of a dragging scheme that seemed to have evolved out of their exploration.

A Variational Dragging Scheme in DGE

1. Create contrasting experiences by wandering dragging until a dimension of variation is identified.
P was dragged to different positions inside triangle ABC in a wandering fashion while focus was put on the numerical values of the length measurements. Side BC (in particular, the point X) was chosen as a controlling variable (a dimension of variation) and while X varies as P was dragged, focus was given to the length measurements of CY, YA, AZ and ZB.
2. Fix a value (usually a position) for the chosen dimension of variation.
The midpoint,X) , of BC was constructed.
3. Employ different dragging
modalities/strategies to separate out
critical feature(s) under the fixed value
(i.e. a special case for the configuration) 351
P was dragged to keep X andX) as close as possible (see figure on the right) and attention was given to the length measurements of CY, YA, AZ and ZB. This was a guided dragging/drag-to-fit strategy. A numerical pattern was observed: the product of YA and ZB "appeared to be somewhat equal" to the product of CY and AZ (a calculator was used). Consequently, YA, ZB and CY, AZ were separated out as two related pairs. During this exploration, some DGE utterances were developed between the two student-teachers: "very difficult to control", "try best to keep on the line", "try to squeeze it", etc.
4. Simultaneously focusing, hence "reasoning", on co-varying aspects during dragging. A preliminary conjecture is fused together.
Further refinement of the dragging techniques (as reflected by the DGE utterances) confirmed the speculation in 3. This is a fusion experience in which co-varying aspects (numerical values, position of P and X, the changing line segments) were simultaneously experienced together. A preliminary conjecture was proposed: when X is the midpoint of BC, the product of YA and ZB equals the product of CY and AZ.
5. Attempt to generalize by a change to a different value for the chosen dimension of variation.
P was dragging in a wandering fashion, however, with random patterns. For example, it was dragged horizontally for a while. After a period of fruitless exploration, the student-teachers decided to place X at a different special position: CX : CB = 1 : 3.
6. Repeat steps 3 and 4 to find compromises or modifications (if necessary) to the conjecture proposed in step 4.
The dragging and reasoning strategies developed in steps 3 and 4 were employed to this modified situation (a new value for the chosen dimension of variation). The student-teachers at this moment were more experienced with the "utilization scheme" that they have developed and used it again to tackle a new situation. More DGE utterances were developed: "the point moves, all will be changed", "it feels like the property has to do with length", "put it on top", etc. They discovered that the product of YA and ZB was not equal to the product of CY and AZ in this case; rather, they found that the product of YA and ZB is 3 times the product of CY and AZ. A modified conjecture was then proposed: the product of YA, CX and ZB is equal to the product of CY, XB and AZ.
7. Generalization by varying (via different dragging modalities) other dimensions of variation
The vertices (instead of P) A, B and C were being dragged in a wandering fashion and different values were assigned to the position of X; literally trying to see whether the modified conjecture still holds. In particular, P was dragged to move X continuously along BC. By seeing that the conjecture remained invariant under variation (by dragging) in all dimension of variation (expect when P was outside the 352 triangle which could be seen as a design fault for the moment), the student-teachers were convinced that they had a generalized conjecture.

The 7-step variational dragging scheme described above may serve as a good starting point to investigate research question 1 and it is the intention of this proposal to undertake such an attempt. To begin with, more in-depth analysis will be done on the above episode (only the first portion of the episode was analyzed here; for the rest of the episode, the student-teachers continued the exploration in DGE and eventually proved the conjecture successfully). As mentioned above, DGE utterances were developed by the student-teachers during their exploration, it would be interesting to note the evolution of a DGE discourse as another strand of study. Further exploration tasks will be designed and persons with good mathematical background (students or teachers from secondary or tertiary) will be invited to participate in the research. It is hoped that by researching into how instrumental genesis in DGE could take place under the framework of variation, research questions 2 and 3 could become more well-defined and tangible.

Pappus in a Modern Dynamic Geometry: An Honest Way for Deductive Proof

Hee-chan Lew
Korea National University of Education
hclew@knue.ac.kr

This study shows that dynamic geometry using the "analysis" method systemized by the Greek mathematician Pappus in the 3rd century AD can provide a good learning environment to teach deductive proof for secondary students. Traditionally, in teaching deductive proof the axiomatic or synthesis method to deduce a new result from assumptions has been far more emphasized at the expense of the mathematical discovery process. The method systemized in Euclid's Elements is not an honest way for teaching deductive proof in that it shows only final results by mathematicians and does not help students to appreciate why and how to prove. To improve deductive

proof abilities through the analysis method, a dynamic environment in which geometric figures can be easily manipulated are required for an "active justification" to find the heuristics for proof. This paper suggests four phases to solve construction problems in dynamic geometry: First is the understanding phase to recognize problem conditions and goals. Second is the analysis phase to assume what to be solved is done and to find the proof ideas by the analysis method. Third is the synthesis phase to construct a deductive proof as a reversed process of the analysis and finally, the reflection phase to reflect on the problem solving process as a whole.
Deductive proof is a process used to deduce a new result from assumptions existed in the problem, axioms, what was previously proven, etc. Since the 6th century BC, it has been the flower of mathematics and marks a distinction between mathematics and other science. Euclid's Elements written in the 3rd century BC has been used as a textbook to develop students' deductive proof over 2000 years. However, the axiomatic method used in Euclid's Elements has been criticized in the sense of showing none of mathematical activities as imagination, intuition, experiment, thoughtful guessing, trial and error, making mistakes, etc. (Clairaut, 1741; Lakatos, 1976; Vincent, 2005). Similarly the proof process that appears in secondary mathematics textbooks shows only the final result produced by some mathematicians and does not help students to see why and how to prove. Students have few meaning in the proof explained by teachers based on textbooks and lose confidence in constructing proof. eventually.
This paper argues that the axiomatic method of Euclid's Elements and current mathematics textbooks are not honest ways for teaching deductive proof, and in order to improve students' proving abilities, an "active justification" to find the heuristics for proving by students themselves should be required rather than a "passive justification" that occurs through teacher's explanation or persuasion about the process. This paper introduces one strategy for active justification to improve 355 students' deductive proof: 'Analysis' with dynamic geometry software. Dynamic geometry provides a good environment for students to develop deductive proof abilities when it is combined with the 'analysis' method systemized by Pappus, who criticized Euclid's 'synthesis' method which shares the same order as the proof process that appears in secondary geometry textbooks.
Analysis and Synthesis Mathematical heuristics related with proof goes back to the Greek era. In the 3rd century, the Greek mathematician Pappus systemized in his book "Collection" the "analysis" which was also emphasized by Euclid but did not appear in his book "Elements". The analysis method, which is the oldest mathematics heuristics in the history of mathematics, assumes "what is sought as if it were already done and inquire what it is from which this results and again what it is the antecedent cause of the latter and so on, until by so retracing the steps coming up something already know or belonging to the class of the first (Hearth, 1981, p.400)." The synthesis as the reverse of the analysis take as already done that which was last arrived at in the analysis and arrives finally at the construction of what was sought by arranging in their natural order as consequences what before were antecedents and successively connecting them one with another.
Greek mathematicians thought the dialectic integration of analysis and synthesis to be a substance of mathematical thought. However, Euclid's Elements considered only synthesis to reduce theorems from the foundation as a way to guarantee the truth of mathematics. As same as Euclid's Elements, current secondary geometry textbooks introduce only the synthesis. The analysis also should be introduced in order to develop students' proof abilities.
Design of an instructional scheme to improve deductive proof ability
Dynamic geometry One problem is that the analysis method is very difficult to be applied in the paper and pencil environment because various dynamic operations such as manipulating geometric figures are required for the method. Particularly, the paper and pencil environment is worse for normal level students than for high achievement studentsIt might be because of the lack of proper dynamic tools that the analysis known well by such Greek mathematicians as Plato and Euclid had not emphasized in schools since the Greek era. Dynamic geometry, which has been developed since the late 1980s, can provide a circumstance for the revived use of the analysis in that it allows students to drag and transform geometric figures.
Four phases of problem solving In this paper four phases of problem solving is suggested as an instructional scheme to improve deductive proof ability: First is the understanding phase to clearly recognize problem conditions and goals. Second is the analysis phase to assume what solving is to be done and to find the construction ideas by using the analysis. Third is the synthesis phase to construct a deductive proof as a reversed process of the analysis and finally, the reflection phase to reflect on the whole problem solving process. 356
Problem situation There are two kinds of geometry problems: Proof problems or construction problems. There are two kinds of analysis. The first kind of analysis is to find proof process by getting a series of previous sufficient conditions of the conclusion to be proven under the assumption that what is required to be proven is already proven. The second kind of analysis is a problem solving strategy for construction problems. This is a strategy to find the construction process by extracting a series of necessary conditions from the assumption that what is required to be constructed has already constructed. In this paper, geometric problems are limited to problems of construction although the analysis method can be applied to both construction and proof
Analysis & synthesis phase for a proof problem
There is a triangle ABC. Make three equilateral triangles ABD, BCE, AFC by using each side of the given triangle ABC. Then prove that quadrilateral BEFD is a parallelogram
The following axiomatic or synthesis proof process usually appears in secondary school textbooks:
1. ABD, 'BCE, 'AFC are equilateral triangles
2. FCA and ECB are 60˚ and FCB is common (DAB and FAC are 60˚ and FAB is common)
3. ACB = FCE and AC = FC, BC = EC (BAC = DAF and AC = AF, AB = AD)
4. ABC □ FEC (ABC □ ADF)
5. AB = FE (DF=BC)
6. BD = FE (DF=BE)
7. Quadrilateral BEFD is a parallelogram
Here, thought flow 1 2 3 4 5 6 7 is a series of sufficient conditions in that 1 is a sufficient condition of 2 and 2 is a sufficient condition of 3 and … and 6 is a sufficient condition of 7. However, this synthesis process does not explain to students why they have to consider "FCA and ECB are 60˚ and FCB is common" from 'ABD, 'BCE, 'AFC are equilateral triangles. Actually it is for showing 'ACB = 'FCE. Therefore students should consider 'ACB = 'FCE first, then they have to find the reason why 'ACB = 'FCE. The reason is "ECB is 60˚ and 'FCB is common". Similarly, students should consider 'ABC □ 'FEC before considering "'ACB = 'FCE, AC = FC, BC = EC" and AB = FE before considering 357 'ABC □ 'FEC, BD = FE before AB=FE and finally "quadrilateral BEFD is a parallelogram" before considering BD=FE.
Thus, the most natural thought in order to prove this theorem is to assume first that quadrilateral BEFD is a parallelogram. Then to find a series of sufficient conditions 6, 5, 4, 3, 2, 1. That is, thought flow 7□ 6□ 5□ 4□ 3□ 2□ 1 is more natural than 1□ 2□ 3□ 4□ 5□ 6□ 7. Here, Pappus called this natural thought flow "analysis" and the reversed thought flow "synthesis."
Analysis & synthesis phase of a construction problem
There is a circle O and there are two lines m and n which are perpendicular to each other. Construct a circle whose center is located on the line n and to which the circle O and the line m are tangent

According to the textbook, the synthesis proof process is as follows (See Fig 1):
1. Draw a circle H with radius OG.. Then let F be the intersection point
2. Draw a perpendicular bisector of OF. Let P be an intersection of the perpendicular bisector and line n. Then 'OPF is an isosceles triangle.
3. Then, TP = PH
4. Then a circle can be drawn with the center P and the radius PH. Draw a circle P with radius PH. That is the circle to find.
Fig. 1 358
Here, thought flow 1 2 3 4 is a series of necessary conditions in that 1 is a necessary condition of 2 and 2 is a necessary condition of 3 and 3 is a necessary condition of 4. However, in this synthesis process students cannot understand why they have to draw the circle H with radius OG in order to obtain the circle P tangent to the given circle O and the given line m. What is important is how to find point F such that OG = HF. Students have to find the way to get point F by themselves. Similarly, they cannot appreciate why they have to draw a perpendicular bisector of 'OF. Students also cannot appreciate the relation between point F and Point P.. Through only the analysis method, they can understand the relation between the circle H and the tangent circle P.
The analysis process of the problem is as follows (See Fig. 2 and Fig. 3):
1. Assume that the circle P is constructed satisfying the given conditions. Let T be a tangent point to the circle O and H be a tangent point to line m.
2. Then TP=PH
3. Draw a circle P with radius OP and Let F be an intersection point of the line n and the circle. Then, 'OPF is an isosceles.4. Then OT=HF. Draw a line perpendicular to OF passing through P. Then E is a mid point of OF
Of course, this analysis process is not an easy route. Students have to find a series of necessary conditions starting from line 1 by using operational activities in dynamic geometry. In this phase, students need special help from their peers and teacher through discussions or dialogues with them. And, after finishing the analysis phase, students have to go to the synthesis phase as the reversed process of the analysis to improve their deductive proof abilities.

Fig 2 359
Fig 3
Reflection Phase in a construction problem
In the reflection phase, students look for another proof. The analysis process is as follows (See Fig 4):
1. Assume that the circle P is constructed satisfying the given conditions. Let L be a tangent point of two circles O and P.
2. Draw OP which passes through L. And, draw OQ which is perpendicular to m. And, make two isosceles triangles OQL and PHL
3. Then segments QL and LH makes one segment QH i.e. Angle QLH is 180˚
The synthesis proof is as follows (See also Fig 4):
1. Draw a perpendicular line to m passing through O and let Q be an intersection point of the given circle O and the line. Then draw QH and let L be an intersection point of the line and the circle O.
2. Draw a line OL and let P is the intersection point of the line OL and line n. Then 'LPH is an isosceles triangle. That is, LP=PH.
3. Draw a circle P with the radius PH
In the reflection phase, students can check whether the construction process by the synthesis is right or wrong. If the relation among components of the figure constructed by synthesis is preserved while dragging it, the construction process can be considered as a right procedure.
360
Fig 4 Fig 5
The functions of dynamic geometry for the analysis method
Three functions of dynamic geometry for the analysis method are as follows: First, dynamic geometry can help students draw a precise figure. To find more easily a series of necessary conditions to a final conclusion, students have to show relations among components in the problem situation. In a figure roughly drawn on the paper it is very difficult for students to find the relation. Second, dynamic geometry has a measure function. It makes students determine a good starting point for analysis by continuously measuring length or angle while dragging the point continuously. In a paper circumstance, it is very difficult for students to make a precise enough measurement to find a good starting point for analysis. Third, dynamic geometry is dynamic. It can make students perform various experiments to find necessary conditions by drawing, erasing and manipulating figures easily as well as dynamically. In a paper and pencil circumstance, it is almost impossible to perform analysis because the figure drawn on the paper cannot be manipulated. Finally, dynamic geometry is a reflective tool. If the relation among components of the picture constructed by synthesis is preserved while dragging it, the construction process can be considered as a right procedure. In a paper and pencil circumstance, there is no way to check whether the construction process is right or not.
Conclusion
In the late 1980s, Cabri and GSP were designed as dynamic tools for students to investigate the properties and relations within and between figures through operating figures on the computer screen directly. It is a very powerful environment in which much more activities than in traditional construction using normal compasses and rulers made possible: Construct, erase, drag and transform figures, measure segments and angles etc. A dynamic method for Euclidean geometry was proposed by Clairaut, a French mathematician of the 17th century (Laborde, 1999). However, then neither did he have the proper tool for the dynamic method. In dynamic geometry, students can make a conjecture to geometric properties and confirm them informally and feel the need to prove the conjectured and informally confirmed geometric facts. In dynamic geometry, students can improve their proof abilities by using the analysis method. Dynamic geometry is a very excellent tool for the analysis method which is a good mathematical strategy proposed by Greek mathematicians but that has been forgotten for a long time, perhaps due to the lack of a proper tool. In mathematics textbooks, the conclusion is a conclusion. In mathematics education, the conclusion should be a starting point rather than a conclusion. Dynamic geometry can provide a better and safe route from the starting point to the development of deductive proof by normal students.361

Cabri 3D: potential, problems and a web-based approach to instrumental genesis

Kate Mackrell, Queen's University, Ontario
katemackrell@sympatico.ca

Cabri 3D is a relatively new software which has great potential in the teaching and learning of both 2D and 3D geometry, in enhancing student ability to visualize, in modeling physical structures and motion and in developing new mathematics. In order to facilitate the instrumental genesis of this software an approach based on a web-based integration of text, hypertext, both static and dynamic "pictures" and interactive demos is being developed. This approach may well be useful with other applications.

Introduction

When I first saw a prototype of Cabri 3D demonstrated in 2001, my reaction was "so what?" Oldknow (2005) suggests that this might be a common response "It is possible to view…Cabri 3D to be just for fun and of no curricular relevance!" After a year of experimentation with Cabri 3D I am now convinced that it is an important software with the potential to radically alter our perceptions of geometry, open up new mathematics and provide engaging mathematical environments for students. This paper will discuss a number of areas in which Cabri 3D could be important together with some issues that may arise and will also discuss a particular approach to its instrumental genesis.

Three-Dimensional Geometry

Laborde (2005) sees mathematics as a science dealing with variable objects. Theorems in geometry, which state that certain geometrical properties remain invariant as a figure varies are comparable to algebraic identities, which remain true as the variable changes. Interactive geometry software is hence of particular importance in that students, in being enabled to manipulate tangible variable objects are introduced to this essential feature of mathematics.

Cabri 3D shares many basic features with 2D interactive geometry softwares such as Cabri 2+ and The Geometer's Sketchpad (Jackiw, 2001). In particular, Cabri 3D is about such tangible variable objects, objects which are constructed in geometrical relationships which are preserved when the position of initial objects is changed. Hence much of the research evidence concerning 2D interactive geometries is likely to generalize. For example, in a summary of research findings on proof, Mariotti (2006, p. 193) states that interactive geometry environments have been successful in enabling students to link informal explanations with formal proof. There is as yet little research specific to Cabri 3D: however, Laborde (2005) has shown how the idea of soft construction, an important aspect of generalization in which certain properties are deliberately constructed by eye in order to empirically explore the locus of possible figures, can apply to Cabri 3D in exploring the altitudes of a tetrahedron. 363

Cabri 3D has some important differences with 2D interactive geometry, which can act as both affordances and constraints. One difference is that many of the features of Sketchpad or Cabri 2+ are still in the process of being developed. The most significant feature lacking in dealing with three-dimensional geometry, particularly in the context of the school curriculum, is measurement, although, as will be seen in the section on pedagogical models, this does not rule out the use of Cabri 3D in this area. Other features not yet implemented are macros and loci. However, some of the limitations are also enabling. For example, the absence of number made the construction of the volume and cross-product pedagogical models an interesting mathematical challenge, rather than just a useful task.

Cabri 3D also has features not shared with 2D interactive geometries, such as the ability to create polyhedra, cut these polyhedra to form new polyhedra, and to create the nets of polyhedra.

A more fundamental difference is that, while a 2D interactive geometry represents 2D space with no loss of information, in the 2D representation of 3D space provided by Cabri 3D there is an inevitable loss of information (Parzysz, 1988) as any point on the screen represents a line in space. This is overcome to some extent by the ability to change the viewing angle, but has the consequence that creating or dragging any unconstrained object may have unexpected results: what looks like a small difference from one viewing angle may create a large change . Hence free "play" with object creation may be less satisfying than in 2D. On the other hand, geometric properties have greater importance: the student is forced to continually consider the geometric relationship between objects, as any apparent spatial relationship is unlikely to hold true.

It is also not possible to easily infer the properties of objects on the basis of spatio-visual information. Accascina and Rogora (2005) found that students using Cabri 3D found it difficult to infer the properties of objects on the basis of spatiovisual information. They were unable to decide whether all parallelogram crosssections of a cube were rectangles. On the other hand, the consequent uncertainty may act as incentive for proof (Hadas, Hershkowitz &Schwarz, 2000).

Cabri 3D is a good 2D representation of 3D, with a choice of perspectives and objects rendered to give an impression of distance, but inevitably has the limitation that the verisimilitude of the representation is dependent on the precise position of the viewer with respect to the screen, which will vary. Hence, experience with the software is needed in order to perceive objects as realistically three-dimensional.

Cabri 3D in 2D geometry

Constructions in 2D geometry may be performed on any plane, and hence can be easily viewed from different directions, which may enable students to more readily distinguish between incidental spatio-graphical properties such as the position or orientation of an object and the necessary links between its spatio-graphical properties which arise from the way the object was constructed. This distinction is critical for understanding the nature of these links (Laborde, 2005). This is illustrated by the two views of the construction of an equilateral triangle below. 364

Looking directly down on the base plane. The orientation of this figure is readily changed.

A view from an oblique angle: an accurate construction which has given rise to an "inaccurate" diagram, necessitating separation of the visual and the geometrical for its interpretation.

Cabri 3D also provides a link between 2D and 3D geometry. Familiar 2D objects need to be constructed in new ways, or change substantially in 3D, as illustrated below:

A circle is defined by a point and an axis.

The perpendicular bisector of a segment is a plane.

Rather than 3D space being an extension of 2D space, 2D objects may hence be seen as embedded in 3D space, which may consist of a "cartoon" world, with links to the world of experience. Here is an example which uses a character called Claude to mediate the mathematical meaning of reflection:

The Claude "behind" the mirror is a reflection.

Claude, reflection, and mirror seen from above.

Visualisation

Visualization is an important aspect of doing mathematics, the ability to visualize is not developmental and hence a major issue is the development of "effective pedagogy that can enhance the use and power of visualization in mathematics education" (Presmeg, 2006, p. 227). Research evidence shows that dynamic computer software facilitates visualization processes (Presmeg, 2006, p. 220). Cabri 3D may facilitate 3D visualization through allowing students to manipulate structures which are not limited by gravity or solidity and which can be given varying degrees of visibility. In a computer environment, such manipulation 365 involves an explicit awareness of the nature of actions such as rotation upon objects (Gutiérrez, 1996). Here are some questions using Cabri 3D which are designed to require student visualization:

What shape is this cross-section?

What happens to the cross-section as the plane moves towards the bottom vertex?

What characterizes this hexagon? Is it possible to get a regular hexagon as a crosssection?

Physical Modelling

One of the reasons for the early importance of Logo was its connection with body motion: the turtle represented an object turning in the physical world. However, the lack of correspondence between the geometry of Logo and the Euclidean geometry of the school curriculum has been problematic (Laborde, Kynigos, Hollebrands & Strässer, 2006).

Cabri 3D can also be used both to embody motion and to create models of real-world structures, and depends upon the Euclidean geometry of the school curriculum.

Little House by Jean-Jacques Dahan

Tower Bridge by Adrian Oldknow (file available at www.counton.org/cabri/index.htm)

Unlike real-world model building, the creation of these structures requires the use of geometrically based tools and hence an explicit awareness of the geometric relationships embodied in the structure.

This is also true when modeling motion: to create Claude on the swing with a shadow requires the use of the rotation and parallel line tools. To make Claude row requires a specific awareness of bodily motion and the means by which this may be modeled geometrically. 366

A Microworld?

The objects above show that in Cabri 3D there is certainly scope for students to design and create using mathematical tools, in which mathematical problem-solving and experimentation is required. However, with no textual interface or ability to create macros, it cannot be called a microworld in the sense defined by Hoyles and Noss (2003). Is the distinction important? It may be, if we find that the integration of symbolic and visual learning is universally important.

Pedagogical Models

These models, which cannot be entirely reproduced in the physical world, are designed to illustrate mathematical dependencies:

Effect of changing length, width or height on volume and surface area.

The cross product of two unit vectors as the angle between them varies.

A cone of variable height and radius can be transformed into a sector.

New Mathematics

As well as enabling new results in research mathematics (e.g. Oldknow (2005) generalized the Soddy line of a triangle to a tetrahedron), objects may be created which give rise to areas of new mathematical exploration which are both attractive and accessible to students. An example is the "net" of a truncated icosahedron in which the dihedral angle between connected polygons is progressively being decreased (Mackrell, 2005a): 367

The unexpected emergence of the final three objects, with high degrees of symmetry, gives rise to the question "why", which leads to further investigation and proof.

Problem:

Given the potential of Cabri 3D, how do we engage learners? In the early years of the use of technology, it was assumed that learning would emerge simply from the interactions between the student and the machine. It is now recognized, however, that the choice of task and learning environment is crucial (Laborde, Kynigos, Hollebrands, & Strässer, 2006, p. 279). An initial problem is that of instrumental genesis: how can we provide a learning environment in which Cabri 3D progresses from being an artefact to becoming an instrument (Rabardel, 2002) which can be used in problem-solving or design where appropriate and laid aside in favour of other instruments when inappropriate?

Laborde, Kynigos, Hollebrands, & Strässer (2006, p. 280) recognize that there is an intrinsic link between mathematical knowledge and knowledge about how to use a tool and that hence developing the ability to use a tool may also involve developing mathematical knowledge. This accords with my experience with teacher education students engaged in learning how to use Cabri or GSP in Ontario and the

UK. Many learners have very little geometrical awareness and hence cannot easily distinguish between a geometry problem and a problem of not knowing how to use a particular tool. For example, a student, unable to create a sequence of equally spaced points on a line commented that this was due to not knowing how to use the "equidistant" tool.
Hence, for many learners, teachers as well as students, the process of instrumental genesis must also include enhancing geometrical understanding. This is an important justification for using interactive geometry software in a classroom: with relatively straightforward interfaces, learning how to use the software is mainly about coming to grips with the underlying geometry. In the process the software will become the geometry in some sense for the student (Mariotti, 2002), and its particular features may have a profound effect on geometrical thinking. A concept image of "perpendicular bisector" based on the use of a straight edge and compass will differ from that of students creating a concept image through using the Cabri 3D "perpendicular bisector" tool.
Possibilities:
An early effort with multi-leveled text was a resource consisting of three documents for learning how to construct a kaleidoscope using GSP or Cabri. The first document 368 gave a framework for the task and asked specific questions and suggested extensions. The other two documents showed the process in detail, using screenshots, one with Cabri and the other with GSP. Learners were encouraged to use the documents as they felt comfortable: the confident could use the framework as a set of challenges to meet whereas those lacking in confidence could follow the process in detail. This has had a positive response in a number of workshops for teachers. It allows learners to work at their own pace, choose their level of challenge and create a mathematically and aesthetically pleasing object.
I correspondingly designed an introduction to Cabri 3D, consisting of activities now posed at three levels of challenge with details communicated by screenshots, followed by extension questions (Mackrell, 2005b). One issue, however, is that all hints and details are visible and it is hence hard to ignore the details. Another is that younger learners may not feel encouraged to continue exploration. Using similar materials showing how to create Claude on the swing, a mathematically able sixteen year old felt challenged, but was able to create the figure. A 12 year old with extensive experience with Cabri was able to follow the materials and create the figure, but showed no interest in further work with Claude.
I have recently been designing interactive demos using the software TurboDemo. These show brief movies of the steps involved in solving a problem, but also ask the viewer to anticipate what might happen next, to consider mathematical questions and to engage in extension activities. The viewer is in control, choosing whether to proceed at the end of a step or to view the step again. Combining this with the idea of multi-layered text, I am now in the process of writing an HTML resource to introduce fold-up polygons such as the truncated dodecahedron shown above. This includes hypertext (with links to a glossary), popups for hints, pictures, embedded Cabri 3D files and interactive demos. Part of this resource may be found at http://educ.queensu.ca/~mackrell .
In trying out this resource, it has become clear that 12 year olds can easily follow a demo and create a fold-up dodecahedron. A major question, however, is whether students are learning a sequence of moves to follow or are learning about the rotation which is the purpose of these moves, particularly as little interaction with text is required when following a demo. This will be the subject of further research.
In conclusion, Cabri 3D has great potential, but, as with any interactive geometry software, instrumental genesis is problematic due to lack of geometric understanding on the part of both teachers and students. New approaches are needed to overcome these difficulties and a web-based approach is being developed.

Dynamic statistical software: How are learners using it to conduct data-based investigations?

Katie Makar, University of Queensland, Australia
Jere Confrey, Washington University in St Louis, USA
k.makar@uq.edu.au

Bakker (2002) identified two categories of learning software in mathematics: landscape-type software and route-type software. Route-type software was designed to guide learners through a hypothetical learning trajectory with a fairly fixed destination. Alternatively, landscape-type software is designed to support learners in conducting open-ended investigations. The use of these dynamic software tools for the learning of mathematics and statistics has gained increasing prominence in schools because of its ability to support multiple purposes defined by the user rather than the software. Little is known, however, about the diversity of approaches in which learners use these software packages to conduct investigations. This paper reports on a study of eighteen prospective secondary mathematics and science teachers' approaches to conducting a statistical investigation using the dynamic data analysis software Fathom™ (Finzer, 2001). Three distinct approaches were identified by the research—Wonderers, Wanderers, and Answerers—each with measurable differences in their approach. This paper describes qualitative and quantitative differences in these approaches as well as their potential epistemological roots.

Introduction

Bakker (2002) identified two categories of learning software in mathematics: routetype software and landscape-type software. Route-type software was designed to support a predetermined learning trajectory with a fairly fixed destination. Alternatively, landscape-type software is identified by its ability to support learners in conducting open-ended investigations by providing them with dynamic tools—for purposes defined by the user rather than the software. The use of these dynamic software tools for the learning of mathematics and statistics has gained increasing prominence in schools because of its ability to support multiple learning routes with varied destinations. Little is known, however, about the diversity of approaches in which learners use these software packages to conduct investigations. This paper reports on a study of eighteen prospective secondary mathematics and science teachers epistemological approaches to conducting a statistical investigation using the dynamic data analysis software Fathom™ (Finzer, 2001).

Dynamic statistical learning software

Two significant shifts have been made in the teaching and learning of statistics, largely due to the influence of technology and improved theories of learning in 371 mathematics. The first shift, beginning around the time of the first ICMI study on technology (late 1980s), was largely due the availability of computing software such as Excel, SPSS, and SAS which freed the user from tedious calculations. This change affected primarily upper secondary and tertiary instruction in formal statistics coursework (e.g., hypothesis testing, regression) as statistics was deemed too challenging for younger students. The shift provided an opportunity for instruction to evolve from a focus on learning formulas and practicing calculations towards a greater emphasis on conceptual development. These newer approaches to teaching statistics relied more heavily on technology for calculations, putting new emphasis on activity-based learning, development of conjectures and data collection, and more complex analysis of larger data sets. Like in mathematics, this opened opportunities in statistics for learners with a variety of backgrounds and learning styles, including access to powerful statistical tools for secondary students.
The drawback of employment of software to calculate statistical measures and hypothesis testing, however, was its use as a black box. That is, students would input data into the software, apply a few keystrokes to request a particular graph, calculation, or statistical test, and the results would be "spit out" by the computer. This generated much complaint by researchers that learners were developing a blackand-white view of statistics (Abelson, 1995; Gardner & Hudson, 1999), a deterministic mindset of data as a means for providing "answers" to complex questions. An opposing epistemological stance was of statistics as a tool for inquiry and analysis which acknowledges a complex world.
Statistical software packages developed in the past few years counter this "black box" approach by taking a more visual approach to statistical analysis. Software packages such as Fathom™ (Finzer, 2005) and Tinkerplots™ (Konold & Miller, 2004) were developed as learning software for doing statistics, by encouraging learners to visualize statistical relationships and develop skills in informal inference. Software packages designed to support statistical learning through open-ended investigations with data have the potential to provide users with multiple opportunities to become data wonderers, those who explore a series of "I wonder" questions as they explore data, generate and test hunches, seek insight into the phenomenon being investigated, and communicate statistical evidence for discussion and debate. Whether these software packages actually support learners in this way, however, has not been investigated. This is the goal of this paper.

Study context and method

A study conducted at a large university in the United States examined preservice teachers' development of statistical reasoning through exploration of assessment data (Makar, 2004; Makar & Confrey, in press). The participants in the study were eighteen prospective mathematics and science teachers enrolled in an innovative course on assessment developed and taught by the authors. The course themes examined standardized and classroom testing, analysis of data using technology, and focused on developing analytic tools to highlight issues of equity in test data. 372 Structured investigations were used throughout the course to introduce the teachers to ways in which interpreting data distributions could uncover hidden issues in highstakes testing (Confrey & Makar, 2005).
The primary purpose of the study was to examine the interaction between the prospective teachers' understanding of variation and distribution and their use of data as statistical evidence in an open-ended data investigation of equity in testing. This paper will focus on the epistemological approaches that the preservice teachers made use of the software Fathom™ to conduct a semi-structured data investigation.
Individual interviews were videotaped as each teacher conducted an investigation in Fathom; their work on the computer was also captured. Videotape data, linked to their computer capture, were transcribed and analyzed qualitatively using Grounded Theory (Strauss & Corbin, 1998). One analysis focused on individual actions performed (e.g., observations, evaluations, and conclusions) and a second macrolevel analysis documented patterns of inquiry. The action-analysis was coded by two researchers independently, with 95% agreement.

Hispanic - Urban vs. Rural Dot Plot
Figure 1: Representation created by nearly all participants
A random sample of data on 273 students' scores on a state exam was provided to the prospective teachers for the investigation. The dataset contained fourteen variables

(demographic information, current and previous test scores, economic level, Englishlanguage background, etc.) on sixteen-year old students of Hispanic descent from rural and urban communities. Before seeing the dataset, the teachers were asked to state a conjecture about the relative performance of Hispanic students in urban and rural schools. After stating their conjecture, they were told to investigate their conjecture in Fathom until they felt they were ready to reach a conclusion. They were given the data set but no representations (tables or graphs). Most of the participants began by creating a graph similar to Figure 1. The upper distribution is of urban student test scores and the lower distribution is of rural student test scores.

Results

All of the preservice teachers demonstrated facility with the software in conducting their analysis and did not find the process difficult, even though the dataset was 373 relatively large. An analysis of the patterns of inquiry resulted in three categories of epistemological approach to conducting their investigation: Wonderers, Wanderers, and Answerers. Briefly, Wonderers are those who took an inquiry approach through cycles of "I wonder" questions: investigating the phenomenon by following a hunch, then seeking further explanations in the data through refined conjectures. Rather than using the data to investigate hunches, Wanderers, used the data to create hunches. They systematically examined graphs or summary statistics on each variable until they found a pattern that looked "interesting". Finally, Answerers developed an initial hunch, used the data to test their hunch, and quickly ended their investigation. Further analysis is provided below for each category.

Wonderers

Six of the eighteen participants (33%) were classified as Wonderers. This group exhibited the kind of behaviour for which dynamic software was likely designed. They developed a conjecture of what they expected to find, then were lead through an investigation by cycles of "what if" questions, before finally settling on a conclusion (Figure 2). These questions refined their theories of understanding about the phenomenon being investigated. Their investigations in the data were guided by these theories.

Figure 2: Model of Wonderer behaviour

Wonderers were distinct from the other participants in two measurable ways. First, they spent a significantly longer period of time conducting their investigation (p = 0.02), spending on average 26.2 minutes (s = 12.1) compared to an average of 10.3 minutes (s = 5.1) by the other participants. Wonderers used their time differently as well, making significantly fewer unfocused observations (statements about the data not connected to the context or conjecture) than other participants (p = 0.03), making on average 2.6 observations per 5 minutes (s = 1.2) compared to a mean of 4.4 (s = 2.2) by other participants. Although their investigations were longer, they were focused in their exploration into the situation. Their use of the software appeared to be as a tool for inquiry - to seek insight into the context of their investigation.

Wanderers

The largest category of investigative behaviours was by those identified as Wanderers, with eight of the eighteen participants (44%) being categorized as such. Wanderers used the software to go through the variables available in the data, often systematically, until a relationship "popped out" at them. They did not enter their investigation with any particular theory in mind (Figure 3) nor did they conduct their inquiry in a purposeful way. They appeared to possess a belief that the data would "speak for itself" and that any relationships to be found would emerge on their own. Once a particular interesting relationship was found, they used their understanding of Theor
y
Data Result
s374
the context (rather than the data) to try and explain the phenomenon they had found. To them, relationships pre-existed and their job was to discover these relationships.

Figure 3: Model of Wanderer behaviour

The Wanderers used their time primarily making observations (statements not connected to the context or conjecture, such as comparing sample sizes) or drawing preliminary conclusions; few of their statements were evaluative in nature (interpreting the data with respect to the context). One of the participants summed it up well when she said during her investigation "Well, I always like to look at everything". Their use of the technology was as a filter to "catch" potential insights. The Wanderers (mean = 1.7, s = 0.44) posted a significantly higher rate of conclusion statements per five minutes (p = 0.02) compared to the Wonderers (mean = 1.0, s = 0.46) and posted an average of 70% more observations per five minutes (mean = 4.4, s = 2.4) than the Wonderers (mean = 2.6, s = 1.2), although the difference was not significant (p = 0.09). In general, the Wanderers did not appear to seek insight into the phenomenon being investigated, but looked for significant results in the data devoid of context.

Answerers

The third group of behavior types recorded, the Answerers, used the software as a tool to locate a particular piece of evidence in the data to test a conjecture (theory) and then were quickly ready to draw a conclusion (Figure 4). Four of the eighteen participants (22%) were identified as Answerers. To this group, the computer was an efficiency tool that they could use to answer a question they had. This group was identified by their decision process: they looked for a particular, single piece of evidence and once they found it were satisfied that they had "answered" the question put to them. Their approach was somewhat similar to the use of computers to support statistical analysis using traditional statistical software. Rather than be a tool to explore, it was used as a way to test and decide upon the validity of a hunch.

Figure 4: Model of Answerer behaviour

Answerers were distinct from the other two approaches in two measurable ways. First, their investigations were significantly shorter (p < 0.01) than the other two groups, with a mean time of 5.7 minutes (s = 2.6 minutes) compared to the other Theor
y
Data Result
s
Theor
y
Data Result
s375
participants (mean = 18.5 minutes, s = 10.8 minutes). Second, they spent significantly greater proportion of their time (p = 0.03) drawing conclusions (mean = 2.4 conclusions per 5 minutes, sd = 0.55) compared to the other participants (mean = 1.4, sd = 0.55). Their investigations were very efficient and appeared to use the software to test their conjecture rather than seek insight into the phenomenon under investigation.

Discussion

The three approaches to conducting data-based investigations with dynamic software revealed three different epistemological approaches by learners to computer supported inquiry. Wonderers approached their investigation by developing a hunch or theory about the phenomenon in question. They then used the data to both test their hunch and refine their conjecture. Wonderers possess curiosity in a way that Dewey (1910/1997) argues is vital for reflective thinking and inquiry. "Such curiosity is the only sure guarantee of the acquisition of the primary facts upon which inference must base itself" (p. 31). It is likely that this was the model of a learner that the software developers had in mind when the software was designed, although this category emerged in only one-third of the participants. This approach reveals a learner who acknowledges that their role as an inquirer is to construct a deeper understanding of the phenomenon by creating more and more refined conjectures and demonstrates a deeper epistemological grounding.

Two different approaches, however, also emerged in the analysis. Wanderers were identified by the lack of purpose in their investigatory approach. Rather than use the data to test a hunch, they are more opportunistic in their approach, sifting through the data until something interesting caught their eye. From their findings, they try and develop a theory which they believe the data are telling them, however they explain their theory not with data but by anecdotal evidence. This epistemological approach is one in which the learner believes the data "speak for themselves" and their role as investigators is to seek out predetermined messages hidden in the data. Unlike the Wonderers who take charge of the investigation, Wanderers are led through the investigation by the data. Dewey again describes this group well, saying that their conclusions are "generated by a modicum of fact merely because the suggestions are vivid and interesting" (p. 20), and that they "find it difficult to reach any definite conclusion and wander more or less helplessly among them" (p. 36). Because the software was designed to make graph construction easy through its 'drag-and-drop' technology, it is possible that it may encourage this kind of behaviour in some learners. This can be of concern when the goal is to develop curious investigators, not those who wander aimlessly through graph after graph until an interesting results "pops out" at them, then explaining it post-hoc. If the number of relationships examined by the Wanderer is high, it is possible that the investigator will happen upon a significant result just by chance. 376

Finally, Answerers use the software as an efficiency tool by developing and testing a hunch to find an "answer" to their question. Rather than see the data as an opportunity to seek further meaning of a phenomenon, Answerers see data as having the potential to reveal answers to questions under investigation. This is consistent with Dewey's description of learners hardened by routine: "A conclusion reached after consideration of a few alternatives may be formally correct, but it will not possess the fullness and richness of meaning of one arrived at after comparison of a greater variety of alternative suggestions" (p. 36). Dewey highlights the importance of taking one's time in inquiry: "Time is required to digest impressions, and translate them into substantial ideas. Failure to afford time for leisure conduce to habits of speedy, but snapshot and superficial, judgment. The depth to which a sense of the problem, of the difficulty, sinks, determines the quality of the thinking that follows" (p. 38). The Answerers' approach is similar to one taken by many learners who use traditional software packages; they allow the user to input data, select a particular measure, graph, estimate, or model, and then present the user with the result. It requires a highly creative user with a strong conceptual understanding of both statistics and the context under investigation to use traditional software packages as something more than a black box, often bemoaned by teachers who recognize students' black-and-white approach to statistical analysis.

The epistemological approach taken by the user is of critical importance if the goal of innovative software is to support the learner in the construction of knowledge through inquiry-based approaches. The desire is not just to guide the learner through a set of facts and procedures as it may have been previously. Rather, these software packages are developed to enable mathematical thinking that goes beyond facts and procedures. The purpose is to develop skills in inquiry as well as a mindset of mathematics as a human construction developed through the refinement of proofs and refutations (Lakatos, 1976).

The findings of this study allow us to now investigate how we can support each of these categories of user. For example, how can one encourage a Wanderer to envision a goal of structured inquiry? What kinds of tasks must be developed in order to encourage Answerers to seek further insight into their initial findings? These are important questions for the mathematics community.

The use of new dynamic software packages has provided learners with powerful tools to support a more visual approach to informal statistical inference. A critical next step is to investigate ways that learners are using these tools. This includes both acknowledging the diversity of approaches to learning that they support as well as ways in which tasks can be developed which encourage productive inquiry skills.

New artefacts and the mediation of mathematical meanings

Maria Alessandra Mariotti
University of Siena, Italy
mariotti.ale@unisi.it

The paper proposes a theoretical reflection, based on a long-term research project. The aim is that of presenting a Vygotskian perspective for interpreting the functioning of new technical tools within the theoretical framework of social construction of mathematical knowledge. Our study has developed the relationship between a general hypothesis, concerning the teaching and learning process mediated by artefacts, and specific hypotheses concerning the semiotic potential of specific computational tools. The original notion of semiotic mediation has been

elaborated in order to become a theoretical construct both inspiring the design of the teaching experiments and guiding the analysis of the collected data, according to the methodology of research for innovation. The discussion proposed aims to situate the notion of semiotic mediation in relation to other theoretical constructs, in particular, to the notion of instrument and instrumental genesis, as introduced by Rabardel and now developed in the field of mathematics education.

The impact of new technology

In spite of the great expectation expressed by many educators more than twenty years ago, it is hard to say that new technologies have found a real integration in school practice. For this reason it becomes more and more urgent to identify key points around which to organise the discussion on the way to exploit the potentialities that new technologies (computers and all the new technologies related to them) offer to education: how and why new technologies are going to influence education and in particular mathematics education in the future.

This paper aims to contribute to the debate from a theoretical perspective. Drawn from a number of long term teaching experiments, developed within different research projects in the last years, the proposal of a theoretical perspective will be discussed to explain the functioning of different tools in the construction of mathematical knowledge. Such a perspective has the both modern computational tools and old artefacts, but mainly seems suitable to express this functioning in terms of educational goals.

Historic and social perspective

Human history is accompanied and punctuated by technological innovations. Generally speaking, artefacts and their use can be considered characteristic of human activity and their contribution at the cognitive level (Norman, 1993) is largely acknowledged. Besides this general statement, it seems that there is something in computer related technology which makes it a very peculiar artefact in respect to education and mathematics education in particular. Since the very beginning, even before the appearance of the personal computer, computational technology has been 379 considered as a powerful tool to be used for educational purposes. Papert (1981) certainly had the merit to firstly point on this aspect: interacting with a computer offers many different opportunities of meaningful activities, often neglected in school practice, but involving ways of thinking recognisable as typical of mathematics.

The appearance of new technologies and in particular of new tools related to mathematical activity, led mathematics educator to foresee a deep transformation in the relationship between problems and knowledge, both in respect to the type of problems to be proposed to pupils and the solution processes that new resources may affect.

That is obviously the case of all the environments which have a direct relationship with mathematical knowledge: for instance, symbolic manipulators, such as DERIVE, or more sophisticated products such as Maple or Mathematica; but it can be also the case for other applications which have no direct relation to mathematical knowledge, but never the less incorporate it, for instance professional software such as EXCEL (Sutherland & Rojano, 1993) .

Much work has been done in order to study the effects of acting in computer environments on intellectual processes involved in problem solving and concept formation. As clearly pointed out by Noss and Hoyles (1996, p. 44), availability of computational objects has drawn a deep transformation, in particular, concerning the classic distinction, historically rooted in the western culture, between abstract and concrete. Reification of mathematical objects and relations (Dörfler, 1993) has challenged longstanding assumptions about what mathematics is to be taught and claims for a radical change of perspective (Noss & Hoyles, 1996; Lagrange, et al. 2003; Trouche, 2005).

The cognitive-oriented research, carried out for many years has been principally centred on the learner, but it has also highlighted the need to enlarge the investigation in order to study the effect that activities in computer environments may have on the mathematical classroom as a whole.

In fact, although strictly related and deeply affected by practice, and in particular by practice mediated by tools, the process of construction of mathematical meanings is not directly and simply related to practice. To go back to the origin consider the use of the compass and the meaning of circle

The definition of the geometric figure is certainly related to the use of compass, which on the other hand realises graphic representation of circles. But the passage from the use of the compass to trace round shapes to the conception of the circle as "the locus of the points equidistant for the centre" is not immediate (Bartolini Bussi et al., 1996) neither is it the nature of the definition which can be formulated and used in the solution of geometrical problems, for instance construction problems (Mariotti, 2000).

In conclusion, mathematical meanings, rooted in the use of artefacts, might remain inaccessible to pupils: they may remain "in the eyes of the observer".

This phenomenon can be evaluated differently, according to what possible learning achievements are expected, however the discussion on the results of the interaction 380 with a computer seems to become more and more complex, I would relate it to a general issue that can be condensed in the following crucial question (Mariotti, 2002):

Is it possible to co-ordinate the autonomy of the student to construct his/her own knowledge, and the authority of mathematical knowledge, as a cultural domain of knowledge?

The relationship between artefacts and mathematical meanings asks a particular analysis, taking into account the fundamental role played by the emergence of signs, related to the instrumented activity, and their evolution within social interaction.

The instrumental approach

An instrumental approach, developed in the domain of mathematics education in a number of research studies and rooted on the work of Rabardel (1995), provides a very powerful frame for describing situations where the use of tools is involved, in particular, to account the differences that might appear in students' use of a tool and the relationship they may construct between the use of a tool and the mathematics knowledge .

In the analysis, carried out by Rabardel (1995), the main point consists in separating the bare object from the ways of using it in relation to accomplishing a task. In other terms, he proposes the following distinction between:

• the artefact, i.e. the particular object with its intrinsic characteristics, designed and realised for purpose of accomplishing a particular task:

• the instrument, that is the artefact and the modalities of its use, as are elaborated by an individual in accomplishing different tasks.

The introduction of an instrumental approach makes it possible to analyse and to interpret the cognitive complexity of an instrumented action and in particular, to see its potential in terms of socially shared meanings related to this action. The cognitive development (instrumental genesis), related to the acquisition and evolution of utilization schema of an artefact, carefully described by the author and subsequently elaborated in different studies (Artigue, Lagrange, Trouche, Drijvers), may contribute to explain some of the difficulties encountered by students, and at the same time fruitfully inspire the design of classroom activities.

Semiotic mediation at school: the role of the teacher

In the process of instrumental genesis the evolution of the artefact into an 'instrument', may support the emergence of sign, and consequently of meanings, related to those utilisation schemes. As clearly explained by Radford:

"In other words, to arrive at the goal, the individuals relay on the use and articulation of several artefacts and semiotic systems through which they organize their actions across space and time. [...] these artefacts and varied systems of signs that individual use in social meaning making process to make apparent their intention and carry out 381 their actions in order to attain the goal of their activities I call means of semiotic objectification." (Radford, 2001, pag. 4)

Meanings are expressed through signs, words, gestures, drawings ... and in so doing they may become socially shared and evolve. Imagine this process in the school environment, in particular in the community of the mathematics class, where social interaction means not only general interchange between human beings, but also interchange oriented by the common goal of teaching/learning mathematics.

Signs sprouting from activities with the artefact are socially elaborated: in particular, they can be intentionally used by the teacher to exploit semiotic processes, aiming at guiding the evolution of meanings consistent with mathematical meanings that are objectives of the educational activity. In this case one can say that the artefact, used by the teacher for her/his educational objectives, is functioning as a "tool of semiotic mediation".

In summary, the process of semiotic mediation develops on two different levels:

- The pupil uses the artefact, according to certain utilisation schemes, in order to accomplish the goal given by the task. In so doing the artefact may function as a semiotic mediator, i.e. meanings emerge from subject's involvement in the activity in relation to particular utilization schema and to particular emerging sings.

- The teacher uses the artefact and the signs derived from its use in specific activities, according to a specific educational motive, that is the evolution towards mathematically consistent meanings.

The mathematical meaning, related to the artefact, become accessible to the learner by its use, but the construction of meanings is supported by the guidance of the teacher, as long as specific activities are organised, the motive of which is the evolution/construction of meanings recognisable and acceptable mathematically. According to that perspective the following hypothesis can be stated.

Meanings are rooted in the phenomenological experience (actions of the user and feedback of the environment, of which the artefact is a component) but their evolution is achieved by means of social construction in the classroom, under the guidance of the teacher.

In the dialectics between these two levels the social construction of mathematical meanings occurs, as the product of a process of internalisation guided by the teacher.

The organization of the activity

The process aimed to guide the development of the dialectics between the two levels (the individual and the social) has different components, which can be separately studied although has to be considered as a whole. Consider, for instance, the notion of instrumental orchestration (orchestration instrumentale) introduced by Trouche, as the author explains:

"Orchestration instrumentale est exactement l'agencement systématique par un agent intentionnel des éléments (artefacts et humaines) d'un environnement en vue de mettre en oeuvre une situation donnée et, plus généralement, de guider les apprenants 382 dans les genèses instrumentales et dans l'évolution et l'équilibrage de leurs systèmes d'instruments".

(Trouche, 2005, p. 126)

In same paper, the author carefully examines the aspects of the orchestration centred on what he calls specific configurations didactiques, related to different types of organization of classroom work with the artefact; the author proposes some examples of configurations where the teacher guides the students through the process of evolution of the instrumental genesis.

Consistently with the general hypothesis formulated above, in the last years a long term research projects have been carried out, with the aim of testing the effectiveness of this theoretical hypothesis, in the case of particular artefacts and particular mathematical meanings. According to a methodology of "research for innovation" (Arzarello & Bartolini Bussi, 1998) teaching experiments have a dialectic relation with specific theoretical framework, on the one hand the theoretical framework shape the design of the particular teaching experiment, on the other hand results coming from the analysis of the collected data lead the researchers to develop their assumptions, and generally speaking to develop the theoretical framework.

The long term teaching experiments followed a common methodology, consistent with the hypothesis concerning the functioning of specific tools of semiotic mediation and aimed to further elaborate the theoretical perspective. The methodology is based on the following basic points.

- Selection of the artefact. Analysis of the artefact and of its use from an epistemological and cognitive point of view; the objective is that of identifying its semiotic potentialities, in rapport to a mathematical ideas, processes, ..., that can be generally referred as meanings.

- Design of the teaching intervention. Design of a sequence of activities, including different types of tasks; some of the tasks are centred on the use of the artefact, other centred on semiotic activities related to the use of the artefact, and aimed to generate germ signs (for instance writing reports on lab experiences, or writing the mathematics notebook). Among these semiotic activities a special role has been played by collective discussions (Bartolini Bussi, 1998), where germ signs have to be developed under the guidance of the teacher.

- Analysis of the experimental data, in particular the analysis of the collective activities, recognising in social interaction that interpersonal context where the evolution of signs may occur. Results showed, both within a single collective discussion and along a sequence of successive discussions, the evolution of what can be called a semiotic net, i.e. a system of related meanings progressively merging towards the mathematical meaning. A complex and delicate semiotic process is accomplished, rooted in the activities with the artefact, but put into place only thanks to the active direction of the teacher (Mariotti, 2000, 2001; Mariottiß Cerulli, 2001; Cerulli & Mariotti, 2003; Mariotti et al. 2003; Falcade et al., 2004). 383

Since the beginning, the role of the teacher has been considered crucial, and the fine grain analysis of the semiotic process, taking place during the collective discussions has shown both its effectiveness and its complexity. In particular, specific actions have been described, that the teacher intentionally, but also automatically put in place, with the aim of guiding and prompting the emergence and the evolution of meanings, consistent with the mathematical meaning which is the goal of its teaching endeavour .

The analysis of the teacher's actions highlights that, besides the general categories of actions, directed to manage the didactic contract in the class, the teacher has to put in place specific actions directed to promote the semiotic process (Bartolini Bussi & Mariotti, 1998). This has opened a new and promising field of investigation and a specific research project is now in progress aimed to develop this direction of study.

Conclusions

Taking an instrumental perspective and exploiting the process of semiotic mediation that artefacts make possible permit to consider new technologies in a broader problematique context: computer technologies, as "older" technologies, have a potential which comes from their being products of human culture, embedding knowledge and expertise (Bartolini Bussi et al., 2005; Bartolini Bussi & Mariotti, 1999), but overall being able to evoke mathematical knowledge consistent with

possible educational goals.
Moreover, the instrumental approach articulated in the semiotic perspective, presented in this paper, has the great advantage of proposing a common perspective for any kind of tools, as a consequence the discussion on new technologies may profit from the comparison with the results coming form research studies concerning 'old' technologies (Bartolini Bussi & Mariotti, 1999; Bartolini Bussi et al. 2005), and more generally any kind of artefact that presents semiotic potential consistent with our educational goals.
A conscious use of available technologies in terms of 'semiotic mediation' requires an attentive and careful planning of classroom activities, taking into account the double use of the artefact in play, both form the point of view of students' actions with the tool and from the point of view of teacher's actions with the tool as an instrument of semiotic mediation. Besides a deep knowledge about the artefact and the evolution of the instrumental genesis, which overcomes the simple familiarity with the use of the artefact itself, it is necessary to analyse the artefact and its potentialities in terms of instrument of semiotic mediation in order to organise and carry out classroom activities according to this function.
All that represents a great challenge in the field of math education research, in order to provide teachers the knowledge and the support that they need. Further studies and investigations are requested, mainly concerning the identification of patterns of actions that teachers may accomplish to exploit semiotic mediation.

Theoretical Approaches to Learning with Digital Technologies
Michael Meagher
Brooklyn College/CUNY, USA
mmeagher@brooklyn.cuny.edu
Introduction
There is a growing body of research oriented towards theoretical approaches to the use of digital technologies in mathematics education. One thinks of the work of the "French school" in Computer Algebra Systems (CAS) (Artigue, 2001; Lagrange, 1999), Kaput (2001) in visualization and dynamic relationships, and the likes of Stroup and Wilensky (2000) in networked classrooms. There remains a considerable amount of work to be done showing how certain theoretical approaches to the understanding of digital technology, and its place in the classroom, inform how students learn in a technology rich environment and how we can harness that understanding to improve student learning. In this paper I will offer a theoretical framework, based on my research (Meagher, 2004) and inspired by the work of Brian Rotman (1993, 1995), for understanding the place of digital technology in student learning. The research was based on the use of CAS in students learning calculus but I believe the framework applies well to digital technology generally.
Digital technologies and theory
Perhaps one reason that theoretical frameworks are running behind use of digital technologies is that calculators/computers are, in many ways, a stealth tool in the classroom. Use of digital technologies in the classroom demands innovation (at least inasmuch as any new agency on a classroom demands innovation) but doesn't make clear the operationalisation of that innovation. Indeed it is impossible to judge those demands in advance as they are manifestations of the difference between what Moursund (2002) has called first-order use of technology (amplification) and secondorder use. Moursund argues that, in the first instance, we use technology to do what we can do already, but to do these things faster and more accurately. The classic example of this is the car which was first thought of as a "horseless carriage." Therefore, the car was first conceived of as a technology which would move people from A to B just as a carriage does, only faster. The second-order effects of cars are now well-known to us: complete transformation of the very conception of the city, dismantling of public transport, rampant pollution, raise in the age for legal drinking, etc., but were certainly not part of the design and conception of cars. The following example shows how digital technology introduced into the classroom setting, without attention to theory-informed use of technology, can bring second-order effects to the fore which corrupt and subvert the work of the classroom.
An example of technology use 387
In typical high school algebra classes students learn to factor quadratics in order to solve quadratic equations and are subsequently introduced to the relationship between the solutions of such equations and the roots of the graphs of quadratic functions. I have seen students being taught to use the functionality of the graphing calculator to find the roots of a function from a graph and, using those roots, work backwards, to factor quadratic expressions. I offer this example not so much to criticise this approach but, rather, to point out the contradictions that can become manifest in the coherence of the standard mathematics curriculum when digital technology is introduced into the classroom. Students often think of mathematics as a school-based game which they can play well or not. When digital technology is used in this way to subvert a curriculum is it any wonder that students perceive mathematics as such a "bag of tricks"? (A perhaps more enlightened approach is to recast the approach to teaching of this subject to concentrate on functions, as opposed to equations with equations becoming particular instantiations of functions.)
I discuss this example at some length because it serves to show the nature of the change that the introduction of digital technologies in the classroom can impose on the classroom environment. Furthermore it begs the vital question that needs to be asked when digital technology is introduced: In what way is my classroom now different? This is the key question toward the path to theoretical approaches that illuminate learning in a technology rich environment. As we see in the example above the classroom is not the same: the goals have changed, the paths to those goals are new, the dynamics of interaction are new. This is an example of Moursund's (2002) second order effects.
The benefits of graphing calculators are many and obvious: an entire strand of dynamic visualisation is added to the classroom and student's ability to experiment with parameters of functions and their effects on graphs is clear. We see, however, in this example a second-order effect: suddenly the learned procedure of factoring quadratic equations is brought into question. If the goal is simply to solve the equation then, surely, using the digital technology is more effective. A second order effect has occurred whereby the goal of factoring shifts perhaps to an understanding of the relationship between the algebraic form and the coordinate geometry being the driver of the concept rather than a noticed consequence once the student has gone through the conceptual path from algebra to coordinate geometry. Another possible shift is that what matters in terms of factoring quadratics is an awareness of algebraic structure: some quadratic forms can be written as products of linear forms. In this case the second order effect of the technology is to force the broader, structural mathematical issues to the forefront of the understanding of the concept. In either case, and there are many other cases, the introduction of the digital technology does more than simply "soup up" the existing status and dynamic of the class. 388
Approaching theoretical approaches
As suggested above, as a first step to exploring theoretical approaches to the use of digital technology it behooves us to draw on experiences of using technology in teaching and ask what is different about the classroom when digital technology is introduced.
Another example: When I first taught with CAS it was in an Algebra I class where the students had hand-held devices (TI-92s) with inbuilt CAS capability. The beginning of one of the worksheets was as follows:
Type 3a + 2a. Press enter and record the result
Type 4b + 5b. Press enter and record the result
Type 3x + 2y. Press enter and record the result
What do you think will be the result of 3m + 2m? Record your guess and check.
What do you think will be the result of 3r + 2q? Record your guess and check.
Do you observe a pattern or rule? State the pattern or rule.
The students worked through this sheet with great success and their attempts to articulate the rule provided a good opportunity for discussion of definitions, vocabulary, and concision in mathematical definitions and descriptions. What struck me as curious about all of this is when I thought to myself: would this be different if I, as the teacher, went to the blackboard and wrote "3a + 2a = 5a; 4b + 5b = 9b" etc. and asked the students to do the examples and tell me the pattern/rule. Having taken both approaches I can attest that each approach plays out very differently in the classroom. Students regard the mathematical authority of a calculator/computer differently to how they regard the authority of a teacher. There is a clear sense in which students felt they were discovering something when getting feedback from technology rather than responding to my probing. This difference begs many questions about how students relate to a calculator/computer (as opposed to a person) and, in particular, how students relate to the authority of a calculator/computer. The way that I found to characterise, and theorise about, the interaction that was going on was to regard it as a "trialogue" between the students, the technology and the mathematics.
In looking for theoretical approaches to help illuminate students' learning of mathematics in technology-integrated environments this tripartite relationship led me to the Rotman Model of Mathematical Reasoning (1993, 1995).
The Rotman Model of Mathematical Reasoning 389
Drawing on the work of C. S. Pierce, Rotman's (1993, 1995) semiotic reading of mathematics discourse constitutes mathematical reasoning as the unison of three agencies: the Subject, the Person, and the Agent (Fig. 1.1).
Figure 1.1: The Rotman Model of Mathematical Reasoning
Rotman's (1993, 1995) theoretical model is concerned with ontological questions about mathematical objects and processes. Its principal value for my purposes is its tripartite nature with the student, the mathematics, and the technology at the vertices of the triangle. Nevertheless, it is worth looking in some detail at what Rotman has to say because of his understanding of agency in mathematics and where that agency resides. In his model the Subject is "the agency [which] reads/writes mathematical texts and has access to all and only those linguistic means allowed by the Code" (p.396), the Code being, essentially, mathematics as sanctioned by the mathematical

community. The Person is the agency who works within the Metacode "the entire matrix of unrigorous mathematical procedures" (p.396), such as stories, ideograms and pictures. Finally the Agent is the agency who "acts on mathematical objects in a purely formal way" (p.397), i.e. with a Virtual Code. Mathematical reasoning in this formulation is considered to arise from the interplay between a learner, mathematics as a subject, and a disembodied agent who carries out mathematical procedures accurately and without prejudice. For my purposes the disembodied agent is the digital technology. For Rotman, mathematical reasoning is "an irreducibly tripartite activity in which the Person ... observes the Subject ... imagining a proxy - the Agent ... - of him/herself" (p.397), and is persuaded by the closeness of the Subject and the Agent of the validity of the mathematical activity. My argument is that digital technology can be interpreted as the Agent of mathematics with which students interact to gain access to calculus. This adaptation of the Rotman model is seen in
CODE
Subject
VIRTUAL CODE
Agent
METACODE
Person 390
Figure 1.2:
Figure 1.2: The Adapted Rotman Model of Mathematical Reasoning
Thus one avenue for the development of mathematical reasoning could be engaged in creating or facilitating intellectual space where the learner can experiment and play within the realm of the Metacode i.e. the "stories, motives, pictures, diagrams, and other so-called heuristics" (p.396), through which the learner gains access to the Code but with reference to the Virtual Code i.e. the acting on of mathematical objects in a formal way. My research (Meagher, 2004) shows, in the realm of CAS, that technology can furnish just such intellectual space in mathematics education. My research found that CAS allows students to take experimental steps in working with mathematical objects. Which is to say that CAS provides a Virtual Code (Mathematica) allowing students to act experimentally and observe the consequences of those actions within the Virtual Code (Mathematica) to examine, or negotiate, a relationship with the Code (Calculus) itself. More importantly my research shows that the Model, as I am using it, provides a way of understanding the place of technology in the mathematical activity of the learner. (Digital technology can be thought of, perhaps, as providing various microworlds in the Papertian sense, CAS as an algebra microworld, Cabri as a geometry microworld etc.) The important part of the model is its triangular nature which affords separate agency to three entities: the learner, the technology, and the mathematics. What I mean by agency here is that none of these entities is neutral but that each has a relationship with the other two, effecting and being effected by the other two in a manner such that each contributes continually to the students mathematical reasoning. Each of these entities acts on the other two and thus has agency.
Application of the Model
My research (Meagher, 2004) explored each of the three sides of the triangular model above with significant conclusions found on each side. The temptation to describe the digital technology to mathematics relationship simply as "the machine has been
MATHEMATICS
Code
TECHNOLOGY
Virtual Code
STUDENT
Metacode 391
programmed to perform accepted algorithms" is belied by closer examination. For example, if one looks at the different inputs necessary to "ask" different CASs the same question, and one looks at the different outputs from different CAS systems in response to those questions, it becomes quickly apparent that, while the mathematics and algorithms might be agreed upon by the different programmers, the interfaces of the programs and the presentation of results are radically different.
Mathematica, a program originally written when memory was at more of a premium than it is nowadays, is a program which depends on the user learning a very particular syntax. This syntax is not reflective of mathematics as it is written in textbooks or mathematical journals and cleaves more closely to high level programming languages. Another memory saving device of Mathematica's is the rendering of graphs. Graphs are regularly displayed in a non-standard format (for example the axes do not intersect at (0, 0) in a way that is efficient but may not be easy for the user to interpret. DERIVE, by way of contrast, is a program which was designed, particular in later versions, which considerable attention paid to the fact that the user may be trying to learn mathematics using DERIVE. The program is essentially menu driven, looking more like graphing calculator interfaces and word processing programs than Mathematica. In addition, graphs in DERIVE always include the origin and error messages tend not be as intimidating as those in Mathematica.
In the realm of graphing calculators we see privileging of certain forms such as the "y =" form of equations of lines in order to facilitate graphing. On an even more basic level students need to learn particular syntax orders to perform, for example, exponentiation. This order is different from what they see in text books or typically write in the class.
Understanding digital technology as a separate agency is crucial to exploring students response to and use of technology. My research showed, in particular, that the transition to a new form of digital technology (graphing calculator to CAS) is a delicate moment and the students' relationship to the new technology was heavily dependent on both their history with the old technology and how the transition to the new technology was facilitated. This is further evidence that the introduction of digital technology is not merely a passive add on to the current situation but dynamically impacts students behaviour and achievement in a technology rich environment.
Students' relationship to mathematics itself is also highly influenced by their use of technology in learning. My research showed that students whose idea of success in mathematics is oriented towards successful implementation of algorithms and a 392 strong sense of "getting the right answer" can feel somewhat cheated by digital technology. This is particularly true in the use of CAS where the machine is doing the work which students often take as their domain of success and an emphasis is placed on explanations and reasoning which some students consider to be less authentic mathematical activity.
Conclusion
The theoretical approach outlined above is important in providing a step away from reductive thinking of technology as a simply a mediator between the student and mathematics. The Adapted Rotman model provides a more sophisticated and authentic picture of the learning relationship between students, digital technologies and mathematics. It can also be thought of as residing in a larger network structure which would include, in a more explicit sense, the role of the teacher and teaching in technology-rich environments.
The model is, in many respects, consonant with constructivist theories of learning but emphasises the extent to which the students' knowledge is constructed by the technology: digital technologies become, very explicitly, part of the sociocultural framework of the classroom. However, as explained above, digital technologies have a different agency from other students or a teacher in the classroom environment. The model should also be an important consideration in curriculum design since it places great emphasis on students understanding of the role of technology in their learning and places a non-traditional emphasis on what is considered authentic mathematical activity.

Comments for ICMI STUDY 17: "Digital technologies and mathematics teaching and learning: Rethinking the terrain"
Hartwig Meissner,
Univ. of Muenster, Germany
meissne@math.uni-muenster.de
The paper will reflect the process of learning and understanding mathematics when working with calculators or computers. How do we succeed in developing powerful mental representations, which in German we call "Vorstellungen"? We distinguish two types of Vorstellungen, but the traditional kind of teaching mathematics gives strong emphasis only to one of them, to a reflective, logical and analytical thinking. Most teachers or students or even researchers in mathematics often are unaware of their spontaneous and intuitive Vorstellungen.
But only the interaction of both types, the interference of "reflective" Vorstellungen with "intuitive" Vorstellungen, develops powerful mental concepts, procepts, frames, micro worlds, ... The use of calculators or computers seems to further this development. Working with a computer we often see a typical guess and test behavior or trials to discover properties or repeating similar key stroke sequences just to make sure ...
We regard this mainly unconscious behavior as a vehicle to further the development of "intuitive" Vorstellungen and we designed a special teaching method which we called "One-Way-Principle" (abbr. OWP). The OWP is an intermediate step to discover in a set of examples intuitively common properties to move on then to generalize these observations algebraically. Examples will be given.
Cognitive Aspects
Studying the Discussion Document for the ICMI STUDY 17, I appreciate very much the broad, deep and balanced discussion of the topic field. In this paper I will concentrate on cognitive aspects related to the use of digital technologies. The comments basically will discuss aspects of theme 2 "Learning and assessing mathematics with and through digital technologies". But also aspects related to the themes "Mathematical practices in the class room" ,"Teachers and teaching" and "Design of learning environments" will be touched.
In our research group in Muenster we think the final version of the ICMI STUDY 17 document should reflect in some detail also psychological aspects related to the use of teaching and learning mathematics when using digital technologies. What do we know about advanced mathematical thinking (TALL, VINNER)? Does the use of technology further the development of procepts (GRAY, TALL e.a.) or enhance processes of encapsulation (DUBINSKI)? Being confronted with challenging software, which is the role of reification (SFARD)? 395
The document also should include investigations on the interaction processes between the external representations of a problem, which we call Darstellungen
46
and the related internal mental images or cognitive structures of the problem solvers, which we call Vorstellungen
47
(MEISSNER 2002). The following picture gives a
survey. For a possible scenario of interactions between Darstellungen and
Vorstellungen see page 3 (example decimal grid).
Two types of Vorstellungen
"Vorstellungen" are like "Subjective Domains of Experiences" (in German "Subjektive Erfahrungsbereiche", BAUERSFELD 1983), they are personal and individual. The goal of mathematics education is to develop mathematical

46
We call external representations of mathematical ideas Darstellungen. Darstellungen we can read, or see, or hear, or feel, or manipulate, ... These external representations or Darstellungen can be objects, manipulatives, activities, videos, pictures on the screen, graphs, figures, symbols, tags, words, written or spoken language, gestures, ... In such a Darstellung the mathematical idea or example or concept or structure is hidden or encoded. There is no one-to-one-correspondence between a mathematical idea, concept, etc. and a Darstellung.
47
Human beings are able to "associate" with these objects, activities, pictures, graphs, or symbols a meaning. That means each Darstellung evokes a personal internal image, a Vorstellung (cf. concept image, TALL & VINNER). Thus Vorstellung is a personal internal representation, which can be modified. Or the learner develops a new Vorstellung. A Vorstellung in this sense is similar to a cognitive net, a frame, a script or a micro world. That means the same Darstellung may be associated with many individual different internal representations, images. Each learner has his/her own Vorstellung. And again here, there is no one-to-one-correspondence between a Darstellung and a Vorstellung.
mathematical
concepts

"Vorstellungen" which are extensive and effective, which are rich and flexible. We
distinguish two kinds of "Vorstellungen", which we will call intuitive Vorstellungen
and reflective Vorstellungen. Thus we refer to a polarity in thinking which already
was discussed before by many other authors
48
.
"Reflective Vorstellungen" may be regarded as an internal mental copy of a net
of knowledge, abilities, and skills, a net of facts, relations, properties, etc. where we
have a conscious access to. Reflective Vorstellungen mainly are the result of a
teaching. The development of "reflective Vorstellungen" certainly is in the center of
mathematics education. Here a formal, logical, deterministic, and analytical thinking
is the goal. To reflect and to make conscious are the important activities. We more or
less do not realize or even ignore or suppress intuitive or spontaneous ideas. A
traditional mathematics education does not emphasize unconsciously produced
feelings or reactions. In mathematics education there is not much space for informal
pre-reflections, for an only "general" or "global" or "overall" view, or for
uncontrolled spontaneous activities. Guess and test or trial and error are not
considered to be a valuable mathematical behavior. But all these components are
necessary to develop spontaneous Vorstellungen. And these spontaneous
Vorstellungen mainly develop unconsciously or intuitively.
Both types of Vorstellungen together form individual "Subjective Domains of
Experiences" (SDE). For a well developed and powerful SDE both is essential, a
sound and mainly intuitive "common-sense" and a conscious knowledge of rules and
facts. Both aspects belong together like the two sides of a coin. And whenever
necessary the individual must be able, often unconsciously, to jump from the one side
to the other. Along the following example the reader may realize this situation.
Example Decimal Grid
Select a path from A to B (see grid on the next page). Change the direction at
each crossing. Multiply (with a calculator) the numbers of each step you go. Mark
each path in one of the small grids. Find the path with the smallest product. You have
4 trials. (Worksheet for each child (age > 10), first individual work, then discussion
of the results)
At a first glance, the problem is easy, children start immediately ("reflectively"):
(1) Find the shortest path (minimum of steps) or
(2) Select at each corner the smallest factor
But then ("intuitively")
(3) Perhaps there are better rules than (1) and (2)

48
BRUNER discusses analytic vs. intuitive thinking. VYGOTZKI talks about spontaneous and
scientific concepts. GINSBURG compares informal work and written work. STRAUSS discusses a
common sense knowledge vs. a cultural knowledge. He especially has pointed out that these two
types of knowledge are quite different by nature, that they develop quite differently, and that
sometimes they interfere and conflict ("U-shaped" behavior). 397
(4) Let us try just another path to find out
And after some trials suddenly cognitive jumps (SDEs get changed):
• Multiplication not always makes bigger
• More factors may give a smaller product
• Running in a circle forth and forth (i.e. ... 0.3 x 0.8 x 0.6 x ...)
• infinite path (ß intuitive concept of limit)
And finally at the end: The smallest number will be ZERO! And even one step
more: ZERO on the number line? Or ZERO on the calculator display?
Summarizing, we distinguish two types of internalizing our experiences from
interacting with "Darstellungen". On the one hand we develop conscious reflective
Vorstellungen and on the other hand we create (mainly intuitively) "spontaneous"
Vorstellungen. Both types together create or modify an individual "Subjective
Domain of Experiences" in which this situation is imbedded then.

Reflecting the Role of Digital Technologies
As already mentioned, the emphasis of the traditional mathematics teaching
obviously lies on the development of powerful and conscious "reflective"
Vorstellungen. Overemphasizing the algorithmic and procedural approach we must
face the danger that our children get trained in skills but not in getting enough
insight. This is true for the four basic operations as well as for using sophisticated
CAS programs or others. "The importance of the ability to serve as a poor imitation
of a $4.95 calculator is rapidly declining" (KAPUT). 398
Despite the existence of digital technologies we still observe a lack of chances for the
learner to create their own ideas, to develop or to verify or falsify their own
assumptions, to invent theories and to apply them, or to explore facts or properties or
relations in given situations. The chance to develop intuitive Vorstellungen is limited.
The One-Way-Principle
In this situation we designed a special teaching method that we called "OneWay-Principle". To explain the method we will start with a few examples. In the first
and second we train number sense, in the third percentage feeling and, in the last two
examples, function sense.
Hit the Target
Hit the Target is a calculator game which furthers an
intuitive understanding of multiplicative structures: An
interval [A,B] is given and a number n. Find a second
number x so that the product of n and x is within the
=n
x [A,B]
interval. Our more than 1000 guess-and-test protocols show that the students after a
certain training develop excellent estimation skills (guessing the starting number) and
a very good proportional feeling (very often less than three guesses to find a correct
solution).
Big Zero and Big One
In the calculator game "Big Zero" we hide a subtraction operator and ask "Which is
the input for getting 0 in the display? In the game "Big One" we hide a division
operator and ask "Which is the input for getting 1 in the display? Discovering these
hidden operators by guess-and-test develops an intuitive understanding of additive
respectively multiplicative structures. Playing these games we observe after some
training excellent approximation skills.
Teaching Percentages
There are calculators that work syntactically like we speak in our daily life.
635 + 13 % = ... needs the following key stroke sequence:
6 3 5 + 1 3 % =
We taught percentages with the percent key, without using formulae or reverse
functions or algebraic transformations of formulae. If necessary the missing values
had to be guessed and verified by pressing always the same key stroke sequence from
above. The students became excellent in guessing each
value and they developed an astonishing "%-feeling".
We administered the same test
with 6 problems in our experimental group (white
bars, N $ 250) and in a control group with the
traditional "reflective" approach (N $ 500, dark bars).
The results are shown in the graph below. 399
Functions
Use your plotter software to find via guess and test an algebraic term to plot the
following graph. (Graphs given on a work sheet)
Trigonometric Functions
Use the calculator to find via guess and test at least three different values for x in sin
x = 0.2, tan x = -0.2, cos x = 0.5, sin x = 1.5, tan x = 2.5, cos x = 1, tan x = 4.
The idea of the One-Way-Principle
(OWP) is to solve with calculators or
computers a package of related problems
always with the same key stroke
sequence, independent of which variables
are given and which are wanted. That
means there is only one way to solve all
problems. Either we work syntactically
just pressing the buttons along the once
given sequence or, instead of applying
algebraic transformations or using
different formulae, we work semantically
by guessing and testing, still using the
same sequence of buttons.
Via the semantic guess and test the
user usually develops unconsciously a
feeling for the global "entity of input,
function and output", see table on the
right. The shadowed "?" may be an
operator (examples 4.1 or 4.2) or a
function (examples 4.3 or 4.5) or a
software (example 4.4).
input display

And of course we must work with intervals because the quality of a good estimation
depends on the size of related intervals.
Working along the OWP method is similar to the working with simulation
software (to learn car driving or flying an airplane, etc.). In mathematics education
the OWP is an intermediate step between simple examples and algebraic
generalizations. The OWP is a method to develop intuitive and spontaneous Vorstellungen about the relations between and about the order of magnitude of the many
variables of a mathematical concept before we start with introducing "reflective"
400
Vorstellungen with formulae or functions and reverse functions and algebraic
transformations.
Research Results
Our research group, TIM ("Taschenrechner Im Mathematikunterricht"), have
worked with calculators for more than 25 years (and with "computers" more than 18
years). Our goal is to develop ideas on how to integrate the new technologies into the
existing mathematics education on the base of empirical findings. A main
investigation was done by LANGE (1984). She trained mental arithmetic and number
sense in a primary school project (age – 9) where the calculators were on the table of
the students all the time. In the post-test she found that the subjects did significantly
better in mental arithmetic than the students of a control group.
Almost 20 years later we repeated an international inquiry about the use of
calculators in primary schools. The feed back from about 25 countries was
disappointing. In almost all of the countries the use of calculators in primary schools
just was not allowed. Thus we started a new project by the help of our teacher preservice students and many teachers (8 schools, 186 students, age – 9). Title and goal
of the project: "Use the calculator to become independent from it". The results were
similar those in LANGE's project, details see MEISSNER (2006).
A systematic application of the OWP also was administered in our percentage
projects (see 4.3) and in the dissertation from MUELLER-PHILIPP (1994). She
concentrated on linear and quadratic functions. Her students succeeded impressively
in building up intuitive Vorstellungen between the gestalt of a graph and the related
algebraic term.
In case studies we also used the OWP to teach the topics "Interest", "Compound
Interest", "Growth and Decay", and others. Our observations showed that the
students were working very concentrated with quite different strategies. Very often
they got an unconscious feeling about the new concept before they could explain
their discoveries or their good guesses. Thus we urged them to write down protocols
from their guess and test work because these protocols are excellent Darstellungen
from their Vorstellungen. By reflecting the protocols also unconscious Vorstellungen
may become conscious.
When guessing and testing became boring the students themselves started
asking for more efficient solution procedures. Then we could introduce reverse
functions and algebraic transformations. And when they got lost in the algebraic
approach, they could go back to their guess-and-test procedures and to their intuitive
Vorstellungen.
Important, in all our investigations the students got a conscious or unconscious
feeling for the mathematical relations and properties which also were available when
they just had to guess or to estimate, especially also in situations where a calculator
or computer was not available. In this sense the use of machines had furthered a
certain independence from these machines. 401

The interactive whiteboard (IAW) is a presentation technology currently being used extensively in mathematics lessons in England. A growing research base shows that although use of the IAW initially improves pupil motivation it need not necessarily improve teaching and learning. It is suggested that to maximise impact teachers need to move through 3 stages to that called 'enhanced interactive' where thinking and pedagogy change. At this stage lessons have become more interactive and involve more discussion and pupil activity. However professional development is required to move teachers most rapidly to this stage. Based on observations of over 100 mathematics lessons, discussions with teachers and pupil surveys we believe that there is value to be gained by considering the role of gesture as mathematics teachers use IAWs. We also note that where the IAW has been fully exploited there appears to be a dynamic between activities at the IAW, on the pupil's desk and, we contend, 'in the pupil's head'. Finally we suggest that in order for a revolution in teaching and learning using an IAW there needs to be an investment in professional development to enhance reflective practice and to support pedagogic change.

Background

An interactive whiteboard system consists of data projector linked to a computer which in turn is linked to a large 'touch sensitive' e-screen - the actual interactive whiteboard (IAW) itself. The size of the IAW can be up to 2 metres across by 1 metre high. Usually the IAW is fixed to a wall, the data projector to the ceiling (though both can be 'mobile') and the computer is away from the IAW. Images from the computer are displayed onto the e-screen and can be 'touched', usually by a finger or a special pen, in order to control the computer from the IAW in the same way that a mouse can be used with a standard computer. Figure 1 shows one schematic arrangement.

Figure 1: An interactive whiteboard system with its components

The IAW usually comes with its own software that allows it to be used in one of three ways: with standard or subject specialist software; overwriting other application software (as you would on a transparent sheet placed over a normal computer screen); and with the software that accompanies the IAW. The key point is 403 that you stand at the IAW and use a finger or pen. The cost of the equipment usually depends on the make of the interactive whiteboard and the software provided with it.

During the past decade the interactive whiteboard (IAW) has passed from being a novelty to being part of the equipment of many mathematics teaching rooms within the UK (especially England), and to a lesser extent within parts of Western Europe, North America, S.E .Asia and Australasia. Widespread national introduction, like in England, has followed largely as part of government policy aimed at learning for the globalised digital age by the provision of additional finance. In England special funding for IAWs has followed but purchase of IAWs is also a reflection of self-government within schools and their intention to support individualised pupil motivation and learning through more appropriate pedagogy. Other countries where IAW use is increasing include Brazil, China, Mexico, Singapore and South Africa with some involving government initiatives (e.g. Mexico and Singapore).

Early evidence into the use of IAWs in mathematics classrooms suggests that practitioners pass through stages of developing both technology and pedagogy (Glover et al, 2003), but that the availability of equipment alone is no guarantee of enhanced teaching and learning (Miller et al, 2004). Recent government reports in 2005 by the Office for Standards in Education and the Qualifications and Curriculum Authority in the UK point to the need for teachers to become more aware of the inherent value of interactivity at the heart of a changed pedagogy.

Our contention is that as the technology becomes more widely available it is essential that teachers should be offered professional development that fosters a rapid move to technological competence and pedagogic flexibility. To this end we draw on evidence from on-going research at Keele University, UK, involving analysis of over 100 video-recorded lessons filmed with mathematics teachers, mostly with pupils aged 11-14, in 25 schools from varying socio-economic contexts. All videos have been analysed using agreed criteria for assessment of lesson structure, content, approach, teaching and learning strategies, and conceptual and cognitive development. Teacher and pupil use of the IAW has also been analysed according to techniques, tactical deployment and pedagogic interactivity. Associated survey work, discussion with teachers and pupils, and peer group problem solving has led us to offer a schematic outline for professional development that could encourage competent and flexible use of technology so that pupil engagement and attainment can be enhanced.

There are stages of development that can be considered in the drive to introduce and use IAWs, so some teachers have just a data projector and computer in their classroom, others include the IAW, while others extend this by adding a tablet PC. In some classrooms the tablet PC is used with just a data projector, this option is usually cheaper than purchasing an IAW and computer. To a large extent the more expensive the system the more that it appears to offer for teaching and learning, however without adequate support and training teachers have been observed to use 404 the more expensive systems in the same that they could use a computer and data projector (Glover et al., 2004).

The introduction of any of these systems into a mathematics classroom brings with it the opportunity for teachers to use mathematical and generic software as part of their teaching, but surprisingly this is initially overlooked by many teachers. Our evidence suggests that for maximum impact teachers need to have available a geometry program (such as Geometer's SketchPad, Cabri-géomètre), a graphing and statistical package (such as Autograph), a spreadsheet and interactive software designed to be used with an IAW (such as EXP Maths). In addition access to the internet provides further opportunities to use appropriate resources. The importance of using specially designed IAW programs, also under-estimated, allows teachers to see how the potential of the IAW might be used to benefit teaching and learning – often, though not always, bringing with them new ways with which to work with pupils and encouraging interactive teaching. The aim of such is to develop pupils' knowledge and understanding of mathematics as well as their competence and 'technical' skills. However some such programs consist of PowerPoint presentations, or equivalent, that provide colourful material but lack an interactive pedagogy.

Research into the use of IAWs generally and in mathematics has been so far emanating from those countries where there are many systems in place primarily the UK, to a lesser extent the USA (mostly small scale at a teacher level), though work is now being undertaken in, amongst others, Mexico, Singapore and South Africa.

Developmental framework

Our earlier work (Glover et al., 2004) led to the proposition that teachers pass through a 3 stage process in developing personal confidence in the use of IAWs.These are:

supported didactic: the teacher makes some use of the IAW but only as a visual support to the lesson and not as an integral tool to conceptual development; there is little interactivity, pupil involvement or discussion

interactive: the teacher makes some use of the potential of the IAW to stimulate pupils' responses from time to time in the lesson and to demonstrate some concepts; elements of lessons challenge pupils to think by using a variety of verbal, visual and aesthetic stimuli

enhanced interactive: this approach is a progression from the previous stage marked by a change of thinking on the part of the teacher who seeks to use the technology as an integral part of most teaching in most lessons and who looks to integrate concept and cognitive development in a way that exploits the interactive capacity of the technology; teachers are aware of the techniques that are available, are fluent in their use and structure the lesson so that there is considerable opportunity for pupils to respond to IAW stimuli either as individuals, pairs or groups, with enhanced active learning; the IAW is used as 405 a means of prompting discussion, explaining processes, developing hypotheses or structures and then testing these by varied application; a wide variety of material is used - 'home-grown', Internet, IAW specific, specialist and commercial software designed for use on the IAW.

Evidence from our research projects has shown that 'missioner' teachers (Glover and Miller, 2002) recognise the value of rapidly moving to the enhanced interactive stage. Continuing work with teachers in 7 schools has shown that teachers initially cling to didactic approaches as they gain fluency in the use of the IAW and that the rate of progress towards enhanced interactivity depends on the extent to which they have received support, shared software and experience, and the opportunity for mentoring or coaching to overcome specific problems that are usually related to general information technology skills and understanding how to use the IAW in a way different from non-IAW teaching (i.e. the new pedagogy of the IAW).

Enhancing motivation - understanding techniques

Pupil comment throughout the work has shown that the IAW brings benefits.

Our findings lead us to think that enhanced motivation is secured initially through the use of a range of techniques that attract pupils to what is presented, and then 'once caught' prompt learning through the use of visual and kinaesthetic impact. At its simplest it may be that computer generated numbers and text are easier to read but the use of colouring, highlighting and shading for emphasis add interest to conventional material. It was noticed that the opportunity for over writing material on the IAW was seen as an advantage for early users but this can cause them to cling to didactic approaches and that early encouragement to use more dynamic techniques, known as manipulations, leads to teaching which is more readily appreciated by pupils. These include dragging and dropping elements around the IAW (for example in showing balance in equations); hiding items and revealing them later (answers to calculations); colour and highlighting for emphasis (to show similar items); matching items to show some relationship (equivalent fractions); movement or animation (to show the stages in a proof); and immediate response to one of these (by a computer response or a comment from the teacher or another pupil). However, there is strong evidence that teachers seek to have even more options available. These are collectively summarised as virtual manipulatives and usually are software miniprogrammes that allow immediacy of response when teacher or pupil working at the IAW use them to illustrate some aspect of mathematics.

For example using a word processor a teacher can create with pupils a fraction wall and while doing this discuss the concept of fractions. A fraction wall virtual manipulative, such as one shown in Figure 2, can then be used on the IAW where a moveable rectangle can be used to discuss with pupils equivalent fractions and ideas of addition and subtraction of fractions. Pupils can then work in pairs with their own fraction wall (a manipulative) and use tracing paper to create and move rectangles in the same way that they have seen the teacher do this on the IAW. 406

Figure 2: A fraction wall – a virtual manipulative on the IAW

Applying techniques

As teachers develop facility in using the techniques marking the move from didactic to interactive approaches they seek to use them in a range of mathematical processes. Observation of teachers during their personal learning period suggests that these fall into three groups. The first show the use of verbal-visual approaches including annotating of data on the IAW, connecting elements of a process or argument with coloured lines, framing similar stages or responses in processes, grouping with the use of identification symbols, and emphasising either with highlighting or underlining. The next stage involves the use of the emergent data by discriminating as in the sorting of a range of integers or formulae; sequencing as in using successive IAW 'screens' to build up an understanding of the relationship between sides and the angles of a polygon; matching where differing representations of data can be analysed, and, as pupils gain competence and confidence in the use of the IAW as a medium for them to explain their own mathematical thinking. At this point the observed teachers appear to undergo a change in their pedagogic approaches. One expressed this as 'realising that we have a tool of potentially shattering importance, that it depends upon developing interactivity as a way forward, and recognising that our own lesson planning needs to be more precise and totally different in structure'.

Further discussion with a group of similarly 'convinced' teachers shows that at the final stage they then seek to maximise the potential of the technology through the use of the IAW as a means of group and individual assessment either with pupils showing their responses on individual mini-boards or, as in one or two schools, through the use of electronic tablets. Assessment is but a means to an end and good practice included: rapid feedback through the use of recalled screens which had supported the teaching stages; the development of differentiated materials which were readily recalled to support individual learning; and recapitulation with differing explanations or materials so that primarily visual, numeric or kinaesthetic learners can be offered suitable materials. It was noticed that fluent users of IAW technology and interactive pedagogy become adept at building up a catalogue of curriculum 407 related screens that can be used in successive lessons, revisited in successive years, and shared with other departmental colleagues when satisfactorily developed.

Changing approaches

Enhanced understanding of the ways in which the use of the IAW can be a positive support for teachers and hence learners, thus leads to changes in the way in which they think. Three elements indicate this. Initially teachers recognise the need for improvement in their own personal understanding of the processes involved in explaining, illustrating and developing mathematical understanding … often

achieved through 'having the time to reflect not just on what is to be taught but how this can be broken up into sufficiently small learning chunks often with their own assessment criteria so that we have concept maps and know what we need to get them across'. Consideration of all the evidence from 9 of the most successful practitioners suggests that this then becomes reflexive so that pedagogic reassessment becomes an ingrained behaviour both during the lesson and in planning future learning strategies.

From this emerges a second element – that of changing lesson structure. There are many schools in England already following lesson structure based upon the use of a brief and stimulating starter, an extended main section of the lesson, and a whole class plenary. Inspection reports in the UK indicate that such structures are more successful because they use different thinking skills, promote pace in the lesson, and overcome potentially boring 'chalk and talk' lessons. Effective IAW users favour such approaches because they 'draw on the full range of what the IAW has to offer – the fun of a dynamic and mind challenging starter, the material to support staged learning, and the opportunity to reflect upon what has been learnt and how it fits into the bigger scheme of things'. Our evidence is that early users who have not already developed the use of such a structure tend to revert to explanation, illustration and worked examples without using potentially stimulating software or the opportunity for pupils to develop their own reflective skills. They can rely on presentation software and reproduced series of screens that offer little interaction.

Thirdly, where concepts have been analysed, understood and developed and where practice and reflection become part of the normal lesson routine pupils develop greater confidence in offering explanations, using mathematical language and reasoning. Survey evidence shows that 13% of pupils feel that one of the positive gains from IAW use is that there is now more group work both at the IAW and in preparing materials and arguments for presentation to other pupils. This suggests that the IAW may be prompting a shift in the focus of the mathematics classroom away from the teacher who becomes learning facilitator towards the pupils who are becoming keen to use IAW resources in response to challenge. As one 14 year old expressed this 'lessons with Mr. X are ace because he really makes it seem understandable by using the IAW to show us different explanations, and makes it fun too ... and we rise to the challenge'. It is significant that the class concerned had not408 dispensed with their teacher but they had discovered some joy in learning mathematics.

Evolution to revolution?

An opportunity was provided by the observation of over 100 lessons to ascertain how the changed focus from teacher to IAW might need a reassessment of both mathematics learning and teacher development. Although not restricted to those lessons taught with an IAW it became clear that teachers who had developed an enthusiasm for the use of the technology also communicated their enthusiasm for learning mathematics – shown in their use of gestures. This is beyond the scope of the current position report but our findings echo the work undertaken by Goldin-Meadow (2003) and Rotman (2005) and show that as the focus shifts to the IAW both teachers and pupils develop gestures that enhance personal understanding and group communication, but that after each learning period gesture falls back indicating that concepts and processes have been internalised. If there is to be any value in training teachers to analyse their gestures and those of pupils it must lie in the transferability of gesture patterns. Rasmussen et al (2004) suggest that gesture and argumentation (visual and verbal explanations) together support the establishment of 'taken as shared' ideas and that once established these can then be used in similar but different situations – a vocabulary of gesture develops as a result. Our evidence is that IAW use may lead to patterns of teaching that may enhance gesture development and do so with some consistency in the same schools.

This shared secondary language is a reflection of the dynamic nature of mathematical learning where the IAW has been exploited to the full but our observations indicate that teachers are moving to an enhanced understanding of the learning process so that they can offer learning mediation. This leads to a greater understanding of a three way dynamic of learning which we believe can help the teacher enhance pupils' understanding:

At the IAW – teachers are recognising that the learning process is changing and there is evidence that they are constantly developing a new vocabulary of explanations linking concept and explanation for a variety of learning styles.

Their thinking is however not directed towards alternative verbal or verbalvisual explanations but to the incorporation of kinaesthetic momentum. They link their IAW activities and use of virtual manipulatives, like the fraction wall, to pupil activities.

On the pupil's desk – teachers note a changed practice away from the use of the IAW as the sole source of explanation towards tasks that emulate similarly lively techniques – so manipulatives, like the fraction wall, are used in a kinaesthetic way by the pupils on their desks. There is a continued use of conventional textbooks and worksheets on the desk, but to a lesser extent.

In the pupil's head – our subsidiary investigation of pupil attitudes to learning mathematics has shown that motivation and attainment are fostered where the teacher provides frequent opportunities for pupil discussion and offering of 409 ideas and theories followed by assessment of what has been understood. We believe that linking activities at the IAW with those on the pupil's desk can help focus learning in the pupil's head on understanding rather than calculation capability.

Our early contention is that teachers who are offered access to the technology but who have to take time to go through the stages outlined above may fail to ensure that the IAW is a worthwhile investment unless they are offered access to the exploration of the link between interactivity and mathematical development, coaching to support the use of the range of presentational and pedagogic opportunities and continuing group support to enhance reflective practice … and then the revolution could come! It could be that this evolution begins with the development of a bank of materials for distance learning supported by mentors within schools.

Teachers, technology and cultural diversity

John Monaghan, University of Leeds, UK
J.D.Monaghan@education.leeds.ac.uk

This paper addresses secondary teachers using technology. It considers cultural matters and offers a cultural account. This account is not a model or a theory but a consideration of cultural factors in teachers' use of technology. Different cultures need not be 'far way' and cultural differences within a locality are recognised. Artefacts are considered as fundamental constituents of culture. Artefacts include hand tools and modes of action of using such tools such as beliefs and classroom norms. Pedagogy is viewed as a cultural undertaking. A review of literature suggests that many papers on using technology are 'acultural'. A set of papers is introduced that are considered relevant to building a cultural account. Constructs from these papers include teachers' routines, establishing a dialogue with teachers, teacher privileging, the software of the teacher, motives and goals, emergent goals, ergonomic and anthropological approaches (including orchestration and epistemic and pragmatic values ascribed to techniques) and situated abstractions. These constructs are used to suggest both a cultural account of teachers using technology and ways of working with teachers from other cultures. Mutual respect for teachers from other cultures is emphasised. An end-note considers differences between primary, secondary and university teachers.

Introduction

The essence of this paper is that (secondary) teaching is a complex undertaking that varies across and within cultures and that introducing technology into teachers' class-rooms adds to this complexity. After this introduction I consider artefacts and culture. I then provide a selected review of research on teachers using technology in which I pay particular attention to studies I regard as useful for formulating a cultural account of teachers using technology. I then present this cultural account and look at the implications of it for working with teachers who intend to use technology in their classrooms.

Artefacts and culture

Culture, in a short paper, must remain a tacit construct but "artifacts are the fundamental constituents of culture" (Cole, 1996, p.144) Cole's argument, very briefly, is that the things people do in their everyday settings involve a multitude of coordinated artefacts which mediate their social interactions and their actions on the nonhuman world. Technology is a subset of artefacts, but what are artefacts? Wartofsky's (1973) three levels of artefacts is a widely respected account. Primary artefacts, e.g. hand tools. Secondary artefacts, representations of, and modes of action using, primary artefacts. Tertiary artefacts are imagined worlds, arenas of 'free' play. In considering teachers, technology and culture, attention should be given to 411 secondary artefacts as these encompass beliefs, conventions and norms which are important aspects of culture and pedagogy.

Pedagogy is a central consideration to teachers using technology. The important thing to note about pedagogies is that there are many pedagogies. Pedagogy concerns why and how teachers do things with artefacts around them (and how these artefacts shape and are shaped by what teachers do). There are many things a teacher can do and many things a teacher can use, but what they do and use is intrinsically bound up with their culture – the culture of their country or community and the culture of their school. Pedagogy is a cultural construct and many people not working in education have clear opinions on suitable and unsuitable pedagogies. Daniels (2001, p.69) calls pedagogy "the fundamental social context through which cultural reproduction-production takes place".

It appears reasonable to say that pedagogies from affluent countries have been, implicitly and explicitly, offered to (or adopted by) educators from developing countries. Nkhoma (2002) investigates attempts to shift teachers' practices from being teacher-centred to learner-centred in Black South African schools. He found that the poor material conditions of the environment and the culture of Black township schools were not condusive to Western style learner-centred classrooms but found that rich learning experiences can be provided by committed teachers who teach from the front. He concludes:

It is not beneficial to stereotype classrooms practices into, simply, teacher-centred therefore bad, and learner-centred therefore good … rich experiences can be provided in practices that appear teacher-centred. (Ibid, p.112)

Both the material conditions of life and the secondary artefacts which weave culture are important in considerations of teachers using technology. Noss & Hoyles (1996, p.185) consider doctoral studies which examined Portuguese and Turkish teachers using technology and ascribe differences in attitude to and use of technology (Logo) to different educational contexts and beliefs.

Teachers using technology, a review of literature

I consider the literature in two parts: that which I do not regard as particularly informative for accounting for cultural differences and that which may be informative for this purpose.

Part 1

The majority of mathematics education academic papers, especially older papers, on teachers using technology are, in my opinion, written 'aculturally', i.e. they do not describe the culture of the situations they examine and sometimes make recommendations which do not pay regard to the coordinated artefacts of other cultures. I do not have space for an independent review in this paper and so I call on two refereed reviews to make my points.

Lagrange et al. (2001) is a meta study of literature on technology in mathematics education, 1994-99. The approach has many dimensions, not all of which are possible to describe here. The study involved quantitative and qualitative 412 analyses. I summarise their qualitative analysis which was restricted to the educational use of computer algebra systems (CAS). They found that papers considered could be classified into five types of problématique (I consider the first and last type here). The first type is technical descriptions of possibilities (53%), optimistic accounts which stress capabilities that the authors consider educationally relevant. As a personal note I usually find such papers, e.g. Using CAS to introduce exponential functions, most enjoyable. My point with regard to the focus of this paper, however, is that expecting the teacher or student behaviours described to 'jump' contexts/ cultures is expecting too much. The fifth type is papers focusing on the integration of the technology, the conditions of use (7%). It is only these kind of reports, I believe, that can inform the focus of this paper; only by focusing on the conditions of primary and secondary artefact coordination can we provide a cultural account of teachers' use of technology. Monaghan (2004) is neither a meta study nor a comprehensive literature review but it does attend in some detail to the division in the literature between papers which are 'prescriptive', e.g. encourage teachers to relinquish didactic roles and papers that recognise the complexities of practice. He notes a gradual increase in papers of the latter type over time.

Part 2
The following summarises studies which I consider contain elements that have the potential to contribute to a cultural account of teachers using technology.
Olson (1992) presents a way of viewing teaching and teachers. This book is not explicitly concerned with the use of technology although an important study that contributed to this book was on Canadian primary teachers using Logo. Routines are central to Olson's account of teaching. Routines are not 'thoughtless' but they are based on 'tacit knowledge' which precedes articulated knowledge. "Routines express culture" (ibid., p.24). Teaching is essentially a moral undertaking and teachers have a vision of what is good for their students. Innovations, e.g. exhor-tations to incorporate technology into teaching, must match teachers' visions. "Classroom routines are not what computers will replace, they are where computers must fit if they are to be useful to teachers." (ibid., p.26). With regard to working with teachers for change "A dialogue needs to be established instead of compliance." (ibid., p.90).
Although a background study to this work involved primary teachers I believe that comments on routines, morality and visions apply equally to secondary teachers. The approach values teachers as people and this, I strongly believe, is important in any cultural approach; any approach which treats teachers as 'subjects' in a scientific study does not deserve consideration here.
There is no contradiction in treating teachers as individuals and as representatives of their cultures, the oft used phrase 'shaped and shaped by' applies to individuals and their cultures. Two PhD studies which focused on individual teachers' use of technology are Kendal (2001) and Lins (2002). Kendal worked with three Australian teachers who designed and taught an introductory calculus programme using symbolic calculators. She found great differences in the emphases 413 these teachers placed which was manifested in the differential performance of their students in specific domains (graphic skills, procedural competence and conceptual understanding) although overall test results for the classes were similar. Her analysis used the construct of 'privileg-ing' (elevating one form of mental functioning over another, e.g. algebraic over graphical reasoning), a term she took from Wertsch (1991). Teacher privileging, over different cultures and within specific cultures, is, I believe is a useful construct to incorporate into a cultural account of teaching with technology. Lins worked with four British teachers, two using Cabri and two using Excel. Her theoretical framework was 'anti-essentialist' - technology as a 'text' that teachers 'read'. The meanings produced by the teachers for Cabri and Excel were different. Lins introduces the construct of 'the Excel and the Cabri of the teacher'. This idea, the software or the tool of the teacher, is potentially important for a cultural account of teaching with technology. The fact that a tool was not a neutral 'given' in one culture suggests great variation in the appropriation of technology over cultures.
Another aspect of the non-neutrality of technology is why one uses it, the goal and the motive. These are essential components of activity theory, e.g. Leont'ev (1978). With regard to mathematics teachers globally and any specific mathematics software it would, I believe, be absurd to assume that the goals/ motives are the same. Ostensibly 'objective' issues here (what will I do?) are intricately tied up with affective matters (why do I want to do this?). In the construct frame of Wartofsky primary and secondary artefacts are interrelated, e.g. teachers attitudes to technology use in mathematics classes shape and are shaped by teachers' cultural identity.
Monaghan (2004) introduces another dimen-sion of teachers' goals in using technology, 'emergent goals' as described by Saxe (1991). Emergent goals come into being and fade away according to the situation. Saxe examines emergent goals with regard to four parameters: activity structures; social interactions; conventions and artefacts; and prior understandings. Monaghan used data from a project on teachers using technology to examine how these parameters interact in the development and resolution of emergent goals. His analysis presents some uncomfortable 'home truths' for advocates of tech-nology, e.g. how the emergent goal of a teacher, whose ostensive goal was to provide a rich spreadsheet activity for her students, was managing the printer queue and managing the behaviour of students waiting for work to be printed.
Work following the ergonomic and the anthropological approaches contains many important constructs relevant for a cultural approach. It comprises a large body of academic papers, not possible to list in this paper, so I refer to a recent critique of this work, Monaghan (2005). Work in the ergonomic (instrumental) approach addresses how a tool, a material object, becomes an instrument, a psychological construct. It emphasises the subject-tool dialectic (the tool shapes the actions of the subject and the subject shapes the tool). It examines schemes, the structure of actions, which have pragmatic, heuristic and epistemic functions. 'Gestures' are the bits of schemes we can see and techniques are sets of gestures. A role of the teacher is to 414 guide students' 'instrumental genesis', the evolution of a tool-scheme dialectic. How a teacher does this with a class is termed 'instrumental orchestration'. Guin and Trouche (1999) is a study of a particular technological classroom environment that includes students with TI-92s and exercise books, a rotating (amongst the class) 'sherpa-student' who operates the viewscreen, a viewscreen, a blackboard, specific tasks and a teacher. In commenting on how to support instrumental genesis they argue for strong teacher involvement. Sherpa-student orchestration is culturally specific but what is important for a cultural account of teachers using technology is that, whatever one calls it, some form of instrumental orchestration, even if it is minimal, will take place and that forms of orchestration are unlikely to transfer between cultures.
Papers by Artigue and Lagrange tend to follow the anthropological approach of Chevallard where practices are described in terms of: tasks; techniques (used to solve tasks); technology (discourse used to explain techniques),); and theory. These four Ts are essentially cultural constructs and it would be a mistake of any cultural account of technology to ignore them. An important aspect of techniques is that they have pragmatic (efficiency, breadth of application) and epistemic values. The interplay between different values in traditional and technology classes introduces many complexities.
Noss & Hoyles (1996) discuss, amongst other things, two constructs, 'webbing' and 'situated abstraction' which are ostensibly about student learning but which have cultural implications for teachers using technology. Webbing is about making connections and concerns building a structure a student or teacher can use to (re)create meaning. Situated abstractions concern how people construct mathematical ideas in a specific setting, with a specific tool or set of tools. We come to a mathematical task with knowledge artefacts (mathematical objects and relationships between them) and tool using capabilities. We must see something prior to new learning or we could not approach the task. Bit by bit, moving between established and emerging knowledge, we focus on new knowledge artefacts. The two constructs are interrelated and complementary. They are consistent with a view of using technology celebrating cultural diversity – we build knowledge from that which we know.
Towards a cultural account of teachers & technology
The need for a cultural account of teachers using technology
Speaking of the marginalisation of technology in mathematics education around the world Hoyles et al. (2004, p.311) point to "... a failure to theorise adequately the complexity of supporting learners to develop a fluent and effective relationship with technology in the classroom". There is an equal need to provide a theoretical account of mathematics teachers using technology, if for nothing else, to avoid advocating ways of working that do not help real teachers develop and assist their students. Such an account must, I hold, be a cultural account and must address the history, curricula opportunities and constraints, the routines and the motives of 415 groups of teachers of different cultures. Focusing on the use of digital technologies of teachers from developing countries, as the ICMI 17 Discussion Document suggests, is important, both in principle as a mark of respect and for the insights these contributions may provide. But a cultural account which provided a framework for these individual accounts would be a step forward.
My considerations are an 'account' rather than a theory or model because it is far from fully developed. I am, of course, interested in the practices of teachers from different countries but I feel strongly that such an account should also address differences within countries. This is grounded in my experience of working with a large number of teachers in England on using technology in their classrooms: their motives for using technology, the affordances and constraints offered by their school/departmental practices and the resources that are available vary tremendously. These, at a local level, are cultural differences.
Aspects of a cultural account of teachers using technology
I could present a 'ready made' cultural account of practice and simply tailor it for the case of mathematics teachers. This would have the benefits of being authoritative and more likely to be consistent than a specially developed account. If I did this, then I would look to Cole's (1996) brand of cultural-historical activity theory as he, more than anyone, puts culture at the forefront. But mathematics is a special case and the considerations of mathematics educ-ators, noted in 'Part 2' above, provide insights not addressed by Cole because he is not a mathematics educator. Of activity theory, however, I believe a cultural account must retain artefact (of various levels) mediation and goal-directed actions. One need not accept all the tenets of activity theory to accept this.
The special case of mathematics is due, in part, to its history; mathematics is the oldest subject in the school curriculum and we cannot, even if we wanted to, ignore this history when we address the use of technology in its teaching and learning. This is, in effect, one of the points of Artigue and Lagrange, when they speak of the epistemic and pragmatic values of techniques. Beyond the 'breadth of application' pragmatic value and the 'facilitating understanding' epistemic value of techniques, however, there are the values accorded to this 'breadth' and these 'forms of understanding' over hundreds of years (we cannot ignore history in any attempt to answer why it is "good" to be able to factorise a
2
- b
2
). Lagrange (2000, p.3, my
imperfect translation) states "the impossibility to conceive or to analyse teaching with these symbolic systems without taking into account the new and the usual techniques that interact in the mathematical activity of the students". This 'impossibility' is, in large part, due to the history of our subject and its historically privileged techniques (I assume that there will be some commonality and some variation in 'historically privileged techniques' in different cultures). The work of Artigue, Lagrange and other on values is in its infancy. To date this work has been largely restricted to work with CAS. Apart from considering other software, 416 however, it is important to locate epistemic and pragmatic values in other cultures' school mathematics.
Instrumental genesis and a form of orchestration will be enacted, more or less successfully, by all teachers using technology but how it is enacted and the criteria for success will, I believe, vary across cultures. Recognising the diversity of ways in which people communicate with and through technology, Hoyles et al. (2004) put forward 'situated abstraction' as a complement to instrumental genesis through the construct of a boundary object, a shared, between different communities of practice, knowledge artefact. Boundary objects take form though do not bring meaning with them when they cross communities of practice. Meaning, however, can be negotiated over communities of practice. Gestures in a software system can generate situated abstractions that others (re)construct, "orchestration becomes a mutual act, rather than something one community does to another" (ibid., p.321). These are general claims and putting them into practice is a significant undertaking. My belief is that many unforeseen problems will arise and that these will be due, to an extent, to emergent goals which arise over and within cultures in different ways. Monaghan's (2004) application of Saxe's model may help us to understand these problems.
Mutual acts are, I believe, an important factor in any consideration of one group of teachers learning from another (especially so if one group represents a dominant culture and the other does not) and are consistent with Olson's (1992) call for a dialogue in place of compliance. Mutual acts are founded on mutual respect of the kind Olson puts forward: respect for visions and routines that may not be the same as ours, respect for teachers of other cultures whose coordinated systems of primary and secondary artefacts have a different historical foundation. Mutual acts are also founded on individual differences between and within cultures. The work of Lins (2002) and Kendal (2001) highlight, respectively, how individual teachers within similar institutions in a single country appropriate software differently and privilege different aspects of the same software with their students. We should expect differential appropriation and privileging to increase in teachers from others countries and cultures. Clearly research in this area would be useful but Lins' and Kendals' work provides a basis for appreciating, and working with, these expected differences.
Endnote on primary, secondary and university teachers
I have focused on secondary teachers. Like Noss & Hoyles (1996) I think it unlikely that primary and secondary teachers will have the same roles or beliefs; their routines are different and one group is exclusively focused on mathematics. I further think that, in general, a difference between how secondary teachers and university teachers use technology is likely. I suspect that university lecturers' focus on mathematics over pedagogy creates different goals and different roles.

Our research team has developed and experimented software for the learning of
algebra, named Aplusix, with the idea of being usable and useful for all the classes
having access to computers, and of helping teachers to teach the curriculum. In this
paper, we list 19 principles that we consider relevant to this goal and we briefly
describe the Aplusix system. This system is distributed in France since early 2005
and will be distributed in many countries from 2006. It has proven to be efficient
(students learn) and to facilitate the teacher's work.
Introduction
Interactive Learning Environments (ILEs) is a term used in the AI-ED community
(Artificial Intelligence in Education) for computer systems designed to help students
learn a domain in an interactive way
49
. ILEs can be produced by research teams or
companies. Research teams generally develop prototypes
50
in order to implement and
experiment ideas; generally, they do not develop products
51
that can be used in
ordinary classes by teachers who just want to teach the curriculum. Companies
develop products to be used in ordinary classes. Most of these products do not
include advanced functionalities and have a poor interactivity, which is sometimes
limited to multiple choice questions.
Many mathematics teachers complain they do not have enough time to teach the
curriculum. This produces a strong limitation to the use of ILEs because these
systems consume a lot of teachers time (study of the system, preparation of learning
situations) and time of their students (it replaces well known activities by activities in
the computer room having an efficiency which is not obvious).
This paper is devoted to ILEs in mathematics (more particularly in algebra) to be
used in the usual framework of classes that can access to computers, both in
developed and developing countries. We particularly focus on ILEs that can help

49
ILEs do not include all the pieces of software that can be used at school, for example CASs and
spreadsheets are not ILEs, they are professional software. The fact that they can be used in classes,
at some level, in well-prepared situations, does not make them ILEs.
50
A prototype is an application which is not well finished and debugged and cannot be distributed
as a professional system.
51
A product is a well finished and debugged application which can be distributed as a professional
system. 419
students learn the curriculum with little modification of the class functioning and
without the goal of changing what is learnt. We consider that this is the first kind of
ILE that most of the teachers in the world need. However, we do not mean that this is
the only interesting kind of ILE.
In section 2, we list principles of ILEs for the usual framework of the class and a
few algebra ILEs are situated with regards to these principles. In section 3, we
present the Aplusix ILE project in algebra. After a first period where prototypes were
built and experimented, we adopted the goal of building an algebra ILE for the usual
framework of the class and we redesigned our system according to this goal. At the
present time, experiments have shown that the system verifies these principles. We
are now entering in a deployment phase.
Principles of ILEs for the usual framework of the class
The principles we consider are oriented towards the students or the teacher.
1. The tasks proposed by the ILE must be part of the curriculum.
2. The activities must be close to the usual activities of the curriculum. This
includes a place for errors and a general interaction mode with little
scaffolding (there is scaffolding when the system executes a part of the
task).
3. The main representations at the interface must be close to the usual ones.
Other representations must be added only for didactical reasons.
4. There must be transfer on paper. After an adequate amount of activities
with the computer, students must have better scores on paper tests.
5. Teacher must be able to use the ILE in the theoretical framework, either
explicit or implicit, they are used to.
6. The domain of the ILE must be large.
7. The manipulation of the representations must be natural (not involving
intermediary representations) and easy.
8. The ILE must be in the natural language used in the school.
9. The familiarization with the system must be easy. When the overall
interaction is complex, there must be different stages so that the
familiarization of each stage is easy.
10.When important features of the system depend on human choice,
parameters must allow teacher's decision on the behavior of the system.
11.The ILE must present some added value compared to traditional
environment.
12.The ratio between the time for familiarization and the duration of learning
activities must be low (maximum 20%).
13.The interaction modes and the feedbacks must allow a good level of
autonomy of the students when they use the ILE, so that the load for the
teachers is not heavy.
14.The time the teachers need for preparing learning situations must be short. 420
15.Information concerning the student activities must be accessible to the
teachers.
16.The teachers must be involved in the global learning process.
17.The price of the system must be adapted to schools. When the system
requires the use of another system, like a CAS, this system must not be
expensive, and must be easy to obtain or included in the installation
package.
18.The installation of the system must not be complex, because it is often done
by teachers who have no advanced knowledge in computer science.
19.The organization developing the ILE must be durable (10 years or more),
because an ILE must evolve (correction of bugs, development of new
functionalities, etc.).
Principles 1 to 6 are adequacy and utility principles. Principles 7 to 10 are
usability. Principles 11 to 14 are economical principles at a cognitive level.
Principles 15 and 16 exclude AI systems that would take in charge the entire learning
process and leave no place to the teacher. Principles 17 to 19 are general economical
principles.
Cognitive tutor for algebra [Koedinger et al., 1997] is an example of ILE for the
usual framework of the class. Its domain is elementary algebra: word problems,
linear equations and systems. It has been designed by the Carnegie Mellon University
of Pittsburgh and is distributed by the Carnegie Learning company
[CarnegieLearning], which is a spin-off of this University. It is oriented to the US
curriculum. The Website of Carnegie Learning announces "325 000 students using
the system over 750 school districts across the United States" and better scores of
students using this system with regard to other students.
MathXpert [Beeson, 1996] is an ILE for algebra and calculus designed at the
University of San José and distributed by the MathWare company [MathWare].
Experiments have proven that students benefit from the use of MathXpert. However,
MathXpert does not follow the principle 2: it provides strong scaffolding (at any
time, the student selects a sub-expression and the system provides a menu with the
rules that can be applied to this sub-expression) and makes no place for errors (the
student chooses a rule in the menu and the system applies this rule). This non respect
of the principle 2 may be a reason of a weak success of the system.
The Aplusix ILE
Brief history of Aplusix
During the nineties, we developed an ILE for algebra [Nicaud et al., 1990]. It was
a command-based ILE like MathXpert with rules in menus and calculations done by
the system. The main differences with MathXpert were: (1) more abstract rules; (2)
Presentation of all the rules (not only the applicable ones); (3) Demand of the values
of the rules variables; (4) A small domain (factorization of polynomials). Several
experiments were conducted and provided good results. 421
Figure 1. The Aplusix ILE.
As researchers in computer science and developers of an ILE, we were not
satisfied with the usage of the system: it was used only in small experiments driven
by researchers. So, we decided to redesign the systems with the goal of being
attractive and usable by many teachers and students. At this moment, we did not have
the ILEfor the usual framework of the class idea but a will to have a system that can
be widely used like dynamic geometry software [Laborde, 1989]. So we built the
Aplusix system [Nicaud et al., 2004], see figure 1, with the following main features:
(1) To allow the student to freely build and transform algebraic expressions and solve
algebra exercises by producing his/her own steps like on paper; (2) To produce the
first fundamental feedback, the indication of the correctness of the steps, in a non
intrusive way, see figure 2. This follows principles 2, 3, and 7. According to the
principle 17, we decided to develop ourselves the entire system (without using a CAS
or some other piece of software). For feature (1), we developed an advanced editor of
algebraic expressions and for feature (2), we developed a module of formal
calculations including the calculations of the equivalence of expressions.
Figure 2. A correct step in the left, with an equivalence sign; an incorrect step in
the middle, with a red crossed equivalence sign; a step without feedback, in the
right.
The teachers and the students who used the first version of this new Aplusix were
very interested and the first tests showed that the students learned well. However, the
teachers had soon demands of new functionalities: (1) A second fundamental
feedback, the indication of the correct end of the exercises; (2) A mode without 422
feedback; (3) Exercises ready to be used. At this moment, we entered in the ILEfor
the usual framework of the class idea.
Short description of Aplusix
First versions of the new Aplusix were principally pieces of software devoted to
students, based on the concept of microworld, with a rich replay system usable by
students, teachers and researchers. In last versions, we continued to improve the
microworld aspect of our environment, but we worked to nest it into some kind of
exerciser where the work done by students could be automatically analyzed and
scored, fundamental feedbacks can be hidden to permit use of Aplusix for tests,
exercises could be automatically generated, solutions could be automatically found
out. Both students and teacher were targeted by these new components, and their
works have been facilitated. But we have worked for teachers specifically too, trying
to provide them with tools for the administration of their classes and of their students,
tools for the edition of specific exercises, list of exercises, or richer exercises (for
word problem, or problems with many linked sections), and last, tools for statistical
analysis of student's results, see figure 3.
Figure 3. Statistical analysis of student's results. Fist the total of
well-solved exercises, second, the total of attempted exercises.
As a consequence, the main student's activity envisaged with Aplusix is no more
an exploration activity with the microworld but a training activity on a list of given
exercises under the control of fundamental feedbacks or a test activity when these
feedbacks are hidden, these new activities are closer to the one practiced in class. We
have added also a new activity, we call self-correction, where students, after a test
(i.e., without fundamental feedbacks), can benefit from fundamental feedbacks to
correct their errors. The last activities are visualization of past activities, either
globally (the final form of the exercise) or action by action.
The organization of work with Aplusix according to activities has been a solution
to reduce the use of the parameters. A set of parameters allows customizing the

system for each class and situation. Parameters continue to exist and can define for examples: the mode and scope of the verification of the equivalence; how the system must manage an incorrect or ill-formed step; the access to the solutions and to the CAS-like commands, the order of exercises obtained from a list (randomized or not); 423 the introduction of strong invitation to students to comment their steps. See figure 4. Activities do not set all the parameters but the most important ones and reduce the number of those which still need to be set. Because of the complexity of the use of parameters (set of parameters can be assigned to each class, for each session), there was a real need to find a way to have customized version of the system without big effort. Activities have been our solution to make the system easier to use.
Figure 4. Teacher's panel for choosing the values of the parameters.
The domain available for explorations and exercises concern algebra: numerical calculations (from integers to square roots), expansion of polynomial expressions of several variables, factorizations of polynomial expressions of one variable and maximum degree 4, polynomial equations and inequations of one unknown and maximum degree 4, rational equation leading to polynomial equations of one unknown and maximum degree 4, system of linear equations up to 10 equations and 10 unknowns.
For more precise information consult documentations at http://aplusix.imag.f
Current state of the global project
Aplusix has been developed in French. We have developed tools allowing to easily translate the texts and the help file of the system. Aplusix has now been translated in English, Portuguese, Italian, Vietnamese, and Arabic. Translations are ongoing in Spanish and Japanese.
Until the end of 2004, several experiments have been carried out [Nicaud, 2005a] in different countries (France, Brazil, Italy, Vietnam, and India) and contexts (a few sessions, regular use during the entire school year, one student per computer, two or four students per computer) for a total of about 15 000 students?hours. At the present time, principles 1 to 18 are verified. In particular: (1) students gain autonomy and improve their knowledge; (2) Aplusix facilitates the teachers' work (because of students' autonomy and of already-made lists of exercises). Furthermore, enquiries showed that all the students worked with pleasure with Aplusix.
Early 2005, a contract was signed between our University and a French publisher, and Aplusix began to be marketed in France. This type of contract appears to be 424 unsatisfactory with regards to duration (principle 19), because, according to French law, the royalties received by the University cannot be used to pay engineers for maintaining and developing the system. So we decided to move the development structure. First, it will go for 4 years to a company, which is an affiliate of the University; then a spin-off company will be created. We have contacts, for several months, with publishers who are willing to sell Aplusix out of France. We will be able to sign contracts with them in March or April 2006. We will adapt the price to the gross domestic product of the countries.
Discussion
The above list of principles has been built from our view of ILEs for the usual framework of the class. As Aplusix has this goal for several years, it is not by chance if it follows these principles. However, we may have forgotten some principles in the elaboration of this list and ideas are welcome.
This list may also be used to estimate the distance between an ILE (an existing ILE or an ILE to be developed) and the for the usual framework of the class concept. An important distance does not mean a poor ILE (the ILE may be very good), but we think that an important distance means a limited possible use. In that case, the benefit of the development of the ILE is only at a research level (doing experiments, producing results of these experiments, publishing papers), not at a usage level.
In the case of Aplusix, we are developing new functionalities that will help students and teachers (through students' autonomy): (1) a companion as an ideal student of a given level who can provide suggestions, explanations and calculation steps; (2) a tutored mode in which the students' calculation steps will be analysed and when a misconception is diagnosed [Nicaud at al. 2005b], an adequate feedback is provided, for example: When you move an additive expression from one side to the other side of an equation, you must change its sign.

Using Computing Technology to Enhance Mathematical Learning in a Developing Society
Preety Nigam-Tripathi, India
preety_tripathi@rediffmail.com
Computing technology can offer teachers a means to incorporate more open-ended tasks and problem solving into their repertoire of pedagogical strategies. But can this be done within the parameters set by traditional curricula, textbooks and classroom cultural contexts? What are the pedagogical approaches that will facilitate this task? How can teachers be helped in making decisions regarding the use of such technology in their classrooms? What are the theoretical frameworks that will support the teacher's work? What are the implications of the use of such technology for teacher development programs? In this study, we use the case study of a teacher-researcher collaboration in a classroom to offer some suggestions on these aspects. The study was conducted in a secondary school classroom in India and offers some insight into the use of a tool that is still in its nascent stages in developing societies.
Historically, society has had two important goals in mind while establishing schools for children. One, schools were a useful means of conveying to children aspects of learning that a society had accumulated over a period of time. Two, schools provided children a means of honing and achieving their potential in different spheres of life. Thus, schools were expected to fulfill societal and individual aspirations in a compatible fashion. As institutions that are geared towards the goals of individuals in particular, and society in general, it is expected that schools will change with the changing needs of a society and help young learners to emerge from them with a broad understanding of the world that they inhabit and the potential to contribute to it in a meaningful manner. Thus, the skills and knowledge that learners acquire in a school system change over a period of time so as to keep pace with changing societal goals and aspirations.
However, in developing countries such as India, traditional approaches to teaching and learning have dominated the school scene for a very long time. The educational scenario in India, in particular, has remained remarkably impervious to changes not only in the global society but also to local, fast paced economic and social changes. School curricula and syllabi, textbooks, teaching strategies as well as classroom contexts have changed little in the past several decades. Naturally, teacher education programs – both preparation programs as well as professional development ones – have reflected this strong resistance to change both in their content and approach to education. It is only in recent years that some of the winds of change sweeping across other spheres of life in Indian society have permeated across the school scene, and even though such changes remain confined to few areas, in terms of both – content and geography, they have begun to play an important role in bringing about changes in the wider educational arena. 427
Mathematical teaching and learning in particular has suffered much as a result of the static modes of curriculum design and transaction that have prevailed in the classroom. Students in schools and colleges learn mathematics by and large by the chalk-and-talk method (both instruments – chalk and talk – being pretty much the exclusive domain of the teacher!) and remain largely mute spectators to the entire process of teaching that goes on in the classroom.
It is into this dismal and depressing scenario that some brave teachers are now venturing forth to disturb the prevailing status quo. Various influences have worked to create this situation. Individual educators who have a broader vision, pressure from some (limited) sections of society who want children to be part of the larger global society, educational researchers who are geared towards helping learners become independent thinkers rather than machines that regurgitate memorized facts, a multitude of private business houses who are marketing their wares in India -- either textbooks (very few) or tools such as hand held technological implements or computing software. Whether intentionally or not, all these factors are beginning to create a demand for change in Indian mathematics classrooms and slowly but surely, the old guard is coming face to face with a host of novel challenges.
We may need to offer some information about the Indian schooling system at this point. Broadly speaking, there are two kinds of schools in India – the state administered schools, also called "government schools" and schools run by private bodies such as individuals or trusts, also called "private" or "public" (actually a misnomer since these are managed by private bodies) schools. Private schools usually charge far higher amounts as fees as compared to the government schools where the fee is very nominal. The quality of education offered in the former institutions usually ensures that all parents who can afford to will send their children to private schools. Another important distinction between these two kinds of schools is that almost all private schools across the country use English as the medium of instruction (regarded as an international language) whereas in government schools, regional languages are used for instruction.
Regardless of whether they are government or private schools, the majority of schools in India work within a curriculum prescribed by a national autonomous body called the National Council of Educational Research and Training (NCERT). This body is responsible for framing syllabi and course guidelines, and creating textbooks that are largely followed as such by most schools in India.
At the end of first ten and then twelve years of schooling, students are expected to take examinations that are conducted by national or state bodies that are responsible for holding them. The outcomes of these examinations are extremely important for most students as much of their future depend upon these results. Thus, to a large extent, much of the teaching in the final three years of schooling is geared towards these so called "board examinations" (as they are conducted by central or state level boards) and preparing students to take them. 428
As in many other countries, reforms in the educational system are driven by changes in the social and economic spheres, but for any such changes to become an integral part of the entire school system requires changes in the mindset of the people who are part of the institutions that look after the administration of the schooling system – the NCERT, the analogous organizations at the state levels called the SCERT's, and the boards that conduct the board examinations. However, at the initial stages, these changes are made at the individual level by people and institutions willing to take the initiative to bring about such reforms. Through such individuals (people or institutions), the reforms may spread to others so as to become more widespread.
The use of technological tools in Indian classrooms has been one such reform that has been very slow in coming, and having made its initial appearance has been even slower to spread. Attitudes and beliefs about mathematics and its learning as well as the cultural heritage of mathematics in this country where people have prided themselves on developing mental skills to perform rapidly various operations that have long and complicated standard algorithms have been partly responsible for the slowness of such changes. "Mathematics is about thinking and how can any technology help us to think?" has been the traditionalists' response to the use of digital technology in mathematics classrooms.
In such a culture, this then is the central question: "How can we use technology to help students to think better in mathematics?" We must also remember that this question must be answered within the context of the prevailing educational system – the curricula, the syllabi, the mathematics textbooks and the traditionally prepared teachers. It is therefore heartening that there are some teachers within this system who are willing to take the risk – to make some efforts towards answering this question. Obviously, they cannot be expected to face this challenge alone. Thus, for educational researchers, the crucial question is: How best can we help teachers in using available technology in their classrooms? Even more importantly, we would like to know whether the use of such technology would help in learning or teaching mathematics in this traditional set up.
It is in seeking answers to such questions that we have set out to do this study. We would like to know: (a) how can we help teachers to decide if, why, when, and how can technology be integrated within the prevailing contexts to provide a better mathematical experience to students? (b) what kind of pedagogical approaches can help us to use technology in the mathematics classrooms?, and (c) if technology can be integrated into the classroom, then what are the lessons for teacher preparation and professional development programs that must prepare teachers for future classrooms? Thus, in this paper, we have chosen to work on the theme "Teachers and Teaching" (with reference to the Discussion Document of ICMI 17) and the broad approach that will define our work is the role of the teacher. Naturally, this approach will be complemented by discussions on the kind of mathematics learning that takes place with the use of a specific technology in the classroom. We would also make 429 suggestions on how curricula may be modified to take into account the mathematics learning that occurs in technology-integrated classrooms.
The interventionist design experiment that is the basis of this study took place

in a local private school in New Delhi, India, that is well established and has been known to take the lead in placing different kinds of reforms on its agenda. A supportive principal and governing body of the school make it possible for teachers to seek and implement a variety of innovative teaching strategies. One of the senior school teachers of mathematics in this school, Dr. Jayanti Gopal, has been responsible for bringing about a lot of change not only in the kind of mathematics teaching that happens in this school but also for taking the lead in spreading awareness and information about such changes to other schools in the city.
Jayanti set up a mathematics laboratory in her school at a time when the concepts of mathematics and laboratory did not go together in this country. She used the mathematics laboratory as a means of having students work on simulated real life problems that could be connected to their regular school curriculum. It goes to the credit of the school that in a packed school curriculum, Jayanti was able to find the time and space for an activity -- the mathematics laboratory -- that was nowhere on the regular mathematics curriculum. Jayanti invited mathematicians to help her set up the laboratory and devise activities that would introduce students to varied and fascinating aspects of mathematics. Gradually, motivated students helped her to extend the frontiers of her laboratory. Jayanti then invited students and teachers from other schools to visit the laboratory. She also organized an annual mathematics day at which teams of students could present mathematical projects designed by them. A variety of other related mathematical activities such as talks by research mathematicians, different kinds of mathematical quizzes and contests, and professional development programmes for teachers helped to set up Jayanti's mathematical laboratory as an important landmark in the mathematical firmament of school mathematics within the city.
My own association with Jayanti helped me to discuss ideas related to school mathematics with her on a regular basis. I visited her laboratory on numerous occasions and I have been involved in different capacities in the mathematical activities that she organizes in her school. Jayanti has also shown her keenness to understand different theoretical perspectives that prevail in mathematics education, particularly those related to the teaching and learning of school mathematics. For me, the opportunity to work with her on different projects has given me an insight into different aspects of the field. Thus, over time, we have developed a working relationship that has helped to foster and feed into each of our individual interests.
The introduction of the Geometer's sketchpad (hereafter called the sketchpad) in India provided Jayanti and me the opportunity to work on a project that is of interest to both of us. I had used the sketchpad while working on developing some activities for pre-service elementary school teachers in the United States. Thus, I was somewhat familiar with the software and believed that it would provide a useful 430 learning environment in geometry, a neglected area of school mathematics. Jayanti felt that the software was interesting enough that it would capture the imagination of her students. Both of us believed that it would challenge students to look at different aspects of geometry from a problem solving perspective. Together, we hoped to utilize the software in Jayanti's laboratory with middle school students in order to answer a variety of questions that challenged us regarding the use of technology in the mathematics classrooms.
Besides stimulating our academic interests, the use of different kinds of tools and implements in the learning of mathematics has acquired additional interest in the Indian context because of some other developments that are currently taking place in the school education scene in this country. A year ago, the government made the mathematics laboratory a mandatory component of middle school mathematics. Thus, all schools are now required to create a mathematics laboratory and have their middle school students visit them at least twice a week. The government's directive in this regard has left many teachers quite confused. Many of them have very little idea of how to go about setting up a mathematics laboratory, and even if a room is designated as such by the school, teachers do not how to put them to use. They are seeking some guidance in this area. A second important development has been the revision of syllabi and textbooks in all subjects at the school level. As curricula in mathematics undergo changes there is need to look at the research in areas related to mathematics education and to utilize the results of this research in order to help learners adjust to the changing needs of a global society. Thirdly, there are a number of schools that are willing to invest in computing technology and want their teachers to find ways to make use of this tool in their classrooms. Parents are also keen to see their children become adept users of computing tools in their everyday lives. Thus, teachers and educators are under pressure to find appropriate spaces whereby learners can use digital technology as a means of learning different subject areas, particularly mathematics, as it is seen as a subject that is in close affinity to this kind of technology.
The collaborative model of learning that Jayanti and I worked with is based to some extent on the teacher development model described by Cobb and McClain (2001) where the researcher and the teacher are part of a professional team that situates its learning within the classroom and the development that evolves is grounded in the interactions that take place in the classroom.
The model was particularly useful for both of us as the learning environment had novel features and allowed us to complement each other. For the first time, we were looking at the kind of mathematical learning that evolves amongst secondary school students through the use of digital technology. Both of us believed that this research study would provide us with ideas on how to integrate such technology better in the classroom. For me, additional lessons were to be learnt in the context of profesional development of pre- and in-service school teachers. Besides, our areas of knowledge and expertise complemented each other – Jayanti knew her students 431 quite well as she had been working with them for several months and so she was aware of their strengths and the places where they would need help. Her laboratory and the use of different kinds of technological tools in it bore testimony to the fact that she believed that school students could be helped to learn mathematics through the use of tools and emerging technology. My own expertise lay in the theoretical perspectives that would help us to contextualise and frame the study as also to design the working model within the classroom with the students, and between Jayanti and I. Together, we developed the tasks that we would have our students use in the laboratory.
Thus, in this case, we believe that the first condition for bringing about any change in classroom practice was fulfilled – the teacher supported the developments and was assured of its usefulness in helping her students to learn mathematics. As Ruthven (1999) states, "A more promising source of guidance on improving the effectiveness of teaching is research into classroom processes and their effects. Here in particular, some researchers have been able to identify core features of effective teaching, and then to test the robustness of their findings through intervention studies, leading to the identification of what can be broadly characterized as active teaching." (p. 208). While we are still some distance away from being able to identify the exact aspects of the usefulness of technology that we will benefit from in the classroom, we hope that we will able to use it to foster a sense of exploration among our students. Through such explorations, we hope to have our students draw conjectures and verify them. We also hope that the visualization strategies that students will be using during the mathematical activities with the sketchpad will encourage them to use these in other situations.
Moreover, the students themselves were keen to use the tool. Early results from the study showed that students were able to manipulate the sketchpad tools and tried to use it in contexts that had not been stipulated by us, showing both their ability to handle such tools and their eagerness to explore ideas using this technology. As the study progresses, we look forward to asking our students more specific questions regarding their own interest in this tool, and other ideas that they would like to explore through it.
Discussions between Jayanti and me together with the work done by the students will help us to evaluate the effectiveness of the tool and our strategies. We will also conduct interviews with students as they work on the tasks in small groups. Thus, our own observations, interviews with students, records of their work, our discussions and regular diaries of our reflections will help us to document and develop strategies for effective teaching within our contexts.
As we develop this case study, we hope that there will be aspects of it that can be extrapolated and used in other secondary school classrooms. Primarily, our interest is in pointing to specific attributes of technology that can be useful in the mathematics classroom. While we are doing this study within the confines of the current classroom contexts, we hope to identify some elements of the curriculum that 432 need to be modified given the availability of technology. In particular, we now have visual strategies possible that help students to see the connections between algebraic and graphical representations of different concepts. Finally, we hope that we will be able to make some suggestions for changes in pre- and in-service professional development programs for teachers. These suggestions will not be merely geared towards skill based knowledge that teachers may require in the future. In fact, we hope to address the attitudes and beliefs regarding mathematics and its teaching and learning that hinder the incorporation of digital technologies in traditional classrooms in societies where they have been conspicuous by their absence. We believe that this is essential if mathematical learning has to keep up with the changing needs of our society, and we are to fulfill the aspirations of our learners.

Students' constructions of dynamic geometry

Federica Olivero
Graduate School of Education, University of Bristol, UK
fede.olivero@bristol.ac.uk

This paper draws on a study investigating the development of the proving process in a dynamic geometry environment in the context of open geometry problems at secondary school level. Starting with a paradigmatic example, the paper will explore how the modalities of interaction with Cabri that students show, influence the construction of different 'dynamic geometry instruments' and direct the proving process in different directions. The modalities of interaction with the software will be interpreted within the instrumental framework (Verillion & Rabardel, 1995) and illustrated by students' protocols.

A Paradigmatic example: the Cabri of Bartolomeo and the Cabri of Tiziana

The paper starts with a paradigmatic example, taken from a study (Olivero, 2002), that shows how interactions with a dynamic geometry software in the context of the same problem differ for two students working in pairs, and impact on the shaping of the proving process. Bartolomeo and Tiziana are 15-year-old Italian students who have used Cabri a couple of times before they were given the problem 'Perpendicular bisectors of a quadrilateral'
52
to tackle in Cabri in pairs
53
. They both have an average mathematical background and considerable Cabri experience.
Tiziana has the mouse. After constructing the figure, the students start exploring the situation and quite soon they get to this extract that leads to the formulation of the conjecture 'If ABCD is a parallelogram then MKLM is a parallelogram too', through an episode of dragging.
69
Bartolomeo: what have you done, a rectangle? (Figure 1)
70
Tiziana: yes, well…
71
Bartolomeo: so… it is a point… try to make it bigger…
75
Tiziana drags D up and stops to observe and think (Figure 2)

52 You are given a quadrilateral ABCD. Construct the perpendicular bisectors of its sides: a of AB, b of BC, c of CD, d of DA. H is the intersection point of a and b, K of a and d, L of c and d, M of c and b. Investigate how MKLM changes in relation to ABCD. Prove your conjectures.
53 For more information about the methodology of the project this example is taken from see Olivero (2002). 434
76
Tiziana: excuse me! This (she points at LM) follows what this (AB) does, this (LK) follows this (AD) … (she laughs)
77
Bartolomeo: let's examine some more cases
78
Tiziana drags A up and gets Figure 3
79
Bartolomeo: ah, when it's a rectangle it's always a point… (he writes down the second conjecture) […]
80
Tiziana: No, because now it's a point too. Tiziana drags B so that ABCD is no longer a rectangle but inside there is still a point (Figure 4).
Tiziana
Figure 1
Bartolomeo
Figure 2 Figure 3
D
C
B
A
MHKL
Figure 4
The students start from the same figure (a rectangle) but use Cabri in two different ways, that open a window on their aims, and potentially direct the proving process in different directions: by the end of the process Tiziana discovers the most general conjecture for this problem, while Bartolomeo goes on with a systematic exploration

of particular cases, as the one explored in this extract.
The Cabri of Bartolomeo
In 72, 77 and 79 Bartolomeo shows how he wants to use Cabri: to produce and check conjectures in a very systematic way ("let's examine some more cases" – 77). During this episode of dragging, he pays attention only to the initial and final figure (Figure 1 and Figure 3), as two snapshots, as his aim is clear: checking if HKLM is always a 435 point when ABCD is a rectangle
54
. And, as soon as Tiziana stops in Figure 3 he formulates a conjecture (79).
This episode represents well the overall interaction with Cabri shown by Bartolomeo throughout the proving process. He shows a quite 'controlled' use of the software, and seems not to be absorbed by it. He does with Cabri something that he could have done on paper too. He has a precise strategy, which is to examine particular cases and to use dragging as a tool for validating conjectures, as is made clear at the beginning of the process ("let's see what happens in every case, shall we?"): the software is used to carry out this plan. Photo-dragging
55
(Olivero, 2002) characterises his behaviour
56
because dragging itself is only used to transform a figure into another one, and the attention is focused only on the initial and final state of dragging.
This 'controlled' use of Cabri, in which the software is incorporated in a predetermined solution process, is limited to the exploration of particular cases/ conjectures and may hinder the discovery of new properties/conjectures.
The Cabri of Tiziana
Tiziana's use of Cabri in this episode is different from Bartolomeo's. Tiziana is observing the figure over the dragging which takes her from Figure 1 to Figure 3, through Figure 2, 'reading' what the figure suggests her. She stops in 75 and reads a relationship between elements of the configuration (the sides of ABCD and the sides of HKLM), which opens up a new thread in the proving process and will be transformed into a general conjecture later on in the process
57
. At the end of this episode, Tiziana does not stop on the rectangle configuration but moves to another 'unknown" configuration in which there is still a point inside (80), opening up another new thread for exploration
58
.
This episode represents Tiziana's prevalent type of interaction with Cabri. She does not show a pre-specified plan of action and she shows a more open use of Cabri: she uses Cabri in order to experiment, explore the situation, get ideas and discover new properties. With a metaphor we can say she is 'dragged by dragging', in that she reads what is happening in Cabri while she is dragging. Her modality is film-dragging
59

54 For Bartolomeo "always" means in two cases only.
55 Photo-dragging incorporates "modalities which suggest a discrete sequence of images over time: the subject looks at the initial and final state of the figure, without paying attention to the intermediate instances. The aim is to get a particular figure" (Olivero, 2002, p.141).
56 Sometimes it is 'indirect' dragging when it is Tiziana who is in fact using the mouse.
57 The general conjecture is: ABCD and HKLM are similar.
58 Which will lead to another general conjecture: if ABCD is cyclic then HKLM is a point.
59 Film-dragging incorporates "modalities which suggest a film: the subject looks at the variation of the figure while moving and the relationships among the elements of the figure. The aim of dragging is the variation of the figure itself" (Olivero, 2002, p.141) 436
(Olivero, 2002): she focuses on the intermediate state of the figure while she is dragging and stops whenever she sees something interesting. Cabri does for her something that she would not be able to do on paper and is an integral part of her actions.
This more open use of the software transforms Cabri (and dragging in particular) into a tool for discovering new relationships and facts, leading to general conjectures. The overall process is determined by what emerges from observing what happens in Cabri.
The research problem
The paradigmatic example has shown different ways in which the students exploit and incorporate the software in their solution processes and how this affects in different ways the development of the proving process. What is the research problem suggested by this example?
Educational innovations tend to take on an objectified character in popular thinking. Innovators advocate and administrators endorse the educational use of this new technology or that, as if the instrument were invariant and its use determinate (Ruthven, 2005). This shows how the risk of the "fingertip effect" (Perkins, 1985), that is simply making a support system available and expecting that people will more or less automatically take advantage of the opportunities that it affords, is always there. However, research has shown that technologies do not work by themselves and people do not automatically take on board the technology or software: "The computer is an expressive medium that different people can make their own in their own way" (Turkle & Papert, 1990). This leads to the exploration of students' constructions of dynamic geometry, to be interpreted within the instrumental framework, as developed by Verillion & Rabardel (1995) and elaborated by Mariotti (2002), that may help us understand why this is the case. The research questions we may ask are:
• What are the instruments-Cabri constructed by the students starting from the artefact-Cabri?
• How do students make Cabri their own instrument-Cabri? What elements play a role in the process?
The instrumental framework
The instrumental approach elaborated by Verillion & Rabardel (1995) provides a new perspective on the effect of technical devices
60
on learning processes.

60
This approach considers the use of tools in generals, not necessarily new technologies.437
According to the instrumental approach, any technical device has a double interpretation: on the one hand it has been constructed according to a specific knowledge which assures the accomplishment of specific goals, and on the other hand, there is a user who makes his/her own use of the device. In other terms, in this perspective it is important to highlight the distinction between artefact, which is "the particular object with its intrinsic characteristics, designed and realised for the purpose of accomplishing a particular task" and instrument, that is "the artefact and the modalities of its use, as elaborated by a particular user" (Mariotti, 2002, p.702) within a given activity. "For a given individual, the artefact at the outset, does not have an instrumental value. It becomes an instrument through a process, or genesis, by the construction of personal schemes" (Artigue, 2002, p. 248), or schemes of use. As different and co-ordinated schemes of use are successively elaborated, the relationship between user and artefact evolves, in a long-term process called instrumental genesis, which is linked to: the characteristics of the artefact (its potentials and constraints) and those of the subject (its knowledge and former work habits) (Verillion & Rabardel, 1995). Therefore the instrument does not exist in itself, an object becomes an instrument when the subject has been able to appropriate the artefact for himself/herself and has integrated it with his/her activity. At different moments different instruments can exist even if the artefact used is the same and it may happen that an artefact is never transformed into an instrument.
The Cabri of Carla: A conflict is generated
This section shows how the instrument-Cabri a student constructs is not appropriate for the situation at stake. Carla and Alessandra are 15-year-old students solving the Varignon's problem
61
. They have a weak mathematical background and only used Cabri twice before this problem. After having formulated the conjecture 'if ABCD is a square then HKLM is a square', they prove it correctly on paper. Afterwards, they go back to Cabri to 'check' their proof, but the Cabri figure does not show what they have just proven. So their conclusion is that "it's all wrong".
Figure 5 (on paper) Figure 6

61
Varignon's problem: Draw any quadrilateral ABCD. Draw the midpoints L, M, N, P of the four sides. Which properties does the quadrilateral LMNP have? Which particular configurations does LMNP assume? Which hypotheses on the quadrilateral ABCD are needed in order for LMNP to assume those particular configurations?438
215 Carla: all this stuff…these…they are congruent (the halves of the sides of ABCD - Erreur ! Source du renvoi introuvable.). [Then Alessandra writes down the thesis: LM equals MN, equals NP, equals PL. Meanwhile Carla uses a ruler to measure the sides of LMNP]. so PL equals MN. The same for …PDN triangle and LBM triangle [illegible] PN equals LM…Should I do a cross comparison? PDN triangle and PAL triangle [illegible] PN equals PL. What's missing? These two are done, these two are done…. […] They all have equal angles. So it is a square! Ok! […]
225 Carla: the problem …is that this is not a square (ABCD) […] look… no…(Erreur ! Source du renvoi introuvable.) Because if you say that this equals this (PD and DN) and you say they have an equal angle (D) and then this equals this (PN and LM) and this and this (PL and MN)…then this becomes a square (LMNP), but we've just seen that it is not a square. So it's all wrong!
228 Teacher: why? What puzzles you?
227 Carla: because…if this is the midpoint (she points at P) then it divides this side in two equal parts (she points at AD and AP and PD) so it should be: if it is a square, the quadrilateral inside is a square too. Why the figure doesn't show that?
228 Teacher: What do you trust more, the figure or your proof?
In this episode, a conflict between a theoretical result (proof) and the empirical answer given by Cabri (the figure does not look like a square) arises. This happens because the students try to validate their proof in the spatio-graphical field (Laborde, 2004; Olivero, 2002). This would require looking at the figure from another point of view, not only empirical, as it may happen at the beginning of the exploration process, but also theoretical. When validating the proof the pupils 'read' the figure at an empirical level, they 'read' the properties of LMNP from the measurements: it has not equal sides therefore it cannot be a square. The students do not consider that their hypothesis is ABCD square while the Cabri figure is not a square because the angles are not right angles. Instead of 'reading' the Cabri figures, they should have looked at them from a theoretical point of view, according to which ABCD and LMNP are both 'approximations' of squares. The proof would have then been validated.
If we look at this episode in terms of the research problem highlighted above and in the context of the instrumental framework, we can see that the Cabri instrument they 439 construct has the following characteristics: the Cabri feedback is interpreted in a visual-perceptual-numerical way and the students do not show a theoretical control over Cabri62. The students take on board the software to the point that the answer they see on the screen is believed to be true even if it contradicts what they found without the software, by proving and using geometric properties of the figure. This particular instrument in the context of this problem provokes a conflict.
From this example we can see how the interaction with Cabri in the context of open geometry problems needs to be mediated by the use of the theory that allows a control over the Cabri spatio-graphical field. Also the intervention of the teacher becomes crucial to solve possible conflicts between what the software does/shows and the mathematical theory and to mediate the construction of an appropriate instrument (228).
Students' constructions of Cabri: the role of the cabri/ mathematics experience
The two examples discussed in this paper illustrate how the process of construction of a particular Cabri instrument affects the proving process. From the analysis of the case studies that formed the research Olivero (2002), a pattern emerged in relation to what sort of Cabri instrument was constructed in the context of the problems used in the study
63
. An instrument is constructed in order to solve the given task, which involves the construction of conjectures and proofs. Can we characterise the type of instrument that the students construct and identify what this depends on? The research showed that what play a role in the process of construction of the instrument is the mathematical theory and the use of Cabri, which evolve together throughout the proving process.
It was observed that students with considerable Cabri experience and average mathematical background seem to manage better the interaction with Cabri, showing a wide range of dragging modalities and a successful proving process. They generally do not use paper. They are able to link the spatio-graphical and theoretical field in a productive way, which leads to the production of many conjectures and proofs. In this case, the artefact Cabri is transformed by the students into an instrument that is appropriate to deal with the situation they are presented with. There is a theoretical control over Cabri, which is used as a discovery tool within processes of conjecturing, and is then re-interpreted and used as a validation tool or support for thinking within processes related to the actual construction of proofs. This is the result of both mathematical and Cabri long term experience, which allow the students to transform Cabri into an internally oriented tool (in the sense of Vygotsky (1978)). Some students falling in this category often talk about dragging and the way they are

62 For a detailed analysis of this episode see Olivero (2002).
63 Open problems (Arsac, Germain, & Mante, 1988) requiring conjecturing and proving in geometry. 440

using it, there is a control over what they are doing in Cabri and they understand well what Cabri can do and show.
A second case is when students have with very little Cabri experience but have a strong mathematical background: in this case they do not fully exploit the possibilities offered by the software. In general they show more controlled exploration in Cabri. It seems that the artefact Cabri is never transformed into an instrument for these students. It remains an artefact which is used occasionally but is not really taken on board by the students. The students prefer to use other tools (as for example paper and pencil) they are more used to and show a successful production of conjectures and proofs. Given their mathematical strength, it seems that these students are less eager to experiment with new tools they are not familiar with. This behaviour can be observed with 'experts' at different levels; Cabri offers possibilities of exploring and opening up spaces that the 'expert' does not necessarily need.
Finally, students with very little Cabri experience and weak mathematical background, like Carla and Alessandra, usually experiment a lot with Cabri but do not always use it successfully. Conflicts may arise between results produced in the spatio-graphical field and possible theoretical explanations, and the focusing process may take a wrong direction, as shown in the case of Carla above. In this case, the process of instrumental genesis develops through different steps and the intervention of the teacher is needed in order to direct students towards the construction of the appropriate instrument which allows the evolution of the focusing process in the construction of conjectures and proofs. The artefact Cabri is first turned into an instrument based on a scheme of use that relies on a visual-perceptual-numerical interpretation of the software's feedback. This is not the instrument which serves to accomplish the goal of the problem situations. A new instrument needs to be constructed by the students, based on a theoretical way of 'reading' the Cabri figures. The role of the teacher is crucial in developing this new scheme of use and provoking students to see the same figure from a different point of view which leads them to conjecturing and finally proving.
Conclusions and Implications
To conclude, this paper shows how, given the same tool (dynamic geometry software) and the same activity (proving open problems), students develop different proving processes, both in terms of the way they interact with the software and in terms of the conjectures and proofs they produce. The instrumental approach explains this through the fact that students are constructing different instruments by transforming the same artefact (Cabri). The mathematics and Cabri experience affect and influence the instrumental genesis. Understanding the different instruments and how they are constructed is important because the construction of the instruments affects the development of the proving process in terms of production of conjectures and proofs. Further research will focus on a detailed analysis of the development of 441 the schemes of use related to the particular elements of dynamic geometry software, as for example dragging and measurements.
The fact that students construct different instruments shows that the integration of dynamic geometry in the classroom practice is not a straightforward process but requires a careful analysis. A key challenge for the integration of technology into classrooms and curricula is to understand and to devise ways to foster the process of instrumental genesis towards the construction of the appropriate instrument for a given task. The role of the teacher emerges as important, showing that dynamic geometry per se does not guarantee a successful proving process that manages well the key relationship between the spatio-graphical field and the theoretical field. The teacher constructs different instruments too (Lins, 2003; Ruthven, 2005), which influence the instrumental genesis the students develop and their appropriation of the software. The teacher should act in 'transforming' the tool used by the students into a "semiotic mediator" (Mariotti, 2002) in the proving process so that a process of internalisation of the tool itself takes place and the artefact is then transformed into an appropriate instrument for the situation at stake.

An important question in considering the introduction of new technologies in mathematics curricula is that of their effectiveness in enhancing (or damaging) the real capabilities of students. To answer this question the paper sketches a theoretical framework, which frames the new technologies for mathematics as representational infrastructures: as such, they are analysed both as cultural semiotic systems and as cognitive energizers. The two concepts allow defining suitable adequacy criteria for testing the new technologies in the classroom. A teaching-learning environment integrated with technology is described as a concrete realisation of a technologicaloriented Italian curriculum. An example of how learning can happen in this environment is described and a few final comments are drawn with respect to some questions asked in the Discussion Document of ICMI Study 17.
Introduction
The focus of this paper is on the theme 4 of the Discussion Document. To do that we introduce a theoretical framework suitable to test how the environments integrating digital technologies are adequate for the effectiveness of maths learning (§1). Then we exemplify this definition illustrating a concrete learning-teaching environment where the learning experiences take advantage of the affordances supported by the new technologies (§§ 3, 4). The environment is developed within a concrete technological integrated Italian curriculum, which is sketched in advance (§ 2). In the end (§ 5) we discuss how our theoretical framework and the methodologies illustrated in the examples are useful in understanding the impact upon the teaching/learning of mathematics.
Theoretical Framework
The introduction of Information and Communication Technologies (ICT in brief) in mathematics curricula has been stressed and encouraged in these last years. However the benefits from such an introduction are neither necessary nor automatic; the matter must be considered carefully, looking at its many aspects and possible negative effects. In fact, as shown in Artigue et al. (2001), much of the theoretical and empirical research dealing with the use of ICT in mathematics education is prevalently concerned with the added-value component provided by the technology and rarely faces critically an approach to ICT based on an ecologically sustainable use. A major disadvantage consists in the fact that papers on ICT are more concerned

64 Research program supported by MIUR and by the Università di Torino and the Università di Modena e Reggio Emilia: Significati, congetture, dimostrazioni: dalla ricerche di base in didattica della matematica alle implicazioni curricolari (PRIN n. 2005019721). 444
in "learning how to use technical tools incorporated in the computer ... than [in] understanding the theory behind those tools" (ibid.), namely in what can be called a blind use of technology. This often corresponds to a-critical practices in the classrooms, which are limited to control the functioning of the tool, which is "insufficient for a successful mathematics outcome" (Thomas & Hong, 2004).
What is needed is an aware use of technology, which means to understand if, how and when the technological artefacts can mediate/support/carve the construction of the student's mathematical knowledge in the classroom. To do that, one must consider ICT's in a wider setting, namely to analyse them from a multiple perspectives: that is, from a didactic point of view (e.g. considering the role of the teacher, of social interactions induced by the used technology, and so on); from a cognitive point of view (e.g. considering how technology changes the mental structures of the learners);from a cultural point of view (e.g. considering the framework of rationality towards which the use of technologies may push the student). An interesting analysis in this direction has been developed by Kaput et al. (2002), who introduced the notion of representational infrastructures (= RI):
The appearance of new computational forms and literacies is pervading the social and economic lives of individuals and nations alike....The real changes are not technical, they are cultural. Understanding them... is a question of the social relations among people, not among things. The notational systems we use to present and re-present our thoughts to ourselves and to others, to create and communicate records across space and time, and to support reasoning and computation constitute a central part of any civilization's infrastructure. As with infrastructure in general, it functions best when it is taken for granted, invisible, when it simply "works".
The challenge today is how to design learnable systems within suitable and up-todate representational infrastructures. Roughly speaking, the major point consists in seeing how the ICT involved in a system fit within RI according to the following two criteria: a) as Cultural Semiotic Systemsb) as Intrinsic Cognitive Energizers. Cultural semiotic systems (Radford, 2003) are those systems which make available various sources for meaning-making through specific social meaningful practices; such practices are not (only) to be considered within the strictly school environment but within the larger environment of the whole society, embedded in the stream of its history. For example, Kaput & Schorr (2002) claim that the development of algebra in the history of mathematics was made possible by an entirely new mode of thought "characterized by the use of an operant symbolism, that is, a symbolism that not only abbreviates words but represents the workings of the combinatory operations, or, in other words, a symbolism with which one operates".
Intrinsic Cognitive Energizers are here defined as systems which make available varied sources for meaning-making through specific cognitive meaningful practices; such practices do enter intrinsically in positive cognitive resonance with the subjects, because of cultural and biological reasons. Examples are given by the quick and mainly visual interaction with the information provided on the computer screen in 445 computer games and in access to all kinds of information provided by the internet system.
In the next two paragraphs we shall illustrate this framework introducing a concrete teaching-learning environment developed within a technological integrated curriculum of mathematics. We'll sketch the latter in next paragraph and discuss the former in the successive § 3.
An example of technological integrated curriculum: the Umi65 proposal and the mathematics laboratory
Modern society requires massive use of mathematical knowledge and skills. A significant act with this respect is the UNESCO resolution in 1997, that underlines how "mathematics education has a key role, in particular at the level of primary and secondary school, in the comprehension of mathematical concepts and in the development of rational thinking" (http://www.unesco.org/science/physics.htm).
The UMI proposal of mathematical curricular innovation is inspired by the UNESCO resolution and, in particular, take into account both the instrumental and the cultural functions of mathematics. The essential core of UMI curriculum provides a foundation for pupils' mathematical competencies through 4 content areas (numbers and algorithms; space and shapes; relations and functions; data handling and previsions) and 3 processes areas (argumentation, conjecturing, proving; measuring; solving and posing problems). The 7 areas are essentially the same for the whole pre-university school from 6 to 19 years. The teacher is supposed to tackle these themes in an integrated manner, trying to connect them to other topics and to other subject disciplines. The UMI curriculum (
66
) contains also some reflections on
the Mathematics Laboratory that are very important for the scope of this paper. In fact, the Mathematics Laboratory is conceived as a teaching-learning environment based on the use of instruments and aimed at the construction of mathematical meanings. It is not intended as a physical place other than the classroom, but as a structured set of activities with the goal of building the meaning of mathematical objects. As such, it involves people (students and teachers), structures (classroom, instruments, organization of space and time) and ideas (plans for didactical activities, experiments). In this sense, it passes the two adequacy criteria, stated in § 1. This is shown also by a metaphor introduced in the UMI document, where the Mathematics Laboratory is compared to what happened in the Bottega d'Arte of Renaissance artists, where the novices learned through a cognitive apprenticeship, namely by doing and watching what was done by experts, communicating with one another and with the experts, who pointed out the cognitive difficulties that the newcomers would encounter. The construction of meanings within the Mathematics Laboratory is strictly linked to the instruments used when carrying out the given activities and to the interactions among the participants in the activities (Bartolini et al., 2004). It is

important to remember that tools are the result of a cultural evolution: they have been

65
Unione Matematica Italiana (Association of mathematicians and mathematics Italian teachers)
66
The curriculum is available at: http://www.dm.unibo.it/umi/italiano/Didattica/ICME10.pdf446
produced with specific aims and, as RI, represent ideas in a culturally shared and
technologically up to date way. This has important didactical implications: first of
all, meanings do not live only in the tools and cannot emerge purely from the
interaction of the pupils with the tools. Meanings are rooted in the aims for which the
tools are used as culturally shared artefacts, and in the strategies related to the use of
those tools that are elaborated in the course of the activities, which make palpable
their cultural content. Moreover, the appropriation of the meanings requires
individual reflection on the objects of study and the proposed activities. The
construction of meaning is strictly linked to the communication and sharing of
knowledge in the classroom, through collaborative or cooperative group work and
through the mathematical discussion orchestrated by the teacher.
An example of a technological integrated teaching-learning environment
The UMI document has also many examples of teaching activities; however it does
not contain indications on specific didactical paths that suggest how to develop its
contents. How its curricular indications can be transformed into structured and
concrete didactical paths in the classroom is an affair that has been left to the schools
and to the teachers, in accordance with the Italian curricular tradition. For this reason
a group of upper secondary school teachers has designed a didactical plan from the
curricular indications of the UMI proposals and according to the educational
framework illustrated in §1. The result has been a teaching-learning environment,
where the ICT are integrated as RI, called Mathematics in the Web (indicated as
MW-project in the following).
The main features of this environment are sketched in the following points:
a) using ICT's to design, to build and to realize mathematical activities, which
make sense (attività sensate in Italian); the Italian word is used with three different
meanings: reasonable (that is attentive to the specific possibilities and constraints of
the class); linked to the natural abilities and particularly to perception; ruled by the
intellect and specifically by a theory (the last two meanings were used by G. Galilei
to feature what he called sensate esperienze);
b) using a long-term didactics (contrasted to short term educational projects),
with particular attention to the construction of the meaning of the mathematical
concepts and to the development of a critical thought in the students, considered
essential for citizens' awareness in nowadays society;
c) engaging students in explorations, building, scaffolding, communicating
activities, so that that the teacher can have information not only about their products
but also about their thinking processes;
d) gradually introducing the students to theoretical knowledge (different from the
factual one), where such questions like "why does it work?" make sense and where
the answers give reason not only for links among related facts but also in terms of
logical consequence between the phenomena that one is trying to explain and the
statements that are the foundations of the theory within which the facts are framed.
As far as the specific goals of the project are concerned, there are three main
conceptual areas, which are developed according to the UMI curriculum: 447
(i) beginning probabilistic thinking; (ii) beginning the study of changing
quantities: specifically modelling activities of phenomena that evolve and change in
time, in order to describe them and to foresee their evolution; (iii) fostering students
spatial intuition in all activities where they use exploring, observing, finding
abilities.
We shall make some comments only on point (ii), which is particularly akin to the
topics discussed in this paper. These activities concern the context of change and of
movement, within the core area Relations and functions in UMI curriculum and
approach some of the basic concepts of Calculus: from functions as modelling tools
for phenomena of changing quantities to derivatives and integrals. The project uses
systematically a variety of different ICT devices which incorporate suitable different
aspects of change & motion phenomena (e.g. motion detectors connected to
computers). As widely discussed in Kaput et al. (2002) such devices are genuine new
representational infrastructures, which can produce a positive cognitive resonance in
pupils and support their learning. There are many projects in the world that are
developed according to this philosophy, e.g. Simcalc, Playground, Data Capture,
WebLabsTproject. The use of ITC for the mathematics of change is a good example
of a teaching design which fits very well the adequacy criteria a) and b) stated in §1.
Essentially the concept of function is approached within a very powerful RI,
where cultural and cognitive aspects are in deep resonance.
Specifically, the MW-project is based on some ideas by D. Tall on the approach
to Calculus, which are widely sympathetic to the general philosophy discussed
previously. In fact the approach to the main concepts of Calculus is built up starting
from the three following fundamental cognitive roots (Tall, 2000): the notion of local
straightness as a cognitive root for differentiation; the idea of a graph that "pulls flat"
when it is stretched more horizontally than vertically for the mathematical concept of
punctual continuity; the notion of area under a graph of a continuous function and the
graph that "pulls flat", for the relationships between integration and differentiation.
The project develops such concepts using the software TI-InterActive!, which
works as a generic organizer, in the sense of Tall (Tall, 2000). Such a software is an
interesting example of an ICT, which fulfils the adequacy criteria of §1. In fact, it
collects the functions of different products into a unique environment: a numerical,
graphical and symbolic calculator; a word processor; a spreadsheet; the possibility of
importing data from different environments, specifically from graphic-symbolic
calculators and from probe devices that get measures of physical quantities; a
browser to navigate in the web and to interface with other environments and software
(in § 4 we shall show an example where the students use the software Graphic
Calculus). The project uses TI-InterActive! to design work-sheets in its teachinglearning environment for exploring activities that foster the production of conjectures
by students, as well as their validation. In all this work the activity of the teacher is
essential to coach all the different processes. Successively, the teacher supports
students in structuring and scaffolding the learnt concepts within a theory. In the end 448
the work-sheets can mediate part of the theory, which organizes and systematizes the
learnt concepts and the algorithms in a coherent framework.
An example of a teaching experiment
To give an idea of the type of learning that happens in such an environment, we shall
present some excerpts from the protocols of students who are approaching the
concept of the derivative dy/dx as the limit of the rate of change □y/□x. The excerpts
illustrate in an emblematic way how the interaction with Graphic Calculus, suitably
coached by the teacher, can support conceptualisation processes in pupils. In the
work-sheet, which is built with TI-InterActive!, the students are required to explore
Gradient, a modulus of Graphic Calculus and, successively to write their results in
the TI-InterActive! page. The space does not allow to enter into details and we shall
limit ourselves to some spots. The students are in the 11
th
grade of a scientifically
oriented school, participate to the MW-project and are introduced to the fundamental
concepts of Calculus since the beginning of high school (9
th
grade). They are used to
work in small groups and to participate to collective discussions orchestrated by the
teacher. As said above, they are also accustomed to use technological devices, e.g.
sensors to investigate motion experiments. In the example, they must study the graph
of the function f(x) = 0,5 x3 - 5x2 + 3. As shown in , the software generates: the
graph of the function; its tangent, which moves dynamically along the graph, while a
point traces it; the graph of the slope value of the tangent, while it is moving.
The figure shows some emblematic steps in the genesis of the rate of change
concept. It is precisely the interaction with
the software to generate in the students the
first germs of the relationships between the
rate of change and the slope of the tangent.
In fact they have produced the graph of a
secant to the graph of the function, which
joins couples of points on the graph whose abscissas differ for a constant value □x,
determined by the students themselves. They fix successively □x equals to 0.1, 0.01,
0.001, and so on, so that the secant becomes a quasi-tangent (Fig. 1). It is interesting
to observe in the pictures of Fig.2 how the gestures of the student (more than his
words) show the way he is acquiring the rate of change notion.
Stud1: This straight line must join [Fig 1a], ok, the X interval...it is [always?] the same [Fig 2b],
Teach.: The X interval is the same; delta X [□x] is fixed
Stud1: Delta...eh, indeed, however there are some points where to explain it, one can say that this
straight line must join two points on the Y axis, which are farther each other hence it is steeper
towards... [Fig 2c]
Stud1: Let us say from here, when, here, when however it must join two points, which are farther,
hence there is less distance [Fig 2d] [...]
Teach.: is it decreasing? [Fig 2e] [...]
Stud1: They are less and less far; in fact we can say that the slope is going towards zero degrees.
Teach.: Uh, uh
Stud1: Let us say so
Stud2: Ok, □y over □x at a certain point here it reaches points, ...
Stud1: The points are less and less far [Fig 2f] [...] 449
Teach.: What does this object represent, when h represents this distance, this small interval? ...
Stud3: No, It is neither a tangent, it is a ... secant...the more I make this small, when I have h very
small, then it represents the slope of the tangent in that point, exactly in that point and hence... [...]
Stud2: It is something, which is useful to determine the slope in X; since we cannot do it directly;
that is we need the X + h, which when multiplied by a certain number of things , you see it through
computations, then it goes to zero; so we can eliminate it and we have ...
It is a dynamical idea that contains: the limit process with x that becomes smaller and smaller
(Fig. 2 a, b), the relationship between the slope and the rate of change (Fig. 2c); the relationship
between the □x (here constant) and the□y (Fig. 2 d, f).
The data of our teaching experiment, with all their limits, confirm that this
approach to ICT is an useful research tool to understand the ways in which
technological artefacts can support the construction of the student's mathematical
knowledge. In fact, the analysis of the cultural and cognitive ingredients of the ICT
used in the classroom allows to consider the added-value component provided by the
technology not limited to its purely technical features. In particular, the analysis of
ICT according the two dimensions (cultural and cognitive) stresses students' learning
that happens in such an environment: a rich interplay between the perceptuo-motor
and the symbolic-reconstructive learning, as discussed in Arzarello et al. (2005).
Some conclusions
Our example and the whole MW-project illustrate how the mathematical content and
the methodological issues of a curriculum must take into account suitably the rich
resources made available by RI. It is the same concept of mathematical literacy to
change within such new technologically integrated environments. A major goal of
today math education consists in contributing, together with all other subject
disciplines, to the cultural development of citizens, in order to enable them to take
part in the social life with awareness and a critical eye. The competencies required
for a citizen, to which mathematics education can contribute, include for example:
communicating information appropriately, perceiving and imagining, solving and
posing problems, planning and constructing models of real situations, making
choices in conditions of uncertainty, These goals are much more ambitious than the
old ones, like making computations and remembering a corpus of knowledge, which
was supposed essential for a mathematical culture. The new literacy requires a strong
mathematical experience and the habit of working with mathematical objects and
within mathematical environments integrated with the new ICT. As such, ICT are
specific for mathematics but share a lot of common features with other RI.
The main design principles according to which the new ICT are to be articulated,
should satisfy a twofold principle. From the one side, they should make available rich
and multimodal experiences to approach mathematical conceptualisation within a
rich and meaningful RI. From the other side, the experiences made in such
environments should be 'easier' and more motivating for the students because of
cultural and cognitive reasons. In fact, concepts should be tackled starting from their
cognitive roots and the environment should represent them in a powerful dynamic
and interactive way, so that it can support and enhance a perceptuo-motor approach
to them, namely an approach that involves massively action and perception and 450
produces learning based on doing, touching, moving and seeing (like in the excerpt
of our example). But the ultimate rationale of any ICT remains the teacher: it
depends heavily upon her/his teaching project if the students will be satisfied,
provided they know simply what to do or how to do something, or on the contrary if
they will ask themselves also why things they have found or they are using are
effectively so.

The challenge of teaching and learning math online
Nicolás D. Patetta, Universidad de Buenos Aires, Argentina.
nicolaspat@ciudad.com.ar
As the call for papers of this study expressed, since 1992 there have been
substantive developments in digital technologies, both in terms of hardware and
software. However, the networked use of the Internet, empowering the interactions
among people and contents, states the most significant difference between the first
ICMI study and this one.
The Web is only a medium of delivering learning and instruction that has the
potential to support the creation of significant learning environments providing
opportunities for communication, collaboration, and learner-centered learning.
However it is necessary to change the instructional paradigm to match the
requirements of the information age. A shift is required from a focus on presenting
materials to a focus on making sure that learners' needs are met, from passive to
active learning, and from instructor-directed to learner-directed (or jointly directed)
learning. Teaching online, faculty have to deal with learners who interact in a
completely different way and all have to reflect on their learning assumptions in
order to understand their new roles.
The change in the instructional paradigm that teaching online requires is a
challenge for all disciples, although math has additional difficulties due to the
intensive interactions with content that it necessary to establish in order to produce
the learning process.
Online math teaching requires the design of interactive material that could be
very expensive in time and money if each teacher would design completely a course.
However this can be faced chunking the course content in learning objects and
sharing them. A learning/knowledge object is the smallest 'chunk' of instruction or
information that can stand alone and still have meaning to a learner.
Currently the Web is plenty of math knowledge objects: The Mathlets. They
are the equivalent of a good example that can be explored by learners in an
interactive way. Creating object libraries, different learning programs can share the
same objects using them repeatedly, even for different purposes, reducing
redundancy, lowering costs, and enabling the customization of learning because the
configuration of the objects can be dependent on the needs of learners. E-learning
solutions based in objects can be quickly reconfigured to meet changes in user's
needs. The same knowledge object can be used (and reused) to build different
learning solutions associated to different learning goals and instructional strategies. 452
A Case Study Of Developing Students' Ability to Design Algorithm in Logo
Environment
Aihui Peng
Southwest China University, China
huihui809163.com
The algorithmic idea has been a kind of necessary mathematics quality for modern
people in this information society. In China the algorithm was represented fully as
one of the new mathematics contents in the secondary level for the first time when
The Standards of Mathematics Curriculum for the Senior High School was
promulgated in 2003, so the research about the teaching of algorithm undoubtedly
has its practical implications for mathematics education. In this paper, with the
conceptual framework of The Mathematics Task Framework as the research tool, an
algorithmic teaching case based on LOGO software was introduced in detail, and
data including observations, interviews and worksheets were collected, then the case
was analyzed, and the results showed that the teaching of algorithm is feasible and
effective in the LOGO environment. In the last, some beneficial implications about
the instructional design of algorithm were discussed.
Introduction
An algorithm refers to the step-by-step systematic procedure used to accomplish an
operation, which characterized as finiteness, definiteness, input, output, effectiveness
and named by the ninth-century Arabian mathematician Mohammed al-Khowarizmi.
Due to the way of mechanical operation, the algorithm hasn't been emphasized much
in the long history of mathematics education (Peng, 2004).
With the rapid development of modern information technology, the algorithm begins
to play a fundamental role in the development of science, technology and society, and
even penetrates into every aspects of life. Being considered as a kind of necessary
mathematics quality for modern people, the algorithmic idea is gradually emphasized
in educational circles, which arouses the interests of the related research from
mathematics education. The initial work can trace back to 1978, in which Engel
outlined the comprehensive topics of the mathematics curriculum at school from an
algorithmic standpoint (pp.255, 274). Similarly, Ziegenbalg argued that the concept
of algorithm belongs to one of those fundamental concepts of mathematics (pp. 239,
241).
At present, as the process of problem solving and mathematical application in the
authentic life are highlighted in modern mathematics teaching reform, the learning
and understanding of the algorithmic process is especially emphasized. It's promoted
about mathematics teaching reform in almost every country that the traditional way
of teaching algorithm should be changed to teach students to design their own 453
algorithms and to solve realistic problems through using the algorithmic ideas,
furthermore more, students should decide their own approaches and steps (Xu, 2001).
Although algorithmization is a distinctive feature of mathematics in ancient China
(Ma et al, 1991), the term algorithm hasn't been represented in the mathematical
textbooks for schools until 2003, when The Standards of Mathematics Curriculum for
the Senior High School was promulgated in China and the algorithm was represented
fully as one of the new contents for the first time. From it we can understand that the
research about algorithm is a new issue and the reason why there is not much work in
this field in China, except the research from the angles of cognitive psychology (Xu,
2003), curricular value (Li, 2004; Liu, 2003) and the significance of learning
algorithm (Li, 2004). In particular, the problems about which undoubtedly should
have the practical implications for mathematics education, such as how to design the
mathematics teaching according to students' real level, especially, how to integrate
the information technology into the algorithmic teaching, are topics worthy of
research while still are scarce.
In the following, an algorithmic teaching case in which the main classroom task is to
draw a pentagram based on LOGO software will be introduced in detail, and data
including observations, interviews and worksheets will also be collected, then indepth analysis will be shown with the conceptual framework of The Mathematics
Task Framework as the research tool. In the last, some beneficial implications about
the instructional design of algorithm will be discussed.
Conceptual framework
The framework that guided much of this study stems from work done in the
QUASAR project
67
. Based partly in the ideas and research of Stein and her
colleagues at QUASAR developed a framework that focuses on the cognitive demand
of mathematical tasks and the various phases tasks pass through in their instructional
use (Stein, Grover, & Henningsen, 1996; Stein and Smith, 1998). This framework is
depicted in Figure 1.

67
QUASAR (Quantitative Understanding: Amplifying Student Achievement and
Reasoning) was a multi-year teacher capacity-building initiative sponsored by the
Ford Foundation to change mathematics teaching practices at six middle schools
ended in 1995. 454
Figure 1: Mathematical Tasks Framework
In describing the framework, Stein, Grover, and Henningsen (1996) write:
"Instructional tasks are seen as passing through three phases: first, as curricular
materials; second, as set up by the teacher in the classroom; and third, as
implemented by students during the lesson" (p. 460). Certain cognitive demands are
inherent in the way that a mathematical task is written. For example, tasks that ask
students to memorize a fact or to perform an algorithm rotely encourage a certain
type of mathematical thinking. Tasks that ask students to look for patterns,
generalize, make connections, or think conceptually encourage a different kind of
thinking (Stein & Smith, 1998).
In my research, the Mathematical Tasks Framework guides of my data collection,
analysis, and reporting. It made sense to use this framework as a research tool
because I was particularly interested in understanding how the students perform their
classroom tasks pertaining to the ideas found in the Mathematical Tasks Framework.
While organizing the teaching case, I was guided by my use of the Mathematical
Tasks Framework in making decisions about what data to collect. These data could
have been analyzed in a way that I was guided by my use of the Mathematical Tasks
Framework in choosing "a coherent way of thinking about how to organize and
interpret the data" (Eisenhart, 1991, p. 204).
The mathematics teaching case
Task: drawing a pentagram
The content of drawing a pentagram is chosen from the colorful LOGO-figures
world, a subsection of a learning textbook, LOGO experiment, as a help of new
textbooks compiled according to The Standards of Mathematics Curriculum during
Compulsory Education. What should be mentioned is that although the case is taken
from junior high school, the results showed that it can realize the notion of The
Standards of Mathematics Curriculum for the Senior High School, so it's helpful not
only for the instructional design of algorithm in senior high school, but also for how
to develop algorithmic idea in junior high school.

Student
Learning 455
The students have learned some basic geometry knowledge, and they can use some
basic and simple LOGO orders to operate. Everyone has one computer in the wellfurnished computer laboratory, which is linked by local area network, through which
students and teacher can communicate freely.
Teaching process
Stage 1 Review (about 3 minutes)
The teacher guides students to review the LOGO orders, FD (FORWARD), BK
(BACKWARD), RT (RIGHT), LT (LEFT), which will be used in this lesson, through
the strategy of asking-answer way.
Stage 2 Learning the new LOGO order (about 10 minutes)
The students begin to learn the new order REPEAT, with the help of the teacher,
through drawing the triangle, quadrangle and pentagon. In this stage, students can
describe the complex recycling process and use the format:
REPEAT 3 [FD 60 RT 120]
REPEAT 4 [FD 60 RT 90]
REPEAT 5 [FD 60 RT 72]
Stage 3 Exploration of the experiment (about 27 minutes)
The teacher shows a model of a pentagram and encourages students to draw it
through computer.
As we all know that pentagram is a very popular geometry figure, it can be seen
everywhere, such as the Chinese National Flag.
Many students are very excited when the teacher asks them to draw a pentagram,
because they are familiar with it, and most of them have the experience of drawing a
pentagram in a paper-pencil way. But in the face of computer based on LOGO, they
feel out of place, for it's difficult for them without considerable mathematics
knowledge and the thinking way of precise expression.
The angle is the core of solving the algorithmic problem. Based on the knowledge of
measure of angle in the seventh grade, the teacher guides students to review the
conception of supplementary angles and adjacent angles, then tells them the
characteristics of the pentagram(for example, every angle is 36°)
Students devote themselves to draw right now, and some who are good at computer
can color the pentagrams.
The students find the following approaches to draw pentagrams: 456
Figure 2 Regular pentagram
Figure 3 Hollow pentagram
After discussion with students about the meaning of the data 5, 60, 144, 25, 72, the
teacher gives another approach of drawing.
Figure 4 Solid pentagram

Figure 5 Pentagon and pentagram
This practice provides an approach through connecting the diagonal of the pentagon,
especial and meaningful, which is a bridge of the pentagram and pentagon. It
motivates students to further understand the algorithm of drawing a pentagram, and

do prepare for the continuing learning of the pentagon in the future.
Discussion and conclusion
This lesson is designed from the aspect of how to explore algorithm and how to design various algorithm, aimed at developing and deepening students' algorithmic

idea through the experience of the algorithmic diversity. We'd like to analysis the obtained goal from the exploration of algorithm, algorithmic diversity and mistakes during the study of algorithm.
Students' exploration of algorithm
In this case, taking advantage of the characteristics of LOGO language, such as intuitive and easy-operate, the teacher guided students to explore the way of solving problem during the operation, to develop their own algorithmic ideas step by step and foster their ability to solve realistic problems (drawing a pentagram from many aspects) by using the algorithmic ideas.
Students can experience the algorithmic characteristics of finiteness, definiteness, input, output and effectiveness during drawing the pentagram, and deeply impressed with the input language of FD … and RT …. recycling language of REPEAT …
The following are their feeling and thoughts about exploration of the algorithm, which we got from the observation and interview in the classroom.
It's easier to understand the approaches of drawing a pentagram through computer, when we can think carefully as well as looking at the turtle moving (the order is operated by a turtle).
It's interesting to draw different colors and sizes of pentagrams (by using the order of color, students color red, yellow and blue for the pentagrams).
Programming is not a difficult thing (students can summarize the step of drawing a pentagram as a program, and then put different numerical data into the parameter, thus making the pentagram variable in size. In fact, it has realized the transition from mathematics language to procedure language).
The turtle can finish my demands well, for which I'm highly required that no mistakes would happen during the operation.
What the above mentioned show that with the guiding of the teacher in the teaching of algorithm, it's effective to arouse students' enthusiasm and develop their algorithmic ideas, while letting students take active part in exploring algorithm by themselves.
Students' various algorithms
There are six algorithms of drawing a pentagram developed by the students, which can be divided into two types of algorithms. According to the moving way of the turtle, the first type is based on the drawing through connecting the diagonal of the pentagram (there are two approaches, see figure 2), and the second type is based on the drawing through moving along the sides of the pentagram (there are four approaches, see figure 3).
Other two students used this approach: [FD 60 RT 144 FD 60 RT 144 FD 60 RT 144 FD 60 RT 144 FD 60 RT 144], which we call regular algorithm, for it don't need the order of REPEAT, only but FD and RT. It seems like the ordinary paper-pencil way, which can be finished step by step. 458
From 55 students' procedure records, we get 49.There are 18 students who used the first or second type of algorithm, and there are 4 students who used both (see Table 1).
Types of algorithm First Second First & Second Regular Wong
Numbers of student 18 18 4 2 7
Table 1: The types of the algorithms and the corresponding number of students
According to our interview, the students who used the first or the second were affected by the order of REPEAT taught by the teacher, because it can simple the repeated process. There are only 2 students who used the regular algorithm, and we know that they didn't catch the meaning of REPEAT, so they chose the way of step by step.
These results indicate that:
Teacher's action has highly active or negative effects on students' learning of algorithm;
The algorithmic structure of pentagram in students' mind and LOGO language can help students to express the algorithmic model;
Students' past mathematics knowledge and skills have effects on the subsequent learning of algorithm. The first type of algorithm is simpler in expression than the second and more difficult to get. While the results show the number in any of these two types are the same. It is recorded by the students that because of the transition of the ordinary paper-pencil drawing, they form the habit of connecting the vertex of pentagram to draw. As for the second, it is intuitional, although relatively complex in expression and easier to find for them.
Students' mistakes
There are 7 students whose algorithms are wrong, of course, they didn't get the pentagram on computer. There are some ordinary mistakes in their algorithms, for example, procedure of REPEAT 5 [FD 25 LT 144 FD 25 RT 72] is replaced by the procedure of REPEAT 5 [FD 25 RT 144 FD 25 LT 36]. The mistakes result from the failing to understand the mathematics basic knowledge. Some students know that every angle of the pentagram is 36
0
with the help of the teacher, so 144
0
of the
parameter of LT, rather than 36
0
, which can be learned only though computing
according to the theorem of the total of internal angles of a triangle. It shows that students haven't deeply understood the relationship between the angles. Further more, the angle of LF or RT is also important, which easy to be mistaken without a logic and precise thinking way. 459
From the above analysis, we can conclude that the students have obtained the expected goals and the teaching of algorithm is feasible and effective in the LOGO environment.
Implications for the instructional design
In this section, we'll look back some characteristics of the instructional design of algorithm in this case.
Roles of the teacher and students
The learning of algorithm is a kind of uncreative learning in the psychology. In this case, the teacher didn't indoctrinate the existing algorithm, but let students try themselves to draw a pentagram to experience the initiative of the algorithm through their constructive learning in the LOGO environment, thus transiting the learning of algorithm into a kind of creative learning. It's helpful to eliminating their fear and hate to mathematics and algorithm, also promote students to understand the constructive process of algorithm (P. Dowling & R. Noss, 1990). It's more interesting if students can create an algorithm, then it means that he or she has not only understood the algorithm, but also has known how to apply the algorithm to ordinary life.
So the role of the teacher is to create actively environment for students and to help them take part in exploring and constructing their own algorithm, rather than to teach the existing algorithm. Also, from the time of students' participation, total to 32 minutes, we can see that students are the dominant of the learning.
Task-directed to arouse the motivation
The motivation can arouse students' enthusiasm for learning, provide the direction and goal of learning. In this case, an interesting and familiar problem (drawing a pentagram) was given, catching students right now, and then resulted in requirement of recognition in the algorithm learning during the operation, thus the mathematics knowledge need to be taught and learned naturally. In the LOGO environment, the teacher can choose much more realistic problems, by using the strategies of taskdirected to guide the students.
Taking advantage of the LOGO network
LOGO is such a good mathematical environment that it can help students toward more intuitive mathematical strategies rather than avoid analytic and it together, also it's something of scaffold for the learning (C.Hoyles & R.Noss, 1992). Its good characteristics of friendly face, convenient language and simple operation, is easy to be learned and well liked by students. The most important is its open system that can allow students to create new orders, namely creating new algorithms. In the teaching of algorithm, we should make use of it. 460
On the other hand, everyone have a computer, which allows them to devote to the exploration of algorithm freely. Further more, through the monitoring system, the teacher can see everyone, and every student can ask for help from the teacher. Students can communicate their algorithms and cooperate with one another to share resources and make progress together.

This paper reports the results from a study with 10 to 12-year old students working on activities involving various functional representations (graphs, tables, and numerical relationships) in a motion phenomena simulation environment such Math Worlds. Results from the study suggest that pupils that have not been received formal instruction in algebra symbolism are able to evolve towards a better understanding of functional relationships, when working with a variety of representation systems. Duval's registers theory was used for activity design and data analysis. This study is part of a broader project entitled Enseñanza de las Matemáticas con Tecnología (EMAT) (Teaching Mathematics with Technology), which was developed by the Mexican ministry of education at the end of the 90s (Rojano, T., 2003).
Introduction
At the end of the 90s, Mexico's Secretariat of Public Education (SEP) together with the Latin American Institute of Educational Communication (ILCE) undertook the initiative of implementing an educational innovation and development project known as Teaching Physics and Mathematics with Technology (EFIT-EMAT). The principles listed below were the underpinnings of the project conception: a) Didactic principle through which classroom activities are designed following a phenomenological treatment of the concepts taught. b) Specialization principle through which tools and pieces of content software are chosen. The selection criteria were derived from the specific didactics of each subject (Physics and Mathematics). c) Cognitive principle through which tools are chosen that enable direct manipulation of mathematical objects and phenomenon models through executable representations. d) Empirical principle according to which tools proven in some educational system are chosen. e) Pedagogic principle through which ICT usage activities are designed in order for them to promote collaborative learning and interaction among students, as well as among teachers and students. f) Equity principle with which tools are chosen that enable secondary school students to have early access to powerful scientific and mathematical ideas.
Specifically EMAT (Teaching Mathematics with Technology) is a model that

contemplates use of a variety of technological pieces (specialized software and graphic calculators) each of which is very closely related to the specific didactics. In concrete terms usage of dynamic geometry software was included for topics of geometry; spreadsheets were included for teaching of algebra, arithmetic-algebraic

68 Part of the contents of this study was presented at the Twenty-sixth Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education (PME-NA) held in Toronto, Ontario, Canada. 463
problem solving, and probabilities topics; graphic calculators were included for introduction of algebraic syntax and problem solving; simulation software and software to represent movement phenomena were included to teach mathematics of variation. This article reports on the findings of a pilot study on the activities designed for work with mathematics of variation.
Background
There has been recently a growing interest on children's potential to learn algebra at early stages of their development. In some of these early algebra studies the possibility of teaching algebra to young students (7 to 8 year old) has been explored through problem solving activities that elicit the algebraic nature of arithmetic competency (Carraher et al, 1999 and 2000). Other approaches emphasize the role of young children drawings and representations in word problem solving processes as a basis to develop algebraic ideas (Dougherty and Zolliox, 2003). Smith and Davis (2001) say that the history of algebra may be used as a source of information about the possible difficulties faced by young students when they are introduced to algebraic thinking. L. Lee stresses out the idea of considering the relevant aspects of different methods used to teach algebra (as a language, a way of thinking, a tool, or generalized arithmetic) to encourage the learning of algebra (Lee, 2001). Every study, however, has reported the feasibility of introducing young students to the algebra domain either by using algebra symbolism or through other representations. The purpose of this study is to investigate the possibility of introducing fundamental algebraic ideas to students from elementary schools through the use of representation systems such as Cartesian graphics and numerical tables generated by a learning tool that includes a motion phenomena simulation environment.
Theoretical Framework
Theoretical references on representation devices are based on R. Duval (1999), who describes how semiotic registers provide an effective way to materialize knowledge and deal with mathematical objects. In this regard it is necessary to promote a kind of learning, where several representation devices are integrated and coordinated in such a way that the student does not mix up the mathematical object and its semiotic representation, and relates the mathematical object to several representations. R. Duval claimed that it is necessary to encourage three cognitive activities: 1) formation (create a representation to describe an object); 2) treatment (transform the representation into the device); and 3) conversion (transform the representation of a device into another).
Our research takes these elements as a basis for the development of a didactic strategy to design learning activities, which enable students to approach up algebraic concepts such as functional variation through the cognitive activities of treatment, conversion, and formation.
We must highlight the fact, however, that in certain situations students may or may not be aware of such cognitive activities; for example, when they create a functional table from position graphics (corresponding to a phenomenon of constant and 464 positive speed). This was possible because a software application (a simulator) was used as a mediation tool to create links between the students' algebraic knowledge and cognitive processes. The idea was to introduce 10 to 12-year old students, who had never received formal education on algebra, into the notion of functional relationships through the use of the SimCalc Math Worlds computing environment. Math Worlds provides animated worlds, where animations move according to changes in graphics. Graphics are represented through rectangles meaning speed: The height of a rectangle means "how fast", and the width means "how long". Position, speed, and acceleration graphs are dynamically linked. If there is a change in speed, the corresponding changes in the position or acceleration graphs are instantly displayed.
As for environmental usage, theoretical references are taken from J. Roschelle (1998) and J. Kaput (1998). Ideas such as functions, equations, and variables are used to promote the development of skills in the initiation of algebra.
In this paper we discuss the results from the students' analysis of position and speed graphics that help them gain a better understanding of dependence relationship between two variables, as well as to provide concepts such as "it goes faster" or "this is quicker" with a mathematical meaning.
As other studies based on a functional approach to algebra (Kieran et al, 1996; Nemirovsky, 1966; Heid, 1966), our study used the computing environment to design modeling activities that allowed students to explore quantitative changes in variables, and analyze how these changes modify functional representations.
Methodology
• 12 activities were designed to encourage the three cognitive operations of formation, treatment and conversion among registers (Duval, R. 1998, 1999).
• Such activities are used to promote i) the use of more than one representation register: a) interpreting position graphs, b) building up tables and position graphs, and c) interpreting speed graphs; ii) the notion of constant speed (functional relationship); and iii) problem solving in a motion phenomena simulation environment. This paper is focused on aspects i) and ii).
• A database consisting of: a) a diagnosis questionnaire on basic notions of physics (speed), pre-algebraic operations, arithmetic, and reading and gathering data from tables and graphs; b) structured guided interviews (A. Brown et al, 1998); c) students production from learning activities with Math Worlds (student records); d) videos from interviews; e) learning activities aimed to encourage the formation, treatment and conversion of registers to gain evidence on the students understanding of notions such as variable, functional relationship, speed, and others.
• The participants were 10 to 12-year old children from elementary schools, who had never received formal education on algebraic symbolic language, and were 465 selected from their answers to the diagnostic questionnaire. This paper reports on the results from the six-student group working with Math Worlds.
Diagnosis Questionnaire Results
Based on a diagnosis questionnaire, subjects were grouped in three levels, according to their arithmetic competency, register-handling abilities (data gathering from tables and graphs), and notion of constant speed. Levels I, II, and III vary from a substantial proficiency on arithmetic (Level I) to a limited competency (Level III).
Based on this questionnaire, six students (3 from 5
th
grade and 3 from 6
th
grade) were
chosen to participate in the study. They took part in 12 sessions, working with the computing environment on: a) the use of more than one representation system to interpret position graphs; build up position graphs and charts; interpret speed graphs; b) the notion of constant speed as a functional relationship; c) relating problems to motion phenomena.
In the middle and at the end of each session sequence individual interviews were carried out with all six students to analyze the strategies they use to interpret different representations as they went on solving the proposed activities. This paper discusses the results related to a) and b).
10-year old Students working with SimCalc.
All three students required the use of simulations along the learning activities to verify their answers, complete tables or build up graphs. Only the Level I student (Erick) built up continuous graphs from the first activity, compared to the other two students, who did it in a discrete way, by running the simulation step-by-step or making operations to identify the next section on the graph. In addition, Level III student (Rodrigo) found out in the last two activities that he could build up the position graph continuously by knowing the total distance and duration of a path, as shown in the following table:
The two students from levels II and III seemed to focus their attention on the use of graphs to calculate speed, while Erick showed at first some reluctance to use tables to identify speed when requested to do so, but once convinced, he worked on the table to identify the required information and calculate the answer.
Toward the notion of speed (10-year old children)
Level I (Erick).
Math Worlds incorporates motion of various characters, such as frogs or lifts (according to the World chosen). From the first sessions he shows to deal with a notion of speed involving both variables, and providing explanations such as "the frog moves forward four meters every second, and the clown two meters." After becoming familiar with the simulator, his explanations were "the frog moves forward twice as fast as the clown", or "it moves three times faster than the green lift." As his identification of the variables improves, his answers to the notion of speed include elements such as "Frog 2 moves forward three meters per second, and frog 1 one and a half meter per second." 466
In the middle of the activity sequence, Erick is requested to give a definition of speed. His answer, "speed is what it runs in one second," could be considered as focusing his attention on one of the variables. At the end of the sequence he was requested again to provide a new explanation of speed. This time he uses a specific example, but after a few questions he comes out with a more general notion pointing out both variables:
Er: It is… it moves forward one point five meters (the character's speed in the simulation);
E: And speed involves… what?;
Er: Seconds and distance.
Level II (Ana Karen)
At the beginning of the session she provided explanations such as "The frog's steps are four meters long," or "The clown's steps are two meters long." After comparing the speed of some characters she expressed the following: "The truck goes faster, and the car slower." After moving on through the activities, Ana managed to include a little more information: "The slower clown moves five meters, and the faster clown moves eight meters."
In the middle of the sequence her definition of speed is "the number of kilometers a car or anything else moves forward." At this point she also perceived the possibility of using distance and time to calculate the speed from the information contained in the position graph. By the end of the sequence she employed a particular situation to explain the notion of speed, taking into consideration the time and distance variables, but on a particular example:
E: How would you explain speed?;
Ak: Speed is the distance and time a car travels;
E: How do you read speed?;
Ak: If we take meters and seconds, then it will be 81 meters per second.
Level III (Rodrigo)
His first explanations about motion took into account the physical features of characters, with definitions such as "The clown is small, and that is why his legs go slower," or "The tires of the truck are bigger, and that is why it goes faster." After completing the first activities he included in his explanations elements related to the characters movement, such as "the red one moves slow, and the green one moves fast," until he finally takes into consideration both variables: "It advances one third every second," or "the red one goes up two floors every second."
When first asked about his notion of speed, his answer was "every lift goes up a number of floors per second," making use of an example to generate an explanation. Once the activities sequence was concluded, his notion of speed evolved to include both variables, distance and time, making it easier for him to calculate speeds from a position graph, but avoiding any oral explanation:
Ro: Then we looked at the graph; 467
E: And what did we notice there?;
Ro: The hours (he writes his answer: "We looked at the graphic, and paid attention to the hours and kms");
E: Ok. Now, how would you explain speed to your schoolmates?;
Ro: I don't remember (he could not provide an explanation).
11 to 12-year old Students working with SimCalc.
On both ends of the table, Level I student (Eduardo), and Level III student (Rafael) draw graphs step by step, and it was not until the last activities that they started on building up continuous graphs, using as reference the total distance and period. With this information they didn't have to make any further calculations to identify every portion of the graph. On the other hand, Level II student (Clara) drew continuous graphs from the beginning, when she was asked to build up a register.
As for the verification process, all three levels repeatedly used simulation to get data and match their results. In those situations where the environment didn't provide directly the required information, they made calculations using pencil and paper, an electronic calculator or mentally. For the final activities the use of the simulator in all three cases was restricted to the analysis of situations rather than to getting information to give an answer.
As for the preference on the kind of representations, only Clara (Level II) showed a clear disposition to use graphs rather than tables to get information. Eduardo and Rafael used indistinctively data from graphs and tables to make calculations, solve problems, and answer questions.
Toward the notion of speed (11 and 12-year old children)
Level I (Eduardo)
From the beginning he took into consideration the two variables to build up the notion of speed, with answers such as "Because the frog went over more meters in a second than the clown," or "Clown 1 goes six meters in one second, and clown 2 goes eight meters." These answers were consistent along the sequence. When he was asked to give a definition of speed, he said:
E: How would you explain to your schoolmates what speed is?;
Ed: Through distance and time. You can say that it represents how fast two people or two objects go.
Together with the comments above, he recognizes the need to divide distance by time to calculate speed either from a table or a graph: "We can see how far did he go, and the time, and all that."
Level II (Clara)

Her first explanations about the movement of characters indicate her focus on the physical conditions of the phenomena: "It runs more and gets first", or "It walks slower". After the third activity, she includes other elements such as distance and time: "The second frog, because it runs more meters per second." 468
For her first explanation of speed, she uses a specific example: "The number of floors per second it climbs, the distance it travels per hour." Once the sequence is complete, she takes into consideration the variables involved in her notion of speed, even if she requires a specific example:
E: How would you explain to your schoolmates the concept of speed?;
Cl: The distance traveled every second.
We may consider her definition of speed after completing the sequence as an evolution from a very intuitive and inconsistent notion of speed at the beginning of the study.
Level III (Rafael)
At the beginning of the sessions, his explanations were: "it goes farther than the frog", or "it goes two by two and is slower." His answers indicate that he takes into consideration one variable. From the third activity, however, he includes in his explanations both variables as follows: "it goes only a few meters in many seconds," and "the red one, because every second it climbs three floors."
His first definition of speed indicates the relationship between the distance and time variables: "the distance traveled in a period of time." This may suggest that he is adjusting his notion of speed, since he also recognizes the need to identify distance and time in order to calculate speed:
E: What elements should be taken into consideration to calculate speed?;
Ra: Floors and seconds.
In spite of recognizing both variables in the notion of speed, his defective use of the division produces false explanations, as the following:
E: And now what did you do to calculate speed?;
Ra: A division;
E: What did you divide?;
Ra: Hours and meters.
This was a continuous obstacle throughout Rafael's work, and it could not be overcome.
Results
After working with the activities designed for Math Worlds, the participants showed an improvement on their understanding of motion phenomena and on the dependence relationship between variables. There was, however, a differentiated use of the representational means available in the computing environment, according to children's level of arithmetic competency (identified in the pre-questionnaire). In addition, it was observed that whereas some children during all the sessions required the simulation to analyze the dependence between variables, others were able to focus their analyses on mathematical representations (Cartesian graphs and function tables). These children in turn succeeded in building up a quantitative notion of constant speed. For example, in the final session Erick (11 years old) described his notion of 469 speed as "the frog moves forward four meters every second, and the clown two meters" (referring to the characters in the simulation environment). When he was asked about his conception of "speed", he said: "Speed is what it runs in one second."
Final Comment
Results from this study suggest that students at a pre-symbolic stage (pupils that have not received formal instruction in algebra symbolism) are able to evolve towards a better understanding of functional relationships, making use of a variety of representation systems (including simulations) to analyze different aspects of motion phenomena. Duval´s registers theory was not only used at the activity design stage, but also helped us to define an analysis framework that enables feasible explanations of the way children make use of representational systems when solving problems in a computing environment.

Mathematics Revisited and Reinvigorated
Jim Ridgway, James Nicholson and Sean McCusker
School of Education, University of Durham
Jim.Ridgway@durham.ac.uk, j.r.nicholson@durham.ac.uk
Despite enormous changes in technology over the past twenty years, and numerous changes in the UK curriculum, and elsewhere, the content of school mathematics remains very recognisably the same, notwithstanding dramatic changes in the world's modus operandi and the need for citizens to deploy a far wider range of mathematical skills than before..
We identify areas where changes in the curriculum could usefully reflect changing uses of mathematics and address some of the negative perceptions of mathematics as boring, irrelevant and inaccessible; and develop this in the context of our current work on reasoning from evidence.
Reasoning from multivariate evidence is pervasive in political speeches and in the media, but is largely absent in UK schools. Currently, we do not prepare young people adequately to understand important social debates, decision-making under uncertainty in a business environment, nor to make informed decisions about their personal well-being.
Two strands of work will be described. The first presents evidence that students can work effectively with multivariate data if they are supported appropriately with good computer interfaces. Second, current work with teachers of mathematics, citizenship, and geography on curriculum materials to develop skills in reasoning from evidence will be reported.
Introduction
There are various perspectives from which the rationale for studying maths in the 21 st
Century may be considered: there is a utilitarian aspect, but there are also cultural and aesthetic aspects. The report Mathematical Skills in the Workplace (Hoyles, Wolf, Molyneaux-Hodgson and Kent, 2002) offered many insights into what mathematics is used routinely. Some of the aspects listed on page 5 of the report would be recognisable components of the current curriculum but there are substantial areas which would not: what is used nowadays in the world of work is quite different from 'traditional maths' and the curriculum should shift in response to this. Much of this shift relates to the pervasive nature of the use of ICT in the workplace - many activities which employ mathematical skills involve the use of some form of technology, and could often be described generically as modelling, but the researchers found that often those involved in these activities would not describe what they did as mathematical in any sense. This relates strongly to the cultural aspects of the curriculum: we need to break the cycle of "I can't do Maths" and "I hated Maths at school" which seems to exist across much of society - where it is seen as acceptable to admit to being innumerate: indeed, it is almost a badge of honour to many people who take pride in other achievements. Many fewer people would admit 472 to similar sentiments about illiteracy. Understanding the process of modelling is a prerequisite to critical engagement with many aspects of modern society.
For the report by Hoyles et al. a number of case studies were undertaken, and the type of activities with any mathematical component were recorded. A high proportion of these were related in some way to handling data: these could be at very different levels of sophistication - recording, summarising, reporting, interpreting, and analysing data are an integral part of many processes, and making decisions based on the data and its interpretation can be critical to the success of any business. More generally, the skills related to handling data can be viewed as a part of modelling, and it is in this area that we see the main imperatives for change, with ICT playing an integral role.
Modelling, and fitting parameters in models, is conceptually accessible at school level, and can now be done reasonably [and in realistic contexts] using ICT. Technology allows multiple variables to be investigated in complex data: if students leave school without ever working with more realistic levels of complexity they will find it very hard to make the transition later in their cognitive development. Contexts such as biomathematics, psychology, business studies, geography and citizenship offer a vast array of examples where mathematics plays an integral part which have been largely ignored by the subject itself. Technology offers the opportunity to develop short digital video descriptions of applications of mathematics in such areas which could be used by teachers to motivate the study of certain topics.
It is generally accepted that mathematics has a poor 'image' with the majority of students: it is viewed as hard in many cases, but also as irrelevant and boring. We argue that we should consider the inclusion of areas which are made accessible now by the use of technology to handle the complex processing required, and which are of widespread use in technology today, and that such changes would improve the perception of mathematics, and increase its accessibility at the same time. Areas include: matrices, vectors, calculus and geometry in 3D, curve sketching, large samples in statistics and multivariate data, of which we will say more later.
Mathematics recently has concentrated too much on small scale activities: largely this has been driven by the structure of assessment, and the justification seems to be in terms of ensuring reliability. However, the effect of this is that the whole is less than the sum of the parts, and the validity of the assessment of mathematics is questionable: the abilities to solve problems, to apply simple techniques in new contexts, to combine reasoning and techniques from different areas of the curriculum, and to critically evaluate arguments and data presented in context are parts of mathematics which have been devalued.
Statistics within the mathematics curriculum - the place of reasoning from evidence
Many branches of mathematics have been invented in response to real-world problems. Probability theory and statistics provide vivid examples. In the case of statistics, the early development of theory and technique were constrained by the 473 absence of computer power. For calculations to be tractable, strong assumptions were made, and a somewhat bizarre process of 'hypothesis testing' was invented. This has had a regrettable legacy: if a curriculum were to be devised from scratch the light of current statistical knowledge, it would not be dominated by univariate parameterized distributions and linear bivariate models. It would include bootstrapping methods, nonlinear regression and multiple regression models, all of which are computationally intensive but conceptually accessible. It might include time series modelling with simple autocorrelations, to introduce the concept of feedback loops.
Very large data sets are now available to schools for analysis. Here, almost any way of partitioning the data set is likely to reveal statistically significant differences, which will not necessarily have any practical or conceptual importance: that is, analysis will often show very small 'effect sizes' with no real world 'significance'. Schield (2005) observes that while chance (random error) dominates in small sized, well-designed experiments, bias (systematic error) can dominate in poorly designed studies regardless of size, and confounding (the influence of a lurking variable) dominates in populations or large-scale, well-designed observational studies.
Many other subjects depend implicitly, if not always explicitly at the school level, on reasoning from evidence. While we believe that the core responsibility for teaching and learning statistics lies within the mathematics curriculum, it is vitally important that statistics is not seen as a set of abstract mathematical techniques (Nicholson, Ridgway &McCusker, 2006). There is already pressure on curriculum time, and there are demands for greater fluency in other important areas of mathematics such as algebra, so something has to give. We believe there is scope for substantially reducing the amount of time spent on repetitive, routine tasks such as calculations of summary statistics and graph drawing, which are now automated in virtually every working environment, and replacing it in mathematics by the core skills of reasoning with complex data, supported by the co-ordinated use of those skills in other subjects to encourage transferability. This should make the mathematics curriculum more

relevant and also create some extra time within mathematics to improve other key activities such as algebra, while not reducing the total amount of time students spend on working with data in the curriculum.
In UK schools, we teach the statistical techniques of the 1920s, and (on rather rare occasions where the curriculum extends beyond the practice of technique) choose contexts to which this restricted set of methods can be applied. Reasoning from evidence is a central theme that runs through all empirically based subjects, yet is dealt with very badly in mathematics. It is not simply the case that students are exposed to an impoverished curriculum; we will argue that it is actually a pedagogy that trivialises mathematics, and disempowers students, with unfortunate consequences for public debate on important social issues. Students are not equipped to deal with the world outside the classroom, either to engage meaningfully in political debates on topics such as climate change, poverty, health, and crime, or to make informed decisions about their own lives that depend on understanding 474 multidimensional data - such as their health, career choices, or finances. The second unfortunate consequence is more parochial, and concerns the locus and influence of mathematics within the curriculum. Mathematical thinking should be at the heart of the educational process, not confined within a curriculum box.
Here, we present evidence that young students can reason effectively with multivariate data if supported appropriately with ICT. This offers the prospect of a radical, mathematical based, reform of the whole curriculum. Reasoning from evidence has a number of features that generalise across domains and mathematics, and the community of mathematics educators are ideally positioned to provide an integrated framework to develop generalisable skills associated with reasoning from evidence in students. There are at least three major challenges to be faced. First is the nature of the evidence itself. Much of the data in the public domain is presented in indigestible ways - for example, extensive tables of data in a printed form. Second is the current mathematics curriculum. Statistics, when it is taught within mathematics, focuses on the mastery of a narrow range of statistical techniques that are ill-suited to understanding complex problems. Third is our understanding of the nature of the development of reasoning from evidence. Here, we explore some key ideas that underpin the modelling of complex situations, and identify some components which are accessible to young students.
If reasoning from evidence is to become a key focus in the new curriculum, we need to be convinced that students can actually engage in reasoning from evidence, and we need accounts of the qualitative stages in the development of reasoning from evidence. The latter will be an essential guide for the design of curriculum, pedagogy, and assessment.
Paradoxically, a generic approach that emphasises universal principles in reasoning from evidence is likely to provide a firm foundation for modelling global and regional data, to the benefit of local, regional, and national communities. If educational systems are to help students reason effectively from evidence, then accounts of stages, progress, and pedagogy are essential.
Ridgway, Nicholson, and McCusker (in press) present an analysis of a speech by David Blunkett, then Home Secretary, on the social problems apparent in multiethnic communities, and the actions that politicians might take to alleviate these problems. The paper set out to establish some of the theories about modelling complex phenomena implicit in the speech of a thoughtful politician. A number of principles were identified, including the following ones:
• Every complex problem has a number of components, which are influenced by a variety of factors. Effects occur over a range of time scales, and at different magnitudes;
• Models of change need feedback loops;
• Correlation is not the same as causality. Possible moderator variables need to be considered. 475
Citizens need to understand these principles if they are to engage effectively in political debates and if they are to understand arguments and evidence in the media. If students are to become responsible citizens, they need to be exposed to these ideas in the curriculum. This implies (at least) that their experiences should include:
• Exposure to multivariate problems:
- Exposure to non-linear relationships between variables;
- Working with time lags between causes and effects;
- Seeing different effect sizes;
• Analysis of possible causal links between variables, and an understanding of moderator variables;
• Linking data analysis to the situations from which the data were derived;
• Speculation about possible courses of actions beyond the ones considered.
Such changes may well be uncomfortable for many teachers of mathematics, who are attracted by the certainties that pure mathematics can provide (because of the tautological nature of results that derive from reasoning from premises, and manipulating systems of rules). In mathematics past attempts to use ICT to support mathematical modelling at the school level have been seriously flawed. They have emphasised the teaching of mathematical formalisms that have been applied successfully in particular domains (such as Newtonian mechanics), but have failed to address the process of modelling seriously - either in terms of its philosophical underpinnings, or in terms of appropriate pedagogy.
Digital technologies can make a number of important contributions to mathematics, to pedagogic practice and (we believe) to cognitive development, student empowerment, and richer public debate on important social issues. Here, we will:
• Demonstrate the paucity of the statistics curriculum in the UK;
• Describe some of the key ideas that should be core elements in any attempt to model non-trivial phenomena;
• Show some of our interfaces for presenting multivariate data (extending to 5 variables);
• Provide empirical evidence that students can, indeed, reason effectively about multivariate data where relationships are non-linear;
• Show our early explorations of a hierarchy of 'reasoning from evidence'.
Two strands of work will be described. The first presents evidence that students can work effectively with multivariate data when they are supported appropriately with good computer interfaces. A study will be described where 195 students aged 12 to 15 years were presented with computer based tasks that require reasoning with multivariate data, together with paper based tasks from a well established scale of statistical literacy. All the tasks fitted well onto a single Rasch scale; computer tasks were cognitively more complex, but were ranked as being only slightly more difficult than paper tasks on the Rasch scale. Current work developing measures of students' 476 ability to 'reason from evidence' will be described. Several distinct levels of reasoning are evident in student responses, associated with comprehending; manipulating; and drawing conclusions. Competence ranges from working with single values, one step computation, and elementary reasoning, through to fluency using a variety of representations, fluency with number, and in synthesising evidence and communicating results clearly. We will show examples of computer-based tasks, student work, the Rasch scale, and will describe the development of a short unidimensional scale.
Second, current work with teachers of mathematics, citizenship, and geography will be reported. Here, we are creating curriculum materials designed to develop an understanding of complex issues in the curriculum, and reasoning from evidence in general. Examples of the use of complex survey data on sexually transmitted diseases, which students explore using powerful interfaces, will be shown to illustrate our approach.
Implications for assessment, the curriculum, and public presentations of complex evidence will be discussed.

On the role and aim of digital technologies for mathematical learning: experiences and reflections derived from the implementation of computational technologies in Mexican mathematics classrooms
Sonia Ursini & Ana Isabel Sacristán, Cinvestav, Mexico
soniaul2002@yahoo.com.mx, asacrist@cinvestav.mx
In this paper we reflect, based on the Mexican experience of massive implementation of digital technologies in "real-world" mathematics classrooms, on the role and aim of these tools for mathematical learning. The experience in our country has yielded inconsistent results and the main aim of improved mathematical learning appears to not have been achieved. There have been some positive results (e.g. students' better attitudes and increase of enthusiasm, of motivation, of class participation; the possibility of formulating and proving conjectures and of analysing particular cases that can lead to generalizations) but many factors not present in laboratory settings come into play (from teachers' abilities to administrative difficulties), when attempting a massive implementation such as this one, "out in the real world". Furthermore, the experience has led us to readdress certain questions: a) What is it that students are learning when using new technological tools?; b) What kind of mathematics skills are they actually developing; c) What mathematics do we actually want students to learn with these technologies?; d) Can we put together the learning that does or can take place with the use of these tools, with the learning of what we usually consider as formal basic mathematical knowledge?
For decades, many research studies have investigated the various possibilities that new technologies could offer for improving the teaching and learning of mathematics at different levels (e.g. Balacheff & Kaput, 1996; Hoyles & Sutherland, 1989; Dettori et al., 2001; Mariotti, 2005). These have implied that there are certain ways of using technology that can help students in their learning of mathematics. For example, (although it is not our purpose in this paper to synthesize all the available findings) among the possible results are that:
• Technological tools may offer students a means: to learn to formulate and test hypotheses; to create and experiment with mathematic models; to work within different representational registers; to develop problem-solving abilities (all of which can lead to a better understanding of mathematical concepts).
• Technology can also provide immediate (non-personal) feedback that allows students to discover their mistakes, analyse them and correct them; in this way, errors become a means to assist learning.
• The tendency to work on routine problems in an algorithmic way decreases, while students can focus more on problem-solving activities. Thus, with technology, school mathematics can cease to be a simple mechanisation of procedures and instead become a space for reflection and development of concepts. 478
These encouraging results, derived from serious research in different parts of the world, in experimental settings of various carefully designed computational environments, seemed to be enough guarantee to insure that an adequate use of technology for assisting the teaching of mathematics, could produce satisfactory results and help improve students learning, in a large-scale implementation. As we will discuss in this paper, the step from laboratory setting to a large-scale implementation is far from being straightforward.
On the other hand, the positive results from the use of technological tools in experimental settings have led, first, to an over generalisation of their possible benefits that has spawn campaigns

promoting the use of digital technologies in classrooms without consideration of the pedagogical design, akin to what happened to the Logo programming language when Papert's (1980) Mindstorms book came out and many schools took up Logo without taking into account what to do with it.
Second, and perhaps more worryingly, now there seems to be a tendency of replacing formal mathematics with tool-based approaches that seek to make mathematics more accessible, but where the real mathematics is hidden from the user and thus may only develop a superficial mathematics understanding. In the following sections, we begin by recapitulating the Mexican experience of large-scale implementations of digital technologies in classroom, and end with a reflection on the results, difficulties and a more general concern of the tendencies for the use of those technologies in schools.
The Mexican experience
In Mexico, since the 1980's, the Mathematics Education community has been developing research on the use of computational and other new technologies in education and the Mexican government has tried to address this issue. In 1989, a government initiative called MicroSep shipped specially-built computers to schools, pre-loaded with different tutorials, Basic, Logo, etc. The problem was that it was a very naïve initiative: no training was given to teachers and it was an era when teachers feared computers enormously, both in how to use them but also in that the machine would eventually replace the human teacher. The outcome of the MicroSep experience was that most computers remained unused and the project was a failure (with the consequence that some of the software that came with the machines was also considered a failure, such as Logo). In the subsequent years, there were smaller initiatives to introduce computers to schools, all without much success.
In 1997, the Mexican Ministry of Education began sponsoring a, still-ongoing today, national project called EMAT (Teaching Mathematics with Technology), that has been led by a group of researchers in Mathematics Education, and which aimed at incorporating computational technologies to the mathematical curriculum of secondary schools (children aged 12 to 15 years old). Specifically, the EMAT project aims at promoting the use of new technologies using a constructionist approach to

Currently, in Mexico, there is a large government-sponsored campaign, that includes many advertisements in radio and television, claiming that computers (without any reference to the way they are used) improve children's learning. 479
enrich and improve the current teaching and learning of mathematics. A study carried out in Mexico and England (Rojano et al., 1996) involving mathematical practices in the Science classes, revealed that in Mexico few students are able to close the gap between the formal treatment of the curricular topics and their possible applications. This suggested that it is necessary to replace or complement the traditional formal approach, with a "bottom-up" approach capable of fostering the students' explorative,

manipulative and communication skills. Some of the fundamental ideas characterising the project, as described in the official documents (Ursini & Rojano, 2000), are the following:
• A use of computer software or technological tools (e.g. calculators) that
a) makes it possible to deal with mathematical concepts in a phenomenological way;
b) provides objects or representations of (mathematical) objects that can be directly manipulated;
c) is related with a specific area of school mathematics (arithmetic, algebra, geometry, probability, etc.)
• Specializes the users of the technology (teachers and students) in one or more pieces of software and/or tools so they become proficient in its use and are able to apply it for the teaching and learning of specific curricular topics.
• Puts into practice a collaborative model of learning: students work in pairs with one computer, thus promoting discussions and the exchange of ideas.
• Incorporates a pedagogical model where the teacher's role is that of promoting the exchange of ideas and collective discussion; at the same time, acting as mediator between the students and the technological tools (the computational environment), aiding the students in their work with the class activities and sharing with them the same expressive medium (tool).
The first phase of the EMAT project began in 1997 with a pilot phase during which the technology-based educational models were put to trial in secondary schools using relevant results from previous computer-based educational studies carried out in different countries. The project was designed with utmost care drawing from the expertise of the international and national scientific advisors, and was set up in stages so that adequate assessment and corrections in the implementation could be made before massive expansion. The stages of the project were also meant to allow for an adequate training of human resources, which is perhaps where the most emphasis in the development of the project should be placed. Nearly 90 teachers and 10000 students at the secondary school level participated in the project in the first three years. Since 2000, hundreds of schools across the country have incorporated the EMAT materials into their programmes, and we have discovered that many more are doing so in an unofficial way. Recently, a curriculum reform aims to officially incorporate technological tools into math and science education. 480
A main criterion for the choice of the software and tools used in the project (Ursini & Rojano, 2000) was to have open tools; that is, where the user can be in control and has the power of deciding how to use the software. This allows for the construction of learning environments where students are able to decide on how to proceed, as opposed to other types of computer software that direct the student and the activity. These open tools have to be flexible enough so that they can be used with different didactical objectives, such as those of the activities designed for the project. The technological tools and software used during the pilot phase were Spreadsheets (Excel), Cabri-Géomètre, SimcCalc-MathWorlds, Stella, the TI-92 algebraic calculator, and the Logo programming language, all aiming at covering curricular topics such as arithmetic, pre-algebra, algebra, geometry, variation and modelling. For each tool, activities and worksheets were developed by national experts, in collaboration with external international advisors. The calculators and the spreadsheets, and later the Logo programming activities, were easily incorporated. Cabri-Géomètre has also been well received, despite some difficulties due in part to the lack of preparation of teachers in the area of Geometry as well as licence problems. These tools have continued to be incorporated in the expansion phase of the project, but Simcalc and Stella were dropped because it was hard to fit these tools into the curriculum without more teacher-training that was hard to achieve due to administrative reasons.
Some results from the EMAT project and the problem of large-scale implementations
The pilot phase of EMAT, despite some difficulties had a positive impact (see Sacristán & Ursini, 2001). That phase was groundbreaking in changing the role of the teacher and the traditional passive attitude of children. It created an irreversible change allowing for technologies to be incorporated into the Mexican school culture, hopefully in an adequate way.
On the other hand, what became apparent since that pilot phase is that factors not present in laboratory settings come into play, when implementing a project such as this one, "out in the real world". The more outstanding issues have been: lack of adequate mathematical preparation on the part of the teachers; lack of experience working with technology by both teachers and students; difficulties in adapting to the proposed pedagogical model; teachers' lack of free time to prepare anything outside the established curriculum (all of these factors have contributed in making the activities much more directed than originally planned); lack of adequate follow-up teacher training and support because of administrative issues; many other bureaucratic difficulties; and lack of communication between the different levels of authorities.
Since the year 2001, we have tried to assess through different studies whether there have been improvements in the mathematical learning of the children using the technological tools. We have not been too surprised to find inconsistent results. One study (Sacristán, 2005), has correlated students' results in multiple-choice 481 mathematics tests, with teachers' performance (e.g. understanding and employ of the proposed pedagogical model and of the materials) as well as teachers' attitudes towards the technological tools. Putting it bluntly, "good teachers" achieve good results: they are able to take advantage of the technological tools and their students benefit from those experiences; but less experienced, poorly trained teachers, or simply teachers who dislike the technological tools, do not do so well. In the EMAT proposed pedagogical model, the role of the teacher is considered very important, as it is she/he who has the job of making students aware of the mathematics they are exploring with the tools (otherwise the knowledge constructed remains "situated" within the technological context); as Clements (2002, p.165) put it: "children do not appreciate the mathematics in Logo [or technology-based] work unless teachers help them see the work mathematically"; but one thing is the theory and another the practice…
By and large – from several studies that have used mathematics tests to compare EMAT students (i.e. students who are using computational tools) with non-EMAT students— the tested large populations of students who have been using the technology-based tools have NOT shown much benefit, if any, from that use, some groups even do slightly worse (Ursini et al., 2005).
We are aware that many factors come into play: not only the teacher's role, but also the amount of use of the tools (which we have detected is also very inconsistent), and most likely, many other factors; on the other hand, the benefit of the use of the tools is perhaps not so much in the development of specific knowledge-content but in the development of mathematical abilities that the instruments used in the studies described above do not measure.
But the crux of the problem is this: the EMAT programme was designed to improve the learning of curriculum-based mathematics. Yet, in curriculum mathematics tests, the use of the tools doesn't show benefits when the populations tested are part of large-scale implementations were many factors are beyond the control of the Project designers or main instructors. This leads us to ask ourselves the following questions, some of which we discuss in the next section: a) What is it that children are learning when using these tools?; b) What kind of mathematics skills are they actually developing; c) What mathematics do we actually want children to learn with these technologies?; d) Can we put together the learning that does or can take place with the use of the technological tools, with the learning of what we usually consider as classic basic mathematics?
We must, however, also give the positive results of the EMAT experience. In general, the use of the computational tools has had a very strong positive impact on children's attitudes towards mathematics. A study developed with 24 teachers and 1113 students (Ursini et al., 2004) shows that there is a clear increase in their enthusiasm and motivation; and although the impact is different for girls and for boys, the behavioral changes observed seem to lead to more gender equity. 482
Another positive results is the changes in classroom dynamics that have modified the traditionally passive attitudes of children and empowered them, giving them a status almost equal (and sometimes even higher than the teacher) when involved in mathematical explorations with the tools.
What is it all about? Some reflections and words of warning
We would like here to go a bit beyond the EMAT experience and reflect on some of the questions we posed before, as well as raise others:
First, what mathematics do we actually want children to learn with these technologies? If we want children to learn classical school mathematics, it is not so straightforward because, as some evidence shows, it doesn't always work. The failure could be attributed to an approach of simply adding technology to teach the same mathematics; but projects such as EMAT have tried NOT to do that, but to actually introduce technology as a means to explore mathematical ideas and concepts and enrich the current curriculum. But they still don't work. If we want something else from the use of the technological tools, then that is what needs to be made explicit and evaluated. Introducing technologies to enrich an actual curriculum "out in the real world", no matter how well thought out the implementation may be, is perhaps a contradiction. The use of new technologies seems to require making fundamental changes in the theoretical and pedagogical conception of the curricular structure and contents.
What is it that children are actually learning when using these new technological tools?
Outside experimental approaches, there are hardly any large-scale implementation studies or even theoretical research approaches for doing so (in great part due to the difficulties in evaluating such massive results of the kind of new knowledge that is being generated) that can give us data on what students actually learn in technologyassisted environments. In Mexico, we are attempting to do this kind of large-scale research for the EMAT programme, as discussed earlier in this paper. Some of the initial results that we can report can be useful but also depend on many factors. First, we can say that what is learned is extremely dependent on the specific technological tool being used, how the implementation is conceived, the mathematical knowledge of the teacher and his/her ability to link and make explicit the knowledge developed and situated within the technological environment, and formal mathematics. Nevertheless, we do know that the use of technological tools does develop motivation, a more positive attitude towards mathematics, an increase in student participation, in student abilities to defend their ideas; that the technology-based environments allow students to generate and test conjectures and to go from the particular to the general.
Therefore, if what students are learning is to develop certain abilities, then the use and implementation of the technological tools should not be conceived as an aid to improve current mathematics learning, but simply to develop those abilities that 483 underlie mathematical knowledge. In fact, that is what a tool like the (classic) Logo programming language does.
But, where are we going?
We would like to address several tendencies in the use and implementations of digital technologies for mathematics education that worry us. First, there is the idea that with technological tools, mathematics can be made more accessible through "new infrastructures" for the great majority. For example, there is a tendency to present students to representations of (often advanced) mathematical ideas, sometimes called by many "microworlds" – though contradicting Papert's vision of that term (since in this case the user doesn't create: s/he only explores)— but that we would simply call 'models' or 'interactive software structures' (such as applets or other closed structures over more open platforms). This tendency is further encouraged as officials and educators try to accommodate to the fast changing pace of technologies. The aim of these structures is for students to explore ideas that may be too difficult for them if presented in purely mathematical terms; the problem is that more and more often the actual mathematical concepts that create those models are not transparent or open for the user to see. While these tools may be useful for building intuitions, it is very questionable as to what actual mathematical knowledge students can derive or understand. Thus, while we may be thinking that we are making hard mathematics accessible to all, what we may really be doing is training people to use tools blindly while the mathematical design is not accessible. Even in EMAT, that had as theoretical guideline the use of open tools for students to create and explore, we find many activities that follow the above tendency. The problem with the above tendency is: who will finally benefit from this? It seems to us that deeper formal mathematics knowledge is in jeopardy of being reserved for a small elite. Some would argue that a new mathematical paradigm, based on the new infrastructures, may emerge; but even in that case we are in danger of creating elites of those with access to the technological tools and leaving out large sectors of the population that do not have access to those tools.
Related to the use of these models or structures, we are also worried about the tendency to rely only on the "point-and-click" method and the use of icons. Fifteen years ago, many in the mathematics education community called for the incorporation of more visual elements into mathematics teaching to complement the dominating algebraic/symbolic approach of mathematics, and researched how the use of digital tools could help in this endeavour. Today, some of us are worried that the use of symbolic and algebraic expressions is taking a back step in favour of easier, but perhaps less formal, forms of expression. The main question rises again: what will be the consequences of doing this and who will finally benefit from it?
Finally, another tendency is to want to use "state-of-the-art" technological tools: always the latest, fastest, most advanced, etc… This doesn't allow for creating a stable use of a technology; furthermore research of any particular technology thus soon becomes obsolete, so with this tendency, whatever is being used is relatively 484 untested (except perhaps for general implementation philosophies). True, we should acknowledge and research new tools, but this shouldn't imply abandoning technologies that have proven to have the potential to be beneficial.
So, why are we actually teaching mathematics and what happens to formal mathematics?
New technologies should always serve the learning and teaching of mathematics and not the other way around. Let us not forget that there is some basic mathematical knowledge that children should still learn. After all, mathematics is part of culture and not only a tool for solving problems. We thus would warn against loosing sight that what we want is for students to learn mathematics and not just that kind of implicit mathematics that may remain situated within a technological context. What, of course would be ideal is to make a use of the technologies that could allow to make the formal mathematics (e.g. algebra) accessible for all. Is this possible? How

should we use the technology to reach this goal?
What Seymour Papert and his colleagues had in mind when they developed the Logo programming language, had this potential as there was an emphasis on symbolic descriptions that were truly mathematical. We would like to end by reflecting on this valuable tool.
Logo has probably been researched perhaps more than any other and proven its benefits under appropriate conditions. Yet, we believe the potential of this tool was never adequately developed and now, sadly, in many places, particularly in the Western world, Logo has been abandoned because it is considered old or even obsolete, and has been replaced by other tools. But what Logo provides is not as easily found in other tools: to begin with it provides an invaluable tool for symbolic expression and for symbolically describing geometric figures. The benefits of Logo are well-known and it is not our intent to review them here. What we do want to claim, is that Logo – even when we refer to what we call "classic Logo" and not second generation Logo-based environments – is far from obsolete and is still an invaluable tool. Classic Logo activities were incorporated in the fourth year of the EMAT project. Most students who have used Logo in EMAT, claim it is their favourite tool; furthermore, there are instances where the use of the other tools has been enriched by the Logo experience: children demand a different use of Spreadsheets or Cabri, where they feel they can program these tools, like they do in Logo; they begin using the tools more according to their own needs and projects, rather than simply following preset activities. All of this from a tool that many consider outdated. The purpose of this reflection on Logo is a call to attention to look back on the valuable pedagogical lessons that we learned from that tool and that we can still learn, in particular in terms of a use of technologies that fosters the development of true mathematical knowledge.
Summary
We have attempted, in this paper, to reflect, based on the Mexican experience of massive implementation of digital technologies in "real-world" mathematics 485 classrooms, on the role and aim of technological tools for mathematical learning. The experience in our country has yielded inconsistent results leading to the necessity of making a deeper reflection of some questions. We have considered some of these here, but our main aim is to provoke reflection for further discussion during the study conference.

Assessment within computer algebra rich learning environments
Christopher J Sangwin
School of Mathematics, University of Birmingham, B15 2TT, UK
C.J.Sangwin@bham.ac.uk
This paper considers the design of learning environments and curricular, with a particular focus on automatic assessment. Mainstream computer algebra systems (CAS) are currently being used to support assessment, particularly in higher education. For example, the CAS can establish the algebraic equivalence of the student's and teacher's answers. This application of CAS is quite different from the traditional use, which is to model in an exploratory manner rather advanced mathematical ideas. While mainstream CAS have been used successfully for this application for the last five years, this paper examines the affordances and constraints of using CAS in this way. By using CAS-supported assessment it is possible to use open-ended questions which are traditionally difficult to assess, but which the educational literature suggests can be pedagogically valuable. In assessing an answer to such a question the CAS is used to establish various mathematical properties of the student's response. To focus this paper we concentrate exclusively on the assessment function, while bearing in mind the place of assessment in learning cycles and online learning environments.
Introduction
Mathematically rich computer based learning environments are increasingly being used at all levels of mathematics learning to support various functions in the learning cycle. It is the design of learning environments and curricular, with a particular focus on learning and assessing mathematics with and through technologies which is the issue addressed here. This paper is a discussion of some affordances and constraints of using computer algebra systems (CAS) to underpin such assessment. This a relatively novel use of CAS, an understanding of which is important given the crucial place of assessment in any learning cycle, and its role as the primary driver of many student's learning.
As an illustration, consider the situation in which a student enters his or her response to a mathematical question into a computer aided assessment (CAA) sub-system of a learning environment. The CAA system then uses a CAS to subtract the student's response from the teacher's response and to simplify the resulting expression algebraically. If the result is zero an algebraic equivalence between the student's answer and the teacher's answer has been established. Note the important pedagogic principle being implemented: the CAA system evaluates the student's answer which contains mathematical content, rather a selection from a list of teacher provided answers, such as in multiple choice or multiple response questions. A mathematical property of the student's answer has been established, with algebraic equivalence as 488 the prototype. Appropriate action, such as providing feedback, assigning a mark and storing these outcomes in a database, can then be taken.
To focus this paper we concentrate exclusively on the assessment function, but keep firmly in mind the place of assessment in the learning cycle and as an integral part of a coherently designed online learning environment.
Approaches
Roles of different digital technology
Until around 2000, the use to which CAS had been put in the learning and teaching of mathematics was "almost exclusively [...] to model in an exploratory manner rather advanced mathematical ideas", (Hoyles and Lagrange, 2005). However, during the last five years a community of practice has developed for automatic assessment of mathematics which makes significant use of CAS for the following.
1. Random generation of structured problems, (see Section 2.2)
2. generation of feedback,
3. to establish mathematical properties of the student's answer.
One of the most commonly cited advantages of CAA is the ability to generate feedback almost instantly. A CAS can be used to manipulate the answer of the student, and calculations based upon this can be incorporated into this feedback. For example, if a student makes an incorrect attempt at an integration problem, feedback of the following type might be given.
The derivative of your answer should be equal to the function which you were asked to integrate. However, the derivative of your answer with respect to x is ..., so you must have done something wrong!
Here, the ... is automatically replaced by the derivative of the student's answer, and such feedback encourages the student to check the result for themselves by differentiating. The ability to do this requires CAS tools within the assessment system.
The third function CAS enables within a CAA system is establishing a range of mathematical properties of a student's response. Algebraic equivalence with a correct answer is the prototype property, however algebraic equivalence with expressions arising from a range of mistakes common to the particular question can also be established. In this case feedback can be given, all of which may take place in the context of random question versions.
There are many other properties which we might look for in a student's answer, including whether an expression is factored, "simplified" or perhaps a solution to a given equation. In establishing these properties a CAS manipulates a student's expression, and as a further illustration, we consider how a CAS might establish if a student has found the general solution to a differential equation such as
y''(t) - 9y'(t) + 18y(t) = 0. (1) 489
First the CAS substitutes the response of the student into the left hand side of the equation and simplifies, which includes performing the differentiation of the student's expression where necessary. If the result of this calculation is zero, the property of primary importance has been established: the student's answer satisfies the differential equation. Other tests can be devised to ensure the expression is a general solution. In particular, that the answer consists of the superposition of two linearly independent solutions, and the presence of general constants, can be established. However, the choice of which letters used to express the general constants can be at the discretion of the student. The CAA system does not use a CAS to simply establish the algebraic equivalence of the student's answer with an expression such as
Ae
3t
+Be
6t
.
While solving (1) is a relatively standard problem, the use of a CAS allows the teacher to set and assess questions which would require significant computation to establish the required properties, or have non-unique or complex solutions. We examine such questions in more detail in Section 2.2 below.
The first system to make CAS a central feature was the AIM system (Klai et al. 2000). This system operates using Maple, as does the Wallis system of Mavrikis and Maciocia, (2003), and Maple's own proprietary MapleTA. Other systems have access to a different CAS, such as CalMath which uses Mathematica, CABLE, (Naismith and Sangwin, 2004), which uses Axiom and the STACK system (Sangwin and Grove, 2006), of the author, which uses the CAS Maxima, see www.stack.bham.ac.uk. Private correspondence indicates that Derive is being used in a similar way.
A common feature of these systems is their use of an existing CAS. There are significant differences between CAS implementations, which have been discussed elsewhere, for example Grabmeir et al., (2003), or Wester, (1999). These and other comparisons are from the point of view of the research mathematician or student essentially using CAS as a "super calculator". The functionality required for the application of CAA is quite different. We give concrete mathematical examples to illustrate some of the issues involved.
The problem of recognizing that an expression entered by a student is factorized (over some field), is significantly more subtle than comparing the student's expression with the result of applying the CAS's "factor" command to the teacher's answer. For example, a CAA system may have to respond to any of the following expressions
(x-3)
2
, (3-x)
2
, (x-3)(x-3), (3-x)(3-x), 9(1-x/3)
2
.
Only the first of these is returned by the "factor" command, while the others could all be argued to be correct factored forms. Similar problems occur with other syntactic forms, such as partial fractions. To be useful as part of a CAA system, functions which establish properties, either syntactic or semantic, are needed. 490
The reader might consider all the different senses in which the word "simplify" is used in an average textbook on elementary algebra. Often "simplify" seems to be a synonym for "do what I have just shown you". Two different examples occurs with what Nicaud et al., (2004) terms sorted and reduced form, when a polynomial is represented as x
2
+2x+1 rather than x+1+x+x
2
. If a CAA system is to provide useful

feedback to students it must be capable of distinguishing between expressions which are not fully simplified in various senses, and respond. However, such functions are usually not present in a CAS designed for computation and subsequent automatic simplification to canonical forms. Indeed, most CAS perform automatic simplifications which cause technical problems for CAA, and do not currently provide the level of fine grained control necessary for this application at the most elementary levels. Despite the fact that CAS-supported CAA is now commonly used in higher education, specifying the characteristics required of a CAS for CAA is a substantial project which has yet to be undertaken. It will require close collaboration between mathematics educators, research mathematicians and computer scientists. This is an important issue in the design of learning environments.
It should be noted that a CAS is not required for the three functions described in this section. Indeed, there are very many examples of highly mathematical CAA and computer based learning systems which accept and respond to student's answers without using a CAS. However, the authors of such CAA systems often replicate libraries of CAS-like functions, which represent and manipulate mathematical expressions. Hence, while they do not make use of a recognized mainstream CAS we would argue that they are in fact implementing computer algebra in its broadest sense. Examples of such systems are the CALM system of Ashton et al., (2005), the Aplusix system of Nicaud et al., (2004) and the Metric system of Ramsden, (2004). The issues raised here are just as relevant to these, and similar, systems.
Contribution to learning
Mathematically rich CAS functions are ideally suited to generating random versions of a particular problem within carefully structured question spaces. Worked solutions, with various steps, can similarly be constructed from templates. Such problems can be used for repeated practice or to reduce plagiarism. Indeed, so far CAS supported CAA has predominantly been used to provide traditional practice of routine techniques. Since the systems cited above originated in higher education they have also seen application to questions from linear algebra, vector calculus and differential equations.
It might be argued that since the CAS can perform simplifications and other calculations, the student should not be required to do so fluently themselves. Even if fluency in the actual calculations is not necessary, basic competence will always be and so practicing routine manipulations will remain a valid application.
However, by harnessing CAA within a learning cycle group work can be encouraged to aid understanding of a topic, with each student evidencing their own learning by completing their unique set of tasks. Often no one cares about the actual answer 491 itself, and the numbers used in a typical mathematics questions are themselves unimportant. Hence, the ability to randomly generate questions within constrained variation may be used to help students perceive the structure of the problem underlying that which their version represents. This embeds the assessment into the learning cycle, ensuring it is integral to the experience of the student.
Given that CAS enabled CAA establishes properties, rather then simply checks for "the correct answer", more open-ended questions can be set and assessed. As an example, consider the following question. "Give an example of a function with a stationary point at x=1." To assess this, the CAS differentiates the student's answer with respect to x, substitutes x=1 simplifies. Hence there is an infinite family of correct responses and as one student commented, in an anonymous feedback questionnaire to a course taught by the author, after answering this question using the AIM CAA system:
Recognising [...] the functions produced in question 2 was impressive, as there are a lot of functions [...] and it would be difficult to simply input all possibilities to be recognised as answers.
More than one property can be requested, such as the following.
Give an example of a function with a stationary point at x=1 and which is continuous but not differentiable at x=0.
The CAS functions are used to establish whether the student's answer (eg |x|(x-2)) has each of the required properties.
In questions such as this the student must decide what properties are required, and then construct a mathematical object, such as a function, which satisfies them. The cognitive processes required are quite different from following or repeating a routine procedure given by the teacher. The pedagogic potential for this style of question is well documented in the educational literature, for example Watson and Mason, (2002) or Michener, (1978). The work of Dahlberg and Housman, (1997), suggests that it "might be beneficial to introduce students to new concepts by having them generate their own examples or having them decide whether teacher-provided candidates are examples or non-examples, before providing students examples and explanations".
Such questions are usually absent from contemporary teaching, probably because of the practical constraints of time under which teachers operate. Using CAS-enabled CAA to assess such questions is considered in, for example, Sangwin, (2005). Considering how CAS-enabled CAA supports learning in this way is an important issue of curriculum design, and of learning environment design to support this.
Role of the teacher
Using CAA forces the teacher to consider the properties required of an answer, and describe carefully what outcomes should result in advance of the assessment being set. For example, how should the system respond if a student enters 0.5 as part of an 492 expression? While this is five tenths, ie 1/2, the use of floating point numbers is often discouraged. Conversely, if a student approximates a rational number using a floating point number, such as 0.3333 for 1/3 the CAA system will not establish algebraic equivalence even if the student is essentially correct. Hence, it is no longer sufficient for a teacher to be able to recognize a correct or worthy response when a student provides one. They have to consider carefully the various possibilities and be able articulate what they require in CAA terms. The issues of how teachers author CAA materials in this new context is addressed in Sangwin and Grove, (2006), which argues that teachers are themselves "neglected learners".
The open ended problems described in Section 2.2 require a different classroom approach from the teacher. Work of the Standards Unit in the United Kingdom has piloted very similar activities with students using personal white boards, and sets of cards containing mathematical expressions. The freedom of expression which very open ended questions affords students requires the teacher to think on their feet when responding to students. While the CAA system can help with computations to establish properties, the explanations for various outcomes will still be given by the teacher.
When using CAA a teacher risks becoming detached from their students. Marking written work by hand, while immensely time consuming, gives an insight to a particular group of students' learning which CAA cannot currently replicate.
Impact on mathematics
Novel forms of assessment should be subject to close scrutiny from the mathematics community. However, this should be a comparison of the new with the strengths and weaknesses of traditional methods of assessment. Assessment drives learning, and any novel assessments will hence affect what is learned and how this learning takes place. Given the central role of assessment, the perception of what constitutes mathematics is likely to be altered by new assessment regimes. This is not the place to engage in epistemic argument about the nature of mathematics, other to acknowledge that we send out strong messages about what we, as a community, value by what we assess.
Detailed inspection by the author of high stakes public examinations in the United Kingdom, indicates that much of what is currently actually assessed are routine tasks rather than open-ended problems and these can be automated by CAS supported CAA. However, it is hard to envisage how such systems would ever be used to assess method or the quality of the type of argument one might expect in a proof. Hence, it is imperative that the community establish what is really valued in the mathematical work of students before adopting CAA to simply replace existing paper-based work.
In CAS supported CAA the student interacts with the system, both to enter a response which contains mathematical content, and to read mathematical expressions on the computer screen. Hence, one specific area where CAA is likely to have an impact on mathematics is in the area of notation and symbolism. When used as a sophisticated 493 calculator, all existing CAS allow a linear syntax for expression entry. Here a user has the ability to edit their input, look up the syntax in the online help and possibly experiment. In computer aided assessment the stakes are higher: the user is being evaluated on their input. By implication this evaluation mixes their ability to express themselves using the correct linear syntax and their ability to actually solve the problem in hand. The work of Ramsden and Sangwin, (2005) details significant variations between CAS as to what symbols mean. The inconsistencies between linear syntaxes have implications for CAA, particularly if used in high stakes assessments. Other methods, such as an "equation editor" or pen-based character recognition, are also in use for CAA, however they also suffer from many of the same fundamental problems.
Conclusion
It appears likely that automatic assessment will become increasingly important at various points in learning and teaching. To make such assessment mathematically rich it is necessary that these include a CAS, or CAS-like functionality. In doing this we can automate the assessment of pedagogically valid and rich questions which are traditionally impractical. This application is rather different from the traditional use of CAS as a "super calculator". This is an existing and rapidly expanding field but one in which many challenges, both pedagogic and technical, remain.

Students' Development of Mathematical Practices Based on the Use of Computational Technologies
Manuel Santos-Trigo & Luis Moreno-Armella,
Center for Research and Advanced Studies, Cinvestav, México
msantos@cinvestav.mx, lmorenoa@prodigy.net.mx
We document and discuss themes and aspects of mathematical practice that appear relevant during the development and implementation of activities associated with a research project whose aim is to analyze students ways of reasoning that emerge in problem solving classes that promote the use of diverse computational tools. In particular, we focus on identifying (i) the types of questions and conjectures, including arguments to support them, that students exhibit as a result of using dynamic software, (ii) the students' construction of mathematical relationships that come out from examining dynamic geometric configurations that are formed by simple mathematical objects, and (iii) the curriculum changes that we need to think of in order to validate and promote mathematical practices that favor the use of digital technologies.
The availability of computational tools to represent and explore mathematical ideas has influenced notably the ways to generate or develop mathematical knowledge. In this context, the formulation of questions or problems, the problematique, and mathematical practices, including methods, used to investigate those questions are shaped and mediated by the use of those tools (Moreno & Santos, submitted). In school mathematics, the use of Computer Algebra Systems (CAS) or dynamic geometry software has increased the awareness for students to develop numeric, symbolic and geometric sense during the study of the discipline. Thus, it becomes important to document and contrast features and mathematical processes shown by students that emerge in problem solving environments that enhance the use of technology.
Professional worlds as well as society at large have a pragmatic relationships with computational tools: their legitimacy is mainly linked to their efficiency…The educational legitimacy of tools for mathematical work has thus both epistemic and pragmatic sources: tools must be helpful for producing results but their use must also support and promote mathematical learning and understanding (Artigue, 2005, p. 232).
What type of reasoning do students develop as a result of using distinct digital tools in their mathematical learning experiences? What type of mathematical representations of problems or mathematical objects do students construct during the

process of understanding mathematical ideas or solving mathematical problems?
How do students and teachers participate or interact during the learning and the development of instructional activities in educational scenarios that promote the use of technology? These are relevant questions that guide the development of an ongoing research project that aims at documenting the type of mathematical competences that students develop when they systematically use dynamic software, 496 Excel and algebraic calculators during their problem solving approaches. This project also aims at understanding how mathematical concepts and objects are transformed as they are given a new life through the use of digital tools.
The project began two years ago and we have worked directly with high school teachers who have been implementing series of mathematical tasks in their regular mathematical classes. Fundamental principles that helped structure and frame the project involve: (i) the recognition that students need to think of their mathematical learning as a problem solving activity in which contents, problems or phenomena are seen as dilemmas that need to be examined, explained, and solved in terms of formulating and pursuing questions or inquiry methods (Schoenfeld, 1994); (ii) the importance for students to think of distinct ways to represent, explore or solve mathematics problems. That is students need to develop distinct modes of thought and habits that reflect the proper use of mathematical resources and strategies (Cuoco, 1998); (iii) The relevance for students to use various computational tools to represent mathematical objects in order to identify, explore, and support mathematical conjectures or relationships. Here, we argue that different tools offer students different opportunities and ways to think of a problem or situation and as a consequence, it is important for them to use several tools to develop diverse problem solving approaches to solving those problems (Santos, et. al, in press).
At this stage, we have collected data regarding the process of designing the tasks that help student think and reason mathematically, ways in which the tasks were implemented within instructional scenarios favoring students' development of mathematical ideas, all with the mediation of digital technologies. Based on the analysis of the gathered data, some preliminary results have begun to emerge and we would like to focus on relevant aspects related to:
(i)The type of conjectures and arguments that students propose as a result of representing the problems dynamically using dynamic geometry software.
(ii)The process of using simple objects (segments, lines, triangles, perpendicular bisector, etc.) to ensemble a geometric configuration that becomes a platform to pose and pursue question that lead students to reconstruct or develop series of mathematical results or relationships.
(iii)The contents and curriculum transformations that seem relevant to make explicit when the use of the new mathematical instruments become relevant in mathematical instruction. As Hoyles and Noss (2003, p. 325), stated "…exploiting the real power of technology requires such innovative approaches, that comparison to a traditional class is inappropriate".
To elaborate on each of the above themes, we have chosen examples that illustrate students' ways of reasoning or thinking of mathematical problems that have emerged while using digital tools during their mathematical problem-solving experiences.

1. Formulation of Conjectures and their validation. 497
With the use of dynamic software, students can construct executable representations of mathematical objects and problems that reflect changes or invariants in different contexts. Thus, in general, students tend to construct dynamic representations of problems that lead them to quantify attributes (lengths of segments, perimeters, angles, areas, etc.) and observe their behaviors or loci as a result of dragging particular elements within that representation. Students also tend to examine the viability and pertinence of a particular conjecture in terms of using the software to (i) identify the conjecture visually and dynamically, (ii) examine whether the conjecture includes a structural relationship (dragging test), (iii) construct a macro that crystallizes the construction and verify whether the conjecture is held in objects generated by the macro, (iv) quantify and verify properties of mathematical objects to detect patterns, and (v) present formal arguments to prove the emerging conjecture.
An example illustrates the way students deal with a conjecture.
The problem: Cross's Theorem:
Squares are drawn on the three sides
of a triangle. Show that the areas of
the four shaded triangles are the
same (figure 1) (Faux, 2004). Fig.1: Are the triangles' shaded
areas the same?
Students represented the problem dynamically and provided distinct arguments to support it. They also had opportunity to examine a related conjecture: What about if we draw rectangles instead of squares on each side of the given triangle, how are the shaded areas? While representing dynamically figure in this question, students noticed that they could draw many rectangles taken as the base one side on the given triangle and as a consequence it was difficult to trace the area behavior of the shaded triangles. How can we relate the construction of all rectangles? Discussing this question led them to assume that the corresponding sides of the rectangles should share the same proportion. They decided for
EC

proportional sides
The software became a powerful tool to explore both the plausibility of the conjecture and the search for ways to validate it. We illustrate the ways students dealt with this conjecture: 498
Visuo-perceptual Recognition.
An important feature while using dynamic software is that mathematical figures can be drawn accurately. Students drew triangle ABC and the corresponding rectangles (with the same constant of proportionality among their sides) and concluded that the area of triangles CEF, AGH, and BDI were the same. The initial (perceptual) conjecture is supported with the corresponding areas calculation (figure 3).
Fig. 3: Visual recognition of a relationship in triangles CEF, AGH, and BDI
The Dragging Test.
Here students explored the validity of the conjecture for a family of triangles. They dragged the position of the vertices of the given triangle ABC to generate a family of triangles with the same construction, perceiving a structural relationship. They observed that when one vertex is moved, the family of triangles generated held that the area of triangles CEF, AGH, and BDI was the same (figure 4).

Fig. 4: Verifying the conjecture for different positions of triangle ABC
Constructing a Macro.
Another way to explore and eventually verify the conjecture was that students built a macro to reproduce the construction for any given triangle. That is, students identified initial objects (triangle ABC and ratio R of rectangle sides) and final objects triangles CEF, AGH, and BDI. This procedure adds a formal status to the involved figures while trying to validate the conjecture. Applying the macro to different triangles, students confirmed the conjecture, that is, they verified that triangles CEF, AGH, and BDI all have the same area.
Quantifying attributes and Patterns.
In addition to observing the behavior of the triangles areas, students focused on comparing (ratios of) areas of triangle CEF and triangle ABC for distinct values of

for different values of r.
Formal Analytic Proof. To prove both conjectures, students followed different approaches that were discussed within the whole class. Here, we present an analytic proof that was constructed during the class discussion. The idea is to construct a triangle with one vertex on the origin of the Cartesian system and other on the X-axis and the third a point on the first quadrant. That is, the vertices of the triangle will be A (0, 0), B (c, 0) and C (a, b) as is shown in figure 5.
Fig. 5: Identifying coordinates of vertices of the given triangle
What is the area of triangles AGH, BID, CEF and ABC? Given the coordinates of the vertices of those triangles, students recalled that the area of each triangle will be:

Area('ABC ") r
Comments
There is evidence that the use of dynamic representations of the problems and the treatment of mathematical objects that students showed with the mediation of the software became an experience-enhancing platform to identify and explore mathematical relationships. The easiness to quantify mathematical attributes and the exploration of visual representations of problems were fundamental activities that permeated the students' process of formulation of conjectures. To assess the validity 500 of the conjecture, students relied on using the tool to explore particular cases visually, to examine family of cases by dragging particular elements within the representation (perceptually discovering structural relationships), to construct a macro to also examine a family of cases (a higher level of formalization), and to observe patterns that emerge as a result of exploring invariance in the behavior of particular data (recognition of a mathematical object). In this context, the use of an analytical method to prove the conjecture came out only as a way to confirm the validity of the conjecture.
A core idea is that the processes of formalization and abstraction are not best served - from a didactical viewpoint- when we conceive of abstraction as an extraction process. It might be better to view it as an additive process (Noss&Hoyles, 1996) in which it is important to connect, in terms of mathematical properties and meaning, distinct representations of the problem, including those generated with the use of the software. Thus, these representations are seemed as abstraction domains from which to build mathematical objects and relationships. Here is where the full power of the "dragging exploration," for instance, is revealed. In this process, students think deeper: situating mathematical results within a digital environment and generating new mathematical explorations. As a result of this activity, new conceptualizations of mathematical objects will emerge and will be important to frame mathematical practices in classrooms.
Construction of Relationships
Another type of activities that students explored with the use of dynamic software is the construction of geometric configuration by using simple mathematical objects. For example, in one of the problem-solving session, a student constructed a dynamic configuration that involves perpendicular lines. That is, line L2 is perpendicular to line L1; line L3 is perpendicular to L2 and line L4 is perpendicular to line L1 (figure 6).

Later, he drew the perpendicular bisector of segment QR that intersects lines L1, L4 and L3 at S, T, and U respectively (Figure 7). 501
Here, the student moved objects within the representation and observed path or invariants left by other objects. When he moved point P along line L1, the path left by point S appears in figure 8

U
S
S
Fig. 8: What is the locus of point S when point P is moved along line L1?
At this stage, the student's goal was to provide an argument to show that the locus actually represents a parabola. It is easy to show that point Q is the focus and L3 is the directrix of this parabola. This became an interesting scenario to discuss the classical definition of conics. Thus the dynamic environment mediates the construction of the definitions and concepts.
Comments
An important feature in constructing geometric configurations is that students do not have initially a well-established problem to be solved; rather they rely on simple objects (line, points, segments, perpendiculars) to build a platform for identifying and exploring mathematical relationships. In this case, it is observed that by moving a point along a line, a particular path left by other point can be visually identified as a parabola. However, it becomes important to provide an argument to actually show that the locus corresponds to that conic. Students used distinct arguments to explain and "prove" that, in this case, the locus was a parabola. They include verifying empirically, using the software, the definition of parabola and other geometric arguments. Dragging objects, observing behaviors, formulating conjectures, presenting arguments and communicating results seem to be important activities that students can practice systematically with the help of dynamic software in order to detect and explore mathematical properties. Mathematical objects are, now, evolving objects that students constantly explore in terms of using more refined and robust resources and strategies.
Curriculum Transformations
The use of digital tools seems to offer students the possibility of formulating and exploring mathematical conjectures from diverse perspectives. In this context, rather than thinking of a sequence of themes or contents to be included in a curriculum proposal, what it seems relevant is to structure the curriculum in terms of fundamental mathematical ideas and concepts dynamically conceived for students to solve problems and use in further studies. Thus, students need to develop mathematical resources, strategies and ways of thinking that are necessary to comprehend and apply mathematical ideas. It is evident and clear that as part of the scaffolding process to conceive of a technology oriented-curriculum, a new way to conceptualize mathematical objects and their study is needed. For instance, as formalization is relative to the medium in which it takes place, there is a need to 502 reflect on the new ways students have to prove mathematical assertions in the classroom. Take for instance, the Hilbert space-filling curve:

To prove it along classical lines can be an intricate task, but what happens when one turns the result into a digital one? For instance, to argue in favor of the validity of the theorem, we can translate it: given a (screen) resolution, there is a step in the recursive process that generates the curve, that fills that screen. This is a way to empower students in order for them to have access to deep results properly translated. As Schoenfeld (1994, p.76) stated, "proof is not a thing separable from mathematics…is an essential component of doing, communicating and recording mathematics", nevertheless the use of new digital media requires a fresh approach to this important mathematical and curricular topic. It is central for a new and needed epistemology.

Using visual microworlds in teaching mathematics
of computation in primary and secondary schools
Alexei SemenovMoscow
alsemenov@mtu-net.ru
The most rapidly growing branch of mathematics is mathematics of computation. Today it deals with modern information processing as well as with human reasoning and formal acting. Comparatively slow it appears in secondary school curricula. It is not evident that computers can effectively support learning in this field, but it happened that many key topics of it have been visualised (structural programming, parallel processing, interpretation of logical formulas, etc). The visualisation is of two kinds: 'one-to-one', where all objects and processes of mathematical reality are represented on a computer screen, with the only limitations being the object's size and process time, and 'specialized', where specific objects and processes are

represented, but this is enough to form general skills of students applicable for all problems of the topic. The major challenge here can be summarized in one word: 'integration'.
Changes in mathematics and changes in civilisation
Over the last century (starting in 1870s and even before) the content and methods of mathematics changed dramatically. One of the most important areas of these changes was connected with mathematical investigations of human thinking and acting. The first summit of the events was achieved in 1930-s in Gödel's completeness and incompleteness theorems and Church's thesis. Naturally, the primary results were on mathematical thinking (formal mathematical reasoning) and mathematical acting (execution of formal mathematical algorithms). They constituted, respectively interconnected branches of mathematical logic and theory of algorithms.
In the following 30 years many results of mathematical logic and theory of algorithms were implemented in hardware and software of the rapidly developing information industry. In 1930s it was hard to predict development of integration circuits, but the "coincidence" in time of ICT and the preceding mathematical events are astonishing. The precedence of mathematics appeared further. For example, the major concepts of structural programming (constructions, invariants, inductive proofs) were fully developed and used for rigorous proof of correctness of a compiler by Andrei Markov (Jr.) in the framework of his theory of algorithms based on string processing.
In the next years on the one hand the field of mathematics of computation based on mentioned mathematical logic and theory of algorithms became perhaps the most massive and rapid development. On the other hand computers became a powerful tool of visualisation and became personal.
We can say that machines of material and energy processing were implementations of continuous mathematics, as well as many processes in nature. Computers are 504 today implementations of discrete mathematics, as well as processes of human thinking and formal behaviour. We believe that these dramatic changes in mathematics and in the world should be resembled in education. As was indicated by many people and considered in details by Don Knuth, rigorous thinking on algorithms is mathematical and concerns abstract mathematical objects and methods of reasoning constitute a special type of mathematical thinking - the algorithmic one. There should be a shift from training how to execute routine algorithms that are much better executed by machines now to learning, on the one hand how to use these machines, and on the other hand, the mathematical basement for these machines' construction, operation and using.
The content of mathematics of computation on the secondary level
We believe that the major achievements of mathematics of computation constitute today an important part of the general culture. As an example we quote here the Russian standards for general school education (1-11) approved in 2004 with minor changes for standards that are in the process of development now.
General notions
Systems constituted by acting elements, states of elements, signals. Control, feedback, stability. Information, information objects of different types (symbols, numbers, sounds, images). Universality of discrete (digital, in particular, binary) presentation of information, accuracy of presentation. Quantity of information. Compression of information.
Process of information transmission, information transmitter and receiver, coding and decoding, distortion of information in the process of transmission, transmission speed.
Storing, transmitting, processing of information in social, biological, and technical systems. Information perception, memorising, processing and transmitting by living organisms and humans. Value of information.
Language as medium of presentation for information: natural and artificial languages, semantics. Formalisation of description and simulation of real objects and processes. Formalisation of problem. Computer simulation.
Mathematical concepts and their applications
Transforming of information by formal rules. Algorithms. Different ways to describe algorithms, flow-charts. Logical values, operations and expressions. Constructing algorithms using names, branching, cycles. Top-down analysis of a problem, using sub-algorithms. Objects of algorithmic processes: strings of symbols, binary numbers, lists, trees, graphs. Algorithms (the following list is flexible): Euclid's, conversion from binary to digital and vice versa, examples of sorting, search (for a winning strategy in the tree of a game).
Computable functions, formalization of the notion of computable function, its completeness. Complexity of computation. Complexity of information object. 505
Non-existence of algorithms. The problem of exhaustive search (P-NPproblem).
The quoted approach was a cornerstone in building up Russian curriculum on computer science and technology in the mid-1980s. The mathematics of computation was originally presented there as a non-computer activity. So, the course was introduced in all schools of the Soviet Union and was criticised for "teaching to ride a bicycle without a bicycle". That was evidently correct in the aspect of computer technology but was not so true in the aspect of development of algorithmic thinking. A little bit later a set of microworlds (see 'Visualisation' below) was developed for 8-bit, 32K or 64K memory computers.
Can computers help?
The content given previously can be changed in different traditions cultural and technological surroundings. At the same time, the core essence of this content is invariant and associated with the concepts of discrete objects and discrete processes. The very natural idea of computer application in learning and teaching the field of mathematics is that computers can represent any discrete object and discrete process. So, if a specific process deals, for example with numbers, the numbers can be stored and transformed by a computer. So, we can compare the result of implementation of our algorithm in the computer with our intention and verify our design. But the most important reason for using computers in learning mathematics of computation is visualisation.
Visualisation
Visualisation is considered as one of the most powerful processes in mathematical discovery and mathematical education. There is a long discussion on different styles of mathematical thinking, but in any style there is a space for visual presentation of objects and processes.
So, the background idea of visualisation in learning mathematics of computation is to find such specific environments, or micro-worlds, rich enough to present important features of algorithmic processes and algorithmic constructions.
The Turtle
One of the first and the most famous microworlds is the microworld of Turtle. The Turtle lives on a plane - a finite part of an infinite plane, or the same assembled as a torus, or a potentially infinite plane. The Turtle can act - move forward to a given distance and turn on a given angle. This environment today is extended to different directions and has different applications in primary and secondary education:
• A creative environment for children's self-expression and development through making texts, pictures, and animations;
• An environment for learning concepts of mathematics such as angle, polygon, approximation of a circle by a polygon, probability, etc. 506
• An environment, where a child can control the Turtle (primarily in its moves in the plane on the computer screen). The control can be direct and immediate: 'command - action' or, on the later stages, programming it.
The programming is done in Logo language. The language was originally developed by mathematicians and AI researchers from a military oriented company, BBN, and Seymour Papert, who joined them. Seymour's inspiration made the Logo community the strongest one in the field of advanced approaches of using computers in schools. Logo became associated with the Piagetian constructivist and Papert constructionist philosophy of education.
Turtle microworlds as well as programmed Drawer were used in Russian schools among other microworlds (the Robot, discussed later was the most important one).
Over the last decade a version of Logo (called Icon Logo, or LogoFirst) was developed in Russia. The main feature of it is that programming starts there without and before textual literacy. Programming itself (not execution of programs only) became visual: the primitives of the language are iconic.
Through visualisation Logo helps students to understand better such important essentials of algorithmic thinking as iteration, recursion, top-down analysis.
The robot and structural programming
The natural behaviour of the Turtle does not assume conditional branching. Of course, we can add to it some additional features like seeing a colour of plane underneath. But there is something more natural and more intriguing that involves conditionals. This is the microworld of Robot in the maze.
It needs some additional investigation to find out all origins of this creature. Some of these are Slovakia, formerly - part of Czechoslovakia - the native land of robots - fantastic creations of great Czech writer of the XX century Karel Capek (pronounced Cha;pek), Cornell University where Karel the Robot was used to teach students structural programming starting from the beginning of 80s, and Moscow state university, where the same happened approximately at the same time, and then was used in mid-80s to teach algorithmic thinking to 2.5 million Soviet high-school students.
Let us go to the essence. A maze is a rectangle surrounded by walls. It can also contain walls inside. The only limitation is: all walls are vertical or horizontal segments with integer ends. The Robot is a creature (or a machine) with four options of moving: by one unit up, down, right, left, and four senses: to see a wall immediately up, down, right, left. (This definition can be changed, for example we can expect the robot to turn to four directions and to see a wall in front of it.) A problem is usually formulated as: "program the Robot to move from one position to another". For example, the first position can be unknown a priory, and the second one can be upper-left corner. Even more important is that the maze can be also unknown beforehand, but some restriction on the wall's position can be given, for example: there arbitrary number of wall segments, but all should go in the vertical direction. These unknown parameters represent the major feature of algorithms and 507 algorithmic thinking: to invent a general instruction of behaviour that is valid for a possible infinite number of situations.
In the practical school context it is important that the programming, on the one hand is presented as text construction, like in Logo and 'adult' computer languages. On the other hand, the construction is done by using 'building blocks' in a structural way, not letter by letter. The result is also presented in a structured, visualised way. In the process of execution the executed command can be indicated on the screen.
Investigating different kinds of restrictions we can obtain a big variety of problems constituting a natural space of tasks of increasing difficulty up to the problems of proving impossibility (non-existing of algorithms). In this case the non-existence is not caused by the general limits of computability but by specific limitations of the computational model. One more dimension of variety here is the different primitives of programming, for example, numeric variables can be permitted or not.
Lacking the creative power of Logo, as an instrument of doing something relevant for the world outside mathematical education, the described microworld is a very important environment to learn the basic methodology of structural programming.
The builder and parallel programming
One more visual environment used in Russia for teaching algorithmic thinking is a microworld of building construction. The process of construction (to be programmed by a student) consists of putting together building blocks, and can done in parallel by different brigades. A problem is an assignment to build a construction in the shortest time with a given number of brigades.
This microworld is interesting enough and provides some space for variety of problems for secondary school. Its major limitation is connected with the fact that one program is being constructed for one building only, it is not assumed to work in multiple situations.
An IT extension: Controlling real moving objects
The natural extension of the visualisation idea can be called "materialisation". This means controlling and programming, not events inside a computer, not visible on a computer screen only, but happening in physical reality. For example, a "real" electro-mechanical turtle is a popular device in British primary and secondary schools.
An additional dimension comes with an opportunity of assembling the moving models from blocks of a construction set. Such construction sets are produced by LEGO and other companies.
Turing Machine
In the mathematics of computation traditionally more simple devices than abstract computers are considered such as Turing machines. We think that considering them could be helpful in the development of algorithmic thinking in connection with hardware - software relations, understanding more about complexity, specific syntactic algorithms, etc. At the same time, Turing machines in their standard 508 presentation are very far from being intuitive. A group in Stanford University developed a visualization of the machines. As they write in [1]:
'In Turing's World, a collection of graphical tools lets you design Turing machines by directly drawing their state diagrams. When you run a Turing machine in Turing's World, the operation of the machine is displayed graphically, both on the tape and in the state diagram window. On the tape, the read/write head moves, making the changes required by the machine you've designed. In the state diagram, the nodes and arcs highlight to show the changing state of the computation. Turing's World also allows students to display the text-based "4-tuple" description of their machines, though we have found that they rarely do.'
The Turing machine looks out of the scope of the secondary education. At the same time finite automata presented in a visual way on computer screen can naturally fit into mathematics of computation for secondary and even primary school. (There were several attempts to do this even without computer.) So, first - finite automata can be presented similarly to Turing machines, second - in the case of finite automata are in a course, it is easier for Turing machines to appear.
The Life Game
Several attempts were made to implement the microworld of the Life Game of Conway. It looks like this microworld can be used not only in mathematics of computation study, but also as an environment for student's investigation of a 'natural science' phenomena (in this case - phenomena of artificial nature). These phenomena resemble different phenomena of biology and can be productively investigated even on the primary school level. As in other cases it is helpful to start with pen and paper exercises and then pass to the computer environment.
Pre-computer experiences in algorithmic thinking

Algorithmic thinking and other elements of basic mathematics of computation can be developed a non-ICT context. Formally it is outside the subject of the study but we believe that some of the non-computer activities should be integrated into the learning process, for example:
• Students can count seeds in a jar and learn divide-and-conquer principles
• Students can sort LEGO bricks and design sorting algorithms to be implemented on computer
• Students can play games with complete information, construct winning strategies, possibly using tree of the game, etc.
Static microworlds of logic and mathematics of computation
Some problems concerning objects of mathematics of computation can be pretty sophisticated and importantly not being immediately associated with any process. For example, it can be a problem of finding the truth value of a formula, or constructing an object satisfying a given condition, etc. The objects can be visualised on the computer screen.
'Tarski's (Micro)World' was designed by the mentioned team from Stanford University. In this microworld as in some others (Robot etc.) a virtual interpretation 509 of some general concepts is given. Here the general notions of relation is interpreted via a handful of (quasi) spatial relations: 'to be a cube, 'to be a pyramid', 'to be small' 'solid (or 'block'), 'A is back of solid B', etc. It looks very limited, but the microworld happens to be rich enough to develop in its visual context the major skills and heuristics, associated with first-order logics. Visualisation here gives a model for a formula and used also in formula interactive analysis.
Let us mention also another product of Patric Suppes group at Stanford – it is Hyperproof. Being beyond secondary level it gives an interesting example of visualising syntactical structures and inferences.
A different example is given by the Informatica microworld, used in teaching basics of discrete mathematics including mathematics of computation in thousands of Russian schools for last decades. In this case the microworld contains and graphically presents on a computer screen such objects as strings, bags, trees and tables (of beads, symbols, digits, numbers etc.) as well as provides graphical tools to construct objects and to operate with them: add bags, or unite them (maximum operation), represent bag as a table, multiply to bags (as algebraic expression), concatenate strings, etc. This microworld is supported (or, in many cases, substituted) by 'penand-paper microworld' of graphical objects. In this case it is interesting that, as it happens in algebra with graphics or in dynamic geometry, the objects of a child's work can be always presented on the screen with the size of them being the only limitation. Next to this there are Tabletop and, especially, Tabletop Jr. of TERC – instrument for data and operations on data visualising.
Games
It would be interesting to construct microworlds for specific (possibly, to be invented) games (of two persons with perfect information), where, on the one hand dynamic strategy thinking is developing, and on the other hand, understanding of quantifiers as opponents' moves appears. A known example is the Nim game. Here is one more brilliant case of such a game from the field of recreational mathematics:
Let us have a round table and two players with infinite stock of congruent coins. They put coins in alternative moves, one by one, non-overlapping. The player that has made the last move wins.
The known winning strategy (to be given in the conference talk) proof needs discussion of termination of computational processes, invariants, and inductive reasoning as well as general mathematical concepts of symmetry.
In this field of recreational mathematics and Olympiads there are more problems in the field (not games only) that can be visualised and studied with computer.
Not covered yet
Naturally, not all topics of mathematics of computation are visualised or can be visualised at our level of understanding today. At the same time, we remember, that, for example, Euclid's algorithm was developed as a geometric one. So, experience in 510 visualisation of actions in dynamic geometries (Geometer's Sketchpad, etc.) can be used here.
Conclusions
As we can see, there are several virtual environments visualizing objects and processes of mathematics of computation including logic and algorithms on the potentially secondary and, even primary, level. Some of these environments represent some part of mathematical reality in a full form, others are of generic nature, where you see and work with some specialization of general notions (e.g. structural programming) but can develop general skills, needed in a general context.
The important interconnected tasks for the future work are:
• To redesign primitives and interfaces of the microworlds
• To implement the microworlds in the modern operating systems' coding, possibly, as open source Java, or Flash, etc. code, to cover mobile devices as well
• To provide some kind of unification over the microworld (in the interface details, terminology, etc.)
• To design specific topics and whole mathematics of computation part of the modern mathematical curriculum
• To integrate math of computation into mathematical curricula and into general education
• To reconsider the goals and content of mathematical education on the basis of ICT technology, mathematics of computation and modern society needs.

Teaching with technology: complexity theory as a lens for reflecting on practice
Margaret Sinclair, York University, Toronto, Ontario, Canada
margsinc@rogers.com
The main thesis of an article by Davis and Simmt (2003) is that "mathematics classes are adaptive and self-organizing complex systems". Several years ago I examined three technology experiences in light of that thesis, to determine how software, organization, and task impact the blossoming of a complex learning system in the lab-classroom. Since that time I have continued to think about the implications of these ideas in the broader context of implementing, and helping preservice teachers implement, technology in teaching mathematics. Complexity theory, as applied to education, is a relatively new theoretical framework; however, I believe that it is very appropriate. Based originally on biological models, it offers a perspective from which to examine multiple intertwining relationships, emergence of new ideas from seemingly insignificant events, the creation of unexpected connections, and the development of student understandings that are more than the sum of the parts. In this paper, in light of some ideas from complexity theory, I reflect on my own teaching experiences with technology, and the consequences for my research.
For us, perhaps the most important conclusion of complexity science is that, in any learning system, complex co-adaptive activity is always happening across several levels simultaneously. It is impossible to affect a part of the complex unity without affecting its global character, and vice versa." (Davis & Simmt, in press)
In addition to familiar examples such as anthills, brains, and cities (Johnson, 2001), Davis and Simmt (2003) argue that mathematics classrooms are instances of complex systems – self-organizing, self-maintaining, adaptive phenomena. Like living organisms they grow and develop, responding on many levels to even minor changes. Davis and Simmt identify five necessary (but insufficient) conditions for such a system to be able to learn – internal diversity, internal redundancy, distributed control, organized randomness (in recent work (Davis & Simmt, in press) "enabling constraints"), and neighbour interactions. Complexity theory says nothing about the quality of this learning; for example, a class may learn to be apathetic; but it does provide a perspective for analysing the complex entity that is the classroom.
I suggest that, in a similar way, complexity theory offers a powerful framework for analysing teaching with technology. I believe that it can help us explain some of the problems we face, particularly with regard to implementation. Research has shown that appropriate opportunities to use technology help students develop a deeper understanding of mathematical concepts (cf., Clements & 512 Sarama, 2002; Jones, Autumn 2002; Ruthven, 1999). As a result, school districts are providing support; for example, the Ministry of Education in Ontario, Canada has licensed Geometer's Sketchpad (GSP) and Fathom for student use, and has released new curriculum documents that mandate the use of technology in elementary and secondary mathematics. School boards in Ontario have responded with funds for inservice and the purchase of hardware and graphing calculators. Yet in many (perhaps most) Ontario math classes, technology is used infrequently or not at all. The case in other provinces in Canada – and in other countries is similar. For instance, Artigue (2000) notes that despite the active support of digital technologies by the Ministry of Education in France, integration at the secondary level has been minimal. She proposes that this is because: 1) computer technologies, though having strong scientific and social legitimacy, have poor educational legitimacy; 2) issues around the "computerisation" of mathematical knowledge have been underestimated; 3) opposition between technical and conceptual dimensions of mathematical activity (which is not new) has been affected by the introduction of technologies that make the technical aspects easier; and 4) and the "complexity of instrumentation processes", i.e., dealing with the impact (both mathematical and technical) of technological tools, has been underestimated. (p. 9) She says:
Various characteristics of the mathematical culture and various constraints act as obstacles to integration and the strategies spontaneously developed by the educational system are not necessarily the most adequate. A better understanding of the way these characteristics and constraints shape teaching and learning processes in technological environments and the way they mutually intertwine, is today more than ever a necessity for research. (Artigue, 2000, p.9)
Artigue's analysis indicates that introducing technology in (secondary) mathematics has been difficult because of the "intertwined" interactions of numerous factors – both mathematical and technical. That is, the situation challenges our ability to use a straightforward cause and effect analysis; I suggest therefore that complexity theory may be an appropriate theoretical framework within which to investigate issues around implementation.
In a small way, I have used complexity theory to examine some experiences in my own practice of teaching with technology.
Several years ago I wrote about three technology activities I had used with my high school students: a linear transformations project using a spreadsheet, a set of proof tasks with JavaSketchpad, and an independent study that made use of a variety of technological applications – Maple, AsEasyAs, and GSP. I used complexity theory as a framework to consider the question: Can we – or how can we – nurture the development of a "learning system" in a technology-supported environment? The paper examined the three mathematics activities with respect to the five conditions mentioned earlier. My analysis suggested that these conditions were present to 513 varying degrees but were affected in the lab environment by: a) lab configuration; b) program ease of use and/or depth of options; c) task design; and d) student opportunities to share knowledge with peers, and to communicate with the teacher. While these practical concerns are still important, I want to focus on other aspects of one activity.
I found that the independent study project environment was the only one that satisfied all the conditions for the development of a learning system. The broad range of student knowledge (mathematical and technical) guaranteed sufficient internal diversity for students to move ahead; shared understandings of mathematical topics, common terminology and familiar algorithms provided enough redundancy for meaningful communication; the out of class timeslots automatically allowed for distributed control, and the individual topics provided the matter over which to exercise that control. Although the class did not focus on a single goal, shared understandings emerged with regard to the use of technology, and the nature of mathematics; for the first time many students saw mathematics as a creative endeavour. With regard to "enabling constraints", I saw in the independent study project many examples of "serious play" (Reiber, Smith, & Noah, 1998), that is, absorbed, intense, self-directed action. I attributed this to the fact that the tasks were proscriptive, rather than prescriptive. [Davis and Simmt (2003) note that tasks that are proscriptive (i.e., that tell you what you can't do), allow more options for responding than tasks that are prescriptive (i.e., that tell you what you must do).] Students in the classes were free to interact with one another and with other pairs; their interactions gave rise to new ideas and explorations. In addition, students interacted with the software, the hardware, the reference materials, and the mathematical topics; all of these interactions provided fruitful opportunities for emergent understandings. Learning flourished as the classes 'gelled'. I wrote:
Observations of the Independent Study Project groups suggest that a structure allowing for sharing, play, and individual choice, that involves activities based on broadly applicable and adaptable software can result in the emergence of a beneficial complex learning system in a technological environment. (Sinclair, 2004)
A second critical experience involved a group of students in a masters' geometry course.The students in the course were novices to the investigative study of geometric concepts on a sphere. Some had gone beyond the Euclidean geometry studied in high school; however, even those students viewed geometry as formal, abstract, and logic-based. In-class activities focused on the manipulation and analysis of concrete models, but early in the course students were briefly introduced to two programs that permit the dynamic exploration of spherical geometry concepts – Cinderella, and Spherical Easel. There was neither subsequent use of the programs in class, nor any requirement that they be used; yet program screenshots appeared in the 514 assignments of some students. Assignment comments revealed that use of the tools had contributed to students' sense of confidence about what they knew and about how they could continue to learn. The programs had provided extended opportunities for investigation and allowed the students, outside of class, to deepen their understanding of spherical relationships by developing stronger mental images.
This particular group of graduate students had embraced technology for their own purposes, and had used it in a natural way – whenever it seemed appropriate and in conjunction with other methods. How different from the behaviour of my preservice and undergraduate students. [The undergraduate course is designed for teacher candidates or those considering teaching, who want to strengthen their ability to "think mathematically". It is not open to those taking other university math.] Each year in my courses I encouraged students to use technology. I uploaded activities and resource links to the class conferences, gave sessions in the lab on GSP and EXCEL, provided tutorial files, and developed assignments that required technology use. Despite this support and encouragement, few student projects even hinted at

technology use, and I heard many versions of, "It's nice, but..."
Nevertheless, my own delight at seeing 3D graphs in Maple, my secondary
students' excitement over playing with mathematical ideas, and the graduate
students' unexpected and natural use of software to explore spherical geometry, led
me to look for a new approach to teaching with technology. I pulled back from my
focus on technological tasks to consider the broader realities.
We know that technology is important to students. They surf the internet to
find information; upload, download and edit digital photos and graphics; use word
processing software to prepare assignments; and talk to one another via email and
chat. However, it isn't always part of their mathematical experience. Aside from
using scientific calculators, many students have never used technology to do math.
But my students had used technology for mathematics. In the short time
allotted for a pedagogy course (36 hours) I had provided opportunities for them use
technology to make connections between numerical, visual, and symbolic
representations, to work with multiple examples and to examine the behaviour of
mathematical objects. They had responded enthusiastically to activities in the lab -
but I recognized that they still did not use technology in their teaching or in their own
mathematical work.
What about the teachers at their placement schools? We know that teachers use
technology in their own lives. They use the internet, use word processing software to
prepare assignments and tests, and many regularly use email and chat. But teachers
often see technology as an add-on in teaching mathematics. They may do specific
technology activities, but deep down they 'know' that they can teach math without it.
After all, if they couldn't - they wouldn't have learned mathematics. My students
admitted that technology use was not being modeled in their host classrooms.
My research has focused on the design and use of technological tasks for
mathematics -- and I want to emphasize that these are important areas of research and 515
development work -- however, on reflection, I recognized that in my teaching I was
not using technology in a natural way, reaching for it at any appropriate time as I did
in my own mathematical work. Instead, I was teaching applications of technology.
This year I set out to make technology an integral part of my teaching. In
addition to scheduling lab sessions I decided to use technology whenever
appropriate, throughout the course. To ensure that I would follow through, I ordered
a computer and LCD projector for each session, and planned a very brief use of
technology for each class (e.g., showing pictures of tilings, examining an applet,
using a GSP sketch or an EXCEL graph to start a discussion.)
Over the past four months I have noticed changes in my own attitude and
practice. Although I only plan a brief use of technology for each class, I have found
myself using other technology examples, accessing the Internet to explore an idea
that has been raised, or creating a sketch or graph "on-the-fly" to illustrate a point or
to provide a shared image for a class discussion. Similarly, while I have not collected
data in a systematic way, I have noted differences in students' attitudes towards, and
use of, technology. For instance, four out of twenty students in one class handed in
an assignment that contained GSP images (they had obtained Geometer's Sketchpad
on their own through the Faculty library); another student asked if she could submit a
GSP file with an assignment. Many have requested that I upload examples to the
class conferences, and two have asked for my advice on preparing lessons that made
use of technology for their math practice teaching.
It is also clear that the students, through observing, have gained an
understanding of how to use the software, and how technology can be used to explore
mathematics. For example, during class students have asked me to create a GSP
sketch that has particular features (e.g., a quadrilateral with a right angle), to alter a
sketch or graph for them to analyse the result, and to surf to a particular website they
have discovered. Thus far, two of the three classes have had lab sessions in which
they used GSP. Students who had already obtained a copy of Sketchpad were well
beyond the beginner stage, but even those who hadn't used the program were aware
of its capabilities and the contents of the menus. I was impressed that most students,
after a paper-folding experience and a discussion of the properties of a rhombus,
were able to use Sketchpad to construct a rhombus with very little help.
Reflection
Complexity theory played a large part in my thinking as I examined my own
practice. It enabled me to step back and see the broader picture and to consider
whether the conditions that Davis and Simmt identified were met. Thinking about my
classes this way led me to conjecture that these "learning systems" were not ready to
embrace the use of technology - they lacked a shared, foundational language and
experience in the area. As a result I concluded that there would be few opportunities
for neighbouring ideas to bounce off one another, and even fewer opportunities for
new conceptions of what it means to learn mathematics, to emerge. My decision to 516
build foundational technological experiences for the students by embedding
technology use in my own teaching grew out of this analysis.
The experiences of this year have caused me to rethink a project that I, along
with several other researchers, will be starting soon; it involves evaluating the use of
a linking system for graphing calculators with grade 9 applied students [the applied
stream leads to apprenticeship and some college programs]. Originally the plan was
to inservice a number of teachers on the use of the linking system, encourage them to
use the system in their classroom, and then to use surveys, interviews and
observations to evaluate the impact on student achievement. However, Davis and
Simmt note that "it is impossible to affect a part of the complex unity without
affecting its global character and vice versa" (in press). If math classes are complex
learning systems, changes will impact the environment at many levels. An
implication for research is that any intervention must be designed to take into account
the possible effects on the whole system, especially in respect to the conditions that
have been identified as necessary for a system to learn. In the revised proposal
students will be expected to take their calculators home; the linking system and
projection equipment will be available and switched on for every meeting of every
class in the experimental group; and parents will be interviewed and surveyed.
Teachers will receive professional development sessions on using the technology but
also on developing mathematical ideas with applied students. The additions address
the need to create an environment in which technology will be embedded. The
broadened analysis recognizes that the changes will impact many aspects of the
learning environment.
Conclusion
Though these comments on my teaching practice are subjective and limited in scope,
I believe that they illustrate that the concept of a complex learning system is a useful
construct for thinking about teaching with technology. While such topics as task
design, student interactions, and developing understanding of particular mathematical
concepts are critical foci for research, complexity theory challenges us to see the
whole system in a new way. Based originally on biological models, it offers a
perspective from which to examine multiple intertwining relationships, effects that
are magnified by feedback, emergence of new ideas from seemingly insignificant
events, the creation of unexpected connections, and the development of student
understandings that are more than the sum of the parts.

Distance Learning: Mathematical Learning Opportunities
for Rural Schools in the United States
Margaret Sloan & John Olive
University of Georgia, USA
mhsloan@alltel.net and jolive@uga.edu
Much has been written about technology in the mathematics classroom, in the
computer lab, and in students' homes. Such technology includes calculators,
SmartBoards™, computers, Internet access, VCR or DVD recorders or players,
digital cameras, computer projection apparatus, and other technological solutions to
particular teaching and learning needs. Many schools, especially those in remote,
often impoverished locales, cannot provide such a cornucopia of goods and services,
but there is one technological resource that can provide students in almost any
location with the very best learning opportunities available anywhere in the world.
This technology is known as Distance Learning, and even at its most basic level, any
school with Internet access can open new doors of opportunity for its students. When
access to interactive video systems can be achieved, Distance Learning can enable
those students to become acquainted with world-class mathematicians and scientists.
All schools, including the rural schools which seek to educate almost one third
of the children in the United States (Beeson & Strange, 2003), make decisions about
the use of technology on a more or less continual basis, and all schools have similar
factors to consider -- the population they serve, the resources at their disposal, and
the technological expertise of their staff. According to a recent NCES report, rural
schools are leaders in U.S. education in at least one area of computer based
instruction: distance learning (Setzer & Lewis, 2005). In many ways, schools in the
rural United States are similar to schools in developing countries that have limited
fiscal resources for education and may be remote geographically. The intent of this
paper is to provide information and insight into some of the ways that distance
learning can benefit mathematical learning opportunities in such schools and how
this technology might be procured and utilized.
In the NCES report, distance learning courses are defined as those offered in a
district with the teacher and the students in different locations. Approximately 46%
of rural districts in the United States have students enrolled in distance education
courses, and two-way interactive video, the crème de la crème of distance learning, is
the technology most often used as the delivery method (Setzer & Lewis, 2005). With
two-way interactive television, or I-TV, distance learning is instructor-led, classbased, and synchronous -- providing real time instruction and communication
(Yaunches, 2004).
As typically implemented, I-TV is the technology that most closely resembles
a traditional classroom, and in thousands of rural schools, educators are discovering
the instructional benefits and cost effectiveness of this technology. According to a 519
report about distance learning opportunities for elementary and secondary students,
of the 15,040 school districts in the United States, 5480 (44% of secondary schools
and 36% of all schools) had students enrolled in distance learning classes.
Administrators were so pleased with the results that 72% of participating schools
were planning to expand their distance learning programs. Fifteen percent of students
in distance learning courses were taking mathematics. Nationwide, 14% of students
in distance learning classes were taking Advanced Placement or college level
courses, but in more than half (53%) of the rural schools offering distance learning
classes, students were taking such accelerated offerings. Similarly, for 56% of the
schools in areas with high poverty, where distance learning was offered, students
were taking advanced courses (National Center for Education Statistics, 2002). This
suggests that for students in rural and economically stagnant areas, distance learning
is vitally important for gaining access to the highest levels of academic work.
Research comparing distance learning of mathematics to traditional learning
has been limited, usually at the college level, and often indicates there is no
significant difference in achievement; but most mathematics educators in rural
schools would quickly point out that for rural schools, the question is often not a
choice between traditional and distance instruction but whether an advanced
mathematics course can be offered at all.
A driving force behind rural schools' embrace of distance learning, beyond the
ability for small rural schools to provide an expanded mathematics curriculum for
their students and continuing professional development for their teachers, is that
distance learning is often an effective response to the ever-looming threat of
consolidation (Yaunches, 2004). Nearly 54% of rural and small town secondary
schools in the U.S. have enrollments of 400 or fewer students (Hoffman, 2003), and
state legislatures often turn to consolidation of schools or entire districts in an attempt
to cut costs and provide better educational opportunities. Research has shown,
however, that small schools can be effective, with lower dropout rates and higher
percentages of students graduating (Hobbs, 2004); and, as it turns out, attempts to
lower costs through consolidation almost always fail (Rural School and Community
Trust, 2003). The preservation or demise of small schools is a vitally important issue
for many communities, and providing distance learning opportunities for students, as
opposed to pursuing consolidation strategies, certainly seems to be a more effective
solution to the problems spawned by isolation, teacher shortages, and fiscal
pressures.
Having limited numbers of students interested in taking an elective
mathematics course presents challenges for school administrators who have to
balance demands for classroom space, teachers, and other resources -- and without a
distance learning alternative, such requests often must be denied. Distance learning
programs can provide access to such coursework, even for just one or two students.
Students in need of remedial work, as well as those ready for advanced mathematics
courses, can benefit from these offerings. At most schools, even those with limited 520
technology, students can be directed to computer resources on an as-needed basis,
before, during, and after school. Because many colleges and universities in the
United States offer distance learning courses, high schools with this technology can
offer dual enrollment for students who are ready for college-level mathematics but
have not graduated high school.

Some schools have found that distance learning can provide a virtual schooling alternative across the curriculum. Alternative school programs are commonplace throughout much of the United States, many of them relying on computerized instruction of some sort; and the high school in Cairo, Georgia, has a novel approach to the problem of students who are unable to meet traditional requirements. These students spend the school day in a computer lab at Cairo High School taking on-line courses offered by Griggs University in Maryland; but this is not a remedial or tutorial program. As soon as they have enough credits to complete graduation requirements, the participating students receive a high school diploma from the state of Maryland (Williams, 2005).
Web-based instruction generally refers to distance learning as well as instructional programs that include on-line sites for access to data sets, software applications, or other instructional materials. Unlike the fixed content in conventional computer-based instruction (CBI), Web-based instruction can be modified to meet specific needs, is accessible from almost any location, and can be linked to related sources of information – factors that establish what has become known as "anytime, anywhere" learning.
Ultimately, successful integration of any technology, including web-based instruction, into the mathematics curriculum is dependent on teachers and administrators who embrace new technologies and are willing to participate in professional development programs designed to help them take advantage of the benefits and opportunities embedded in computer-based learning (Huffaker, 2003). Much of the research about technology integration assumes that once technological tools are in place, everyone will enthusiastically support technology-based instructional methods; however, this does not usually occur without a conscientious effort by school officials to address a multitude of issues. Schools must explore issues dealing with professional development, equitable access to appropriate hardware and software, Internet access and controls, and out-of-class availability of computers (Alexiou-Ray, Wilson, Wright, & Peirano, 2003).
Providing support to teachers may involve extensive and on-going professional development. Many distance learning providers expect that a teacher will be available to assist students with the course content as well as the technology, and those teachers often need additional training – often through web-based professional development programs. The InterMath
70
Project, a collaborative effort of The

University of Georgia, CEISMC - Georgia Institute of Technology, and regional technology centers in the state of Georgia, funded in part by the US National Science Foundation, is one functioning example of a web-based professional development resource for middle school mathematics teachers. InterMath focuses on building teachers' mathematical content knowledge through mathematical investigations that are supported by technology. The Project includes a workshop component as well as an ongoing, web-based, support community that includes a lesson plan database and a discussion board.
Clearly, all of this technology costs money, a commodity often hard to come by in rural areas. Initiatives such as the e-rate program, which is a telecommunication, Internet access, and internal networking discount program administered by the Federal Communications Commission, and technology challenge grants from a wide range of sources can alleviate some fiscal difficulties. Many school districts band together to develop distance learning consortiums, establishing partnerships with other schools, higher education partners, and/or other outside vendors to provide cost effective options for distance learning by sharing teachers, maximizing the benefits of the I-TV network investment, sharing costs of operations, combining classes across multiple schools, providing access to professional groups, and maximizing the use of technology by addressing objectives for athletic, administrative, health, and other educational staff (Hobbs, 2004).
After receiving a grant in 1992, the North Carolina School of Science and Mathematics (NCSSM) developed a distance learning program with the goal of distance learning becoming a school outreach program. They began with the delivery of three courses, AP American History, Precalculus, and Science of the Mind, utilizing one-way video and two-way audio. In 1994, NCSSM became a state-funded provider of educational programming to teachers and students, utilizing the North Carolina Information Highway. Now, with two-way video and audio, their system supports full interactivity between school sites and teachers and among school sites with each other, sharing resources and curriculum. Through distance education NCSSM can provide rural and isolated areas of the state with courses, enrichment programs, paired teaching collaborations, workshops, and graduate level courses (The North Carolina School of Science and Mathematics, 2002).
In Florida, the Florida Virtual School (FLVS) was funded through a $1.3 billion dollar initiative to ensure that the project did not threaten general education funding. Now, while many other states struggle to maintain a virtual-schooling option for their students, FLVS has a substantial revenue stream, generating approximately $500,000 in profits during 2004 (Wood, 2005). The advance governmental support enabled FLVS to provide educational opportunities not only for students in Florida but also for students around the world as FLVS has joined the

Project Director: Dr. James W. Wilson, Department of Mathematics and Science Education, The University of Georgia, Athens, Georgia. Email: jwilson@uga.edu 522
ranks of courseware entrepreneurs, selling to other schools its curriculum and offering franchises with hardware, software, curriculum, and professional development for teachers (Wood, 2005).
Rural schools are not alone in their effort to take advantage of grants as a means of financing technology to meet the special needs and challenges facing rural educators. In a press release from Merrill Lynch in December 2004, it was announced that students in Pennsylvania, Ohio, and Georgia will benefit from a new $5 million grant from the U.S. Department of Education's Office of Innovation and Improvement to fund the development of a national model for increasing educational opportunities for students attending small and rural schools.
Over the next five years, the Association of Education Services Agencies (AESA) and Catapult Learning, LLC will establish a streamlined contracting and purchasing system so that small and rural school districts will have greater access to high quality supplemental educational services (PRNewswire, 2004). These supplemental educational programs are an integral part of many districts' school improvement plans, especially in regards to the provisions of No Child Left Behind (NCLB). During the pilot program, 2,300 Pennsylvania, Ohio, and Georgia students will receive live, individualized, direct instruction delivered through Catapult Learning's online tutoring system (PRNewswire, 2004).
Distance learning is not a fad, nor is it a panacea for all of the shortcomings of the traditional mathematics classroom, but all evidence indicates that its widespread adoption is likely to continue into the future, with students accessing the technology at school, public libraries, and their homes – perhaps even via their cell phones. For their very survival, rural schools have to provide this technology. Issues such as curriculum controls, accreditation, course evaluations, teacher certification, accountability, academic integrity, Internet filters, per-student funding, preservice teacher training, and professional development need to be addressed as distance learning becomes a more substantial part of students' educational experience.
There is no benefit to be derived from ignoring the fact that technology is essential to today's education environment. In the United States there are ways to fund it and ways to train staff to utilize it; but schools, rural and otherwise, need to spend their money wisely, critically examine research reports, and realistically assess the ways in which various technologies can attend to the needs of the students in their schools. In an upcoming research effort, the first author of this paper will be examining in depth the mathematics program in a rural school in the southeastern United States, and of particular interest will be the extent to which that school, located in an area of extreme poverty, has been able to provide access to Web-based instruction, including distance learning, to enhance learning opportunities for its students. 523

Geometry Through the Lens of Digital Technology: Design and the case of the non-euclidean turtle
Ian Stevenson, Kings College, London
ian.stevenson@kcl.ac.uk
This paper addresses the theme of designing learning environments and curricula with a focus on geometry. It approaches the theme by first analysing role(s) that digital technology plays in learning by considering the multiple meanings of the microworld concept. Highlighting the fundamental role that pedagogy plays in a microworld, the paper proposes a descriptive theoretical framework derived from Activity Theory to capture those meanings. After discussing the close epistemological relationship between technology and the logical structure of geometries, the paper compares the differences between Euclidean dynamic geometry environments and turtle geometry, and their implications for school curricula. Finally two principles for designing digitally-based environments for geometry are illustrated in the case of non-euclidean turtle geometry: learner-centred development of tools and activities that mediate understanding in specific geometries, and the use of an iterative design process.
Introduction
What is the relationship between mathematics and digital technologies? Central to this paper is the theme of designing digital environments for learning geometry, and the dynamics of the relationship between technology and epistemology. The paper approaches the theme by considering how designing learning environment using a microworld paradigm relates to pedagogy- conceptualised using aspects of Activity Theory-and the relationship between of digital technology, geometry and learning. Key aspects of designing learning environments for geometry are illustrated by the case of a turtle-based microworld for non-euclidean geometries.
Microworlds and pedagogy
Papert's seminal notion of a microworld provided learners with computational tools to engage actively in building their own meanings, and control the trajectory of their learning. (1980: 122). His turtle geometry microworld enabled young children to use powerful computers, with the turtle seen as a transitional object for individual learners within a Piagetian inspired framework. More recently he has identified six dimensions that draw out the sense in which a microworld contains a model of a knowledge domain, a set of tools for learning and a theory of cognitive development. (Papert, 2002).
Other conceptions of a microworld locate its meaning in the relationship between learners, technology, knowledge domain and pedagogic setting. Hoyles, Noss and Sutherland's experience in developing a microworld for ratio and proportion led them to extend its definition to take account of the pedagogical context. This includes "carefully sequenced set of activities on and off the computer, organised in pairs, 525 groups or whole classes each with specified learning objectives." (Hoyles, Noss and Sutherland, 1991:3). More recently, Jackiw and Sinclair (2002) have developed a social definition of a microworld which makes whole-class activities the central focus of microworld design. Pedagogy takes centre stage in this design process which, although present in earlier conceptions, now involves groups of learners and teachers.
Papert's early notion of a microworld aimed at tapping into the sense of intrinsic motivation and play which can drive reflective abstraction. However the implied "adidactic" pedagogy led to the "play paradox"-by intervening learners are denied the opportunity for pursuing their own interests, yet, learners do not learn what is required by the designer. (Noss and Hoyles, 1996). Non-intervention can lead to learners not becoming aware of the epistemological base of the microworld, making unreflective use of tools, and avoidance of using certain tools or analysis. (Noss and Hoyles, 1992). With the emergence of social-cultural views of mathematics and their emphasis on the role of context, (Lerman, 2000; Steffe and Thompson, 2000) pedagogy has become a central concern in discussion of mathematics education. From this perspective, microworlds can be seen as the site of structured social interactions that develop over time, involving teachers, learners and technology.
Modelling Microworlds

Two implications for designing microworlds follow from these descriptions. First, microworlds are systems which can include "capable others" as well as technology and learners. A second implication is that a broad range of approaches to pedagogy and learning need to be described in connection with microworlds. These span the "classic" approach with its focus on individual or pairs of learners using technology through to groups working together with a range of resources, including digital technologies.
Edwards (1995) identifies both the structure and function of a microworld in the ways that the knowledge domain is made available to learners through the tools and activities that they undertake. Drawing on notions of an Activity Structure (Leonte'v, 1977) and System (Engeström, 1987) microworlds can be modelled to take account of their structure, function and variety. As an Activity System, microworlds make tools and resources available to both teachers and learners, and structures their pedagogical roles and the organisation of their context. As an Activity Structure, microworlds have three interdependent levels which connect their purpose and outcomes to their structure and sequencing within a context that is constrained by a range of factors. Interactions between tools, the roles adopted by the participants and their organisation condition the sequence and structure of a microworld's evolution. Figure 1 shows how the outcomes and the structure mutually determine one another, and the constraints condition what kinds of structure and outcomes might be possible. These could include the type and configuration of hardware available ranging from single machines to rooms of more than 12, and types of mathematics software DGE, CAS, Graph plotters, browsers, calculators and topic specific applications. 526
Figure 1 Structure of a Microworld. The outcomes, structure, and constraints mutually condition one another.
Table 2 shows spectrum of possibilities for the configuration of tools, roles and organisation, drawn from and validated by OECD/CERI (1999) and Hoyles and Sutherland (1989), which enables this framework to be used for describing microworlds. Combinations of statements from each column can describe a particular pedagogical structure, which can be sequenced to give a full account of a microworld.

Teachers stimulating reflections or other critical analysis
Learners directing conversation with peers or teacher.
Teacher using ICT
Learners using ICT initiated by the teacher
Learners using ICT initiated by themselves
Learners interacting via ICT, initiated by the teacher
Learners interacting via ICT, initiated by themselves
Learners creating using ICT (visual arts, music, mathematics)
Table 2 Spectrum of descriptions for the central section
A classic microworld might be described by a single phase so that "Learners working individually" (Organisation), with "Learners directing conversation with peers or teacher." (Roles) and "Learners using ICT initiated by themselves" (Tools). Outcomes for this approach are self-defined by the learners, and they use a single machine with appropriate software. Alternatively, there maybe a more complex structure with several stages such as Jacklw and Sinclair (ibid.) describe. A teacher may start a set of activities that make use of technology in different ways, with learners subsequently taking control as they develop their understanding.
Digital Technologies and Geometries
Arguably the oldest and most common form of mathematics found in cultures across history is geometry. Practical techniques for measuring land, making buildings and laying out public and private spaces can be found in writings and sites dating back to the dawn of time. (Gray, 1989). Geometry emerged alongside the growth of advanced cultures to resolve disputes, and as a means for transforming the natural

world into niches suitable for humans. In this sense geometry reverses the Darwinian notion of natural selection: humans construct niches in which they thrive rather than being selected by those niches. (Berger and Luckman, 1966).
With the emergence of Euclid's Elements in the third century BCE, geometry became a systematic and organised body of knowledge that provided the paradigm for mathematical reasoning. However, the practical origins of the geometry still play a significant role: euclidean geometry is synthetic. It relies on the use of a straightedge and compass in the process of establishing its results. (Bkouche, 1989). Only with Hilbert's treatment of Euclid at the start of the twentieth century did the constructional assumptions and practices implicit in the process of proving results become apparent. (Stillwell, 1992). By the same token these technologies also constrained what was possible to achieve with the geometry. All problems have to be interpreted in a way that the geometry and its technology can be applied.
This raises the question about what kinds of geometry should be taught and learnt. History indicates that euclidean geometry is not unique, and represents a normative rather than a natural interpretation of our spatial experience. (Riechenbach, 1957). It is arguable that learners need to be able to move between geometries that are appropriate to their experience in different situations. Euclidean geometry is intimately related to the technology of straight edges and compasses, and has been used effectively over "local" distances for millennia. Spherical geometry has been used for over four centuries for practical navigation, and is accompanied by a range of instruments and mappings for practical uses. (Kreyzig, 1991). Hyperbolic geometry and its euclidean models, by contrast, have emerged recently as a working tool with the development of computational representations to navigate the web. (Lamping et al., 1995). What these examples have in common is the interdependence between geometry as a theoretical discipline and the technologies which enable it.
4. Dynamic geometry-what is it?
A new generation of computational environments to support learners of euclidean geometry combine tools for creating on-screen objects with their direct manipulation. Known as dynamic geometry environments,(DGE), they enable learners to construct euclidean diagrams, and, through selecting points on the figures, move the diagrams around to examine the logical dependences. (Jacklw, 1995; Laborde and Laborde, 1995; Richter-Gebert, J. and Kortenkamp,1998). DGEs rely for their semantic power on learners intuitively identifying DGEs' functionalities with their own experiences of paper and pencil constructions. Most DGEs make use of the technical vocabulary of euclidean geometry in menus and icons to represent a range of operations. However, there is not a one-to-one correspondence between DGEs and "paper and pencil", since design decisions make DGEs different to euclidean geometry in significant ways. (Goldenberg and Cuoco, 1998). It remains to be seen what the implications of this semantic disparity are for learners.
Although DGEs do have tools to animate diagrams and produce loci of points, their principle source of dynamism comes from learners who move diagrams physically around the screen. Such "external" dynamism contrasts with the internal 528 dynamism of turtle geometry in which movement is an integral part of the commands that control the turtle: forward, backward, left, and right. Turtle geometry differs from DGEs in two other respects. Although the turtle produces euclidean objects, it is conceptualised as syntonic or body geometry. (Papert, 1980). Objects are created by learners as they walk the turtle over the shape rather like they might do in a physical setting, and express that process in terms of its four commands and other programming structures, such as procedures, control structures, and loops. Turtle geometry, although it can produce euclidean objects, is essentially differential. It is defined locally and intrinsically without reference to an external and global coordinate system. (Abelson and DiSessa, 1980). Turtle geometry differs from DGE in a second key respect; it's a space-time geometry. Motion is an integral part of defining a turtle's state, which refers to events rather than spatial objects.
The "failure" of turtle geometry to become a central element in mathematics classrooms may be viewed not as a lack of will or pedagogic ingenuity. (Noss and Hoyles, 1996). The contrast with other more successful dynamic geometry environments suggests that the problem lies in the type of geometry that turtle graphics enables, and what counts as geometry within the school curriculum. Current applications that are normally referred to as DGE (e.g. Cabri, SketchPad, Cinderella) are tools for exploring the euclidean model of spatial experience. By contrast turtle geometry, which is also dynamic, mediates other kinds of geometry that model our spatial experience but do not form part of the school curriculum. It remains an open question as to whether the DGE categorisation of software should include just the euclidean-based applications.
Euclidean DGEs success lies in the fact that they have been created principally to support the learning of school geometry, since they reproduce and automate many of the functions that are routinely undertaken using paper and pencil. Unlike turtle geometry DGEs are apparently designed around what their creators perceive as being the necessary functionality derived from epistemology of Euclidean geometry, rather than what learners might need. (Squires and McDougal, 1994). However given the tensions that Hoyles, Noss, and Adamson (2002) identify in relation to what they call "superstructure"-what is available to the learner in a microworld, and "platform"-the environment in which the superstructure is articulated, focussing on learners is a complex and time consuming process. The next section explores the process of learner-centred design and its connection to "superstructure" through a specific example.
Learner-centred design: spherical and hyperbolic turtle geometry
Two principles derived from the construction of a turtle-based microworld for noneuclidean geometry illustrate the importance of the interplay between design and learning. (Stevenson, 1996; Stevenson & Noss, 1999; Stevenson, 2001)
Learner-centred development of tools and activities that mediate understanding in specific geometries. Papert's turtle was chosen originally for its syntonic link to cognitive development, and finding cognitive links for non-euclidean contexts was, therefore, a central design issue. The links emerged by working with learners to find 529 what engaged them with the structures of the new geometries. The turtle's screen behaviour was governed by euclidean models obtained from projecting spherical and hyperbolic geometry onto the screen "plane". Three types of links were needed to help learners connect with non-euclidean turtle geometry because of the complexity of the screen images: physical surfaces, metaphors, and on-screen structures. Tracing paths on the physical surfaces with their fingers enabled learners to make sense of what they saw on screen by metaphorically linking their action with the screen turtle. Using the metaphor "turtles walk straight paths" helped learners identify "straight lines" on curved surfaces with straight lines left by the turtle. (Abelson and Disessa, 1980). A second metaphor used to understand the turtle's behaviour was the screen's temperature. (Gray, 1989). Spherical geometry projects a surface that increases in temperature as one moves towards the screen's edge, while hyperbolic geometries gets cooler towards the edge. Dashing the turtle's path so that the dashes grew longer or shorter according to the geometry indicated that the turtle's steps were expanded or contracted by the "temperature" of the screen. A corresponding speeding up or slowing down of the turtle's movement as it left dashes, coupled with a tool that drew the large-scale path which a turtle might take given a particular position and heading provided a dynamic structure for learners to build up their understanding.
The key point is that the microworld's physical, conceptual, and virtual resources emerged through paying careful and systematic attention to learners' needs in these specific geometrical context. As Harel (1991) points out, learning and designing are intimately connected both for "learners" and "designers".
Iterative design process. Paying careful and systematic attention to learners' needs took the form of a thorough evaluation of the pedagogical, technical, and cognitive aspects of the microworld. The microworld emerged through analysis of a series of structured activities and observations based on the relationship between the roles, tools and organisation of resources in Table 2. Over three cycles of development a combination of didactic intervention, reflective discussions, task-based interviews and non-participatory observation of learners were used. Each of these roles was applied explicitly in designing activities to achieve particular research objectives. In terms of Table 2, for example, "didactic intervention" consisted of "teacher working whole group", with "teachers directing conversation" and "teacher using ICT". Reflective discussions, however, consisted of learners working individually with teachers (researcher) stimulating reflections and learners using ICT initiated by themselves. Interspersed between working with learners were periods of reflection to redesign tools and resources, activities, and pedagogic approaches based on analysis of video tapes, field notes and dribble files. Each new section of work with the learners was carefully sequenced according the pedagogic structure described by use

of tools, roles, and organisation.
Conclusion
Microworlds are essentially pedagogic. The descriptive framework proposed in this paper is intended to articulate the range of meanings that microworlds can have, and provides a means for designing learning environments. The example of designing a 530 turtle-based environment for non-euclidean geometry illustrates a number of key issues. Geometries other than Euclid are available and they form part of our everyday experience. They can be mediated by digital technology, but they are constrained by the standard euclidean representations of the "screen". For that reason designing learning environments must pay careful and systematic attention to what mediates understanding in specific geometries. This implies an iterative approach to design that places learners at the centre of the process, and the framework derived from Activity Theory provides the means to undertake this systematically.

Dynamical Geometry Environments: Instruments
for Teaching and Learning Mathematics
Rudolf Sträßer
Giessen/Germany & Luleå/Sweden
rudolf@sm.luth.se
Informed by experiments and experience with Dynamical Geometry Environments ("DGE"), the paper elaborates on changes, which are linked to the use of DGE. DGEs allow breaking out of the narrow confines of Euclidean Geometry – best illustrated by the use of the dragmode to introduce movement into static Euclidean Geometry. DGEs offer ways of teaching and learning Geometry, which are not available in a traditional paper-and-pencil environment. The macro-functionality of DGEs appears to be an excellent possibility of structuring the material and cognitive representation of a construction process. On the other hand, the explorative potential of DGE often implies a "de-goaling" from the initial task. Worksheets and the intervention of the teacher are suggested to cope with these difficulties of learning with the help of DGEs. An excursion additionally shows that some of the design decisions within (Geometry) software are constrained by unavoidable mathematical necessities – with implications for pedagogical and cognitive (dis)advantages. Following an'instrumental genesis' approach, design decisions should be made after close inspection of the ways the users 'instrumentalize' the software. Some of the findings on DGE can obviously be generalised to other types of mathematical software available or forthcoming in the near future.
Euclidean Geometry left with DGE
Comparing traditional, especially Euclidean Geometry and its teaching and learning with a more recent Geometry education using Dynamical Geometry Environments (in the following: "DGE" - like Cabri-géomètre, Geometry Inventor, Geometer's Sketchpad or The Supposer – to name but a few of a whole variety of DGEs, for an early description see Sträßer 1992), the most obvious difference is the dragmode, i.e. the possibility of moving initial points of a drawing with the mouse while the construction is "updated" according to the construction commands used. It is obvious that DGEs have left the narrow confines of static Euclidean Geometry (and philosophers and historians of Mathematics do name the avoidance of motion as one of the characteristic features of Euclidean Geometry). According to the designers of DGEs like N. Jackiw (for Sketchpad) or J.-M. Laborde (for Cabri), this was not intended when creating these pieces of software. As a consequence of the software design and only after some time, the designers, mathematicians, educationalists and users realised what DGEs do to Euclidean Geometry (see for instance Laborde 2001). They also had not expected the problems linked to this potential of DGE (see section 3). 533
Looking more closely into DGE use, another major change becomes evident, which is not as well researched (and not so widely used in Mathematics education) – namely the use of geometrical transformations like reflections, translations and rotations. Even if again closely related to movement (especially with translation and rotation), DGE nowadays have a functionality to transform geometrical elements as a whole, showing the image of a reflection, rotation or translation after one click of the mouse.
Example 1:
With a DGE like Cabri, it is easy to study the transformation, which takes place when a quadrilateral is successively reflected at two different straight lines. We can even drag the lines and study the consequences of different respective positions of these lines (e.g.: parallel or intersecting). Such an exploration would offer excellent handson experience to study the composition of line reflections, more general: congruence transformations in plane Euclidean Geometry.
The "locus-of-point" feature of Cabri can also be used to go for complete images of certain elements of a drawing (for a detailed analysis of this feature see Jahn 2002 and the underlying PhD-thesis of Jahn). In all, DGEs offer a potential for transformational Geometry, which is only seldom exploited – even if disciplinary Geometry indicates this possibility (see Felix Klein's "Erlangen program").
In addition to this, the dragmode offers a more fundamental potential within DGEs: If appropriately introduced and interpreted, the dragmode can facilitate the understanding of the difference und relations between a material "drawing" and the underlying geometrical "figure" (for the introduction of these concepts see Parzysz 1988, related to DGE: SträßerßCapponi 1991; for a slightly different conceptualization see Mariotti 1992). Offering a huge variety of drawings belonging to the same figure at a click and drag of the mouse, DGEs can help to distinguish between the material representation of a geometrical configuration, its drawing(s), and the underlying logico-geometrical relations, which -after the cutting of the ontological binding (see Freudenthal)- are most relevant for the mathematician.
Example 2: The'Varignon'- parallelogram in a quadrilateral
To end this section, it should be mentioned that models of non-Euclidean Geometry are also easily available within this type of software (see the set of macros for hyperbolic Geometry created for Cabri by Lister 1998 or the possibilities in CINDERELLA described in Richter-GebertßKortenkamp 2000). 534
Teaching Geometry with DGE
If we look more closely into the teaching and learning of Geometry with the help of DGEs, there is more to DGEs than the dragmode. transformation Geometry and the distinction of 'drawing' from 'figure': For the constructive part of Geometry and its analysis, it is most helpful to structure this activity not according to the functionalities and menu of the individual software, but to be able to think in units defined within Geometry. DGEs normally offer a most helpful feature to meet this demand: the possibility of defining macros. After having done a specific construction and under certain restrictions, DGEs can be told to repeat a defined part of a construction with an input defined by the user and a necessarily unique output (no 'if-then'-decisions allowed at present – for a discussion see Kadunz 2002 or Sträßer 2003).
Example 3: Square-Macro
In contrast to a traditional construction of a square ("construct a segment, perpendiculars in the endpoints, a circle through one endpoint with the other endpoint as centre, ..."), a well-defined DGE-macro can draw a square just by indicating a segment or two points as input by using a macro pre-defined by the user and stored in her/his computer. To appreciate the consequences, imagine you want to draw a configuration illustrating Pythagoras' Theorem!
A macro definitely reduces the cognitive burden of a construction and gives a chance to cognitively structure the construction in a way appropriate for the geometrical problem under study – provided a well filled set of pre-defined macros is available for the user. Sometimes, the absence of a macro-feature in CINDERELLA is given as a reason not to take this piece of software as a full-fledged DGE.
Even in the early days of DGE, one major problem implied by the use of DGEs to help teaching and especially learning with the help of DGEs became obvious: The intuitive interface and easily understood handling of the software really facilitated the exploration of geometrical configurations, but – when handed over into the full responsibility of the learner – DGEs most often lead to a "de-goaling" in terms of the initial purpose of the construction. The user often played around with the DGE and – being intrigued by the nice drawings – forgot about the task set by the teacher (for an early description of this phenomenon see Hölzl 1994).
From the very beginning, DGE-use for teaching and learning Geometry has to cope with a dilemma not only linked to DGE-use: How to handle the non-trivial relation between the personal constructions of a learner and the often very precisely defined concepts and definitions from disciplinary Mathematics? This dilemma seems to be especially difficult to handle in a constructivist approach to learning Geometry, more general: Mathematics.
A suggestion brought forward by practitioners of teaching in the 1990ies not only tries to avoid this de-goaling: "Worksheets", prepared in advance and with clear tasks and questions to be answered, try to control the trajectory of the learner's activities in a way to avoid not only the de-goaling problem, but also try to save time by offering 535 prefabricated DGE-files. These ready-made files should directly offer the configurations to be explored – saving time and avoiding the construction mistakes often made by un-experienced users of DGEs (for this approach see Elschenbroich 2001 and Heintz 2001).
A different way to cope with this is a suggestion brought forward by Italian colleagues and grounded in a more fundamental approach: As a consequence of a social constructive understanding of teaching and learning and inspired by Vygotsky, the importance of collective discussions in the classroom are stressed. In order to guide the learners in a way to help them arrive at socially, also mathematically accepted solutions, the interventions of the teacher are of fundamental importance and cannot be left aside (see for instance Bartolini-Bussi 1996).
Excursion: Mathematics strikes back!
The end of the last section already illustrated: Using DGEs to teach and learn Geometry is not a simple success story. On closer inspection of the dragmode for

instance, the story gets even more complicated. Two demands on the dragmode seem obvious: Using the dragmode should not imply a discontinuity, the drawing should change continuously if the dragmode is used ('continuity' of the dragmode).
Example 4:
Try the angle bisector of an angle bisector and move the point defining the initial angle to make the initial angle greater than 90°. Construct only one second angle bisector to see the jump (e.g. in Cabri).
On the other hand, the user expects that the drawing should be the same after a drag of a point when this point is brought back into the initial position ('reversibility' of the dragmode, producing 'deterministic' drawings; see counter-example next page!). Unfortunately, these two somehow natural demands cannot be met together. The software designers have to make (and indeed: make) a choice between 'continuity' and 'reversibility (as shown by Gawlick 2001). The designers of CINDERELLA for instance are proud of having produced a 'continuous' piece of DGE (and there are even limit cases where the software also produces unwanted jumps), while most of the other DGEs go for 'reversibility' (for instance Cabri-géomètre), but have to cope with discontinuous changes of the drawing produced with the DGE.
When a straight line g intersects with a circle in E and F (see drawing 1 above), in a way, that g can be moved not to intersect g (drawing 2), then moved back to intersect g (drawing 3), the intersection points E and F change position.
The interesting point is that algebraic, differential Geometry can prove that this choice is inescapable, a DGE is either 'continuous' or 'deterministic'. As a consequence, the software designer has to make a (hopefully deliberate, at best pedagogically motivated) choice. 536
Example 5: Non-reversability in CINDERELLA (see Laborde 2001)
I want to add another example of the 'same' making: Numbers can be represented in software within a finite number of bits - as long as we stay with the usual discrete and binary code in digital (!) computers. The different ways to represent and store numbers in widely used pieces of software like spreadsheets (as EXCEL: at best floating point numbers with clear restrictions about numbers accurately represented, numerical analysis provides the details) and Computer Algebra Systems (CAS, especially DERIVE with its representation of numbers as quotients of natural numbers as long as storage is available, that is: rational numbers accurately represented "in principle", hence irrational numbers approximated) also show that simple Mathematics does constrain the use of software in doing, teaching and learning Mathematics. This implicitly was already an issue in the first ICMI-study, where the role of "Discrete Mathematics" (especially for college Mathematics in the USA) was fiercely discussed - without reaching a consensus. The question of discrete Mathematics seems to be open and still has to be solved for the upper secondary school mathematics curriculum worldwide.
From the two examples above (continuity versus determinism and representation of numbers), we can conclude that sometimes it is not a simple, deliberate design decision how a piece of software is constructed. Heavy, sometimes unavoidable mathematical constraints force software development into decisions, which may not be desirable from an educational point of view, but inevitable because of unavoidable mathematical constraints.
From artefacts to instruments
If we go back to the most obvious characteristic feature of DGEs, namely the dragmode, we can illustrate another major lesson to be learnt about teaching and learning with the help digital technologies: For mathematics education, (one of) the most important insights into DGE-based teaching and learning came from detailed user studies undertaken by colleagues from Italy (for a comprehensive overview see Arzarello et al. 2002). With a meticulous analysis of the different ways how students use the dragmode in a DGE, they offered not only an inventory of the utilization schemes of the users, but gave excellent hints how to profit from this most prominent feature of DGEs for teaching and learning Geometry. From the analysis published in different places, one can develop a position on the most intriguing question related to (traditional) Geometry teaching - namely whether DGE-use hinders or enhances the teaching and learning of proof in Geometry. In fact, it seems to depend on the 537 occasions and challenges offered by the teacher (or the teaching material), if DGEuse destroys or necessitates the need for mathematical proofs.
In my view, the results of this study very well illustrate how a detailed analysis of the use of software can enhance the teaching and learning of Mathematics. It is not enough to study the artefact as such, to study the features and potentials of a piece of software. Only a detailed analysis of the actual software use offers a sound and pedagogically useful understanding of its use. To put it into the words of the 'instrumental genesis' approach: the artefact together with its utilisation schemes converts digital technology into an instrument of learning! For a short description of this approach see RabardelßSamurçay 2001. Artigue 2002 shows how the approach can be helpful for better understanding the use of Computer Algebra Systems (CAS).

Solving Equations in a Spreadsheet Environment
Michal Tabach Alex Friedlander
The Weizmann Institute of Science, Israel
michal.tabach@weizmann.ac.il alex.friedlander@weizmann.ac.il
The use of spreadsheets in a beginning algebra course is considered traditionally with regard to their potential to promote generational activities. However, much less is known about their possible use to construct and solve equations. The overall purpose of this paper is to consider the potential of spreadsheets to enhance conceptual understanding of equations and their solutions. For this purpose, we analyzed the work of beginning algebra students with an activity that required algebraic modeling, solving equations, and interpreting results that were obtained as an Excel output. As a result, we recommend expanding the traditional use of spreadsheets from mathematical investigations of variations and patterns to include a conceptual understanding of algebraic relations and transformations as well.
This paper is related to Themes 1 and 2:
1. Mathematics and mathematical practices
- What new types of mathematical knowledge and practices emerge as a result of access to digital technologies?
- How are new types of technology-mediated mathematical knowledge and practices related to current classroom curricula and values?
- What role can the "mathematics laboratory" play in different educational contexts, including secondary education?
2. Learning and assessing mathematics with and through digital technologies
- How can the benefits of existing technologies be maximized for the benefit of mathematics teaching and learning?
Background
The use of spreadsheets in teaching algebra - both at a beginning stage and at more advanced levels, has been reported in various research reports. Usually the potential to produce ample numerical tables, the need to use general expressions to create these tables, and the possibility of obtaining a wide variety of corresponding graphs allows the use of spreadsheets as a tool for promoting a functional approach in teaching and learning algebra (Filloy & Sutherland, 1996; Heid, 1995; Wilson et al., 2005). According to Kieran (2004), most investigated spreadsheet activities are conducted at a generational or at a meta-global level, and according to Thomas & Tall's (2001), categorization of algebraic activities, these activities belong to the domains of generalized arithmetic or evaluation algebra. 540
However, the usefulness of spreadsheets for investigating relationships, such as solving equations or inequalities (according to Thomas & Tall, manipulation algebra) or performing transformational operations (according to Kieran) is less clear. Moreover, some studies show that attempts to use spreadsheets as a means of strengthening a conceptual understanding of algebraic techniques encountered considerable difficulties. Dettori and her colleagues (2001) investigated 13 to 14-year-old students' work on algebraic problems using spreadsheets and concluded that "spreadsheets can start the journey of learning algebra, but do not have the tools to complete it. Being able to write down parts of the relations among the considered objects, but not to synthesize and manipulate the complete relations, is like knowing the words and phrases of a language, but being unable to compose them into complete sentences" (p. 206). Friedlander and Stein (2001) investigated the abilities and preferences of 14-year-old students in solving linear and quadratic equations and systems of two equations with both paper-and-pencil and various technological tools (Excel, Derive, and graph plotter). The interviewed students demonstrated a high ability to choose, employ, and integrate technological tools into their work, but on the other hand, the students' use of spreadsheets for this purpose was quite ineffective. The purpose of this presentation is to analyze the potential of spreadsheets in promoting understanding the concept of equations, intended for beginning algebra students.
The activity
The activity Elections was administered in two 7th grade classes that attended a beginning algebra course based on a functional approach, and on the use of Excel as a technological tool (Hershkowitz et al., 2002). For several lessons before beginning the activity, the students encountered for the first time the concept of an algebraic equation, and solved linear equations of the form ax + b = c by trial and error or by a method of "undoing" the operations involved. At this time, the students had not encountered any conventional methods of solving linear equations.
The Elections activity presented the following problem-situation involving a campaign for a class committee:
Avi, Ben, and Gil are candidates for the election.
Avi received 24 votes more than Ben, and
Gil received 1.5 times more than Ben.
Next, the students were required to consider several situations of equalities between the number of votes received by the candidates, and to model them as equations of the form ax + b = cx + d. For these equations, the method of "undoing" or trial and error cannot be applied easily. In the activity the students were allowed to use Excel, and were provided with appropriate instructions. 541
Excel is not an algebraic manipulator, and it does not have the ability to provide directly the solution of a given equation. As a result, the activity presented the following procedure:
• Write in one column several values for the independent variable (i.e. the number of votes received by one of the candidates).
• Use the independent variable to write an equation at the beginning of another column.
• Copy (drag) the equation down the column.
• The resulting output is a sequence of TRUE or FALSE values - indicating the equality or inequality obtained by substituting the corresponding value of the independent variable in the equation.
• A TRUE value indicates that the substituted number is a solution for the equation (but not necessarily the only one).
• A sequence of only FALSE values can be the result of either an equation that has no solution or an equation whose solution was not included in the set of values selected for the independent variable.
As a result of the possible situations described in the activity, the students constructed four types of equations:
1. An equation with a unique solution that is also meaningful for the given problem-situation.
2. An equation with a unique solution that has no meaning in the given problemsituation.

3. An identity, i.e. an equation with all real numbers as a solution set.
4. An equation with an empty solution set.
Because of the space limitation, we will consider the rationale and analyze the students' work only for equations of the first two types.
1. An equation with a unique and meaningful solution. Item 2a referred to the possibility that "Avi and Gil receive the same number of votes", and the expected algebraic equation is x + 24 = 1.5□x (where x represents the number of votes received by Ben). The recommended Excel procedure was to insert in column A whole numbers from 1 to 50 as possible values for Ben's votes, and to write and drag down the equation
=A2 + 24 = 1.5*A2 in column B. In this particular case, one cell in column B will contain a TRUE output (indicating the solution), and all the other cells in the output column will contain FALSE values (see columns A and B in Table 1). Next, students are expected to interpret the output, and conclude that the situation described in this item can occur if Ben received 48 votes, whereas Avi and Gil received 72 votes each. Note that the expected solution process includes formulating an equation, (in both algebraic and Excel, or only in an Excel format), "dragging" it down, and finally interpreting the obtained output. 542
2. An equation with a unique solution that does not apply to the given situation (e.g., a fraction or a negative number as a solution). Item 2d referred to the possibility that "the number of votes received by Ben and Avi together is the same as the number of votes received by Gil". In our particular case, the expected algebraic equation is x + x + 24 = 1.5□x (where x represents the number of votes received by Ben), and its solution (x = -48) cannot represent a number of votes. Copying down the Excel format of this equation (=A2 + A2 + 24 = 1.5*A2) for positive values of A produces a column of only FALSE values, since the equation has no solution for the selected substitution set (see columns A and C in Table 1). Next, the students were expected to interpret the output, and to conclude that the situation described in this item cannot occur.
Data collection
Thirty-seven students worked on the activity, mainly in pairs, for 45 minutes, and saved their work in 20 files. In addition, the work of ten pairs was audio recorded. The recorded pairs were chosen at random, so we considered their work as representative of the whole class. The following analysis is based mainly on the work of the ten audio-recorded pairs of students.
Table 1. Excel output for items 2a and 2d.

	A	B	C
1	Number of votes received by Ben	2a: Avi and Gil receive the same number of votes	2d: Ben and Avi's votes together equal Gil's votes
2	1	FALSE	
3	2	FALSE	FALSE
4	3	FALSE	FALSE
5	4	FALSE	FALSE
6	5	FALSE	FALSE
.			
.			
47	46	FALSE	FALSE
48	47	FALSE	FALSE
49	48	TRUE	FALSE
50	49	FALSE	FALSE
51	50	FALSE	FALSE

1
This output is the result of entering the equation =A2 + 24 = 1.5*A2
2
This output is the result of entering the equation =A2 + A2 + 24 = 1.5*A2 543
Analysis
In this section we will present students' answers to items 2a and 2d as representatives of their work on a wider, similar collection of items in this activity.
Item 2a: Avi and Gil receive the same number of votes.
We identified four types of reactions to this item.
- Six pairs of students completed independently the solution process (i.e. formulated the algebraic and the Excel equation, copied it down the column, and interpreted the output).
- One pair formulated the algebraic equation correctly, entered in cell B1 its Excel version, and received FALSE as an output. At this stage, they became confused and asked the teacher to help. The teacher encouraged them to continue, and as a result, they were pleased to obtain a sequence of one TRUE and otherwise FALSE values, and were able to identify the first as the desired solution.
- Two pairs read the item, but did not follow the expected solution path. Instead, they used columns A, B, and C to collect their data: similarly to others, column A was used to indicate possible values for the independent variable (Ben's votes); column B indicated Avi's votes (obtained by copying down =A1 + 24); column C contained Gil's votes (=A1*1.5). Next, they searched in columns B and C and found a row with the same number of votes for Avi and Gil. The teacher accepted their strategy, but asked them to apply the new procedure as well. They followed the activity's instructions without any difficulties, and were so pleased with the results, that one student's reaction to the teacher was "Why didn't you teach us this method earlier this year?"
- One pair of students did not understand the situation, and needed the teacher's help to obtain the equation, to write it on the spreadsheet, and to interpret the results. They could work independently only after receiving the teacher's help on two additional examples.
Item 2d: The number of votes received by Ben and Avi together is the same as the number of votes received by Gil.
All pairs wrote a correct equation (=A2 + A2 + 24 = 1.5*A2), and copied it down the column. Since the solution of this equation (-48) was not included in the first column, they received a sequence of only FALSE values. The students attempted to interpret this output in various ways.
- Two pairs concluded that there is no solution for this item since "Avi and Ben together received 2x + 24, whereas Gil received only 1.5x, and these two cannot be equal."
- Four pairs did not provide an explanation, besides noting that this situation "does not make sense". 544
- One pair looked at their neighbors' computer screen and concluded that since they received a similar output, apparently their solution was correct.
- Three pairs concluded that they must be wrong, and asked the teacher for help. The teacher encouraged them to think again about the given situation, and only then they reached the conclusion that there is no solution to the given item.
The interpretation of the output for this equation was also considered during the summarizing class discussion.
Discussion
The main purposes of the activity were
- to enhance the understanding of the concept of algebraic equations,
- to provide an opportunity for algebraic modeling, and finally
- to present a situation that requires interpreting and understanding the meaning of the solution of an equation.
The Excel procedure for solving an equation (substituting a set of numbers in the equation and searching for cases of equality) is not efficient as a routine solution tool. However, the findings indicate that from a technical aspect, the procedure can be learned and applied easily.
More importantly, this solution process provides opportunities for achieving conceptual understandings of important algebraic ideas. The need to interpret the logical TRUE/FALSE values encourages students to consider several equationrelated issues.
- Not all equations can be solved by trial and error or by undoing operations.
- As shown by the many FALSE values in the Excel output, most equations have a large set of values that do not satisfy the given equality.
- Receiving a sequence of only FALSE values as output indicates an empty solution set or that the required solution is not among the values selected and substituted for the independent variable.
Our findings indicate that these insights occurred spontaneously, in the context of the activity, and were the result of a natural need to interpret the Excel output, and furthermore to solve the problem. Some of these conceptual understandings were acquired at the stage where students worked on the activity or during the following class discussion.
Analyses that concluded that spreadsheets are not appropriate to serve as a tool for algebraic transformational activities may be based on a tendency to separate or even contrast conceptual versus procedural knowledge. An analysis of the Elections activity and of student work reveals some interesting possibilities of integrating conceptual and transformational approaches into teaching and learning algebra. Similar recommendations and conclusions were reached by Kieran (2004) and by Star (2005). 545
We consider this approach of a "conceptual solution" of equations particularly suitable and important at the early stages of learning algebra. We believe that a deep understanding of the involved concepts can provide a basis for learning the routine solution procedures employed at a more advanced stage. This notion needs of course further validation by additional research.

Teachers using computers in mathematics: A longitudinal study
Michael O. J. Thomas
The University of Auckland
moj.thomas@auckland.ac.nz
The computer has been in mathematics classrooms for over 20 years now, but with widely varying implementation in mathematics teaching and learning. This paper describes a ten-year longitudinal research study that has investigated the changing nature of how secondary school teachers use computers in their mathematics classroom, and their perception of constraints or obstacles to improving, or extending, such use. The results show that while there are now many more computers available in schools, access remains a key obstacle to their increased use as mathematical learning tools. There is also a change in the kinds of software used, away from content-specific programs and towards generic software, especially the spreadsheet. Teacher attitude remains a key factor in progress.
Introduction
While many mathematics educators, including the author have been positive about the possible role of computers in the learning of mathematics (see e.g., Thomas & Holton, 2003), there have been doubts raised about a) whether computers have any real value in learning (Cuban, 2001) and b) whether current teacher use is qualitatively and quantitatively sufficient to promote any benefits that might exist. Around 10 years ago Askew and William (1995) reported on a review of research in mathematics education in the 5-16 year old age range, and found that "Although computers have been in use in mathematics education in this country [UK] for well over twenty-five years, the pattern of usage is still very varied and very sparse." (p. 34). A UK Department of Education report (DFE, 1995) also noted a low level of usage of computers in mathematics, with an average of 15.6 minutes of lesson time per week spent using the computer, and in the United States the position was very similar (Ely, 1993). While some might hope that this position has changed in more recent years, a survey by Ruthven and Hennessey (2002) on school computer use concluded that "Typically then, computer use remains low, and its growth slow." (p. 48).
There are a number of possible reasons for a low level of computer use in mathematics teaching and learning, including teacher inability to focus on the

mathematics and its implications rather than the computer and many teachers not believing that the computer has real value in student learning. Certainly, Veen (1993) has argued that teacher factors outweigh school factors in the promotion of computer use. More recently Becker (2000a) reported on a national US survey of over 4000 teachers and concluded that "...in a certain sense Cuban is correct–computers have not transformed the teaching practices of a majority of teachers." (p. 29). However, he noted that for certain teachers, namely those with a more student-centred 547 philosophy, who had sufficient resources in their classroom (5 or more computers), and who had a reasonable background experience of using computers, a majority of them made 'active and regular use of computers' in teaching. Becker (2000b) has added a description of some characteristics of such an 'exemplary' computer-using teacher, but concludes that extending these to other teachers would be expensive. This paper reports on a ten-year longitudinal study describing the changing pattern of computer use in the mathematics classroom in New Zealand. Both the level and kinds of use were recorded, together with some of the obstacles teachers perceive to increased use.

Method

Genuine longitudinal studies, where at least two sets of data are acquired from the same population over an extended time span, are relatively rare in mathematics education research. This longitudinal study, which has as its population all secondary mathematics teachers in New Zealand, began in 1995, when a postal questionnaire on computer use was sent to every secondary school in New Zealand. Replies were received from 90 of the 336 schools (26.8%), a reasonable response rate for a postal survey. Apart from information about the mathematics department in the school we received information from a total of 339 teachers in these 90 schools.

Some of the results of this survey were published at the time (Thomas, 1996). This original survey was followed by a second in 2005 in order to gain longitudinal data on how the situation might have changed over this period. In the years since 1995 teaching has become an even more stressful profession in many ways, particularly in terms of demands on time. Hence, teachers are more reluctant than ever to spend their valuable time filling in forms or research questionnaires. However, we had learned some lessons from 1995 and this time stamped, addressed envelopes were enclosed for all the schools and it was followed up several weeks later with a faxed copy. Using this approach we achieved a response from 193 of the 336 secondary schools in the country, an excellent 57.4% response. Completed questionnaires were received from a total of 465 teachers in these 193 schools, as well as the school information. In both years we are confident, due to the sample size, that the responses form a representative sample of the population of secondary school mathematics teachers, especially since we received a good proportion of responses from noncomputer users (over 30% in each case). Of the respondents, in 1995 51.5% were male and 48.5% female, with a mean age of 41.5 years, whilst in 2005, 52.6% were male and 47.4% female, with a mean age of 44.8 years; the teachers are getting slightly older. While the questionnaires sent out in the two years were not identical, for example questions on the use of the internet were added in 2005, they had a considerable number of questions in common. On both occasions they used both closed and open questions to provide valuable data on issues such as: the number of computers in each school; the level of access to the computers; available software; the pattern of use in mathematics teaching; and teachers' perceived obstacles to computer use. This data enables us to come to some conclusions about the changing 548 nature of computer use in the learning of mathematics in New Zealand secondary schools.

Q1 Do you ever use computers in your mathematics lessons?
If you answered 'No' please go straight to Q14

Figure 1: Sample questions from the 2005 survey (some formatting changed).

Results

In 1995 67.2% of the teachers said that they used computers in their teaching, and this remained steady at 68.4% in 2005. Looking at how often the teachers are using the computer in teaching, in 1995 5.9% said they used them at least once a week, but 549 in 2005 this had risen to 13.3%. In 1995 the schools reported a mean of 40.0 computers per school, with 1.7 computers in the mathematics department. By 2005 there had been a jump in these numbers, with a mean of 74.4 computers per school (excluding an outlier school with 1800 laptops), 21.9 of which are laptops, and 26.9% of the schools now have over 100 computers. Mathematics departments have 6.5 computers on average (4.2 laptops). One change has been the increase in the number of ICT rooms, up from 71% of schools in 1995 to 96%, with a mean of 2.46 per school, up from 1.79 in 1995. However, while in 1995 89.1% of mathematics teachers usually used computers in labs this dropped to 59.1% in 2005, with 10.7% using them mostly in their classroom. The question arises though as to whether these increased numbers of computers have changed the pattern of use in the teaching of mathematics.

Computer use in mathematics teaching

The mathematics curriculum in New Zealand schools is divided up into Number, Statistics, Geometry, Algebra and Measurement strands, along with a Processes strand. Number and Measurement are principally primary and intermediate school activities (secondary school usually starts at age 13 years) so those using the computer were asked in which of the remaining curriculum areas (along with specific topics of graphs, trigonometry and calculus) they used them (see Table 1).

Area of Use % of 1995 teachers (n=229) % of 2005 teachers (n=318)
Some Use Most Often Used
Some Use Most Often Used
Geometry 34.1 4.8 28.2 3.9
Statistics 75.1 38.0 85.4 59.5
Graphical work 74.2 35.4 75.5 28.0
Algebra 32.3 4.8 33.4 3.5
Trigonometry 22.7 3.1 22.5 2.3
Calculus 24.0 3.9 22.5 2.6

Table 1: Curriculum areas where secondary teachers are using computers.

These figures show a significant increase in the use of computers for the learning of statistics, both as first choice curriculum area (,2 =24.5, p<0.001), and for some use (,2 =9.47, p<0.01). This not surprising since there is a strong emphasis on Statistics in New Zealand schools, and it lends itself readily to an approach where the computer can be used to perform routine calculations, as well as graphical and investigational work. It is rather surprising in view of the excellent packages Cabri Géomètre and Geometers SketchPad, that there has been a fall (although not a significant one; ,2 =2.07) in the use of geometry packages. Cost may well be a factor in this. Of the 193 schools in the 2005 survey only 20 mathematics departments had a technology budget. The amount of money available ranged from NZ$200 to $NZ15000, with a 550 mean of NZ$2762.50 (NZ$1=US$0.68), and one head of department commented that "Annual [software] fees also take up a lot of the allocated budgets ".

To gain some idea of the variety of uses that computers are being put to in schools each survey asked the teachers to rank in order of regularity of use the types of software they employed in teaching mathematics (see Table 2). It appears that there has been a significant change in the kinds of software used in mathematics classrooms over the period, away from specific content-oriented graphical (,2 =5.59, p<0.05), mathematical (,2 =38.7, p<0.001), and statistical packages (,2 =12.3, p<0.001), and towards generic software, especially the spreadsheet (,2 =28.0, p>0.001), which may handle statistical work well enough for secondary schools.

Area of Use % of 1995 teachers (n=229) % of 2005 teachers (n=318)
Some Use Most Often Used
Some Use Most Often Used
Spreadsheet 67.2 31.9 86.2 62.6
Mathematical Programs 61.1 25.8 34.3 5.0
Graph Drawing Package 61.1 22.3 50.9 17.7
Statistics Package 44.1 11.8 29.6 5.0
Internet --- --- 46.1 6.6

Table 2: Types of software used with computers.

The trend away from specific graphical packages is a little surprising since there are now some excellent programs, such as Autograph, available. Possibly the graphic calculator has made inroads into the use of the computer for graphing functions.

Questions on the use of the internet were new in 2005, and 46.1% of the teachers reported some use of it to teach mathematics. 61.1% of the teachers have access in their classroom (and 68.4% in a staff room). For the students, only 26.4% have classroom access, although 95.6% of schools have ICT rooms connected for them. The question of how teachers organise their lessons around computer use arises.
Since 1995 a number of student-centred constructivist perspectives on teaching very have been widely encouraged in mathematics education circles (e.g., von Glasersfeld, 1991; Ernest, 1997). Has this influenced how computers are used, as one might predict?
Method % of 1995 teachers (n=229) % of 2005 teachers (n=318)
Some Use Most Often
Used
Some Use Most Often Used
Skill Development 67.7 37.6 58.5 24.5

Demonstrations 40.6 10.9 59.6 29.7
Programming 8.7 1.3 6.9 1.6
Table 3: Teaching methods used with computers.
We can get some idea of what has happened in the classroom by looking at Table 3, which describes the methods that teachers employ when using the computer. The constructivist approach broadly encourages student-centred investigation and problem solving, rather than teacher-led instruction and enforcing of skills; so one might expect teachers to use the computer to do one or the other, but not both. However, in both 1995 and 2005 it appeared that a substantial proportion of teachers used both methods and did not see themselves on one side of a dichotomous ideological fence. This was shown by around 60% reporting computer use for skill development and demonstrations, as well as investigations. There was, however, a significant decline in the proportion of teachers using the computer for skill development (,2
=4.79, p<0.05), and in those allowing free use of the computer
(,2
=18.0, p<0.001). However, the use of demonstrations significantly increased
(,2
=19.5, p<0.001), and so the data implies that while directed use and demonstration is more common in 2005, it is not as often skill-directed. Again this is not entirely what one might expect from a constructivist perspective. We note that the percentage of teachers who value programming sufficiently to spend some time on it has remained reasonably constant, if somewhat low. It may be that those who are convinced that programming may encourage the formation of mathematical thinking have strong convictions. More recent ideas related to the value of programming suggest that allowing students to interact with games where they are in control, programming attributes and functions in microworld-like games software (Noss & Hoyles, 2000) may be beneficial for learning.
Obstacles to computer use
In the original 1995 survey 93.5% of the teachers responded that they would like to use computers more in their mathematics teaching, however, in the latest survey those agreeing with this sentiment had dropped to 75.1%. While this is a highly significant decrease (,2
=47.0, p<0.001), one must take into account the increased rate
of use of computers, and hence some teachers may feel that they have reached their optimum usage level. In any case there is still a sizeable proportion of the teachers who would like to use them more, and so we are led to ask 'what factors do they perceive as preventing them from making greater use, or using them at all?' The results from the two surveys on this aspect are shown in Table 4.

Table 4: Obstacles teachers mention as preventing computer use in teaching.
In 1995 there were two areas where the teachers wanted to see improvement in order to reach their goal of using computers more. They were the provision of resources, in terms of available hardware and software and the increasing of their confidence through satisfactory training. In 2005 we see that the lack of training has been better addressed, with significantly fewer teachers mentioning it (,2
=15.2, p<0.001),
although only 39.6% of the teachers had recently been on any kind of professional development covering use of technology to teach mathematics. Clearly there is still a need for training, since when department heads were asked how many of their mathematics teachers would not feel confident using technology in their teaching, the mean response was 3.1, compared with a total of 7.2 full time and 3.1 part time mathematics teachers. In addition, significantly fewer feel that they lack confidence in computer use (,2
=15.0, p<0.001), possibly due to greater penetration of computers
in homes over the period. Further, the need for software may have been covered by the greater use of the spreadsheet, which is now provided with virtually all computers. However, the problem of the availability of computers remains the major issue. Although the number of computers in schools is increasing, since they are primarily located in large ICT rooms access to them by mathematics teachers is still the primary problem preventing greater use. The 2005 survey asked teachers if they seldom used the computer room what was the reason, and 38.7% said that it was because of the difficulty with booking the room, and a few said that it was too difficult to organize. There were very few other reasons of note given. Typical teacher comment were "Access to computers at required time (of year and within school timetable blocks)" was difficult, there is a problem "...getting into overused computer suites" and "Due to the increased demand for IT classes it is very difficult to book a computer room for a class of 20-30 students". In addition, in 1995 13% of teachers mentioned some other obstacle, and in 2005 the figure was 18.4%. These included the time and effort needed by both students and teachers in order to become familiar with the technology. It appears that some teachers are concerned that this instrumentation phase would impact on time available for learning mathematics.
Conclusion
What does this research tell us about the changing face of computer use mathematics teaching in New Zealand secondary schools? The percentage of secondary 553 mathematics teachers never using them has remained constant, at around 30%. While there are many more computers in the schools and an increased frequency of use, access to them is still the major obstacle to use in mathematics. They are usually in ICT rooms, and 89.6% of mathematics departments do not have their own technology budget. The primary uses of the computer are for graphical and statistical work, with the spreadsheet and a graph-drawing package the two most common pieces of software. There has been a significant decrease in the use of mathematical programs and statistical packages, and an expected increase in the use of the internet. While teachers are using computers less for skill development, its use is still high, and they have increased the use of demonstrations. Use of the computer is directed over 80% of the time. This pattern of changing use could not really be described as teachers warmly adopting the computer, and there are two important factors worth mentioning here. Only 20.7% of the schools had a technology policy in place, and when they did it usually comprised general statements such as "Technology should be used wherever possible as an aid to learning", "All teachers are expected to integrate ICT into their teaching and learning practices", "Access for all students to internet" or it specified what technology would be used by which year groups, or set rules for internet access and computer room use. Only rarely did it include the acquisition and replacement of software and hardware or the professional development of staff. Such an important omission has been noted previously (Andrews, 1999). It is not surprising that without such a policy the use of computers in schools will tend to lack clear focus and direction. The second issue arose when the 2005 teachers were asked what they thought were the advantages and disadvantages of using computers (technology) in mathematics. While just 8% believed that it aided understanding (compared with 32% who thought it made working quicker or more efficient), 16.8% claimed that it impeded learning or understanding. As Manouchehri (1999, p. 37) reported many "...teachers are not convinced of usefulness of computers in their instruction...", they still feel, like Cuban (2001), that benefits are small or exaggerated, and students rely on technology too much. As several teachers in this research put it "I feel technology in lessons is over-rated. I don't feel learning is significantly enhanced...I feel claims of computer benefits in education are often over-stated.", "Reliance on technology rather than understanding content. ", and "Sometimes some students rely too heavily on [technology] without really understanding basic concepts and unable to calculate by hand." Clearly teachers have a crucial role to play, and their beliefs and attitudes are major elements in the progress in computer use. This is an area for further research.
Acknowledgement
I should like to acknowledge the support of a Ministry of Education of New Zealand, Teaching, Learning and Research Initiative (TLRI) grant, without which this research could not have taken place. I am also grateful to Charles Tremlett for his assistance with some data analysis.

Developing resources for teaching and learning mathematics with digital technologies in Enciclomedia, a national project
María Trigueros, María Dolores Lozano, Ivonne Sandoval, Ana Elisa Lage, Emanuel Jinich, Heréndira García, Erika TovillaIICE, Enciclomedia, México
mdolores@ilce.edu.mx
Enciclomedia is a Mexican national project that intends to complement already existing materials for primary school classrooms with computer programmes and teaching resources that are to be used with an interactive whiteboard. In this paper we report on the process of development of resources for teaching and learning mathematics with Enciclomedia. Our approach is guided by an enactivist theoretical perspective and methodology (Maturana and Varela 1992; Varela, 1999; Reid, 1996) which invites us to consider our work as a learning process in which we continuously refine the resources we develop. Our work includes analysing existing teaching materials, having conversations with teachers, reading the literature and doing research with the purpose of identifying the kinds of activities the new programmes foster in the classrooms. Throughout this work, we discuss the different

aspects of this process of development of resources. We illustrate our way of working through three different mathematical themes: fractions, probability and area. We have found that working with the multiple perspectives which are prevalent in our group has enriched the production of resources. Finally, the circular nature of the process helps us in refining our methods and in questioning our assumptions; that is, in developing our own learning and making our educational initiatives more effective.

Introduction

Enciclomedia is a large-scale Mexican project that has been devised with the purpose of enriching primary school teaching and learning by working with a computer and an interactive whiteboard in the classrooms. An electronic version of the textbooks that are used in Years 5 and 6 in all primary schools is being enhanced with links to computer tools designed to help teachers with the teaching of all subjects. Our task, as part of the Mathematics group, consists in creating resources which complement the textbooks and can help teachers in their teaching of mathematical concepts.

In this paper we focus on the way of working that has emerged in the practice of creating resources and investigating their use in the classrooms. The process includes the analysis of the textbooks used by the students; the identification of some of the difficulties students and teachers have with the mathematical concepts we are addressing, found both in the literature and in conversations with teachers; the production of resources and the investigation of the way the materials are used in the classroom. We begin by considering some ideas related to enactivism, a theory about learning which guides us both theoretically and methodologically. Later, we discuss the different aspects of the process we are immersed in and which we outlined above. 557 Finally, we talk about the way in which this process has helped us in refining both our ideas and the resources we are creating so that they are more effective in the teaching and learning of mathematics.

Theoretical Framework

Our ideas about learning are based on enactivism, a theory of knowing which considers learning as effective or adequate action (Maturana and Varela, 1992). In enactivism, our minds are seen as 'embodied' and cognition as 'embodied action'. These ideas of 'embodiment' entail two fundamental senses: on the one hand cognition is seen as 'dependent upon the kinds of experience that come from having a body with various sensorimotor capacities' and on the other, individual sensorimotor capacities are considered to be 'themselves embedded in a more encompassing biological and cultural context' (Varela, 1999, p. 12). The first meaning of embodiment locates cognition in our bodies, and prevents us from thinking about it as an abstract notion that is detached from our everyday experience. The second situates our learning in a wider social and cultural context.

In enactivism learning occurs when individuals interact with each other, changing their behaviour, that is, their actions, in a similar way. In a particular context or location, the participants create together the conditions that will allow actions to be adequate. Learning outcomes cannot be predetermined or predicted, but the criteria for the adequateness of actions are, at least in part, specified by teachers and students. With this in mind is that we are interested in developing initiatives that can help teachers to create contexts in which certain actions, related to the learning of different mathematical concepts, can be fostered.

Learning mathematics with computer tools

From an enactivist perspective, the use of computer tools is part of human living experience since 'such technologies are entwined in the practices used by humans to represent and negotiate cultural experience' (Davis et. al., 2000, p. 170). Tools, as material devices and/or symbolic systems, are considered to be mediators of human activity. They constitute an important part of learning, because their use shapes the processes of knowledge construction and of conceptualization (Rabardel, 1999).

When tools are incorporated into students' activities they become instruments, which are mixed entities that include both tools and the ways these are used. They are not merely auxiliary components in the teaching of mathematics; they shape students' actions and therefore they are important components of learning (ibid, 1999).

Every tool generates a space for action, and at the same time it poses on users certain restrictions. This makes possible the emergence of new kinds of actions. The influence that tools exercise on learning is not immediate. Actions are shaped gradually, in a complex process of interaction. In the classrooms, students can construct meanings through the use computer tools, in a process of social interaction and with the guide of the teacher (Mariotti, 2001). The purpose in, Enciclomedia, is to develop programmes which can broaden students' and teachers' experiences with mathematics. 558

Some ideas about methodology

'Enactivism, as a methodology [is] a theory for learning about learning' (Reid, 1996, p. 205). Research is considered to be a way of learning, and therefore researchers are seen as individuals developing their learning in a particular context. From an enactivist perspective, researchers interpret the world in a particular way, influenced by their previous experiences. In addition, in the process of doing research researchers influence and shape the context in which they are immersed (Reid, 1996, p. 206). The interdependence of context and researchers makes the research process a flexible and dynamic one. Research does not occur in a linear fashion; rather, it is seen as a recursive process of asking questions. The enactivist ideas apply not only to research we carry out in the classrooms, but to the whole process of development of resources in Enciclomedia. We think of our educational initiatives as dynamic suggestions which are under constant modification. Teachers are intended to work with our proposals in their practice which is inevitably an ever-changing process. The interactive materials related to specific concepts in the curriculum are used by students in a process which is also dynamic. Researchers' and developers' ideas will be modified as they interact with textbooks, teachers, students, and with each other.

The process of development of resources

Analysing the textbooks

When we work with a particular mathematical concept or process, we usually start by looking at those chapters in the textbooks which are related to it. We try to identify areas where a multimedia resource could be of help. The approach taken by the National Curriculum and the textbooks consists in 'taking to the classrooms those activities which elicit students' interest [in mathematics] and invites them to reflect, to find different ways of solving problems and to formulate arguments that validate their answers' (SEP, 2003, p. 7). We find most problems and activities posed in the textbooks challenging and useful; however, we have also noticed limitations in the presentation of concepts. The problems in the textbooks require of mathematical knowledge which students usually do not have. Complex ideas are often presented without providing the students with any strategies for dealing with them. For example, we have found that the idea of probability is introduced before the students have had enough experiences with random events. Also, sophisticated problems involving rational numbers are presented without providing students (and teachers) with activities that could assist them in their learning. Our purpose is to complement the textbooks providing teachers and students with resources that can help them in working with the problems posed in them.

Conversations with teachers

As we have already mentioned, we work with teachers through the whole process of development of resources. Three teachers who use the resources in their classrooms work part-time in Enciclomedia. They carefully go through the materials we produce and make comments about them. We visit schools regularly, and we work, in 559 particular, with four teachers from two different schools. We have also worked in several workshops including 200 teachers in total.

Teachers find many of the problems in the textbooks difficult. They often say that the books do not provide students with enough exercises for them to learn the concepts. Most teachers also say they do not understand the goal of the chapters and that they do not know how to solve the more complex activities in the textbooks. For example, they often avoid teaching lessons related to probability since they consider it too difficult and not relevant. Regarding area and perimeter, even when teachers say to have a good understanding of the concepts, they prefer to use conventional formulae instead of working with non-standard units as is suggested in the textbooks. We have found that teachers' strategies often differ from the approach taken by the National Curriculum and the textbooks. During the lessons they give definitions for concepts and work on repetitive exercises. Students are frequently left to work on the textbooks' problems on their own and they verify answers in the group without discussing them. Collaborative work is seldom used and students often get distracted.

Looking at the literature

Finding out what is said in the literature about the teaching and learning of the mathematical concepts we are addressing in our project provides us with valuable ideas for our work. We are familiar with different areas of the mathematics education literature; some members of our group have experience in doing research on the teaching of mathematics with the use of digital technologies and each of us has looked at research studies on different mathematical concepts.

For example, regarding the learning of fractions we have found that many studies show that it is a complex process where plenty of difficulties arise (e.g. Cramer et al., 2002). Studies often suggest activities that might help children in developing meanings for rational numbers, such as the use of multiple concrete models. Concerning probability we have found that identifying a random event is difficult as students often confuse a random experiment with a sequence of results (e.g. Schlottmann, 2001). Children often use non-conventional strategies to find the probability of winning a game and many students believe that in all random experiments the events are equally likely. Researchers give suggestions such as the use of simulations to help students observe the temporal and spatial features of many random phenomena and facilitate the development of probabilistic reasoning (Drier, 2000). As to the learning of the concept of area, research shows that many students do not see it as a measure of the spread of a surface, even when they can use formulae to calculate it (e.g. Baturo and Nason, 1996). Students often confuse perimeter with area, and researchers advise to work with this distinction from the beginning. Early introduction of formulae is seen as a contributor to this problem and therefore the use of non-standard units and of ways of obtaining areas and perimeters is suggested.

From the analysis of the textbooks, the conversations we have with teachers and the findings from the literature, many questions arise. We ask ourselves what kinds of experiences can help teachers and students in their learning of the 560 mathematical concepts we are thinking about and whether digital technologies can be of particular help. For example, we start thinking about how multiple representations and computer simulations can help teachers and students reconsider their ideas about these concepts. We then start the production phase, in which we develop interactive programmes and teaching guides.

Producing the materials

Computer programmes. We have developed different types of programmes. They vary, for example, in the kinds of interactivity they promote and in the types of problems they pose to the users. The programmes are closely related to the activities in the students' textbooks, but they are mostly thought of as spaces for mathematical exploration. They usually provide users with something they would not get if they used the textbook only. Programmes give the students immediate feedback on their actions on the computer and they often simulate situations that are difficult to recreate or experience in the classroom. For example, the interactive programme Dados, which is related to probability, simulates large number of occurrences of random events by recreating different games with dice. The Balance, a programme that reproduces a problem situation from the Year 6 textbook in which scales need to be balanced using fractions, provides the users with feedback that helps them in identifying which parts are balanced and which are not. Finally, the programme Perimarea invites students to work with non-standard units and with different ways of calculating the area and perimeter of different shapes.

Teaching guides. Our work includes the development of teaching guides with suggestions on how to use the computer programmes with the interactive whiteboards. We believe learning occurs through interactions, and therefore we recommend teachers to promote collaborative work in their classrooms. The activities we propose include discussions and small-group work. We also advise teachers to promote the manipulation of concrete objects before getting students to work with abstract ideas. We acknowledge the complexity of teaching and learning and the uniqueness of every classroom. Our intention is to provide teachers with guidelines, and to work with them in the development of their practice of the teaching of each particular concept.

Doing research in the classrooms: Back to the beginning

After a first version of the programme related to a particular topic is completed, we start doing research in the classrooms. We make observations and ask questions to students and teachers in order to identify mathematical actions they undertake and to obtain more information on what their difficulties and strategies are. We investigate students' behaviour and, in particular, their mathematical actions. We look for patterns in effective behaviour, which for us define a classroom culture (see Maturana and Varela, 1992). We use audio and video recording as well as fieldnotes to collect data.

The data show, for example, that the use of The Balance invites students to act mathematically in a number of ways. They work with mathematical concepts such 561 equivalent fractions and they operate on mathematical symbols. They use different representations when dealing with fractions and they often ask mathematical questions such as "why is ¨ heavier than #?". We have also observed students giving explanations to justify their answers to the group. Justifications are usually incomplete although we have also recorded sophisticated explanations, such as using graphic representations (of pizzas) to show how a fraction with odd numerator can be divided into two equal parts. Classroom observations have also shown that, using the program Dados students are able to interpret graphs of frequencies, to identify equally likely events and to make predictions taking into account the probability of the events. All this is only possible with teachers' support and intervention. Even when programmes prove to be useful as a means of enriching children's experiences with mathematics, teachers' organisation and strategies are found to be crucial.

We have also observed students as they use the programme Perimarea, where they need to calculate the area for different shapes by counting the squares on a grid. We noticed, both during the lessons and on the video from those sessions, that students often give the answers by trial and error. They get feedback from the programme, showing them graphically whether they are missing or they give too many square units in their answers. Many students write random numbers, while others count squares. In both cases, they do not relate these actions to the concept of area or the formulae they have used beforehand. The original purpose for which we developed Perimarea was not accomplished. For this reason, we decided to modify

the programme so that students were not given automatic feedback and so that they could establish relationships between their counting actions and the concepts of area and perimeter. We have already done some changes to the programme and others are in process. Figure 1 shows the way in which the interface has changed. For example, it new button 'Listo', which teachers can use whenever they want the programme to give feedback to the students, was incorporated.
Figure 1: Changes in Perimarea
Research on how this version of the programme works in the classroom is currently being carried out. We are also wondering whether we can develop more activities that can help students deepen their understanding of area. Revisiting the textbooks and the literature are places to start. Classroom observations often make us reconsider our ideas about the concepts we are working with and about the 562 programmes we are developing; therefore taking us back to the beginning of the process (see Figure 2 for a diagram that shows the recursive process of development of resources).

Figure 2: The circular process of production of resources in Enciclomedia
Conclusions
Research done shows that, when the materials we are developing in Enciclomedia are used in the classroom, students look interested in solving mathematical activities. They reflect on problems and they give explanations to justify their solutions, which are key elements in the approach taken by the National Curriculum. The culture in the classrooms includes interaction and collaborative work. We believe that the open nature of most of our interactive programmes promotes this kind of work.
Difficulties have been encountered in the process of incorporating the new tools in classroom activities. Teachers are often afraid of using Enciclomedia at the beginning and they usually need support and encouragement. Not all the programmes have worked in the way we expected them to and therefore, as in the case of Perimarea, modifications have been needed. We have also changed teachers' guides when, after having been in the classrooms, we find that teachers need particular suggestions. The circular process in which we are immersed has been extremely important in the refinement of our materials thus making them more efficient.
Collaborative work amongst ourselves, the members of the mathematics group in Enciclomedia, has been of prime importance in the process of development of our initiatives. Throughout the process, we use multiple perspectives, which is another feature of the enactivist methodology (Reid, 1996, p. 207). This refers to the exchange of ideas with other researchers and also to the examination of different kinds of data. Through the comparison of different events we are able to explain more. The analysis of the books is done by each member of the team separately; we

then discuss our ideas with each other and with teachers. The development of the programmes and the teaching guides involves multiple views, as a number of programmers, designers, mathematicians, educators and students collaborate with us. Doing research in the classrooms also involves the use of multiple views as we collect many types of data and we analyse them from different perspectives.
In the future we will carry on developing our resources as we continue exploring classroom cultures in which the digital technologies provided by Enciclomedia are used. Our recursive way of working helps us in enriching teachers' practices and in developing our own learning about the teaching and learning of mathematics.

Gender and socio-economic issues in the use of digital technologies in mathematics education
Colleen Vale
Victoria University, Australia
colleen.vale@vu.edu.au
This paper has been prepared to address the issues and questions of the theme 'access, equity and socio-cultural issues'. Findings from two studies are reported. In the first study gender issues in mathematical learning environments when computers were used were investigated. In the second effective practices for teaching disadvantaged or marginalised students with digital technology are canvassed. Teaching for equity and social justice in the digital age is complex. Teachers need to be aware that their beliefs and classroom practices may exacerbate gender and cultural inequalities in mathematics learning. Approaches that are consistent with social-constructivist and democratic theories need further investigation.
In this paper a synopsis of previous research of equity issues in computer-based secondary mathematics, especially gender issues, and findings from current work that is focussing on responding to diversity and disadvantage of students in mathematics when using digital technologies, are described. The issues raised in this paper concern students' engagement in and attitudes to mathematics learning with digital technologies, teachers' practices and pedagogical approaches that erode or enhance equity and social justice in these environments and the theoretical frameworks that inform and arise from the studies.
Equity involves equal access, equal treatment and equal outcomes in mathematics learning, participation and attitudes (Fennema, 1995). Teaching for social justice requires a commitment to 'closing the gap' and involves fairness, respect, inclusivity and redressing power imbalances (Boaler, 2002; Skovsmose & Valero, 2002).
Impact of digital technology on gender equity
In an earlier ICMI Study 'Gender and Mathematics Education' it was reported that the use of technology in mathematics might erode the advances made toward gender equity in mathematics (Hanna and Nyhof-Young, 1995). Only a few people have investigated gender issues with respect to the use of technology in mathematics. In the context of a narrowing gap in gender differences in achievement in Australia but persistent differences in senior secondary mathematics participation (Vale, Forgasz & Horne, 2004) I began to explore the proposition of threats to equity.
The research involved a grade 8, grade 9 and grade 10 mathematics class and their teachers. The classes were located in two schools where the students came from socio-economic backgrounds that were in the mid-range in Victoria, Australia. The research focussed on classroom practices and culture when using computers in mathematics as previous studies had shown the relationship between classroom practices and differentiated learning outcomes (Fennema, 1995). It was naturalistic in 565 the sense that it sought to study what was actually happening in classrooms rather than to invoke change or innovation using ethnographic methods. Mathematics lessons were observed and video-taped, teachers and students were interviewed, and students completed a questionnaire. Teachers determined the content and learning approaches used in the classrooms and we negotiated the timing of the study. Qualitative and quantitative methods were used to analyse the data collected.
The grade 8 class was timetabled in a computer laboratory for one lesson each week. Students in the grade 9 class owned (or leased) laptop computers that they brought to school each day. They were used for some lessons, when appropriate to the content as determined by the teacher. Students in the grade 10 class used computers for only one topic in the year. They accessed a computer laboratory for three consecutive lessons for this topic. These learning settings are typical of the range of contexts in which teachers can access computers for mathematics lessons. The content of the lessons observed included algebra, number and geometry. Grade 8 students used PowerPoint to present and explain the solution of multi-step linear equations and a spreadsheet to solve applied problems about percentage change. Grade 9 students learned to use dynamic geometry software, completed two guided investigations on geometric properties and a project on the construction of various geometric shapes. Grade 10 students learned to use Graphmatica and used it to investigate the family of quadratic functions and to solve problems about the paths of bouncing balls.
The classroom cultures and students' attitudes and the factors influencing these findings are presented here. Data are to support these findings are published elsewhere (Vale, 1998; Vale, 2002; Vale, 2003; Vale & Leder, 2004). The students in these classrooms were motivated to complete the tasks and with a few exceptions they worked individually on their computers. While the behaviours and attitudes of girls and boys were similar in many respects, the classrooms were masculine domains since the behaviours and interests of the boys defined the cultural norms of the classroom. The boys were louder and took up more space (and in the year 9 class they outnumbered girls 2:1); they were more demonstrative and public about their computer knowledge and competitive about their achievements in mathematics and with computers, a finding consistent with previous studies of gender (Boaler, 1997; Forgasz & Leder, 1996; Schofeld, 1995). Boys benefited in these computer-based mathematics classrooms because they took control of their own learning to learn more about computers. They did this through their off-task activities such as loading software and searching the Internet. Girls and their needs and interests were on the periphery in these classrooms; they did not participate in general classroom discussions, male students denigrated their achievement and the teachers were generally ignorant of their computer skills, especially girls with lower mathematics achievement. Some high achieving girls worked individually as 'silent' participants. Students were positive about the use of computers in mathematics and considered it a natural learning environment for the 21
st
century. However, girls viewed the use
computers in mathematics less favourably than boys. Boys believed that computers 566 were a male domain and that they provided pleasure, relevance and success in mathematics. Girls more often commented on whether computers aided their learning or enabled success in mathematics and high achieving girls in particular were concerned that the use of computers may lead to deterioration in their mathematics skills. More positive attitudes to computers by males have been commonly observed in studies of computing in education. Forgasz (2002) found that the socio-economic status of students mediated gender differences in attitudes to computers in mathematics. Students of high and low socio-economic status were more likely to gender-stereotype the use of computers in mathematics.
In these classrooms the students used the computers as a tool for doing mathematics. There were relatively few interactions between students about the mathematical concepts that they were exploring. When these did occur they were between high achieving boys, who were more likely to comment that computers aided learning of mathematics. High achieving girls also displayed efficient strategies when using the computers to solve problems in the different classrooms. Attitude to the use of computers for learning mathematics was more strongly correlated with attitudes to computers than to mathematics, and this was more strongly the case for boys than girls (Vale & Leder, 2004). Galbraith, Haines and Pemberton (1999) also observed this phenomenon among tertiary students of mathematics but they did report any findings by gender.
Teachers' practices
Teachers' practices, beliefs about computers and mathematics learning, expectations of students and lack of experience with computers and software in junior secondary mathematics, contributed to the culture of these classrooms. The data showed that the approaches and views of the teachers were more strongly in accord with the learning preferences and views of boys.
Many of the tasks observed in these classrooms were consistent with a constructivist approach to learning mathematics, and they had the potential of promoting collaboration in the classroom and engagement in mathematical thinking but this rarely occurred and not for lower achieving students. Furthermore, the teachers in this study perceived computers to be a tool and an opportunity for student enjoyment in mathematics and the grade 8 teacher believed he had a responsibility to teach and use generic software in his mathematics program and sought ways to do this. The grade 9 teacher believed that high achieving mathematics students would benefit the most from using computers.

Teachers differentiated their interactions between girls and boys in the classrooms and according to the mathematical achievement level of students. They were more likely to interact with high achieving students about the mathematical concepts. The grade 8 teacher spent long periods of time individually instructing students with fewer computer literacy skills or confidence. They held gender stereotyped views of students and assumed boys' to be the computer experts in these classrooms and called on them to solve problems. They did not acknowledge the computer skills of 567 lower achieving girls who took on different roles in these classroom settings as successful tutors. Opportunities to engage these students in mathematical thinking while using technology were missed. If mathematics teachers believe boys "know" about computers and girls "learn" computers, then teachers will have different expectations of students in computer-based mathematics lessons.
These teachers needed to be more explicit about the mathematical learning objectives of these tasks, to facilitate collaboration among students and to discuss the processes and findings of their investigations and problem solving in the public forum, for the benefit of all students. They could have provided opportunities for students to generate their own questions, draw on their own ideas, use other software or mathematics knowledge and to work in groups. According to the data gathered from student interviews these approaches would have appealed to the girls and boys in this study. The findings from this study indicate that teachers need to reflect on their own practice and beliefs and the way that these impact on the attitudes and performance of the different groups of girls and boys in their classrooms.
Type of digital technology
A range of software accessed through computers, either desktops in a laboratory or laptops were used. Did this make a difference to gender equity? One might argue that the cultural norms would be similar in normal classroom settings for these teachers and students. The "control" that students exercised with computers, especially laptops, resulted in gendered patterns of activity. Boys used these lessons as an opportunity to learn more about computers and to have fun. Girls were less likely to have computers at home and had less experience of computers. Girls with fewer opportunities to use computers relied on learning their computer skills in classrooms. Without adequate support from their peers or the teacher, students who were not computer literate were excluded from the mathematical learning. Fennema (1995) argued that there has been little progress toward gender equity for lower-achieving girls and findings from this study suggest that this phenomenon is evident in computer-based classrooms. Would hand-held digital technologies be any different? Shaoff-Grubbs (1995) reported positive achievement and attitude outcomes for girls using graphics calculators, but there have been few gender-based studies. The propensity of girls to use and perform better than boys with by hand methods for algebra items in graphics calculator and CAS environments (Forster & Mueller, 2001; Tynan & Asp, 1998) suggests that further research is warranted.
RESPONDING TO DIVERSITY AND DISADVANTAGE
In the current research and work with teachers I have begun to document teaching practices that will support the learning of disadvantaged and marginalised students in technology-based mathematics. Teachers who regularly used digital technologies in their junior secondary classrooms and who gave priority to enabling all students to experience success when using digital technologies were selected. Eight junior secondary mathematics teachers have been involved in the first stage of this project. They are teachers in some of the most disadvantaged schools in Melbourne. Their 568 schools are located in communities with below average socio-economic status, high proportions of students from non-English speaking backgrounds where the most disadvantaged are recent refugees or students living in poverty. I interviewed each of the teachers and we spent one whole day together presenting and sharing teaching materials and strategies.
Each teacher defined equity in terms of equal treatment and fairness, and developing mutual respect. Two teachers were also committed to 'closing the gap' by improving the outcomes of their students relative to students from more advantaged socioeconomic backgrounds. They talked about empowering their students.
The framework for beginning to document and analyse teaching practices is drawn from a number of studies on inclusive practices and social justice (for example, Boaler, 2002; Hayes, Lingard & Mills, 2000; Skovsmose & Valero, 2002). It is summarised using six main characteristics of teaching for equity and social justice: equal access to learning and the use of digital technologies; connected learning; collaborative methods; supportive environments; intellectual quality and respect for difference. Brief descriptions of these ideas and a few examples gathered through this project are presented below.
Equal access is non-trivial. Ensuring that students in schools that are poorly resourced with digital technologies or from poor family backgrounds means that this concept extends beyond merely ensuring that students in a class have equal time hands on with materials and digital technologies. Furthermore as observed in the previous study, the cultural norms of the classroom are critical if students are to be included in mathematical practice and thinking. Teachers in the current study talked about the strategies that they are using to get access to digital technologies for their students and also to find ways of 'closing the gap' for their students. These included school initiatives to provide computers for some families and the provision of additional hands on time in class and homework sessions for students who do not have computers or the Internet at home.
The teachers used some approaches related to constructivist, inclusive and democratic theories of connectedness and empowerment. They described learning tasks that enabled students to build on their prior knowledge, in particular their skills with technology. This was especially the case for two of the teachers who used integrated projects that were socially and culturally relevant to their students. In these projects students explored mathematical concepts or applications and presented their findings using a range of digital media or conducted other inquiries using mathematics and statistics with technology to communicate their findings. These projects were open-ended and aspects of the tasks were negotiated with students. Making mathematics relevant was clearly a goal for teachers. But what are the empowering mathematical concepts, skills and teacher practices in the context of digital technologies? Four of the teachers believed that a focus on the language of mathematics was particularly important for their empowering their students. 569 Selecting or designing tasks based on what students knew and understood about mathematics was less apparent in their practise. One teacher described an investigation of the relationship between the diameter and circumference of a circle after discovering that her grade 9 students held some misconceptions about pi. Each student in the class entered data into a spreadsheet on one laptop connected to a data projector. This teacher described a strong sense of community inquiry as students discussed and asked questions in response to the immediate feedback available by the technology being used in this way.
Collaborative practices recognise the importance of discussion and social interaction for the learning of mathematics and students are encouraged to share their knowledge and skills and to explain their thinking. Presentation and discussion of findings from integrated projects and problem solving tasks was important practice for two of these teachers, but group work with technology was not a common practice. Perhaps this was because all but one of the teachers used computers rather than graphic calculators with their students and they wanted to ensure hands on access for all students. Three teachers used particular seating plans in computer laboratories in order to facilitate peer tutoring and assistance, but effective practices for group work with computers needs to be documented.
In supportive learning environments students feel safe, free from abuse, and respected. Expectations for mathematical thinking and practices are made explicit for students and teachers model and scaffold mathematical thinking in the classroom. The concept of fairness, equal treatment and respectful relationships with students were common meanings of equity and social justice given by the teachers. One teacher deliberately used the grouping of students and seating plans in the computer laboratory to develop more understanding, respect and harmony among his students of diverse cultural backgrounds and educational talents. Each of these teachers demonstrated the technical skills to model mathematical practices with technology and they used guided investigations. Three of them believed that detailed step-bystep instructions were important. In three of the schools students accessed learning tasks through the school network. One of these teachers included voice-overs and another imbedded hints as comments in the instructions and examples that she provided her students for problem solving tasks. Another teacher talked about the need to design questions in written instructions that would support students to interpret the dynamic visual feedback afforded in digital environments.
High expectations and engagement of all students in meaningful mathematical thinking are central to social justice. One way in which teachers in the current study conveyed their expectations was through the dissemination of criteria for assessment tasks, especially the integrated projects. One teacher showed her students examples of similar projects. She gave particular importance to thinking creatively and providing the opportunity to display high-level skills with technology. Four of these teachers regularly used non-routine problems in digital environments to engage students in higher-order thinking and provide challenge. They commented that the 570 instant visual feedback of the digital environment afforded students the freedom to experiment without the fear of failure and public disclosure.
Two teachers in particular talked about the need to understand students' cultural background and create tolerance and respect within their classrooms. While teachers generally recognised gender differences and used real data and applications of mathematics related to the interests of their students, both boys and girls, only one was concerned that they were using mono-cultural contexts for their real life applications of mathematics.
Conclusion
Australia is one of the few countries that have consistently shown no significant gender differences in achievement in the large international studies over the last decade (TIMMS and PISA studies) but socio-economic differences in achievement are more dramatic in Australia than for the OECD average. The research into gender issues summarised in this paper reveals practices that threaten advances toward gender equity. Paying attention to gender issues when using digital technology in mathematics is necessary if further progress is to be made in achieving gender equity in achievement and participation in mathematics around the world.
Further there is reasonable concern that the use of technology in mathematics may focus on the learning and needs of the most successful and socially advantaged mathematics students (Hoyles, 1998). Indeed, a report of a recent global survey to gather cases of exemplary innovative practises in the use of digital technology in education included very few cases that focussed on disadvantaged or marginalised groups (Kozma, 2003). I have attempted to shed some light on the practice of teachers working with disadvantaged students. We need to continue to work toward empowering disadvantaged and marginalised students in the digital age.

Online homework, quizzes and tests enhanced with an equation editor and tools for collaboration
Vu Quoc Phong, Ohio University
Athens, OH, USA
qvu@math.ohiou.edu
An effective use of the Internet for teaching and learning mathematics cannot be accomplished without a method of displaying and manipulating mathematical expressions on the web. There are currently several equations editors used for this purpose, but none of them can be regarded as a standard method yet.
This session contains an overview of currently available equation editors, including: i) MathType, ii) TeX and related tools such as LaTeX2HTML, TtH, JsMath and mimeTeX, iii) MathML and WebEQ, with a discussion their advantages and disadvantages. This overview of available methods of mathematics publishing on the web demonstrates that at present there is no one single solution which is superior to all others in all aspects.
Motivated by the principle that users have various needs and therefore should be given options to choose between different platforms in the most convenient way, we propose another online equation editor, in which we combine ingredients of ITeX, mimeTex and some ideas behind TtH and MathML to offer a solution that can meet today's needs as well as take advantages of possible future improvements in MathML. We discuss features of the new online equation editor that make it a possibly more useful tool for online teaching and learning than other existing equation editors, and we demonstrate the use of this equation editor in online class activities such as discussion boards, chats, online office hours and tutorials.
As an example of the potential application of the equation editor, we describe a project under way at Ohio University on a centralized system of homework, quizzes and tests for undergraduate introductory calculus courses. The central idea of the project is collaboration between instructors and students to build a database of problems with solutions, for which the online equation editor serves as a working instrument. We use the well known WebWork for part of our online homework system, but we also use resources created by instructors, especially for those tests which require detailed written answers. We discuss methods for facilitating the fast and efficient entry of mathematics problems into the databases, and for using these databases in teaching, learning and students knowledge assessment. Finally, we discuss possible collaboration of mathematics teachers between institutions in the U.S. and other countries in the creation of online learning content in mathematics. 573
Use of Graphing Calculators in Pre-university Further Mathematics Curriculum
Ng Wee Leng, National Institute of Education, Singapore
wlng@nie.edu.sg
In Singapore, the use of graphing calculators in the pre-university level Further Mathematics examinations was first permitted in the year 2001. This study examines Further Mathematics students' performance and usage of GC in solving problems on Curve Sketching, Linear Spaces and Statistics. A total of 190 students enrolled in the second year of the two-year pre-university course in Singapore who took Further Mathematics were surveyed on 3 occasions at intervals from March to September 2003. The results obtained seem to suggest that graphing calculator users perform better academically than non-graphing calculator users. Temporal benefits of graphing calculator usage in a timed pencil-and-paper assessment are also alluded to. Further in-depth studies need to be performed to ascertain the factors surrounding graphing calculator usage, such as teacher proficiency and instruction, and a formal teaching scheme that incorporates the use of the graphing calculator on a regular basis needs to be developed and systematically carried out to ascertain the many facets of graphing calculator usage and its potential as a learning and teaching tool at the pre-university level in Singapore.
Introduction
Ever since its birth more than 40 years ago, the electronic calculator has undergone a number of changes as a result of progress in technology: from models that perform the four basic operations of addition, subtraction, multiplication and division, to complex machines that are able to perform extremely specialised algebraic and symbolic computations instantaneously and to do so with precision (Pomerantz, 1997). Consistent improvements have been made on older models of electronic calculators, the products of which are devices with increased speed and more sophisticated capabilities. Apart from being used frequently in a large variety of vocations, electronic calculators have also gained the attention of mathematics educators and researchers in mathematics education as a tool in the teaching and learning of mathematics. In the local context of Singapore, scientific calculators have been used in the teaching and learning of secondary school mathematics from Secondary One through to Secondary Four and in junior colleges (JC; pre-university level) for a number of years. However, the use of the graphing calculator (GC) in the teaching of pre-university level mathematics is a fairly recent endeavour locally. In fact, students were only allowed to use a GC while taking the GCE Advanced Level Further Mathematics examinations since the year of 2001. As there is a dearth of research on the impact of GC use and JC student achievement in Singapore, the 574 purpose of this study therefore, is to determine whether the use of graphing calculators by Year 2 JC students in Further Mathematics enhance academic achievement and overall performance in problem solving.
Since its inception in the learning and teaching of mathematics, a number of researchers have studied the use of calculators in the classroom. Campbell and Stewart (1993) have found that calculators stimulate problem solving, extend number sense and reinforce comprehension of arithmetic operations. Research conducted by Hembree and Dessart (1986) also show that students who utilise calculators regularly obtain higher achievement scores and improved paper-and-pencil skills in basic operations and problem-solving. This directly addresses the concerns that paper-andpencil skills will be rendered obsolete with the frequent use of the calculator.
Suydam (1987) surmised, through scrutiny of over 100 studies, that the use of calculators encourages achievement, improves skills in problem solving and heightens understanding of mathematical concepts. Some researchers propose that the use of calculators make available precious time that was used previously for manual computations that allow teachers to introduce more mathematically investigative work and therefore let students have the opportunity to access previously limited concepts and experiences, specifically in exploration and experimentation in mathematics (Fey & Hirsch, 1992; Pomerantz, 1997).
Despite the rise in popularity of technology, the use of calculators in classroom teaching and learning has been an area of contention since its introduction. Pomerantz (1997) addresses what she calls "myths" in classroom calculator usage that have been raised by various individuals involved in children's education such as mathematics educators and researchers themselves as well as parents. These "myths" include notions that calculators are a crutch for lazy students, that they reduce the level of challenge of mathematical tasks and prevent students from learning the basic mathematics required in many vocations. As a result of frequent calculator usage, individuals might also develop overdependence on these instruments which will therefore cause helplessness in manual computations should the need for paper-andpencil approaches arise. Boers & Jones (1994) found that students were particularly concerned about the possible outcomes of over-dependency on graphing calculators and Dunham (1991) noted that this was particularly true of female students. Some parents have also expressed reservation about the use of calculators in school on the basis that acquisition of mathematical concepts and skills requires paper-and-pencil computations, algorithms and drill work encompassed in traditional mathematics education, which they have been part of. While these are practical concerns that could have stemmed from the misuse of calculators in education, research has shown that the use of calculators in the teaching and learning of mathematics does have its merits. As with all teaching and learning tools, the calculator needs to be utilised appropriately in order for students and teachers alike to reap its benefits.
The value of calculators not only lies in the improvement of students' mathematical cognition and achievement as discussed above. Other studies have shown that 575 calculator usage increases students' self-concept and fosters a better attitude toward mathematics (Dunham, 1995; Hembree & Dessart, 1986). Strong evidence has been found that the use of graphing calculators has significant influence on students' mathematical achievement and on the ways they approach the solution to a problem (Ruthven, 1995). Later work by van Streun et al. (2000) supports Ruthven's findings but goes further in noting that the calculator does not confer any additional advantage in data interpretation. These findings align themselves with research that calculators in general are a merely aids in problem solving and do not think on the behalf of the student. Calculators remove the tedious computation steps that frequently deter students from taking mathematics education to a higher level, which means accessibility to more complex mathematics and allows students to focus on developing mathematical understanding and their repertoire of problem solving techniques (Pomerantz, 1997).
With the progress of technology in mathematics, there have also been questions raised by countries such as Britain regarding students' use of calculators while they are being assessed in mathematical knowledge and skill (Qualifications & Curriculum Authority, 1999). Ellis and Brown (1997) propose that assessment modes should complement the curriculum since students who are expected to utilise a calculator throughout the course of their study need to be assessed fairly. Many examination boards in the world have started incorporating technology in the teaching and learning of Mathematics curriculum of late. For example, Principles and Standards for School Mathematics published by the NTCM in year 2000, advocates the use of electronic technologies - calculators and computers as essential tools for teaching, learning and doing Mathematics. Also, the various tests administered by the College Board (SAT, SAT II, Advanced Placement) either permit or require the use of a graphing calculator. From May 2000, the use of graphing calculators (GCs) was compulsory for three out of the four Diploma Programme Maths course in the International Baccalaureate (IB) curriculum. Victoria state in Australia has been approving the use of a GC in many of its Mathematics examinations since 1999 and it is looking further into a CAS calculatorbased Mathematics module. In Britain, the Qualification and Curriculum Authority (QCA) has listed the use of contemporary calculator technology" as one of the five assessment objectives within its "Subject Criteria for Mathematics" (QCA, 1999). Other countries, such as Denmark, Norway and Portugal which have a national curriculum for 16-19 age group are making the use of GCs compulsory (Edward, 2000).
In Singapore, students taking the advanced level Further Mathematics examinations at the end of their second year of junior college have been allowed the use of a GC since 2001, though the questions set will be GC neutral. This has tremendous implications on the learning and teaching of Further Mathematics at the JC level in Singapore. As yet, students appear to be underutilising the GC that might be due to the lack of familiarity with GC use on the part of teachers and as a result, students themselves. The aim of this study is to ascertain whether students' utilisation of GCs 576 throughout curriculum time have an impact, either positive or negative, on the subsequent assessments of local JC students in Further Mathematics.
Design of Study
The research participants comprised of all 190 Year 2 students (in Year 2003) who took Further Mathematics at a junior college in Singapore. Of the 190 students, approximately 60% possessed either a TI83 or TI83 Plus GC. The research was carried out by conducting surveys of students' performance on 3 different tests covering 3 different topics over a period of 6 months, from March to September 2003. The surveys were conducted after each test was marked and returned to students.
Survey 1 involved students' usage of the GC while attempting Question 6 of the June Common Test on Curve Sketching, where students were requested to state whether they used a GC in obtaining or checking the graph. Survey 2 on Linear Space which was part of a lecture test and required students to indicate the length of time spent on the question posed and whether they utilised a GC in obtaining the solution or for checking their solutions. The final survey, Survey 3 on Paper 2 of the Preliminary Examination was obtained based on students' academic overall academic score and GC usage patterns.
Table 2: Surveys and their related test items
Survey Question
1
Curve Sketching (June Common Test Question 6)
(a) The curve C has equation x
y x
*
= + *+
where
* - 0, 0 x -
.
(i) Find the set of values of
*
for C to cut the x-axis at
two distinct points. [2]
(ii) If 1 <
*
< 2, draw a sketch of C, labelling the
asymptotes, stationary points and any intersections with the
coordinate axes, if they exist. [5]
[Please indicate on the cover page whether you made use of the graphical calculator.]
2
Linear Spaces (Lecture Test)
If x is an eigenvector of each of the square matrices A and B with the corresponding eigenvalues . and p respectively. Show that x is an eigenvector of
(i) kA,
(ii) A + B,
and find their corresponding eigenvalues. 577
[4]
Find the eigenvalues and the corresponding eigenvectors of the matrix A, where

A =

3
Preliminary Examination Paper 2
One of the questions that GC could be useful is Question 7 as
follows.
A certain local authority was looking into the length-of-service
characteristics of its employees. Jobs were classified as being
manual, technical or administrative. Records were available
showing how long each employee had served with the authority.
150 employees, chosen at random from all the employees of the
authority, were investigated and the results were as follows:
Type of Jobs Length of service
Manual < 6 months 6 months to 2 years > 2 years
Technical 30 11 19
Administrative 13 13 20
9 8 27
Examine whether the data provide evidence of an association
between the types of job and the length of service of the employee
at the 1% significance level. [6]
RESULTS AND DISCUSSION
The results of study are divided into 3 sections, each based on the corresponding
survey that was carried out. The outcome of the first survey that is presented in Table
2 shows that out of the 33 students who responded that they used a GC in either
checking or obtaining the graph, 20 of them (60.6%) received 4 or 5 marks out of a 578
possible 5. Conversely, 23 students out of the 55 who responded that they did not use
the GC in attempting the question received 4 or 5 marks (that is, 41.8%). The
difference between the percentages of students obtaining 4 or 5 marks for with and
without GC is 18.8%, which seems to suggest that students who used the GC
obtained better results. Similarly, a comparison between students who obtained 0 or 1
mark shows that those who utilised a GC are less likely to perform poorly. This
appears to be in keeping with Dunham's review of research that students who utilise
graphing technology have greater overall achievement on questions that require
graphing solutions (Dunham, 1993).

(60.6%)
No graphing calculator used
(Total of 55 students)
13
(23.6%)
19
(34.5%)
23
(41.8%)
Table 3 shows a breakdown of survey responses obtained from students during the
lecture test. As the results show, students generally take less time in obtaining the
solution to the computationally intensive Linear Spaces question when they utilised a
GC during the problem solving process. 22 of the 34 students in class 06 used a GC
in getting answers and found that they did not spend a lot of time on the question in
general. On the other hand, classes where majority of students did not use a GC at all
show that a considerable number of them spent a significant amount of time on the
problem (e.g. classes 01 and 09). However, as the duration of "a lot of time" is
subjective, the results are certainly not definitive, but rather indicative in nature and
hints at the possibility of the temporal benefits of GC utilisation.
Table 4: A comparison of the number of students and time spent on a
Linear Spaces question based on their usage of GC
Class

only
01 2 0 17 5 0
02 8 0 14 4 7
03 3 1 16 1 2
04 6 1 7 2 9
05 22 0 2 1 11
06 10 1 10 4 0 579
07 0 0 17 11 3
08 6 0 15 7 7
09 0 0 21 6 1
10 1 0 13 0 3
In the final survey examines the number of students who utilised a GC and their
corresponding marks in Paper 2 of the Preliminary Examination. A total of 182
students took the test conducted in late September 2003. 115 students (63%) used a
GC in either solving or checking solutions and 67 students (37%) did not use a GC.
The number of students who utilised the GC increased to 63%, presumably due to
their improved familiarity with the GC towards the end of the year through increased
usage or else they might have found that the GC's capabilities were more suited to
solving questions on Statistics.
Table 5: Comparison of student achievement in the Preliminary
Examination based on usage of GCs
Used a GC Did not use a GC
Total marks < 45 45 to 70 0 70 < 45 45 to 70 0 70
No of
students
30 70 15 21 40 6
% of total 16.5% 38.5% 8.2% 11.5% 22.0% 3.3%
% of
category*
26.1% 60.9% 13.0% 31.3% 59.7% 9.0%
*Category refers to those who used a GC and those who did not
The percentage of students who obtained less than 45 marks in total was slightly
higher for non-users of GC at 31.3% than for GC users at 26.1%. While the
percentages of students who acquired a total mark between 45 and 70 are comparable
(60.9% for GC users and 59.7% for non-users of GC), there was a higher percentage
of students who obtained greater or equal to 70 marks for GC users (13.0%).
Although a detailed breakdown of marks for Question 7 (see Table 1) was not
acquired, the student distribution of marks obtained for that particular question might
be similar to the pattern that is observed through the total marks for the paper. This
suggests that academic achievement of Year 2 JC students of Further Mathematics
who use GCs is likely to be in keeping with observations made by researchers on the
general improvement of student achievement evidenced through the use of
calculators (Dunham, 1993; Hembree & Dessart, 1986; Kitchen, 1998; Suydam,
1987).
Conclusion
The 3 surveys reveal that the GC is likely to be a useful tool for most of the Year 2
JC Further Mathematics students surveyed in terms of improved academic
achievement and might confer temporal advantage during test and examination 580
situations where time is limited. The advantages in using the GC, however, are also
contingent upon appropriate usage as Burrill et al. (2002) have determined. As
evidenced from the number of students surveyed who have yet to utilise the GC and
the results of some GC users, the instrument's strengths have not been fully
capitalised in terms of its capabilities in the learning and teaching of Further
Mathematics.
The results of GC users in the surveys, while better in general than those who did not
use GC users were marginal in some cases and there were individuals who utilised
GCs but yet took a longer time in obtaining the solutions to questions. The reason for
this is yet unknown in the local JC context. However, this result does indicate that
there is a possibility that GCs might not contribute to academic achievement and
improved problem solving skills or that students are not utilising the GC to full
advantage. From the general trend of the findings in this study and those of others,
such as Dunham and Dick (1994) and Ruthven (1995), the former is not likely the
case. Students' competency in GC usage is liable to be influenced by a number of
factors, such as accessibility to the GC, familiarity with its functions and the extent to
which students are exposed to its use, often predetermined by teachers. As such, this
study is lacking in terms of qualitative data that surround the learning and teaching of
GC skills. Hence the results obtained, while not definitively conclusive, do intimate
the potential and pitfalls in the application of GC in the learning and teaching of
Further Mathematics.
Further refinement of the current mathematics curriculum needs to be considered as a
GC-neutral mathematics syllabus does not promote the usage of handheld
technology. Moreover, maintaining a GC-neutral stance in set problems is difficult to
achieve as evidenced by the question identified in the Preliminary Examination
(Table 1). Proficient GC users will therefore gain an added advantage due to their
skill in the instrument, resulting in what might be construed as an unfair advantage to
those who choose not to utilise the GC for a variety of reasons, based on the
knowledge that the syllabus is GC-neutral. Future research needs to look specifically
into some of the factors outlined above, such as teachers' competency in GC usage
and the impartation of GC skills as well as conflicts in local curriculum and
assessment.

Challenging Known Transitions: Research of technology supported long-term learning

Michal Yerushalmy, University of Haifa, Israel
michalyr@construct.haifa.ac.il

In this paper I address questions related to the implementation of curricula. I offer a framework for research that build on the assumption that although the uses of digital technologies offer ways to redesign curricula with an attempt to create as smooth as possible sequence there is no a single design that can achieve this challenge. Thus, it is important for research to study the stability of known transitions and to explore new critical transitions. A transition is a learning situation that is found to involve a noticeable change of point of view. This change could become apparent as an epistemological obstacle, as a cognitive discontinuity or a didactical gap. The implementation of new curricula and practices in the classroom depends on the ways research would help teachers and designers anticipate transitions. Examples of studies that sought rational for students' progress throughout analysis of curricular decisions will be given below.

Long term learning with technology: A role for research

Technologists and educators speculate about the degree to which new technologies will lead to replacement of current curricula with new content (Papert, 1996; Schwartz,1999; Noss,2001). How does the use of a new curriculum that is based upon new epistemological assumptions change our capability to anticipate students' difficulties and strengths? To start answer the question I would introduce the term: transition. A transition is a learning situation that is found to involve a noticeable change of point of view. This change could become apparent as an epistemological obstacle, as a cognitive discontinuity or a didactical gap. Transition would be identified as a necessity in entering into a different type of discourse (in terms of the language, symbols, tools and representations involved) or more broadly as changing "lenses" one uses to view the concept at hand.

Obviously there are transitions in any sequence of learning. In attempting to design a smooth as possible sequences Tall (2002) defines cognitive roots to be the kernel of continuous cognitive sequences and argues that while cognitive root would not always work for all students as creating cognitive continuity it would in many cases offer a solution to some critical transitions. Technology, when appropriately designed and used, can help to design learning environments that may change to various degrees the assumption about previous knowledge and the order new concepts are introduced. In designing new technology supported sequences we would expect that some known discontinuities disappear but others would not and very probably new gaps will appear. Noss (2001) who is elaborating on the implications of rethinking the mathematics learned with new technological environments is expecting that the epistemology of the mathematics learned with technology would change our ideas about cognitive hierarchies and the didactical attempts to construct them. Thus, an interesting challenge for research is to question stability of known transitions when new computational environments are 583 introduced to the learning and teaching, to go beyond known transitions to distinguish types of transitions and to illuminate the nature of critical transitions in technological based curricula. The implementation of new curricula and practices in the classroom depends on the ways research would help teachers and designers anticipate transitions that might be reflected in students' difficulties. In fact I believe that the degree to which technology is likely to be essential productive part of new curricula depend on the availability of studies that sought rational for students' progress throughout analysis of curricular decisions.

Visual Math: An example of long-term learning sequence

The Visual Math curriculum (1995) is an algebra, pre-calculus and calculus curriculum where technology is being used to help learners develop knowledge from their perceptions of the world and to develop conceptual understanding of symbols. The growing research in the field of embodied cognition suggest the idea that bodily activities are centrally involved in conceptualization of mathematics and that important parts of Algebra and Calculus are understood via conceptual metaphors in term of more concrete concepts (Lakoff and Nunez, 2000). In particular the notion of continuous functions and directed graphs are viewed as mathematical concepts developed through human motion experience. The learning of algebra in VisualMath is preceded by semi-qualitative modeling and an environment that allows users to construct and model motion generated by the movement of the computer's mouse supports the introduction of modeling of motion. Another challenge of the innovative development is rooted in the symbolic world where technology that supports multi representations of functions allows students to develop symbolic understanding using the feedback from graphs or table of values, generating and viewing a rich repertoire of non-prototypic examples. In general, an important goal of this curriculum is to help students develop strong symbolic skills and to learn to do a variety of standard algebraic manipulations. But, the curriculum is aimed at helping students learn to do such manipulations with an understanding of the graphical and tabular meanings of these manipulations, as well as a sense of the purposes for which such manipulations are useful. Such proficiency involves moving across the various views of symbols, graphs, equations and functions and to help students learn to shift their point of view.

We will look at how such new epistemological structures afforded by digital technology impact the cognitive hierarchies; resolve or change the nature of known transitions or mark new critical discontinuities in the curricula.

Known critical moments demanding new transitions

The lion's share of the early parts of the Visual Math Algebra curriculum focuses on functions of one variable and equations of one variable conceptualized as the comparison of two functions of one variable. With this way of thinking about equations that is now taken by a few new technological based developments, students acquire alongside the algebraic procedures alternative methods to solve equations. Studies report that algebra beginners viewing an equation as a comparison of two functions, students who had not learned procedures beyond the linear equation can solve problems for which they have not 584 yet been taught an algorithmic solution method with and without use of graphic software (see for example: Huntley et al. 2000, Hershkowitz et al. 2002).

In typical algebra instruction, solving an equation in two variables and then a system of equations requires to shift from a non explicit form (x+y=2) to an explicit function form: y=2-x. One then substitute and use similar solution techniques as in a single variable case. While technique does not require dramatic change the shift from an equation in a single variable to two variables requires a shift in understanding the nature of the solution: from a single definite solution to a set of solutions. For the Visual Math function approach students the equal sign of the equation represents a symmetric comparison sign and the function equal sign represents an a symmetric assigning sign. Thus, the fact that simple manipulations techniques can help move from one form to the other does not seem to be useful. Thus many would not choose this option and would keep viewing equations as comparisons of two functions f(x,y)=g(x,y). Taking this view the nature of the solution does not change brutally - it remains the intersection values of the intersection of the two functions. But then they have to overcome another transition: The graphical and tabular representations of functions of two variables must be developed in order to help students see their connections to the ways of representing functions of one variable with which they are familiar. Thus the transition remained critical; either one has to develop new ideas about presentations of function in two variables or one has to rewrite the equation in a way that violets the distinction between function and equation. It is required to acknowledge that simple algebraic technique can change the mathematical objects in hand: from equation in two variables to a function in a single variable. Thus, in looking at critical known transitions we would have to study the probable different nature of the transition in this new domain.

The second example offers another familiar critical moment that technology might not smooth but rather introduce a reformed transition that develops in a different direction than in the traditional sequence.

Using technology such as simulations' software, MBL or other modeling tools that includes dynamic forms of representations of computational processes, it is now possible to construct graphical models without first writing symbolic expressions with x's and y's. Several studies suggest that such emphasize on modeling offers students means and tools to reason about differences and variations (rate of change). Apparently, throughout the curriculum's focus on qualitative modeling, the students we will describe had developed ways of using tools to solve complex problems that concern non-constant rate of change. Graphs and what we will call staircases (a graphical depiction of differences in y value for a set change in x Schwartz and Yerushalmy 1995) emerged as models of situations, and also as models for reasoning about mathematical concepts. Using the grammar of objects and the operations on them, young students constructed complex mathematical models, based on qualitative analysis of variation. Technology, like the one implemented in Visual Math or a spreadsheet may suggest that a closed rule is no longer a more natural way to describe a function (for related thoughts based on student performance see Stacey and MacGregor 2000). Thus, if students become familiar first with ideas of continuous change 585 and finite differences, explicit closed forms may become less natural aspect of expressing phenomenon. For example: in Yerushalmy (2005) I describe students whose earlier experience with ideas of differences complicated their use of explicit forms. They were seeking help in understanding why two numerical phenomena they identified as appropriate: the linearly increasing differences and the squaring describe the same quadratic phenomenon. In other words: why does the solution of the difference equation f(x+1) -f(x)= ax+b is of the type: f(x)=x^2. This complication might not have arisen if they had not had earlier support for recursive reasoning. However, the other option, the one most sequences follow of emphasizing explicit rules (closed forms) and then learn to describe it as analysis of differences is problematic as well. Thus the affordances of technology that made the recursive thinking the natural way to think about a phenomenon and to symbolize it in a model is viewed as strength however, it challenges thinking about teaching that can support the transition to algebraic close rules.

A similar state of a known critical difficulty that introduce a transition although the technological based curricular sequence has been redesigned is described by Tall (2002) and by Schnepp (unpublished). Tall describes the strength of a sequence that is based on visual notions of the function to explain the chain rule (the derivative of a composite function) coming from the derivative of addition of functions. However, Tall argues, the teaching of the product rule (derivative of multiplication) is yet to be supported by this sequence. Schnepp points on similar difficulty and argues that the discontinuity can be fixed if coming to the multiplication from the composition. Thus known critical transition remains a challenge but the use of technology turns the order of the sequence in which this transition occurs and reforms the cognitive hierarchies developed and thus the difficulties might arise.

Identifying new critical transition

The third example challenge what the examples above suggest as stability or partial stability and it attempt to support the claim that such critical moments could be mutable. I will argue that a new epistemology introduces new critical moments rather than just changing the cognitive hierarchies as demonstrated in the first two examples.

Research suggests that mature problem solvers of word problems in algebra devote a substantial portion of their work to representation of the problem at the situational level. Forming the situational model is a necessary stage in understanding the story of the problem and is a major component of model-based reasoning. Recently Gilead (Gilead 2002) studied Visual Math students and equations' based algebra students solving word problems. 87.3% of the 196 solutions given by the Visual Math students for problems in context included graphical description of the situation that formed a situation model either using a sketch (73%) or an accurate graph (14.3%). A comparative investigation of the Visual Math students with comparable algebra students suggest that the students who were the more successful students of a traditional algebra sequence which focus on unknowns and stress manipulations of equations were substantially less capable to solve the same problems that were part of their curricular sequence as well. While 90.8% of the solutions 586 of the Visual Math were correct solutions only 57.2% correct solutions were given by the equations' based approach students.

This same study that was designed to analyze the index of difficulty of algebra word problems as related to the approach students learn algebra included a set of problems that were hard to the Visual Math students. They succeeded to provide 41.8% correct solutions on these problems (while the traditional algebra students provided 51.5% correct solutions.) The harder problems were problems that we categorized in another study (Yerushalmy & Gilead 1999) as non canonic problems or problems that have Sketchable Situation Structure. We define canonic problems to be Graphable: those for which the functions in the situational structure can be uniquely described symbolically and graphically as functions of time. In fact Gilead found that a main problem in solving Sketchable problems is the complexity involved in formulating an equation that represents rules describing behavior of unknowns. The following summary of results strengthen this view: While in 70.9% of the correct solutions of canonic problems the equations were based on coherent graphic model only in a single correct solution of a non-canonic problem a situational model was coherent to the equation used to solve the problem.

Function's approach to algebra that we took stressed the algebra signs and symbols and the expressions and equations using these symbols to be a meaningful language to express ideas. One of the ways to observe meaning is to view equations as describing situations out of the mathematics and as graphical models. This habit has been proved to support students learning when solving constant rate problems. However, situations that were difficult to be described by graphical models that can be easily mirrored in an equation were less natural for students. Thus, while known complexities disappeared and students were successful in solving new problems as mature problem solvers, we identified a range of problems that were found to be complex to the function's approach students and were not at all harder to the equation's approach students.

The study of this transition sprang of a learning experiment and in a way was incidental. It led us to a systematical investigation of the structures of algebra word problems that suggest new insights on epistemology of constant rate models (Yerushalmy & Gilead 1999). It also raised a more general question regarding strategies that could guide profound studies of curricular decisions to support teaching and learning with new technologies.

Concluding remark

I have demonstrated the necessity to study changes of cognitive hierarchies that involve learning with technology. Studying these changes is appropriate when one has a chance to follow learning and teaching for a substantial period of time, observing students' strengths, identifying the resources for these strengths, watching how the students get involved in a transition and analyzing the reasons for the discontinuity. Although, I believe that obstacles should be reconsidered when new tools are involved, I suggest that often transitions between mathematical views of concepts remain complex and suspect them to be found independent of the technology used. Computational technologies allow us to improve the design of mathematical learning environments. In order for research to be helpful for 587 teaching and learning in the new context it is important to devise and use strategies that

would support systematic analysis of critical transitions.

The study aims to produce a state-of-the-art summary of relevant
research and to go beyond that summary to develop new insights and new areas of
knowledge and study about task design. In particular, we aim to develop more
explicit understanding of the difficulties involved in designing and implementing
tasks, and of the interfaces between the teaching, researching, and designing roles
- recognising that these might be undertaken by the same person, or by
completely separate teams.
Background
In her plenary address to the International Group for Psychology of Mathematics
Education (PME) Sierpinska (2003) identified task design and use as a core issue in research
reports and in mathematics education research more generally. She commented that research
reports rarely give sufficient detail about tasks for them to be used by someone else in the
same way. Few studies justify task choice or identify what features of a task are essential and
what features are irrelevant to the study. In some studies using intervention/treatment Introduction
8
comparisons to investigate cognitive development, the intervention tasks are often vague, as if
the reader can infer what the learning environment was like from a few brief indications. A
similar view had been expressed by Schoenfeld (1980). Yet we learn from applications of
variation theory to learning study (e.g., Runesson, 2005), from studies of learning from
worked examples (e.g., Renkl, 2005), and from the Adaptive Control of Thought model
(ACT-R) (e.g., Anderson & Schunn, 2000) that seemingly minor differences in tasks can have
significant effects on learning.
At the same time Burkhardt has drawn attention to the importance of design, with the
founding of an international society and a journal, Educational Designer
(www.educationaldesigner.org). (Schoenfeld, 2009) makes a plea for more communication
between designers and researchers, making the point, among others, that many designers are
not articulate about their design principles, and may not be informed by research. In 2008, the
International Congress on Mathematics Education (ICME) hosted a topic study group (TSG),
Research and development in task design and analysis, which provided a forum for that kind
of interaction (http://tsg.icme11.org/tsg/show/35). Designers had to be explicit about their
principles and demonstrate how they used them. Participants were given the opportunity to
experience various tasks, and compare and critique design principles. Drawing from a wide
international field, an overview of the papers makes it apparent that:
(1) it is necessary to have theories about learners' intellectual engagement to have
successful design; and
(2) most design principles included the use of several representations, several kinds
of sensory engagement, and several question types.
The TSG increased its membership during the conference, indicating that a serious,
organised look at task design was of growing interest. A further TSG is due to take place at
ICME 12 in July 2012 in Seoul, Korea. Working groups on task design using digital
technologies, and design of digital learning environments, proliferate, but we are not aware of
a similar level of activity in other environments.
Mathematics educators have focused to a great extent on the social cultures of
classrooms and designed learning environments, on patterns of argumentation, on emotional
aspects of engagement, and on measures of learning. A distinct mathematical contribution can
be made in understanding whether and how doing tasks, of whatever kind, enables conceptual
learning. For example, Lagrange (2002) suggests that applying routine techniques can achieve
results, and also provide the basis for conceptual understanding and new theorising; (Watson
& Mason, 2006) have shown how a set of procedural exercises, seen as one object, can
provide raw material for conceptualisation; Realistic Mathematics Education (RME) from the
Netherlands and Mathematics in Context materials (from the United States) show how
carefully designed situational sequences can turn a learners' attention to abstract similarities.
Our statement that task design is core to effective teaching is well-illustrated by the
success of theoretically-based long term design-research projects resulting in publications
such as those from Shell Centre (Swan, 1985), Realistic Mathematics Education (de Lange,
1996) and Connected Mathematics (Lappan & Phillips, 2009). In these, design and research
over time have combined to develop materials and approaches that have appealed to teachers.
In addition, research related to the QUASAR project (Quantitative Understanding:
Amplifying Student Achievement and Reasoning) found that the cognitive demand of
designed tasks was often reduced during implementation (Henningsen & Stein, 1997). A
research forum at PME in Mexico (Tzur, Sullivan, & Zaslavsky, 2008) offered cogent
explanations for the inevitability and even desirability of teachers' alteration of the cognitive
demand of tasks. Further, Choppin (2011) suggests how adaptation differs among teachers.
Thus, a possible area of investigation is how published tasks are appropriated by teachers for
complex purposes. In variation theory, a distinction is made between the intended, enacted, Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
9
and lived objects of learning. The Documentational Approach of Didactics (Gueudet &
Trouche, 2009, 2011) also refers to the practitioner perspective in terms of the resources on
which teachers draw. Didactic engineering was the topic of the 15
th
summer school in
mathematics didactics in 2009 (Margolinas, Abboud-Blanchard, Bueno-Ravel, Douek,
Fluckiger, Gibel, Vandebrouck, & Wozniak, 2011). The discussion focused not only on
various principles of task design (see the contributions of Bessot, Chevallard, Boero, and
Schneider) but also on the problem of the influence of task design on the development of
actual mathematics teaching (see contributions of Perrin-Glorian, René de Cotret and Robert).
The tasks in these references are all complex, multi-stage tasks which address complex
purposes, such as those usefully summarised in Kilpatrick, Swafford, & Findell (2011),
namely the development of conceptual understanding; procedural fluency; strategic
competence; adaptive reasoning; and productive disposition.
We would like to encourage an interest in tasks that have more limited but valid
intentions, such as tasks that have a change in conceptual understanding as an aim, or tasks
that focus only on fluency and accuracy. Research can investigate how students perceive and
conceptualise from the examples they are given, or on which they work. Most mathematics
learners world-wide learn procedures and possibly concepts through 'practice', regardless of
the de-emphasis on procedures held by reform enthusiasts. Thus, the design of sequences of
near-similar tasks deserves attention. For reasons of global reality and equity, the study
conference shall also focus on textbook design partly because textbooks are often informed by
tradition or by an examination syllabus rather than through research and development
(Valverde, Bianchi, Wolfe, Schmidt, & Houang, 2002), but also because in some countries
textbooks are the major force for change. Textbooks are not the only medium in which
sequences of tasks, designed to afford progressive understanding or shifts to other levels of
perception, can be presented, and we expect that study conference participants will look also
at the design of online task banks.
Work from Sullivan indicates the need to educate new teachers in the use of complex
tasks (Sullivan, 1999) and it is inevitable that teacher education will cross several of our
suggested areas. A volume of the Handbook of Mathematics Teacher Education was devoted
to the tasks and processes of teacher education (Tirosh & Wood, 2009). A particular
relationship between teacher education and task design is the design of tasks for teacher
education purposes. Mathematics teacher education, as a subfield of mathematics education,
has paid significant recent attention to the nature, role and use of tasks with a triple special
issue of the Journal of Mathematics Teacher Education (volume 10, 4-6) edited by Mason,
Watson and Zaslavsky, and a book edited by Zaslavsky & Sullivan (2011)
The meaning of 'task'
The word 'task' is used in different ways. In activity theory (Leont'ev, 1975) task
means an operation undertaken within certain constraints and conditions (that is in a
determinate situation, see Brousseau (1997)). Some writers (Christiansen & Walter, 1986;
Mason & Johnston-Wilder, 2006) express 'task' as being what students are asked to do. Then
'activity' means the subsequent mathematical (and other) motives that emerge from
interaction between student, teacher, resources, environment, and so on around the task. By
contrast, in some professional traditions, 'activity' means a situation set up by the teacher in
which a student has to engage in a certain way. Other traditions (e.g.Chevallard, 1999)
distinguish between tasks, techniques, technology and theories, as a way to acknowledge the
various aspects of a praxeology. We also aware that 'task' sometimes denotes designed
materials or environments which are intended to promote complex mathematical activity (e.g.
Becker & Shimada, 1997), sometimes called 'rich tasks'. In this study, we use 'task' to mean
a wider range of 'things to do' than this, and include repetitive exercises, constructing objects, Introduction
10
exemplifying definitions, solving single-stage and multi-stage problems, deciding between
two possibilities, or carrying out an experiment or investigation. Indeed, a task is anything
that a teacher uses to demonstrate mathematics, to pursue interactively with students, or to ask
students to do something. Task can also be anything that students decide to do for themselves
in a particular situation. Tasks, therefore, are the mediating tools for teaching and learning
mathematics and the central issues are how tasks relate to learning, and how tasks are used
pedagogically.
Task design
The design and use of tasks for pedagogic purposes is at the core of mathematics
education (Artigue & Perrin-Glorian, 1991). Tasks generate activity which affords
opportunity to encounter mathematical concepts, ideas, strategies, and also to use and develop
mathematical thinking and modes of enquiry. Teaching includes the selection, modification,
design, sequencing, installation, observation and evaluation of tasks. This work is often

undertaken by using a textbook and/or other resources designed by outsiders.
The extent and detail of design varies widely among those who work on task design.
For some (e.g., Shell Centre) design includes full necessary materials, task sequences and
advice about effective choices, and detailed pedagogic advice about ways of working, verbal
interventions, likely misconceptions and possibly extensions. For others (Ainley, Bills, &
Wilson, 2004, 2005) there may be provision of a question, or a microworld, or some physical
material, with no written object to describe 'the complete task', but rather a series of things
that the teacher might say, perhaps supported by some written prompts. During the resulting
activity, learners may ask questions or make comments to which the teacher needs to respond,
and part of the design is trying to anticipate these and have a general picture of the shape of
responses which would complement the task design. Another form of design is to refine a
question or problem-situation until it is most likely to promote intriguing mathematical
reactions (e.g., (ATM, various dates)). Sullivan, Zevenbergen, & Mousley (2006) have
identified a need to design whole lesson sequences around certain types of tasks. All of these
approaches have implications for implementation, with some relying on teachers' existing
skills, some providing advice to extend teachers' skills, and others dependent on teachers
maintaining or adapting the original task intentions (see, e.g., Kieran, Tanguay, & Solares,
2011).
Tasks also arise spontaneously in educational contexts, with teachers and/or learners
raising questions or providing prompts for action by drawing on a repertoire of past
experience. We are interested in how these are underpinned with implicit design principles.
Task sequences
This discussion of tasks may lead readers to assume that we are focused only on tasks
as single events, but it is important to address also the question of sequences of tasks. There
are different aspects embedded in the design of sequences and, while this is an obvious
consideration when designing textbooks, it also stretches across the whole field of task design.
To achieve the goal of teaching a whole conceptual field (e.g., rational numbers), we
have to describe the different aspects of this knowledge and the way the aspects are linked
(for interesting examples see Brousseau, Brousseau, & Warfield, 2004a, 2004b, 2007, 2008,
2009). In Brousseau's Theory of Didactic Situations (Brousseau, 1997), particular situations
(or single tasks) are generated from more general situations. The earlier tasks in a sequence
should provide experiences that scaffold the student in the solution of later tasks, allowing
them to engage in more sophisticated mathematics than would otherwise have been the case.
In some published sequences, the earlier tasks might be technical components to be used and Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
11
combined later; in others, the earlier tasks might provide images or experiences which enable
later tasks to be undertaken with situational understanding.
To understand how tasks are linked in order to support teaching, it is important to
understand the nature of the transformation of knowledge from implicit knowledge-in-action
(see Vergnaud, 1982) to knowledge which is formulated, formalized, memorized, related to
cultural knowledge, and so on.
However, there are different ways to create sequences of tasks, some of them are
more commonly known by teachers themselves. One of these types of task sequences is that
in which the problem formulation remains constant but the numbers used increase the
complexity of the task, say moving from small positive integers (for which answers might be
easy to guess) to other ranges of numbers for which a method might be needed. Another type
of sequence is one in which the problem is progressively made more complex by the addition
of steps or variables, such as in a network task where additional nodes are added. A third type
of sequence may be one where the concept itself becomes more complex, such as in a
sequence of finding areas or progressively more complex shapes from rectangles, to
composite shapes, to irregular shapes. These different types of sequences, and their relation to
the teaching unit as a whole, are often the focus of lesson study cycles, such as those reported
in for example Corey, Peterson, Lewis, & Bukarau (2010); Huang & Bao (2006) Yoshida,
(1999).
The importance of sequencing is explicit in Realistic Mathematics Education. In that
tradition, a task sequence starts with situated problems (Gravemeijer, 1999), like dividing
large numbers of people into smaller groups (quotative division problems) to evoke informal
strategies and representations, and continues by changing the focus to formalizing and
generalizing solution procedures, i.e. in this case a general algorithm that can be used for
various division problems. In this type of task sequence the idea of 'guidance with didactical
models' from informal to formal is important as an alternative strategy for the increasing
mathematical complexity of problems students encounter (Van den Heuvel-Panhuizen, 2003).
The situated problems are often already rather complex and can be solved before you know
'the' mathematical solution procedure, and therefore can be good starting points for
problematizing a concept.
Design communities and methods
Of course, teachers also design tasks explicitly and deliberately. Whereas some
authors think it desirable that designing and teaching are separate acts carried out by separate
groups of people (e.g. Wittman, 1995), the experience of the authors of this discussion
document indicates that the communities involved in task design are naturally overlapping
and diverse. Design can involve designers, professional mathematicians, teacher educators,
teachers, researchers, learners, authors, publishers and manufacturers, or combinations of
these, and individuals acting in several of these roles. In the study, we wish to illuminate the
diverse communities and methods that lead to the development and use of tasks. In all
methods, the central consideration is the interaction between teachers and learners through the
designed artefacts and/or the design process. A major focus in the study will therefore be on
learning how design impacts on learners and learning, rather than research which focuses
solely on the design process. For example, research which identifies implicit design principles
would be of interest if connections are made between these principles and the impact on
learning; research about identities of different players in the design process would be of
interest if it contrasted 'teacher-as-task-designer' and 'teacher-as-task-user'. Introduction

Theme A
Tools and Representations
Allen Leung
Hong Kong Baptist University, Hong Kong
Janete Bolite Frant
LOVEME Lab, UNIBAN, Brazil
In the mathematics classroom, concrete tools (for example, compasses and ruler, unit
blocks, interactive ICT platforms) are usually used as resources to enhance the teachinglearning activity (see for example, Bartolini Bussi & Maschietto, 2008; Maschietto &
Trouche, 2010; Radford, 2011). In this context, tools are broadly interpreted as physical or
virtual artefacts that have potential to mediate between mathematical experience and
mathematical understanding. This theme concerns designing teaching-learning tasks that
involve the use of tools in the mathematics classroom and consequently how, under such
design, tools can represent mathematical knowledge. A task here is a teacher designed
purposeful 'thing to do' using tools for students in order to activate an interactive tool-based
environment where teacher, students and resources mutually enhance each other in producing
mathematical experiences. On a meta-level, it is about possible tool-driven relationships
within the design, teaching and learning triad. In this connection, this type of task design rests

heavily on the complex relationship between artefacts and mathematical knowledge.
There are a few theoretical grounds on which to build and expand this discussion.
Instrumental genesis explicates how the usage of a tool can be turned into a cognitive
instrumentation process for knowledge acquisition. A Vygotskian approach examines how an
artefact can be turned into a psychological tool in the context of social and cultural interaction
developed through the zone of proximal development and internalization processes. Semiotic
mediation can be used as an integrated approach to explore the mathematics classroom under
which a tool takes on multiple pedagogical functions (Bartolini Bussi & Mariotti, 2008).
Embodiment theory proposes that there are strong relationships among sensory activities and
cultural artefacts in the appropriation of mathematical practices, and in particular, their
application to inclusive mathematics education (Healy & Fernandes, 2011). The guided reinvention principle of RME (Realistic Mathematics Education) practiced by the Freudenthal
school can be used to direct the design of tool-based mathematical tasks. These theoretical
orientations, and/or others, may serve to facilitate discussion on tool-based task design and
representation in the mathematics classroom.
An important question to address in this theme is: How to design tasks that can bring
about situated discourses (hence representations) for the mathematical knowledge mediated
by tools in the mathematics classroom and how these discourses relate to mathematics
knowledge? This in turn comprises several additional questions.
Possible questions about tools and representation:
• What mathematics epistemological considerations are taken into account when
designing tasks using tools? Theme A - Introduction
16
• How do we create a tool environment for the mathematics classroom to support the
design of teaching and learning tasks for specific mathematic topics?
• How do different types of tools afford different mathematical activities/tasks,
different representations and/or discourses, and different interactions between
representations?
• How do different task designs using tools impact on students' learning and
understanding of mathematics?
• How do we design mathematical tasks that can transform an artefact into a
pedagogical instrument?
• Are there models (theoretical or pragmatic) of tool-based task design for the
teaching and learning of mathematics?

Using crises, feedback and fading for online task design
Christian Bokhove
University of Southampton, United Kingdom
A recent discussion involves the elaboration on possible design principles
for sequences of tasks. This paper builds on three principles, as described by
Bokhove and Drijvers (2012b). A model with ingredients of crises, feedback and
fading of sequences with near-similar tasks can be used to address both procedural
fluency and conceptual understanding in an online environment. Apart from
theoretical underpinnings, this is demonstrated by analysing a case example from
a study conducted in nine schools in the Netherlands. Together with quantitative
results of the underlying study, it shows that the model described, could be a
fruitful addition to the task design repertoire.
Keywords: task, design, sequence, near-similar, crisis, feedback, fading
Introduction
In recent years more and more attention has been paid to task design. In the call for
papers for the 22nd ICMI study on task design the reasons for this are clearly described. One
problem is that tasks are often only described vaguely. Furthermore, Schoenfeld (2009)
advises on having more communication between designers and researchers. In this way
educational research and design can be bridged, as the communities involving task design are
naturally overlapping and diverse. This paper was triggered by some of the remarks that were
made in the call for papers:
The topic of understanding whether and how doing tasks, of whatever kind, enable
conceptual learning. The study reported in this paper supports Lagrange (2002) who
suggested that applying routine techniques can achieve results, and also provide the basis for
conceptual understanding and new theorizing.
To not only address tasks as single events, but also address the question of sequences
of tasks.
It is suggested that the design of sequences of near-similar tasks deserves attention.
Therefore, the paper makes a point of defining a 'task' to mean a wider range of 'things to do'
than just one task, and include repetitive exercises.
Several types of task sequences are mentioned. "One of these types of task sequences
is that in which the problem formulation remains constant but the numbers used increase the
complexity of the task, say moving from small positive integers (for which answers might be
easy to guess) to other ranges of numbers for which a method might be needed.". Building on
an earlier article (Bokhove & Drijvers, 2012b) an extra type of task sequences is proposed,
whereby the complexity of tasks first increases, and then -with the help of feedback-
decreases.
In one sense this can be seen as an adaptation of the 'variation' Watson and Mason
(2006) coined: "From a modelling perspective the term micromodelling' may be helpful to
describe learners' response to exercises in which dimensions of variation have been carefully Theme A - C. Bokhove
18
controlled, because the aim is to promote generalization of the dimensions being varied in the
exercise, and thence to focus on mathematical relationships between dimensions." (p.104)
Summarizing these points we would want to formulate design principles for: (i)
sequences of tasks; (ii) near similar and/or repetitive tasks; and (iii) addressing both
conceptual understanding and procedural fluency. This paper synthesizes, elaborates on and
illustrates design principles of a study first described by Bokhove and Drijvers (2012a, b).
The principles regarding crises, feedback and fading are applied to a sequence of digital
tasks. This paper sets out to describe the three principles in an additional cohesive model, and
describes one case example of student work. Bearing the aforementioned goals in mind it
should be a model that could prove to be fruitful while designing tasks. The model bears
elements of both my roles as a designer and researcher when doing my PhD as a teacher at a
secondary school in the Netherlands. The study called 'Algebra met Inzicht' [Algebra with
Insight] was designed in the Digital Mathematical Environment
(http://www.fi.uu.nl/dwo/en)
1
. The intervention consists of a pen-and-paper pre-test, four
digital modules, a digital diagnostic test, and a final digital test and, finally, a pen-and-paper
post-test. It was deployed in fifteen 12th grade classes from nine Dutch secondary schools
(N=324), involving eleven mathematics teachers. The schools were spread across the country
and showed a variation in school size and pedagogical and religious backgrounds. The
participating classes consisted of pre-university level 'wiskunde B' students (comparable to
grade 12 in Anglo-Saxon countries). As this article is about design principles, I refer to
different articles for more details of the set-up of the study and the actual effects of the digital
intervention (Bokhove & Drijvers, 2012a, b).
Figure 1 shows the proposed model for sequences of (near-similar) tasks.
figure 1: proposed model for crises, feedback and fading
I contend that it is okay to use near-similar tasks and repetitive exercises, but suggest
that the sequence is interspersed by intentional crises i.e. tasks that are hard or impossible to
solve with skills and knowledge that are available. In other words, the "load" of the task is too
high. I will not go into the word "load" in detail. There is a vast body of knowledge connected
to the term Cognitive Load Theory (Sweller, 1988). There also is, rightly so, criticism (De

19
Jong, 2010). For the purpose of this paper, we will only assume that knowledge that isn't
known potentially will bear a larger load than unknown knowledge. Then, let students
overcome crises by providing feedback. To avoid a dependency on feedback for the
summative assessments fade the feedback during the course of the sequence of tasks.
A model for sequences of near-similar tasks
I will first elaborate on the three main ingredients of the model: crises, feedback and
fading.
With a crisis we refer to a principle that the poet John Keats so eloquently described
in the early 19th century 'failure is the highway to success'. This principle corresponds to
similar concepts that have been described during the years. Piaget (1964) used the concept of
equilibrium and disequilibrium. Essentially, whenever the child's experience/interaction with
the environment yielded results that confirmed her mental model, she could easily assimilate
the experience. When the experience resulted in something new and unexpected, the result
was disequilibrium, and a child may experience this as confusion or frustration. Eventually,
the child changes his or her cognitive structures to accommodate the new experience and
moves back into equilibrium. Piaget studied the individual case, on a societal level Kuhn
(1962) referred to a paradigm shift, arguing that scientific advancement is not evolutionary,
but rather a "series of peaceful interludes punctuated by intellectually violent revolutions",
and that in those revolutions "one conceptual world view is replaced by another". Tall (1977)
refers to cognitive conflicts: "one of the distinguishing factors in catastrophe theory is the
existence of discontinuities, or sudden jumps in behaviour when certain paths are taken.". In
his 'levels of thinking' van Hiele (1985) discerns structure and insight. There can be a 'crisis
of thinking', which has a link to the vygotskian zone of proximal development. The common
ground between the two is that there is a need for challenge. More recently, Kapur (2010)
uses the term productive failure and cites Clifford (1984): "However, allowing for the
concomitant possibility that under certain conditions letting learners persist, struggle, and
even fail at tasks that are complex and beyond their skills and abilities may in fact be a
productive exercise in failure requiring a paradigm shift". Kapur explains this by stating that it
is reasonable to reinterpret their central findings collectively as an argument for a delay of
structure in learning and problem-solving situations, be it in the form of, feedback and
explanations, coherence in texts, or direct instruction. The difference with my own work
(Bokhove & Drijvers, 2012b) seems to be whether crisis are an inherent part of learning when
solving open problems, or actually embedding tasks that could intentionally cause a crisis. It
is proposed that intentional crisis tasks are added to sequences of near-similar tasks, for
example in the way depicted in table, which illustrates the way in which crisis items are
integrated within the digital tool. The general structure of a sequence is: pre-crisis items, crisis
item, post-crisis items. But then the question becomes: how can students address this crisis?
Can we add another principle which enables students to use assessment for learning. One way
would be to make use of formative assessment. Black and Wiliam (1998) define assessment as
being 'formative' only when feedback from learning activities is actually used to modify
teaching to meet the learner's needs. From this it is clear that feedback plays a pivotal role in
the process of formative assessment. Hattie and Timperley (2007) conducted a meta-review of
the effectiveness of different types of feedback. The feedback effects of hints and corrective
feedback are deemed best. However, in my personal experience as a teacher I have seen there
can be an over-reliance on feedback that is provided. Assuming that students finally have to
pass an exam themselves, it makes sense to address this over-reliance on feedback. In a
follow-up paper Kapur (2011) notes that scaffolding implies help to overcome failure (Pea
2004). It turns out that when dealing with previously stored information in the long term
memory, these limits tend to disappear. Theme A - C. Bokhove
20
1.1 Tasks: "Solve the following equation:" Pre-crisis items
In the initial items students are confronted with equations
they have experience with. Students may choose their own
strategy. Many students choose to expand brackets as that is
the strategy that they have used often: work towards the form

0 and use the Quadratic Formula. There is
some limited feedback on the task.
1.2
1.3
1.4
1.5
1.6 Crisis item
Students are then confronted with an intentional
crisis: if a student uses his/her conventional strategy
of expanding the expression. The yellow tick at the
bottom of the screen denotes that the equation is
algebraically equivalent to the initial one, but that it
is not the final answer. This is accompanied by a
partial score for an item and some feedback in Dutch:
'You are rewriting correctly'. Although these
students showed good rearranging skills, in the end
they were not able to continue, as they did not master
the skill to solve a third order equation. There is
some limited feedback on the task.
1.7
1.8 Post-crisis items
After the crisis item students are offered
help by providing a 'voorbeeldfilm', an
instructional screencast, and buttons to get
hints ('tip'), the next step in the solution
('stap') or a worked solution ('loop').
These features have in common that they
provide feedforward information at the
task level and self-regulation.

1.9
1.10
1.11
1.12
1.13
table1: Sequence of items illustrating crises and feedback
As Kirschner et al (2006) argued "any instructional theory that ignores the limits of working memory when dealing with novel information or ignores the disappearance of those limits when dealing with familiar information is unlikely to be effective." As a design principle it is therefore proposed that initially a lot of feedback is provided to foster learning, but the amount is decreased towards the end, to facilitate transfer. Using scaffolding this way is based on the concept of fading (Renkl, Atkinson, & Große, 2004). Formative scenarios Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

21
(Bokhove, 2008) are a variation of this concept, starting off with much feedback, and providing a gradually decreasing level of feedback. Figure 2 shows how this principle was implemented in the intervention. At the start feedback is provided for all intermediate steps of a solution. The subsequent part of the intervention concerns self-assessment and diagnostics: the student performs the steps without any feedback and chooses when to check his or her solution by clicking a "check" button. Feedback is then given for the whole of the exercise.
figure 2: Outline of fading feedback in formative scenarios
Finally, students get a final exam with no means to see how they performed. Just as is the case with a paper test, the teacher will be able to check and grade the exam (in this case automatically) and give students feedback on their performance. A student needs to be able to accomplish tasks independently, without the help of a computer. An implicit advantage of implementing feedback in a sequence of tasks is that teachers and designers have to think upfront about possible student responses.
Principles at work: a case example
Let's look at one student named Paula during the course of this module. The student starts off with a pre-test. Apart from the calculation error on the right hand side of the equation, figure 3 clearly shows that Paula's strategy here is to expand the expressions, similar to students in earlier phases of the study (Bokhove & Drijvers, 2010).
Figure 3: Example of Paula's pre-test pen-and-paper work Theme A – C. Bokhove
22
Not surprisingly this strategy fails in the case of this equation. Paula only scores 14 out of 100 for the whole pre-test. With regard to symbol sense, Paula scores a -4 for (for details on the calculation I refer to Bokhove & Drijvers, 2012a). Paula then starts with the sequence of digital tasks. In the first task the student has to get acquainted with the digital environment. The pre-crisis items pose no problem for most students, including Paula. On arriving at the crisis item students roughly exhibit three behaviours, roughly corresponding with the ones already observed in the pre-test: (i) students solve the equation correctly, (ii) students recognize the pattern of the equation but subsequently make mistakes (for example by losing solutions in the process), and (iii) students expand the expressions and get stuck with an equation with a third power. Figure shows that our case student Paula again shows the third type of behaviour. At this moment feedback is still restricted to correct/incorrect. In addition, students are allowed to choose their own strategies, even when they aren't efficient or would lead to problems. In the post-crisis items, as well as feedback correct/incorrect, Paula is provided with buttons for hints, and a movie clip demonstrating the solution. From the log-files of the online environment it becomes clear that Paula fails at the crisis-item (0 out of 10), but succeeds at the post-crisis item with feedback (10 out of 10). When looking at attempts made, Paula attempts the crisis-item 73 times, and the post-crisis item, being aided by feedback, only 3 times.
Figure 4: Paula's digital work. Left: crisis item left. Right: post-crisis item
Finally, in the post-test Paula shows a significant increase in the total score (70 out of 100) and symbol sense behaviour (+1, an increase of 5). Even though mistakes are made they were not caused by a lack of symbol sense any more but errors in calculations. Focusing only on similar types of equations it becomes clear that Paula manages to solve these equations correctly. Paula is not a unique case in this school. Overall, students in participating schools improved on their scores and symbol sense behaviour.
Conclusion
Illustrated by the theoretical underpinnings, the overall results in the study, and case example, it is concluded it would be a good idea to study design principles that can be used to design sequences of near-similar tasks in more detail. By combining three principles from an initial study -crises, feedback and fading- in one model for sequences of tasks, three important aspects of this ICMI study are addressed: (i) sequences of tasks; (ii) near similar and/or repetitive tasks; and (iii) addressing both conceptual understanding and procedural fluency. We propose that educators, teachers, designers and researchers alike can adopt these principles when designing and implementing sequences of (near-similar) tasks. It is, however, important to note some points of discussion. The difficulty of every task or sequence of tasks depends on the context. What can be a simple task for one year eight student can prove to be difficult for another student, even when at first sight they seem fairly similar. Also, the way in Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

23
which a crisis is overcome can differ: some students learn from repeating near-similar tasks, others seem to recognize 'a pattern' immediately and apply this to new tasks. Given this diversity, it is important to field-test and evaluate sequences of tasks, again combining the power of teaching, researching and designing. I think it would be unfair to indefinitely classify certain tasks as 'more creative' and other tasks as 'less creative'. This, too depends on the background and context of the learner: a wonderful, new and creative task can become a repetitive task the second time around. Looking back on this paper I wonder whether the predicate 'near-similar' does not actually apply to all tasks, if a student has seen a task before, even the elaborate, creative ones. It is my wish that we look at the total picture, and integrate all these tasks in one clear picture for the learning student. One way would be to not so much study the nature of solitary tasks but place them in sequences and their corresponding contexts. Hopefully, this paper provides general design principles that can be used, and task design can be taken forward.

illustrates an approach to task design that aims at revealing and enhancing students' understandings of a particular mathematical topic: the roles of examples in proving and refuting mathematical statements. As a preliminary stage we conducted a content analysis that led to the construction of a comprehensive mathematical framework that describes the various aspects of understanding this topic. Based on this framework, we constructed six prototypes of tasks that complement each other in assessing and enhancing students' understanding of the logical connections between examples and statements. In this paper we describe the design principles that guided the construction of the collection of tasks that can be considered a special kind of tool and provide illustrations of how this tool was used.
Keywords: task design, examples, reasoning and proof
Introduction and Background
With the current curricular emphasis on students' engagement in mathematical investigations and proving, it becomes increasingly important that students develop the understanding of the logical connections between empirical and formal aspects of mathematics. Such understanding manifests itself in understanding of the roles of examples proving and refuting conjectures. Despite the fact that several studies indicate that students encounter difficulties in this area (Fishbein, 1987, Antonini et al., 2011, Bills & Watson, 2008), such connections are not explicitly addressed in the school curriculum and are left to students to develop indirectly mostly on their own. Moreover, there is only scarce work in conceptualizing what constitutes an understanding of the roles of examples in proving (e.g., Zaslavsky & Ron, 1998, Barkai et.al., 2008, Buchbinder & Zaslavsky, 2009, Tabach et. al., 2010). The goal of our study was to develop a tool that could be used both to assess students' overall understanding of the above topic and to enhance these understandings. Moreover, we were looking for a tool that would help capture the

2
This study was conducted at the Technion – Israel Institute of Technology with support of Israeli Ministry of Education. Theme A – O. Buchbinder & O. Zaslavsky
26
nature of this understanding. The first question we posed was: What does it mean to understand the roles of examples in determining the validity of mathematical statements?
In order to answer this question, we developed a general framework
3
that describes four types of examples (confirming, non-confirming, contradicting, and irrelevant) and their status in proving or refuting the two types of mathematical statements (universal and existential). We describe the framework in the next section.
The framework
Every mathematical statement can be characterised by the domain (D) of objects (x) to which it refers to and a proposition (P(x)) that specifies some property. A Universal statement states that a proposition is true for all the objects in the domain: . An Existential statement asserts that there exists an object in the domain for which the proposition is true: . For example, if the domain D is 'all integers for which the sum of their digits is divisible by 6' and the proposition P is 'multiple of 6', we can formulate two types of statements: 1. A Universal statement, "All integers, for which the sum of their digits is divisible by 6 are multiples of 6"; and 2. An Existential statement, "There exists an integer for which the sum of its digits is divisible by 6 that is a multiple of 6".
With respect to a given domain D and a property P, four types of examples can be defined, depending on whether (a) the object x is an element of D or not (or), and (b) the proposition P(x) is true for it or not (or). The logical status of these examples depends on the type of statement (Figure 1). The first type of object x, which we term a confirming example, is an element of D for which the proposition P(x) is true ( ). In the above case, 24 is a confirming example. While 24 is insufficient for proving the universal statement, it proves the corresponding existential statement. The second type of object, which is termed a counterexample, is an element of D that does not satisfy the proposition P(x) ( ). For example, 33 is a counterexample, thus, it contradicts the false universal statement; we refer to such an example as a contradicting example (of the universal statement). However, with respect to the corresponding existential statement 33 is insufficient for refuting it. It neither contradicts nor confirms it; thus we term such an example a non-confirming example (of the existential statement). All of the above types of examples are relevant for examining the validity of a given statement. The other two types of examples are objects that do not belong to the domain D: and . From a logical stand both types are equally irrelevant for determining the validity of either type of statement. However, example of type (e.g., 36) is potentially misleading.

Figure 1: A framework for examining the logical status of examples in determining the
validity of mathematical statements
We take "understanding of the logical status of examples in determining the
validity of mathematical statements" as becoming fluent with the types of inferences
that can and cannot be made based on the four types of examples with respect to the
two types of statements. We consider the following four types of cognitive activities
as eliciting evidence of such understanding: construction of examples (spontaneously
or on demand); recognition of and differentiation between types of statements and
types of examples (without necessarily using our terms); making logical inferences
based on examples, and correctly justifying then. Such operational approach to
conceptualizing understanding is consistent with Borgen & Manu (2002), Schoenfeld
(1989) and Zaslavsky (1997) and sets the grounds for task design.
The design principles behind the collection of tasks
Based on our framework, we constructed 6 prototypes of tasks, each of
which addresses a particular aspect of understanding. The set of tasks as a whole
covers all the aspects of the framework and proved effective as a diagnostic and
facilitating tool for 10
th
grade students in Israel.
The overarching design principle was to create a balanced representation of
all of the following variables: 1. Type of statement (universal or existential); 2. Type
of example (confirming, contradicting, non-confirming, and [two kinds of]
irrelevant); 3. The truth-value of the statement (true/false); 4. The content (secondary
level algebra or geometry, all of which students are supposed to be sufficiently
knowledgeable); 5. Number of relevant examples that exist for each statement (e.g.,
no example, a single example or a finite number, an infinite number of examples of a
particular type).
From a mathematical point of view, the specific number of examples that
exist for each statement is irrelevant
4
. A single contradicting example is sufficient for
refuting a statement, even if there exist an infinite number of confirming examples.
However, the number of examples may affect students' inferences, their perseverance
in evaluating the truth-value of the statement, and the methods they use.

4
If a domain of a universal statement has a finite number of elements, it is possible to prove
that the statement is true by showing that the proposition holds for each one of them. However,
showing that the domain is indeed finite is an imperative part of the proof.

28
Thus, the collection of tasks included statements for which all existing
examples are supporting ones, statements that have both supporting and contradicting
(or non-confirming examples), and statements which have only contradicting or nonconfirming examples. The rationale for such design was to create a rich scope of
situations for examining students' understanding of the roles of examples in proving.
While we wanted to ensure that students have the necessary knowledge to
approach the tasks, we also wanted to confront the students with statements that were
unfamiliar to them of which truth-values would not be immediately evident. Such
statements have the potential to evoke uncertainty and doubt, which are widely
recognized as powerful diagnostic tools as well as vehicles for creating situations in
which the need to prove arises intrinsically (e.g. Zaslavsky, 2005; Buchbinder &
Zaslavsky, 2011; Hadas, Hershkowitz & Schwarz, 2000). We expected that the
uncertainty evoked by the tasks would trigger students' discussion and attempts to
convince each other through argumentation, which would allow for various aspects of
their understanding to be revealed.
The design of our tool (i.e., the collection of tasks) was inspired to some
extent by Harel's (2007) DNR principles for learning environments. In particular, the
necessity principle that emphasizes the importance of evoking students' intellectual
need to prove; and the repeated reasoning principle that states that students need to
practice reasoning in various settings. Thus, the design of our tool aimed at providing
multiple opportunities for students to practice reasoning, to reflect on their knowledge
of the logical connections between examples and proving, and to enhance their
understanding of these connections through resolving uncertainty.
The collection of tasks
The collection includes 6 types of tasks: (1) What kind of example is this?
(2) True or false? (3) Always, sometimes, or never? (4) Who is right? (5) Is this a
coincidence? (6) Does it exist? For space constraints we cannot go into equal length
of detail for each task.
Task 1:What kind of example is this?
This task has two parts, each involving different statements: a false universal
or a true existential. Each statement was accompanied by 7 examples of various types.
For each part, the students were asked to determine the types of the 7 examples; to
construct two additional examples (one confirming and one non-confirming); to
decide whether the statement is true or false and to justify the decision.
Figure 2 shows one of the false universal statements and the analysis of the
examples used for the task.
This type of task was the only one that explicitly calls for examining
irrelevant examples and determining their logical status, and that explicitly requires
construction of examples that satisfy a given criteria. Note, that the students did not
receive any explanation of the framework including its vocabulary prior to engaging
in the task.

Figure 2: Examples and design-analysis of the categorization part of Task 1 for the given statement
Task 2: True or False?
Tasks of this structure are rather common. We adapted this familiar model to
fit our mathematical framework. In this task a set of 6 statements were given: 3
universal and 3 existential. Within each type of statement, we included one statement
for which all relevant examples are confirming, one statement which has both
confirming and non-confirming examples, and one statement for which all relevant
examples are contradicting or non-confirming.
Figure 3 presents the structure of the algebraic version of this task. Note that
constructing a case for each row is a non-trivial task for the designer.
This task addresses most of the aspects of understanding of the roles of
examples with respect to the framework. In order to solve the task correctly, students
need to distinguish between the different types of statements and the corresponding
types of examples; they also need to construct counterexamples to disprove false
universal statements (1 & 3), and confirming examples to prove true existential
statements (4 & 5). The task calls for demonstrating the understanding that examples
could be insufficient to prove or refute statements (2 & 6), and that in such cases a
general logical argument is required. Students may arrive at this conclusion either by
constructing and checking examples or by applying algebraic procedures.

Note: E stands for Existential, U for Universal, T for True, and F for False
Task 3: Always, Sometimes, Never
This task is related to the "True or False?" task, with a shift of focus. Given
the propositions from the statements in Task 2, students are required to determine
whether the proposition is always, sometimes or never true (Figure 4). From a logical
point of view, a statement involving quantifiers is either true or false. Thus, a
universal statement cannot be "sometimes" true, even if both confirming and
contradicting examples exist. However, a proposition P(x) can be true for some values
of x and false for others. For example the proposition "x is greater than 5" is true for
x=3, but false for x=13. Thus, a proposition P(x) can be always, sometimes, or never
true (Rosen, 2003).
Figure 4 presents one of the items that were included in Task 3. It is a
different take on item 1 that appears in Figure 3.

Task 4: Who is right?
This task has two parts involving one false universal and one true existential
statement. Each statement is followed by utterances of five hypothetical students
stating their opinion on the truth-value of the statement. The task requires, for each
utterance, to determine whether it is correct or not and to justify the decision.
Figure 5 presents the design structure of the Task 4.

Figure 5: Design structure of Task 4
Task 5: Is this a coincidence?
This task presents a hypothetical student's actions and his/her observation
based on a single example. The question "is this a coincidence?" invites the students
to evaluate the generality of the observed phenomenon in order to determine whether
it holds for every relevant case or just for some specific cases, one of which the
student examined. Successful completion of the task involves either proving that the
described phenomenon is a general one or constructing a counterexample.
A student chose two fractions: and . He generated another fraction by adding
the two nominators and the two denominators in the following way:
. The student observed that the resulting fraction is between
the two original ones: . Is this a coincidence?
Figure 6: An algebraic example of Task 5
Note, that there is no explicit requirement in the task to prove any claim. The
intention was to draw students' attention to the extent of generality of the
phenomenon, and to study the ways in which they deal with the task, focusing on their
need to form an assertion and justify it by means of proof or refutation.

Task 6: Does it exist?
This task focuses on existential statements and the roles of examples in
determining their validity. The task included four statements, two in algebra and two
in geometry worded in the form "Does an object with a certain property exist?"
(figure 7). In some ways this task resembles the "True or false?" one, however, in the
pilot study we found that the wording of the statements as questions appeared to be
more appealing to the students.
Does there exist a triangle with two heights that are perpendicular to each other?
Does there exist a triangle with two angle bisectors that are perpendicular to each
other?
Does there exist a pair of natural numbers a, c that satisfy: ?
Does there exist a pair of natural numbers a, b that satisfy:
a·b[a·b(a·b)] = (a·b)(a·b)(a·b) ?
Figure 7: Examples of Task 6
Concluding remarks
In this paper we offer a holistic approach to task design. Figure 8 illustrates
how the conceptual framework that we developed guided the design of a whole
collection of tasks that formed a diagnostic tool.
The collection of tasks constituted the research instrument for a study of 10
th
grade students' understanding of the roles of examples in determining the validity of
mathematical statements. This tool was also used for task-based interviews with pairs
of students who worked aloud on these tasks. Overall, the rich scope of types of tasks,
as well as the specific statements and examples that were chosen for each type of task,
proved useful in tapping into students' thinking and enhancing their understandings.
Space does not permit to include examples of such manifestations in this paper but
they will be included in a presentation.

Rotational symmetry: semiotic potential of a transparency
toolkit
Yip-Cheung CHAN
Chinese University of Hong Kong
Allen LEUNG
Hong Kong Baptist University
In this paper, excerpts of lessons on using tool-based tasks to
teach the concept of 'rotational symmetry' were analyzed. Theory of
semiotic mediation was adopted as theoretical framework. The analysis
focused on how the tasks could (or could not) bring out the semiotic
potential of the tool used. We hope that this analysis could provide some
insights on how the design of tool-based tasks may enhance the bringing
about of semiotic potential of the tools.
Keywords: semiotic potential, rotational symmetry, tool-based task
Introduction
It has been a long history to use concrete manipulative objects to teach
mathematics (Dienes, 1960, 1971). Designing tool-based learning tasks becomes
popular in recent decades because of the new development of virtual manipulative
software such as Geometer's Sketchpad or Carbri. By a task we mean a teacher
designed 'thing-to-do' using the tool, either concrete or virtual manipulatives, for
students to experience potential mathematical meanings carried by this tool. Empirical
studies suggest that teachers can promote the evolution of mathematics knowledge
through "orchestrating" tool-based learning tasks and post-task mathematics
discussions. (See for example, Jones, 2000; Mariotti, 2002; Falcade, Laborde, &
Mariotti, 2007.) We follow Mariotti & Maracci (2012) to use "orchestration" as a
metaphor for classroom discussions with the aim "of developing shared meanings,
having an explicit formulation, de-contextualized from the artifact [tool] use,
recognizable and acceptable by the mathematicians' community" (p.60). In this paper,
excerpts of lessons on using tool-based tasks to teach the concept of 'rotational
symmetry' were analyzed under the framework of semiotic mediation. The analysis
focused on how teacher's orchestration of tool-based learning tasks and post-task
mathematics discussions could (or could not) bring out the semiotic potential of the
tool. It is hoped that this analysis could provide some insights on how the design of
tool-based tasks may enhance the bringing out of semiotic potential of tools.
Theoretical Perspective
The framework of "semiotic mediation" (Bartolini Bussi & Mariotti, 2008)
which is rooted from Vygotskian perspective on "social construction of knowledge" is Theme A – Y.-C. Chan & A. Leung
36
adopted as theoretical framework. A tool (artefact)
5
which carries mathematical
meanings can become a "tool of semiotic mediation" by which students can
experience the development of mathematical concepts. In particular, a tool of semiotic
mediation provides a means to express mathematical ideas. Bartolini Bussi & Mariotti
(2008) points out that there is "double semiotic link" between a tool, a task and
mathematical knowledge when the tool is used to accomplish a specific task. They
further point out that:
"The main point is that of exploiting the system of relationships among artefact,
task and mathematical knowledge. On the one hand, an artefact is related to a
specific task … that seeks to provide a suitable solution. On the other hand, the
same artefact is related to a specific mathematical knowledge." (Bartolini Bussi &
Mariotti, 2008, p.753)
This double semiotic relationship is called the "semiotic potential" of the tool
(artefact) (Bartolini Bussi & Mariotti, 2008, p. 754). In the mathematics classroom,
teacher plays a crucial role in the process of semiotic mediation. As "the voice of
mathematics culture", the teacher guides mathematical discussions which aim at
bringing out the semiotic potential of the tool: a progression from students'
production of mathematical discourse to mathematical knowledge. Building on this
perspective, in Azrarello, Bartolini-Bussi, Leung, Mariotti & Stevenson (2012, pp.
107-108), a model was used to describe the process of semiotic mediation which
highlights the classroom dynamic relationship among the tool (artefact), the task,
students' productions, the teacher, and mathematical knowledge. The dynamism
consists of a network of interactions wherein the teacher uses a tool (artefact) as a
mediator between mathematical knowledge and tasks performed by the students. The
model highlighted two responsibilities of a teacher: 1. choose suitable tasks based on
the tool used; and 2. monitor and manage the process of progression from students'
production to mathematical knowledge to be taught.
The Context
The excerpts of lesson episodes chosen for discussion in this paper were
taken from a research lesson study carried out in Grade 5 classroom at a Hong Kong
primary school
6
based on the Japanese's Lesson Study (Fernandez & Yoshida, 2004)
and the Learning Study (Lo, Pong & Chik, 2005) models. The research lesson aimed
at improving mathematics teaching through tool-based tasks. Five Grade 5
mathematics teachers worked together over period of five months to design lessons
for a selected topic. The topic selected for the research lesson was rotational
symmetry. One of the teachers implemented the lesson whereas other teachers
observed and evaluated the lesson. A modified lesson was agreed by the teachers and
was implemented by another teacher (at another class). This cycle was repeated until
all the five teachers have taught the lesson to their own classes. A researcher in charge
(one of the authors) acted as a participant observer and gave advice from theoretical

5
Some theoretical perspectives such as instrumental approach make distinction between
artefact and instrument in order to highlight the differences between the potentialities and the actual
uses of the tool respectively. In this paper tool and artefact are regarded as synonyms which refer to
both the potentialities and the actual uses.
6
The authors would like to express their gratitude to the team of mathematics teachers from
St Edward Catholic Primary who designed and implemented this Lesson Study. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22
consideration. All the teacher preparation meetings, lessons and the post
discussion were video-taped.
The Tool and the Task
The objective of the lesson was to introduce to students the idea of a
rotational symmetric figure; that is, a figure 'overlaps itself' at least two times during
one cycle of rotation. A toolkit was specially designed for this lesson. The toolkit,
which we will call the
overhead transparency, pen and a Styrofoam board (
purpose to verify whether a given/constructed figure has rotational symmetry.

potential for the transparency toolkit.
Figure 1: Transparency Toolkit
The lesson structure was basically the same among all the five lessons
whereas there were slightly differences in details. The teacher started the lesson by
giving a brief review on line symmetry through a whole
transition the idea of rotational symmetry was introduced. Then a figure was given to
students and they were asked to verify/explore whether the figure has rotational
symmetry using the transparency toolkit. The last part was the main part of the lesson.
Four identical plastic square
(worked in pair) were asked to design rotational symmetric figures using these four
plastic squares and used the transparency toolkit to verify their works. Afterwards, a
whole-class discussion was led by the teachers along with student presentations.
There were variations among different classes. In one class, a sheet of square
grids (figure 2) was used instead of plastic squares. In another class, a 'virtual toolkit'
using computer software that was designed to be equivalent to the transparency
toolkit was used instead of the plastic squares and the transparency toolkit.
In the following, we will analyze the implementations of the last part (i.e.
designing rotational symmetric figures) in two of the lessons (
B) where the transparency toolkit wa

Analysis
Part 1: Producing rotational symmetric figures using squares
In Lesson A, square grid sheets were provided for students (in groups) to
produce rotational symmetric figures by colouring selected squares. Generally
speaking, students found it a difficult task to handle. After guidance from the teacher,
some students rotated the square grid sheet and could produce some simple figures
with rotational symmetry. In contrast, in Lesson B plastic squares were given to
students. The plastics shapes were concrete manipulative which seemed to provide
students a more tangible experience to comprehend the meaning of rotational
symmetry. It allowed students to rotate individual square piece and consequently
could produce more complicated figures. Some students could detect and correct
mistakes by rotating the individual square pieces. For instance, a pair of students
initially designed an incorrect figure (Erreur ! Source du renvoi introuvable.).
While rotating (some of) the square pieces, they found that the figure has no rotational
symmetry (figure 4). Then they modified the figure into a rotational symmetric one
(figure 5). In this self-correction process enabled by the tool, the students (implicitly)
experienced the fact that the upper half and the lower half of the figure they produced
have the same distance from the centre but in the opposite direction. This may emerge
in students' mind an intuitive understanding of the meaning of a 2-fold rotational
symmetry.
Figure 3: incorrect figure Figure 4: rotate part of the figure Figure 5: corrected figure
When comparing lessons A and B, it was observed by the teachers and the
researcher that the square grid sheet was not as conducive as the plastics square pieces
to bring about the (intuitive) meaning of rotational symmetry. What made the
difference? One possibility was that square grid sheet could not be separated into
different parts. Whenever the whole square grid sheet was rotated, all the individual
squares were changed in the same way. This lack of variation in parts in the creation
process may result in a limited experience to what are typical in rotational symmetry.
In contrast, the plastics square pieces could be manipulated as separate entities and
changed with respect to each other in different ways. This opened up wider variation
and opportunity to produce more complicated figures. As seen in the 'self-correction'
example of Lesson B, students could rotate parts of the created figure (the middle two
squares). This may lead to discernment of critical features of rotational symmetry and
hence an intuitive understanding of the concept may consequently emerge. Thus a
shift of attention between the parts and the whole of the object of exploration (the
rotational symmetric figure) could occur through manipulation of the square pieces
but may not be the case for the square grid sheet. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22
Part 2: Initiating mathematics discussion through verification with the
transparency toolkit
After the above group activity of figure creation, students were asked to
verify whether their created figures have rotational symmet

locate the center, rotate the figure on the transparency, count the number of times of
overlapping, and lastly, recall prior knowledge, and address the discrepancy caused
by the tool utilization. In this orchestration process, the semiotic potential of the
transparency toolkit as a tool of semiotic mediation is emerged through evaluation of
the students' productions by manipulating the tool and speaking out the key concepts
explicitly at the same time. An interesting double semiotic link occurred when the
teacher made use of the tool's 'inaccurate representation' to extend the conceptual
understanding of rotational symmetry from merely recognizing a descriptive
definition to discerning a critical feature about angle size in rotational symmetry. The
occurrence of this discussion could be regarded as an incidental opportunity created
by the semiotic potential of the tool. The original task was to create a rotational
symmetric figure by using four (identical) square pieces. It happened that one pair of
the students did not follow the instruction and used three square pieces instead of
four. It can be calculated easily (by us not the students) that the angle between two
adjacent square pieces needs to be 30 degrees in order to create a rotational symmetry
figure using three (identical) squares. For Grade five students, it is difficult visually to
arrange the square pieces so that all three gaps are of 30 degrees. Rotating the figure
by the transparency toolkit made this discrepancy explicit which gives rise to an
opportunity for the teacher to orchestrate meaningful mathematics discussion with the
students. This suggests that a tool-based task which can capitalize the potential
discrepancy embedded in the tool may bring about a higher level of conceptual
understanding. The insight and flexibility of the teacher is a key factor of whether the
task can be orchestrated to the emergence of mathematical meaning. In the above
teaching episode, if the teacher ignored the discrepancy or he simply told the students
that all the four squares should be used, the mathematics discussion would not be as
rich and fruitful.
Discussion and Conclusion
In this last section, some lesson episodes on tool-based tasks were analyzed.
In the following, we will extend the discussion to propose some suggestions
(hypothesis) on the design of tool-based tasks which may enhance the bringing out of
semiotic potential of the tools. We will focus on four aspects: 1. the tool, 2. the task,
3. students' productions, and 4. the teacher.
The tool
Semiotic potential of the tool may be enhanced if the tool allows students to
freely shift their attentions between the parts and the whole of the object of
exploration
This suggestion is consistent to the perspective of discernment and variation
(Marton, Runesson & Tsui, 2004). Based on this perspective, Leung (2003) pointed
out that "discernment comes about what parts (features) are being focused and
temporarily demarcated from the whole (background)" (p.198). For instance, in
dynamic geometry environment (DGE), part of the geometric configuration can be
varied via dragging while keeping the other parts fixed. The invariant patterns of the
configuration could then be "separated-out" (Leung, 2008). The lesson episodes
above showed an example of a non-ICT tool. The square pieces (without the blu-tack)
allow students to see the object of exploration (the rotational symmetric figure) in
parts and hence 'separate' some parts from the whole object. Whereas, the square
pieces with blu-tack allow the students to see the object as a whole. This flexibility of Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
41
the tools may give an opportunity to have a better understanding on the part-whole
relationship of the object and discern the essential feature of the object from the
incidental one.
The task
A task which provides an opportunity to make use of the discrepancy
embedded in the tool may initiate meaningful mathematics discussion which could
lead to deeper conceptual understanding.
Making mistakes may not be a bad thing. Meaningful mistakes may initiate
mathematics discussion which leads to construction of mathematical knowledge.
Some tasks may have higher possibility to make (meaningful) mistakes. For instance,
in the lesson episodes above, creating a rotational symmetry figure by using three
(identical) square pieces is easier to make 'mistakes' than by using four (identical)
square pieces. Though the 'mistake opportunity' occurred in our lesson episodes was
rather incidental, we suggest that the 'mistake opportunity' should be planned
together with the task design. In order to make these mistakes meaningful to the
students, the mathematics implied in the 'mistakes' should be considered beforehand.
The tool used in a task may influence the chance of making mistakes. For instance, if
instead of concrete square pieces, an ICT tool (e.g. DGE) was used for the task
described in this lesson episode, it was unlikely that the 'mistakes' discussed above
would occur because drawing in DGE is usually accurate (at least the discrepancy
cannot be discerned visually). However, there may be other discrepancies in DGE that
are conducive to rich mathematical discussion. (Some empirical studies found that
sometime students deliberately drew a 'wrong' picture in DGE in the process of
exploration and argumentation. See for example, Leung & Lopez-Real (2002);
Mariotti & Antonini (2009); Baccaglini-Frank, Antonini, Leung & Mariotti, (2011).)
Student' productions
Requiring the students to evaluate their productions using the tool while
simultaneously speaking out the key mathematics concepts with respect to the tool
may effectively mediate the progression from students' production to mathematics
knowledge.
The progression from students' production to mathematics knowledge is not
automatic. Teacher, as an expert representative of mathematics culture, needs to use
students' production as "a tool of semiotic mediation" (Bartolini Bussi & Mariotti,
2008). For instance, Mariotti and her colleagues conducted a series of long term
teaching experiments in DGE to develop students' mathematical thinking in
axiomatic approach (Mariotti, 2002). Students were mediated to experience the
development process of mathematical theory by Cabri (a DGE) commands. There is a
correspondence between these commands and the elements of mathematical theory
(definitions, axioms and theorems). Indeed, the 'labels' of the Cabri commands make
the correspondence explicit. However, for non-ICT tools, such correspondence may
not be explicit because this kind of 'labels' may not exist in the tools. It is the role of
teachers to make the correspondence explicit. The teachers in the lesson episodes
made use of a well-structured orchestration procedure which involves students'
evaluation of their own productions by manipulating the tool and speaking out the key
mathematics concepts explicitly at the same time to achieve this 'labelling effect'. In
this orchestration, the teacher deliberately highlighted the mathematics terminologies
realized in the semiotic potentials of the tool. For example, the push pin corresponds Theme A – Y.-C. Chan & A. Leung
42
to the centre of rotation. The correspondence of the students' productions and the
mathematics knowledge may be seen through this process of "situated abstraction"
(Noss & Hoyles, 1996).
The teacher
Developing teacher's ability to determine whether student production
(correct or incorrect) is conducive to conceptual learning is an important aspect in
training teachers to use tool-based tasks in the mathematics classroom.
Teachers play a significant role in the process of semiotic mediation. As an
expert representative of mathematics culture, the teacher guides the evolution of
mathematical meanings related to the tool and its use within the mathematics
classroom (Bartolini Bussi & Mariotti, 2008). The lesson episodes above suggested
that the quality of the guidance depends on the insight and flexibility of the teacher. In
the second part of Lesson B, the teacher made use of the students' incorrect (or notso-correct) production to extend the mathematics discussion so that deeper conceptual
understanding of rotational symmetry was evolved. This was incidental in the sense
that it was out of the teacher's original planning. Certainly, not all students' mistakes
are equally worthwhile for extending the discussion. Therefore, a teacher's ability to
determine whether a student's (mistaken or unexpected) production (or response) is
worthwhile for further discussion is one of the criterions of success to bring about the
semiotic potential of a tool-based task. We suggest that developing such ability is an
important aspect in training teachers to use tool-based mathematics tasks.
In this paper, four suggestions on tool-based tasks are proposed according to
our analysis of the design and implementation of a tool-based geometry task at
primary school level. More empirical studies will be conducted in order to verify the
validity of our suggestions.

Designing tasks within a multi-representational technological environment: An emerging rubric.
Alison Clark-Wilson
University of Chichester, UK
Jaiwant Timotheus
Holden Lane High School, Stoke on Trent, UK
The advent of digital technological environments that offer linked multiple mathematical representations present a substantial challenge to secondary mathematics teachers as they begin to design tasks for their learners. This paper concludes a design rubric for mathematical tasks as one of the outcomes of a longitudinal doctoral study in which fifteen teachers began to integrate such a tool (TI-Nspire handheld and software) within their classroom practice (Clark-Wilson, 2010a). The research, which was carried out in two phases, provided evidence for the predominant use of the technology to support explorations of variance and invariance. It also gave an insight into the process through which the teachers integrated the technology into their classroom practices. This paper offers a joint perspective of the project from the mathematics education researcher (Clark-Wilson) alongside one of participating teachers (Timotheus).
Keywords: Hiccup, instrumental genesis, mathematics education, mathematical generalisation, multiple representational technology, task design, teacher development, variance and invariance.
Introduction
The research reported within this paper was situated within a pilot evaluation project that introduced a prototype technology 'TI-Nspire' (Texas Instruments, 2007) to a group of English secondary mathematics teachers between July 2007 and November 2009. The project community comprised educational technology developers (Texas Instruments), a mathematics education researcher (the first author), mathematics education consultants and secondary mathematics teachers (including the second author). The first author was solely responsible for the design, implementation and reporting of the project and the second author was one of the participating teachers. In common with other teacher development projects, with and without ICT, there was a clear rationale underpinning the approach taken to establish the ethos and ways of working within the project (Ahmed, 1987; Watson, De Geest, & Prestage, 2003). There was a clear sense of 'researching-with', which resulted from privileging the teachers' classroom stories and by supporting teachers to substantiate their own claims of changed mathematical experiences and outcomes on the part of their students. Within the research, the word 'activity' was used to describe the set of Theme A - A. Clark-Wilson & J. Timotheus
46
situations that the teacher had designed to initiate the students' mathematical work. These activities would include one or more 'tasks' and the outcomes of these tasks were subsequently described as 'episodes' within the teaching sequence. The broad aims for the study were to try to articulate the nature of the teachers' cognitive and pedagogical learning as they began to use the aforementioned multi-representational technology in their classrooms with students.
Theoretical perspective
The research was framed within an activity-theoretic approach that interprets the Vygotskian notion of activity as a 'unit of analysis that included both the individual and his/her culturally defined environment' (Wertsch, 1981). The elaboration of the instrumental approach within technological environments (Verillon & Rabardel, 1995) was developed further by a body of researchers within the context of technology use in mathematics education, leading to the notions of instrumentation, instrumentalisation, instrumental genesis, instrumental orchestration and documentational genesis (Drijvers, 2011; Drijvers & Trouche, 2008; Gueudet & Trouche, 2009; Guin & Trouche, 1999; Trouche, 2004). These ideas concern the complex and interrelated processes of:
• learning to use a new technology for purposeful mathematical activity;
• designing tasks for students to initiate purposeful mathematical activity;
• collating the various artefacts that comprise the 'document system' for the activity;
• supporting students to learn to use technology for purposeful mathematical activity;
• articulating the teacher's role in supporting the students to navigate their respective routes through the various artefacts that comprise the activity to include interaction with the technology.
It is important to comment that within the research contexts from which these notions emanate, the chosen technologies are best described by Pierce and Stacey (2008) as 'mathematical analysis tools', which include technologies such as computer algebra software (CAS), dynamic geometry software (DGS), graphing software and spreadsheet software. The TI-Nspire technology adopted within this research afforded a range of 'applications' that included: calculator; spreadsheet; dynamic geometry; function graphing; statistical calculation and graphing; built in commands i.e. factor(n); and text editing. In all of these environments, the facility to save numeric outputs as variables supported the linking of variables within and between these different applications.
A second important theoretical construct of significance to the study was that of a multiple representational environment, which was postulated initially by Kaput (Kaput, 1986) as he presented a vision for the way in which technology might support higher-level engagement with mathematics. In the intervening years, the aforementioned genres of technologies have afforded opportunities to engage with mathematics dynamically by observing the simultaneous views of different representations. For example, the representations of a function, its graph and a table of its associated coordinate values. The development of 'dragging' a figural image through the interface of a mouse (or pen or finger) has afforded further forms of mathematical interaction.
Finally, the underlying principle that informed the pedagogical approaches within the study were informed by Mason et al's assertion that "a lesson without the Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
47
opportunity for learners to express a generality is not, in fact, a mathematics lesson' (Mason, Graham, & Johnston-Wilder, 2005, p.297). This promoted the use of the technology to provide the students with opportunities to explore variance and invariance within a range of mathematical contexts.
Research methodology
In concluding their research study into teachers' perceptions of the use of technology, which involved secondary mathematics departments in seven English schools, Ruthven and Hennessy (2002) , highlighted the need for, naturalistic studies which provide analyses of the perspectives and practices of groups of teachers across different settings within the context of using technology to support teaching and learning of mathematics. (p.50)
Although this study cannot claim to be wholly naturalistic, as the technology had been prescribed, it did aim to gain a deep insight into the perspectives and practices of secondary mathematics teachers as they developed their use of the MRT in the classroom.
The research was carried out in two phases, the first between July 2007 - November 2008 and the second between April 2009 and December 2009. In each of these phases, a group of teachers was selected and a series of methodological tools developed to capture rich evidence of their use of the technology in classrooms to enable the aims of the study to be realised. The methodological approaches for each phase were distinct, and each is described briefly below.
Phase 1
Fifteen teachers were selected (in pairs) from seven English schools where there was some history of use of technology use within mathematics, although some of the individual teachers had limited personal experience. During the first phase of the research (July 2007 to November 2008), the teachers reported 66 lesson activities that had used the TI-Nspire technology, which resonate with Gueudet and Trouche's "document systems" (2009) comprised a number of artefacts that included some or all of the following:
• an activity plan in the form of a school lesson planning proforma or a hand-written set of personal notes;
• a lesson structure for use in the classroom (for example a Smart NoteBook or PowerPoint file);
• a TI-Nspire software file developed by the teacher for use by the teacher (to introduce the activity or demonstrate an aspect of the activity);
• a TI-Nspire software file developed by the teacher for use by the students, which would normally need to be transferred to the students' handhelds in advance or at the beginning of the lesson;
• a activity or instruction sheet developed by the teacher for students' use;
• students' written work resulting from the activity;
• students' TI-Nspire software files captured during and/or at the end of the activity;
• a compulsory post-activity questionnaire, which prompted the teacher to reflect deeply on the lesson(s). (Clark-Wilson, 2008)
This data was used to analyse each of the lesson activities with respect to the teachers' planned instrument utilisation schemes and, as a result nine diagrammatic Theme A - A. Clark-Wilson & J. Timotheus
48
'instrument utilisation schemes' were developed. For more detail, see Clark-Wilson (2010b).
The analysis of the phase 1 data led to 268 thickly coded examples of 'teacher learning' from 100 data sources and a process of constant comparison led to 38 categories that were subsequently grouped into four domains: activity (task) design, expectations of students, instrument utilisation schemes and meta-level ideas. As this paper is concerned with the first theme, the broader description of the categories related to task design included aspects concerning:
• the teacher's initial choice of examples, its appropriateness and potential for non-trivial mathematical exploration and extension;
• the features of a good 'first activity' when introducing the technology or new instrumental techniques to the students;
• the need to balance the construction and exploration elements within the design of activities;
• teachers' reflections on their personal instrument utilisation scheme when introducing the activity to the students and during whole class discussions;
• the relationship between the students' learning of relevant mathematical concepts with technology and the traditional 'by hand' or 'paper and pencil' approaches - and reflections surrounding the teacher's role in supporting students to connect these experiences;
• an appreciation of the need for a tighter focus on or attention to specific mathematical generalisations within activities.
The first phase of the project revealed rich data concerning teachers' perceptions of explorations of regularity and variation, which seemed to substantiate Stacey's claim that, from the Australian research, this was the most common form of mathematical activity with technology (Stacey, 2008). There was less evidence of activities that made use of opportunities to link representations. However, the analysis of the teachers' developing instrument utilisation schemes suggested that this could be a function of both teachers' time and familiarity with the technology.
Phase 2
The second phase sought to probe the nature of teachers' situational learning through a focussed and systematic case study of two of the teachers who had participated in the first phase (Eleanor and Tim). These two teachers had a level of technical competency that showed that they had grasped the skills needed to create activities using a range of applications within the MRT. The second consideration was that the teachers adopted pedagogical approaches that placed the students' mathematical experiences at the centre of the classroom environment. By allowing the students more mathematical choices within the activities they developed, they adopted a more socio-constructivist philosophy in which their students could form their own mathematical meanings with a collaborative, supportive classroom ethos. My rationale for this choice was related to my desire for the study to generate new knowledge about the way that teachers conceive and learn from their own innovations with complex new technologies.
The data collected as part of the teacher's 'document system' during phase one was supplemented by the following:
• classroom observation data (video, audio and field notes); Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
49
• additional data relating to the teacher's interactions with students, for example, a software file at the time of the interaction;
• data resulting from interviews with the teachers, which included pre- and post lesson discussions;
• field notes, which incorporated extracts from email exchanges with the teachers.
A further 14 lessons were observed between May 2009 - December 2009 and for each one, the data set was imported into Nvivo 8 software to support the subsequent data coding and analysis processes (QSR International, 2008). The analysis of the phase two data concluded the important notion of the lesson 'hiccup', that is the perturbation experienced by teachers during lessons stimulated by their use of the technology, which illuminated discontinuities within the teachers' knowledge. The cross-case analysis attributed the hiccups to seven considerations: Aspects of the initial activity design; Students' interpretations of the mathematical generality under scrutiny; Unanticipated student responses as a result of using the MRT; Perturbations experienced by students as a result of the representational outputs of the MRT; Instrumentation issues experienced by students when making inputs to the MRT and

whilst actively engaging with the MRT; instrumentation issue experienced by one teacher whilst actively engaging with the MRT; and Unavoidable technical issues. However, as this paper is concerned with the subsidiary research findings concerning the emergent principles for task design within MRT environments and the tool-driven implications for the design, teaching and learning triad the discussion that follows will focus on these aspects.

What did the teachers learn about designing tasks within the MRT?

A central tenet of this thesis was that activities and approaches that privileged an exploration of mathematical variance and invariance constituted a legitimate pedagogical opportunity for the use of technology in secondary mathematics classrooms. The teachers' evolving conceptions of variance and invariance were revealed in several ways during the study. This included how they conceptualised the initial representation of the variant property under exploration and the related representations that added insight to, or progressed, the exploration and the way in which any invariant properties would become explicit as a result of the exploration.

Eleanor and Tim learned that there were several important aspects when making the choice of initial example within their activity design and its subsequent representation within the MRT. Firstly, it needed to be an example of the generalisation being sought. A hiccup that Tim experienced during the activity 'Linear equations' led him to conclude that his choice of functions for the initial example, which was a spontaneous decision, was unhelpful. His selection of y=1x+1 and y=2x did not support the students to begin to generalise about the gradients of the linear functions, partly because there were two digit ones inherent in y=1x+1, but also due to the way that the MRT displayed the measured equations

7

(see Figure 1).

7

This hiccup was compounded by the output from the MRT which displayed an unhelpful 'measured' equation. (A measured equation is one which for which the MRT numerically analyses a set of points that define a geometrically constructed line, often revealing unexpected numerical errors.) Theme A - A. Clark-Wilson & J. Timotheus

50

Figure 1 Tim's handheld screen during the activity 'Linear graphs' [STP10(tns-T)].

Eleanor and Tim both seemed to grapple with the notion of the 'example space' in ways that were resonant with Goldenberg and Mason's elaboration of the difficulties encountered when trying to identify appropriate examples for different mathematical generalisations (Goldenberg & Mason, 2008). Tim's choice of functions in the 'Linear equations' activity could be interpreted as him having a 'general sense' of the representation of any two straight lines on a dotty grid alongside the functionality of a 'gradient measure' tool as a sufficient space in which to be able to generalise about slope. However, a more informed choice of functions, alongside the utilisation of the MRT's functionality to measure the slope of the line, rather than its equation, all formed aspects of Tim's redesign of this activity.

Having decided upon the initial input representation, another important consideration for the teachers related to their decisions about the syntactic labelling or notation of variable objects. They learned that this was a necessary element of activities when classroom discourse would be initiated to support students to notice and verbalise their generalisations. As both teachers privileged whole-class discourse focussed on key mathematical generalisations in their classroom practices, they both experienced a number of hiccups that indicated that there was insufficient notation or labelling to enable this discussion to be suitably focussed. This is an aspect that Pierce and Stacey have noted in their recent research into the way that Australian secondary mathematics teachers are developing the use of the TI-Nspire handhelds to privilege linked mathematical representations when teaching about quadratic functions (Pierce & Stacey, 2009). They have highlighted the conflict between the labelling of variables within the "ideal' or pencil and paper mathematics alongside the conventions built into the MRT, as an important element for teachers to consider in the design of tasks.

A final consideration was the development of the teachers' knowledge concerning the grouping or sequencing of examples, that is, determining the scale and structure of the example space. This aspect of their learning not only related strongly to their personal mathematical knowledge and interpretation of the mathematical progression of ideas within the topic matter, but was also intrinsically linked to the pedagogic skill of considering the most suitable activity structure for their students.

In general, having selected an initial example for each activity, Eleanor and Tim expanded the example spaces to add insight to, or support the analysis of the variant and invariant properties under exploration in one, or a combination of the following approaches:

• Further examples were explored within the same mathematical representation by making new inputs in the same numeric, syntactic or geometric form.

• Further examples were explored within the same mathematical representation by dragging objects dynamically.

• Further examples were explored within a different mathematical representation by making new numeric, syntactic or geometric inputs. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

51

• The same example was explored within a new mathematical representation.

Conclusion

The scrutiny of over eighty classroom activities within this study has provided a substantial data set on which to draw a number of conclusions relating to their experiences of designing tasks within the chosen MRT environment.

Mason et al's premise regarding the role of expressing generality within mathematical activity could be considered to have been an initial constraint for the teachers involved in this study when designing their activities to explore variance and invariance (Mason et al., 2005, p.297). However, an element of the teachers' epistemological development was related to their realisation that expressing generality was a very important aspect of the activities that they went on to design. The teachers' increasing attentions to the way that the MRT environment supported or hindered this, and the design of the associated supporting resources and their role in mediating the associated classroom discourse, was another element of their professional development.

Evidence from the study suggests that the process of designing tasks that utilise the MRT to privilege explorations of variance and invariance is a highly complex process which requires teachers to carefully consider how variance and invariance might manifest itself within any given mathematical topic. The relevance and importance of the initial example space, and how this might be productively expanded to support learners towards the desired generalisation is a crucial aspect of activity design.

The starting point for any classroom activity is its initial design and the following set of questions, generated as a result of this study offer a researchinformed approach:

• What is the generalisable property within the mathematics topic under investigation?

• How might this property manifest itself within the multi-representational technological environment – and which of these manifestations is at an accessible level for the students concerned?

• What forms of interaction with the MRT will reveal the desired manifestation?

• What labelling and referencing notations will support the articulation and communication of the generalisation that is being sought?

• What might the 'flow' of mathematical representations (with and without technology) look like as a means to illuminate and make sense of the generalisation?

• What forms of interaction between the students and teacher will support the generalisation to be more widely communicated?

• How might the original example space be expanded to incorporate broader related generalisations?

Responses to these questions uncover a generic 'top level' of thinking which makes little sense in the absence of a clear mathematical context. The next level of thinking is closely related to the mathematical concept under scrutiny for which a number of existing structures and approaches can support teachers to develop further this aspect of their practice. The theory of Realistic Mathematics Education provides principles that can be applied to task design. In this paper, we investigate how these principles apply to the design of online tasks. To do so, we present examples of tasks on algebra, calculus and geometry designed in the Digital Mathematics Environment. As a result, we conclude that the principles of guided reinvention, didactical phenomenology, and emergent modeling can inform and guide digital design, but that some aspects work out differently compared to the design of paper-and-pencil tasks.

Keywords: Didactical Phenomenology, Digital Design, Digital Mathematics Environment, Emergent Modeling, Guided Reinvention, Realistic Mathematics Education

Introduction

Task design is widely recognized as an important, but complex and subtle activity. Based on the experience of skilled designers, design guidelines and heuristics

have been identified (e.g., see Watson & Mason, 2006). Whereas the design and use
of digital content nowadays plays an increasingly important role in mathematics
education, most of these design principles are based on and applied to the design of
paper-and-pencil tasks. The question, therefore, is how such design principles apply
to digital design, and how the rich experience and knowledge in the field of designing
paper-and-pencil tasks can be transferred to the case of digital design.
To address this question, we limit ourselves to three principles that emerge
from the theory of Realistic Mathematics Education and may inform design: guided Theme A – P. Drijvers et al.
54
reinvention, didactical phenomenology, and emergent modeling. We revisit some
tasks designed in the Freudenthal Institute's Digital Mathematics Environment in the
field of algebra, calculus and geometry education.
RME Design Principles
Realistic Mathematics Education (RME) is a domain-specific instruction
theory for the teaching and learning of mathematics. According to RME, mathematics
should be seen as an activity (Freudenthal, 1973), and students, rather than being
receivers of ready-made mathematics, should be active participants in the educational
process, in which they develop mathematical tools and insights by themselves. This
point of departure led to the following RME principles that inform task design: guided
reinvention, didactical phenomenology, and emergent modeling (Freudenthal, 1973;
Gravemeijer, 1994; Van den Heuvel-Panhuizen, 1996).
According to the principle of guided reinvention, students should be given
the opportunity to experience a process similar to that by which a given mathematical
topic was invented. Even if this primarily is a teaching principle, it has consequences
for task design: tasks – or sets of tasks – should invite students to develop 'their own'
mathematics. This process, however, needs guidance from the teacher, to help to
further develop sensible directions, to leave 'dead-end streets' and to ascertain
convergence towards shared knowledge according to the standards within the
mathematical community.
Didactical phenomenology concerns the relation between the thought object
–the 'noumenon'– and the phenomenon –the 'phainomenon'– from the perspective
of teaching and learning. In particular, it addresses the question how mathematical
'thought objects' can help in organizing and structuring phenomena in reality. The
challenge for the task designer, then, is to find such meaningful phenomena that beg
to be organized and structured by the targeted mathematical knowledge.
According to the emergent modeling perspective, a model may play different
roles during different phases of activity. Initially, a model is context-specific: it refers
to a meaningful problem situation that is experientially real for the student, and is a
model of that situation. Then, through working with the model, it gradually acquires a
more generic character and develops into a model for mathematical reasoning that is
possible because of the development of new mathematical objects in a more abstract
framework of mathematical relations that the model starts to refer to. This notion is
elaborated into a four-level structure that represents levels of mathematical activity
(Gravemeijer, 1994). For the task designer, the challenge is to find suitable situations
that ask for the development of such models, and allow for a process of progressive
abstraction.
While applying these RME principles to the design of paper-and-pencil tasks
is not straightforward, their use for the design of digital content is even more
challenging. Although early research on the use of graphing calculators identified
opportunities for an RME-based teaching approach (Drijvers & Doorman, 1996), later
studies describe the tension between RME principles and the integration of computer
algebra software (Drijvers, 2000). Apparently, the match between RME and ICT is
not self-evident.
The Digital Mathematics Environment
As technology for teaching mathematics the Freudenthal Institute's Digital
Mathematics Environment (DME) is used. The DME integrates a content Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
55
management system, a learning management system and an authoring environment.
The content consists of online modules in the form of Java applets. The learning
management system offers means to distribute content among students and to monitor
student progress.
The authoring tool is the DME's design environment. Authors, such as
teachers, text book authors, or educators, can use the tool for adapting existing online
modules or for designing new ones, based on existing materials and basic tools such
as graphing and equation editing facilities. While designing, the author can split up
the screens in different windows, add applications and tasks, and design feedback.
Knowledge of the underlying Java programming language is not required; rather, an
intuitive and mathematical interface makes the digital design accessible to a wide
audience (Figure 1).
Figure 1 The Digital Mathematics Environment Authoring Tool
Examples of the results of digital design using the DME's authoring tool can
be found at www.fi.uu.nl/dwo/demo/en. In this paper, we will briefly discuss some
examples from algebra, calculus and geometry from the perspective of the above
RME principles.
Digital Tasks for Algebra
As an example of the design of digital tasks for algebra, we consider the
work by Bokhove, available at www.fi.uu.nl/dwo/voho/. The digital tasks focus on
solving polynomial equations. However, the online units go beyond procedural
practice and also focus on the development of symbol sense and strategic skills
(Bokhove & Drijvers, 2010, 2012). Crucial factors in the design are the sequencing of the tasks (with sometimes thought
and its timing and fading in particular

Investigation of a family of
functions, representing braking
distances for three different
vehicles
Figure 3 Different views on function in the Function and Arrow Chain module
Figure 3 shows some screens from this module, in which the function
gradually develops from a numerical input-output engine, to a process of co-variation
and, finally, a mathematical object that is part of a family of functions that can be
compared. This sequence of screen shots reflects the emergent modeling heuristic: the
context, in this case one of a vehicle's braking distance as a function of its velocity,
leads to function models of increasing complexity and abstraction. The digital tool
supports this development by means of offering techniques of increasing richness and
an increasing repertoire of connected function representations. Of course, this
approach requires a context that is suitable for this emergent modeling process.
Finding such a context is a question of didactical phenomenology.
In an online calculus course for university freshmen, the co-variation idea is
supported by a Geogebra applet for tracing graphs (www.fi.uu.nl/dwo/sk/en/).
However, in the context of this intensive and short-period remedial course, the
emergent modeling design heuristics was exploited to a lesser extent than was the
case for the Function and Arrow Chain course.
Digital Tasks for Geometry
An example of the design of digital tasks for geometry is the module
available at www.fi.uu.nl/dwo/dpict/en/. The digital tasks focus on exploring,
discovering, and proving properties of bisectors, altitudes and medians in triangles.
The latter aspect, the proving, provides a particular design challenge: how to design
tasks that offer support and guidance for a proof, but leave room for reinvention? Theme A – P. Drijvers et al.
58
Figure 4 Proving that three medians of a triangle intersect in one point
While reading the proving task shown in Figure 4, it should be noted that
Dutch grade 8 students, the target group for this module, have little experience in

proving, and, therefore, need strong guidance: the structure of the proof and the corresponding sequence of images is suggested to the students. Still, writing down the final argument in the reasoning, as is requested in task c, is very difficult to them. The design principle of guided reinvention is easier to apply to tasks in which students explore the properties of bisectors, altitudes and medians in triangles: the dragging options of the dynamic geometry system, in this case Geogebra, in collaboration with DME's feedback, provide a strong learning environment in which students can really experience the geometrical situation and discover the targeted properties.
In the case of this online module, classroom observations show that attention needs to be paid to students' and teachers' instrumental genesis: the interplay between Geogebra and the DME in this module is powerful but it may also be demanding and initially complex to novice users.
Conclusion
In this short paper, we set out to investigate the application of the RME principles of guided reinvention, didactical phenomenology, and emergent modeling for the case of the design of digital tasks in the online DME. To do so, we considered three exemplary tasks. The first example, the task on solving a relatively complex equation, shows that guided reinvention in this case concerns the development of new problem solving strategies, invited by tasks that cannot be solved with the strategies available so far. The didactical phenomenology heuristic here does not lead to the use of real life contexts, but rather takes the world of polynomial equations as a point of departure. In the second example, a real life context –in this case the stopping distance situation– does form the starting point. Emergent modeling heuristics are manifest in the gradual abstraction of the students' view on function. The third example on geometrical proof again takes a guided reinvention perspective, in which the designers chose strong guidance. Again, the didactical phenomenology here does not lead to a real life problem situation, but to a problem in the world of geometry, that is expected to be experientially real to the students. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
59
What can we conclude about the three RME principles and their application to digital design? The principle of guided reinvention seems to apply well to digital design. ICT offers opportunities for exploration and investigation, and in this way for reinvention. The design choice to confront students with unexpected examples can be seen as a way to invite reinvention as well. In general, this guided reinvention approach might suffer from constraints of the technology that may limit the students' exploration space, such as requirements for input formats and styles, and pre-designed tools that may incorporate too much guidance.
The didactical phenomenology heuristics is also valuable for digital design, but it seems that the phenomena that play a central role in the task do not necessarily come from real life: ICT already forms a meaningful 'world' on its own for the student, in addition to the world of mathematics. Having a real life context as an entrance to these two worlds may lead to cognitive overload. This is a question to be considered carefully in the design process.
Emergent modeling can be a fruitful design heuristics for digital design. As in the case of paper-and-pencil design, the models need to lend themselves for further development towards increasing mathematical abstraction and complexity. Specific for the case of digital design is that these emerging models need to be supported by the digital tools available, for example by an increasing repertoire of representations and techniques in the digital environment, or by increasing options to dynamically use these representations, connect them, and switch between them (Duval, 2006).
As an overall conclusion, this brief exploration of the issue suggests that the three RME principles are valuable for digital design, even if some appropriation is needed compared to the design of paper-and-pencil tasks, such as taking into account the constraints of the digital tools and the fact that the technological environment forms an additional 'world' to the student. The transfer of skills, developed in the ICT environment, to paper-and-pencil, for example, may need specific attention, as well as the instrumental genesis involved in the learning process.

Designing tasks for a more inclusive school mathematics

Lulu Healy

Solange Hassan Ahmad Ali Fernandes
Bandeirante University of São Paulo, Brazil.
Janete Bolite Frant
Bandeirante University of São Paulo, Brazil.

In this contribution to Theme A (tools and representations), we detail our approach to designing tasks to be incorporated into inclusive mathematics learning scenarios. These scenarios also involve tools created to represent mathematical knowledge in forms appropriable by students with sensory disabilities and which are developed to privilege multimodal experiences of mathematical objects, relationships and properties. We begin by introducing the theoretical influences which underpin the processes of task design and our attempts to take into consideration the complex relationships between artefacts, their mathematical affordances and the embodied practices they engender in the context of task resolution. We go on to outline the collaborative approach we adopt to simultaneously develop both tasks and tools, and how teachers, students and researchers bring different, complementary, expertise to this process. To further illustrate our approach, we consider two examples from our work with blind learners and deaf learners.
Keywords: Collaborative design, Inclusion, Blind learners, Deaf learners, Tool mediation, Embodied cognition.

Introduction

In recent years, Brazil has experienced large changes in the educational paradigm. One of these relates to the growing influence of political and social movements that defend inclusive education, and the organization of schools to attend the diverse needs of all students, without any kind of discrimination or segregation. Inclusive schools are those which see difference as a factor which enriches the educational process. They aim to support all learners in overcoming barriers to learning as they become participants in a more equitable system. The political policies related to the process of including students with special educational needs have resulted in a significant increase in their presence within mainstream schools, with statistical data from the most recent school census showing an increase of 234% between 2003 and 2010. At the same time, these policies of inclusion have been associated with taking the educational community out of the "comfort" zone and, amongst the many uncertainties, insecurities and conflict the actors in these communities are facing, questions related to curriculum demands and pedagogical Theme A – L. Healy, S.H.A.A. Fernandes, J. B. Frant.
62
actions have a central role. In particular, the increasing diversity of students within the same classroom setting raises questions related to task design: what principles and procedures might be adopted in the design of tasks for the inclusive mathematics classroom?
It is within this context that we began work on a research project aiming to (1) investigate forms of accessing and expressing mathematics which respect the diverse needs of all our students, (2) contribute to the development of teaching strategies which recognize this diversity, and (3) explore the relationships between sensory experience and mathematical knowledge
8
. The project involves the development and analysis of inclusive scenarios for mathematics learning, though a collaborative process involving researchers, teachers and students. In this article, we intend to exemplify our approach to task design and present some examples from our work in São Paulo schools.
In this approach, the process of task design is accompanied simultaneously by the development of the material and digital tools that are also incorporated in the learning scenarios. Together, tasks and tools aim to enable the interaction of different students with mathematical objects and relationships. To this end, they are designed to facilitate multiple ways of interacting with these objects and relations and to respect the diverse experiences of the students with whom we work. The approaches we use involve representing mathematical ideas through colour, sound, music, movement and texture, and hence appeal to different sensory canals, and particularly to the skin, the ears and the eyes. The multimodal nature of the mathematical representations reflects our attempts to offer stimuli appropriate to the particularities of each and every student: for those with visual impairments, the tools enable tactile and auditory stimuli, for deaf learners, tactile and visual approaches are privileged and students who can both hear and see have access to all three modes, allowing even those with specific difficulties in learning mathematics to have a variety of ways to think mathematically. Before describing in more detail the process behind the design of task and tools, we begin by delineating our understanding of the term "task" and how this term figures in our view of learning mathematics.

Learning scenarios: Tasks and activity

Our view is that tasks represent one of the elements that compose the learning scenarios we enact within. In a similar way to Laborde (2002), we see learning scenarios as consisting of specific tasks, or sequences of interrelated tasks, the mediating tools available for their resolution, along with the activities of the participating actors (which may include different combinations of students, teachers and researchers). More precisely, we distinguish between task and activity in the same ways as Dejours (1997, p.39). He argues that "a task is that which is to be achieved or that which must be done. Activity is, in the context of the task, that which is actually done by the operator to arrive as close as possible to objectives fixed by the task". That is, tasks are proposed to the collective, and might be realized by differing individuals in different ways. Dejours (1997) was concerned with the work context and how different people might employ different techniques to attain a particular objective, depending on the tools available, of course, but also on the individuals themselves. The same is also the case in educational settings. The task proposed to a

63
group of mathematics students might be the same, but the interpretation of the task and the activity that results will be shaped by both intrapersonal and interpersonal aspects of the particular students involved. The actions of each of the individuals who engage in a particular given task, individually or collectively, are a function, not only of the task itself, or the means available to interact with it, but also of the meanings that are associated with the activity itself (Leontiev, 1978).
Here, another question is raised, what is the relationship between completing a task and learning mathematics? In our view, tasks are proposed to motivate learners to engage with practices associated with the set of artefacts that have, historically and culturally, come to represent the body of knowledge we call mathematics. In the socio-cultural perspective which informs this view, learning can be defined as participating in, and appropriating, these practices. Using the concept of activity defended by Leontiev (1978), appropriation is a social process in which participants aim to make their own objects already steeped in cultural meaning. The process of appropriation occurs, necessarily in the case of mathematics, on the basis of actions mediated by semiotic systems. Mathematical activity, then, occurs as a dialectical process, in which individuals interact with the environment and with other individuals to attribute sense to aspects of the knowledge and experiences developed in the course of human history. As a result of this activity, objects of the environment, recognised by the senses, acquire the character of objects of reflection (Fernandes, 2008, p.47).
This brings us to another aspect central to the theoretical framework that guides our approach to task design: the role of the senses in mathematical cognition. We see links between the socio-cultural perspective developed by Soviet psychologists in the last century with the views of researchers in the area of embodied cognition today, who argue that our mathematical understandings, like all others, are structured by our encounters and interactions with the worlds we experience via our bodies and our brains (Gallese and Lakoff, 2005). Indeed, Radford (2006) argues that the body itself

can serve as a semiotic system, through acts of perception, gestures and other
movements. Other semiotic systems for Radford include artefacts, language and signs.
Jointly, then these represent the tools through which task demands are to be mediated.
With this view of mathematics learning in mind, we return to the question of
designing tasks, tools and teaching interventions for inclusive learning scenarios.
More specifically, in this article, we concentrate on learning scenarios in which
students who lack access to one or other sensory field act; that is, we focus on learners
who are deaf and learners who are blind. To enable the participation of students with
sensory limitations, it is important to understand how the different channels through
which they experience the world mediate the processes by which they appropriate
mathematical knowledge, and to recognise that the mathematical practices that are
depend on these experiences. Once again, we draw here from the work of the
Vygotsky and his colleagues in the former Soviet Union and particular to work in the
area of what at the time was called Defectology. Vygotsky (1997) proposed an
approach to understanding the learning of students with sensory, motor or cognitive
disabilities which involves considering how and when the substitution of one (nonfunctioning) tool by another may engender different forms of activity (Healy &
Fernandes, 2011; Healy & Powell, in press). His approach stressed the potential for
development of learners with disabilities, rather than positioning them as deficit in
relation to some supposed "norm".
"The positive particularity of a child with a disability is created not by the failure
of one or other function observed in a normal child but by the new structures
which result from this absence […]. The blind or deaf child can achieve the same Theme A - L. Healy, S.H.A.A. Fernandes, J. B. Frant.
64
level of development as the normal child, but through a different mode, a distinct
path, by other means. And for the pedagogue, it is particularly important to know
the uniqueness of the path along with the child should be led" (Vygotsky, 1997;
p.17 - emphasis in the original)
In relation to empowering those without access to one or other sensory field
to participate in social (cultural) activities, for Vygotsky, the solution lies in seeking
ways to substitute the traditional means of interacting with information and
knowledge with another. For example, he suggested that the eye and speech are
"instruments" to see and to think respectively, and that other instruments might be
sought to substitute the function of sensory organs (Vygotsky, 1997). As mathematics
educators, we interpret this message from Vygosky as implying we need to pay
attention to - and where necessary create - a multitude of (substitute) semiotic
systems to mediate mathematics learning.
Our approach to design
The research strategy we adopt is based on the establishing of partnerships
between school- and university-based participants - researchers, school teachers and
school students - who collaborate on the design of tasks and tools for use in the
mathematics classrooms of the teachers and students. In these partnerships,
participants work together to conduct a process of co-generative inquiry (Greenwood
& Levin, 2000), a kind of participatory action research in which all participants cogenerate knowledge through a process of collaborative communication.
The process of designing learning activities is not a simple one and passes
through a number of stages. Not all the participants are necessarily involved in all the
stages, although usually at least one member from the school and one from the
university is present in each. The first stage involves designers in identifying
particular challenges associated with the learning of the mathematical topic in
question and in developing and testing hypotheses about how best to engender the
intended learning. The topics selected are those that are emphasised in the
mathematics curriculum that the schools are following and the starting point for the
design process is twofold, aiming to combine both pragmatic and theoretical
concerns. On the one hand, the teachers and sometimes also the students themselves,
brings examples of particular difficulties and problems they have experienced. At the
same time, we also consult the existing literature to attempt to determine what
previous research tells us about students' conceptions in the chosen topic. On the
whole, we have found relatively little research addressing the mathematical learning
processes of either blind students or deaf students with respect to the majority of topic
areas we have addressed. This means that the first versions of the task are often
developed on the basis of what we know about sighted and hearing learners and hence
may not be fine-turned to the particular strengths of those who do not see with their
eyes or who do not speak with their mouths.
This is one of the reasons that we believe it is crucial to involve the students,
as well as teachers and researchers in the design process. Student participation occurs
early in the design process, as students are invited, either individually or in small
groups, to work on the first prototypes of the tasks and tools under development. For
these first tests, we have tended to work exclusively either with blind students or with
deaf students. The meetings are videotaped and represent a means for reviewing our
developing theoretical models and revising our hypotheses so that they can be
operationalised given the particularities of the schools and students involved. Our
tendency has been to develop tools and task sequences simultaneously and to modify Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
65
both as the sequence is applied in practice during these tests. It is only after the
scenarios have been tested and analysed, that we consider re-enacting the scenarios in
teacher's mathematics classrooms.
Examples of the design process in practice
To illustrate this process in a little more detail, we have selected two
examples from the collection of learning scenarios we have investigated: one in which
tasks were to be mediated using material objects and a second involving the use of a
tactile, digitally-controlled tool designed to permit the exploration of graphs of
polynomial functions.
The first example involves the topic Matrices, a topic that is introduced to
students in the second year of High School (that is the 11
th
year of compulsory
schooling) in the curriculum currently followed in the state of São Paulo. One
motivation for focussing on this topic comes from the comments of deaf students in
one of our partnership schools and blind students in another. The deaf students, for
example, described Matrices as "something that has brackets and numbers", but were
not confident in manipulating paper-based representations these objects. Their
teacher, fluent in Libras (the Brazilian sign language), suggested that the lack of
specific signs for the vocabulary associated with matrices served as a complicating
factor in teaching the topic. The blind students, too, spoke of their difficulties in
solving tasks with matrices, which they described as "drawings with numbers inside".
We found no research studies which addressed interactions of either blind or deaf
students with matrix representations. We decided to attempt to construct a form of
representing matrices which would permit both deaf students and blind students to
construct them and operate upon them (more details of the design process are
available in Silva, G. G., 2012). The tool MATRIZMAT is a very simple one, made
up of plastic boxes (5cm by 5cm by 3cm) which could be joined to each other by
magnets fixed to each of the boxes' four sides (Figures 1 and 2). In the version for
deaf students, the numbers written on foam-rubber rectangles could be placed in the
cells of the matrices (Figure 1), whereas, for the blind students, we made use of the
lids of the boxes, with numbers in Braille stuck onto the top (Figure 2).
Figure 1: MATRIZMAT with written
numerals
Figure 2: MATRIZMAT with numbers
in Braille
The tasks for both student groups had the aim of introducing the language
associated with matrices, their organisation in rows and columns, determination of the
order of a given matrix, identification of equal matrices and matrix addition. It is not
our intention in this article to present in detail the interactions of the students with
these tasks, but perhaps it is worth stressing that the material tools enabled to both
student groups to develop efficient ways of expressing matrix structure. Figure 3, for
example, shows Maria using the signs developed by the students themselves to
indicate position a12 of a 3 by 3 matrix. It seemed that the layout of the matrix in a
physical, palpable form helped the group to develop ways of talking about its Theme A - L. Healy, S.H.A.A. Fernandes, J. B. Frant.
66
structure - something that they had had difficulty to do when operating with the paper
and pencil representation.
Figure 3: Maria signing position a12 of a 3 by 3 matrix
In the case of the blind students, the importance of the tactile tool was most
evident when they were comparing or adding two matrices (see, for example, Figure
4). Being able to explore spatially the positions of the elements of the matrix enabled
them to experience matrices in ways that correspond to those of their sighted
contemporaries. This was rather different to their previous experiences, which had
involved Braille representations in which matrices were presented in a form that did
not emphasise the spatial layout of the elements and in which they had found it very
difficult to locate the elements in different matrices which should be added to each
other.
Figure 4: Adding matrices of order 3x2
The second example evolved as we attempted to develop tasks related to
polynomial functions that would be accessible to blind students. We knew from the
students themselves that tasks involving graphical representations of functions were
something that their teachers tended to avoid assigning (Silva, B. J., 2012). From the
research literature about (sighted) students' conceptions of functions, we conjectured
that a tool in which blind students could experience not only static representations of
the locations of particular points on the Cartesian plane or static representations of the
graphs of specific functions, but could also feel the graphs of different functions
appear as the independent variable changed, might afford more dynamic views of
function and help them understand the dependence relationship that exists between
the independent and dependent variables. The tool that we designed to permit blind
student to engage in such tasks was composed of a digitally controlled board made up
of a rectangular matrix of pins, each of which represented a point on the plane. When
particular point is requested or a graph of a given function plotted, the relevant pins
are raised up (sequentially as the value of the independent variable increases in the
case of the graph of a function), allowing the student to feel the image as it is Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
67
produced. Figure 5 presents the final version of the tool, while Figure 6 shows a blind
user, Alice, as she feels the graph of a function as it reveals itself to her.
Figure 5:The current version of the tactile graphing tool and its digital interface
Figure 6: Alice feeling a graph as it is plotted
To date, we have only tested this tool with students who do not see with their
eyes. Of course, it could also be used by the sighted, but perhaps represents a rather
expensive option to the on screen dynamic graphing tools which already exist. There
is a question though: are the experiences of seeing a graph as it emerges in front of
one's eyes and feeling it emerge with one's hands cognitively identical? Our
conjecture is that they may not be - the act of moving one's hands to find points in
ways not guided by one's eyes seems rather different to having a kind of global access
to the whole plane upon which the graph appears. The difference in the strategies
afforded by these different ways of perceiving and the properties of the graphs
emphasized in these two conditions is something we believe merits further research.
Reflections on the relationships between task and tool design
The theoretical influences that inform our approach to design indicate that
the processes of creating tasks and the tools by which they are to be mediated are best
tackled simultaneously. They also lead us to recognize, as Cole e Wertsch (1996,
p.255) have pointed out, that the insertion of tools into situations with instructional
intent does not simply serve to facilitate the mental processes that occur within them,
it fundamentally forms and transforms these mental processes, conditioning the
practices of the learners who operate the tools to the particular practices associated
with their use. Moreover, it is not only the learners whose practices are transformed:
the introduction of any artefact into a given situation might offer new - and even
more efficient means - to resolve a problem, but it also changes the very nature of the
task (Béguin & Rabardel, 2000, p.2). In this paper, we have concentrated on the Theme A - L. Healy, S.H.A.A. Fernandes, J. B. Frant.
68
process of design and not on the resulting interactions of those who participate in the
learning situations into which the resulting tasks and tools are incorporated, but we
believe that the particularities of the students with whom we work help to illustrate
the extent to which it is not only the material and semiotic tools we provide that
impact upon the practices which emerge in the scenarios. Equally important are the
bodily resources through which tool and task are experienced, with different sensorymotor systems potentially affording different modes of acting mathematically and,
hence, different paths by which mathematical meanings might be appropriated.

Using computers in classroom mathematical tasks: revisiting
theory to develop recommendations for the design of tasks
Marie Joubert
University of Nottingham.
The context for this paper is the ordinary mathematics classroom
lesson, in which the tasks set for students involve the use of computer
software. The paper highlights the importance of paying attention to the
intended mathematical learning of students as they work through the task,
adapting their strategies as they negotiate epistemological obstacles. It
draws on theoretical notions of student activity, or 'dialectics', within the
classroom environment to suggest the sorts of activity that are likely to
provoke mathematical learning, particularly highlighting the role of
computers within these activities. This provides the background against
which approaches to the design of mathematical tasks are recommended.
The approaches focus on the intended mathematical learning of the
students and the obstacles built intentionally and unintentionally into the
tasks.
Keywords: dialectics, computer, validation, feedback, obstacles,
schools
Introduction
This theoretical paper concerns classroom mathematical tasks and activity,
where, in common with the conventions adopted in much of the literature, (e.g.
Ainley & Pratt, 2002; Love & Mason, 1992; Sierpinska, 2004), I use the word 'task'
to mean the work the teacher asks the students to do. The teacher has in mind what it
is she wants the students to learn ('didactical intention'), but, as Brousseau (1997)
explains in detail, she cannot just tell the students and hope that they will learn.
Instead the teacher takes the decontextualised and depersonalised knowledge she
wishes them to learn and recontextualises and repersonalises it by embedding it in a
task. Tasks can therefore be seen as 'the fabric of student learning' (Sierpinska, 2004,
p 25) ; through tasks, teachers provide students with opportunities to engage in
thinking and sense-making in the classroom, which in turn leads to learning (Stein,
Grover, & Henningsen, 1996). Tasks influence learners by directing attention to
particular aspects of content and by specifying ways of processing information
(Doyle, 1983).
The literature distinguishes three main task types; exercises (or routine
problems), problems and investigations (Christiansen & Walther, 1986; Henningsen
& Stein, 1997; Orton & Frobisher, 1996). To some extent, these can be distinguished
by their goals, which are discussed below. However, there is also an argument that
they can be distinguished by the prior learning of the students. As Orton and
Frobisher (ibid) explain 'not all children in a class may view what is taught as a Theme A - M. Joubert
70
problem… what is a mathematics problem for one learner may be an exercise for
another' (p 25) and this, they suggest, depends on the prior learning and experience of
the individual students. Christiansen and Walther (ibid) make a similar argument,
suggesting that what is for one student a task that provides potential for learning can
be a routine task for another, depending on their current developmental levels.
For most tasks, the goal for the student is an answer or some answers (Orton
& Frobisher, 1996). These goals can be seen as the end point of the task from the
students' point of view; this is what the student must do to complete the task. Further,
as Sierpinska (2004) and Mason (2000) point out, the assumption is that the students'
agenda is to complete the task; and as a result the design of the task should include the
mathematical thinking and reasoning that are 'strictly necessary and sufficient to
complete the task' (Sierpinska op cit p12, italics in the original); as she suggests,
completing the task may result in problem solving but does not necessarily do so.
Hence, while the goals described above are (usually) explicit products, it is the
mathematics which the task address which should perhaps be seen as more important.
In my empirical research (Joubert, 2007), I observed authentic mathematics
lessons, where teachers chose the tasks they wanted to students to complete, and I
analysed student activity in order to provide evidence of their mathematical learning
(in vain). The lessons I observed could be described as 'disasters of well taught
mathematics courses' (Schoenfeld, 1988); mathematics lessons in which students
were engaged in activity which looked like mathematics but their activity led to
limited learning of mathematics. In all these lessons, computers were used by the
students and my research confirms how difficult and complex it is to integrate
computers into the teaching and learning of mathematics (see for example, the 17
th
ICMI study book, (Hoyles & Lagrange, 2009)).
An analysis of the tasks the students were set emphasised the importance of
understanding a) the mathematics the teacher intends them to learn and the ways in
which the design of the tasks provokes activity through which students learn b) the
relationship between student activity and their mathematical learning, and c) the role
of the computer, which can perform some or all of the mathematics involved in the
task. In this paper, I draw on my research, revisiting some theoretical perspectives
underpinning task design, particularly the work of Brousseau (1997), to propose an
approach to task design taking into account a), b) and c) above, which might begin to
address the challenge of embedding the computer in classroom mathematics.
Intended learning and the design of tasks
The need for a clear idea of the mathematical learning intended to take place
as a result of student engagement with mathematical activity is frequently highlighted
in the literature about tasks; Henningsen and Stein (1997), for example, suggest that
teachers should be attentive to emphasising meaning and explicitly drawing out the
mathematics underlying the activities. Similarly, Christiansen and Walther (1986)
emphasise the need for teachers to be aware of the intended learning as both process
and product and as addressing different 'dimensions of learning'; on one hand the
'object for the activity… the mathematical core of the given task' and on the other
hand 'establishing the schemata for learning' (p 262).
It may seem obvious that teachers should be clear about what it is they want
their students to learn, but, as Brousseau argues, the detail of the intended learning is
frequently not sufficiently well understood by teachers, can be obscured (as, for
example, in the early introduction of decimal numbers through a measuring system Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
71
Brousseau (1997)) or is unclear (Love & Mason, 1992). This point is also made in the
discussion document accompanying the call for papers for the study group:
There is a tacit assumption that the completion of mathematical tasks chosen or
designed by the teacher will result in the student learning the intended
mathematics.
Even when the intended learning is thoroughly analysed, however, students
will not necessarily learn what the teacher intended (Love & Mason, 1992,
Sutherland, 2007). This may particularly be the case when tools, including computer
software, are used and the meanings students make from the feedback on the
computer screen are sometimes at odds with the intended learning (e.g. see Sutherland
(2007) and Hoyles and Noss (2003)). Further, their learning may be influenced by the
design of the software which frequently has some mathematical and design
assumptions built into it (Sutherland, 2007). The implication is that the design of the
task should attend to the mathematics embodied in the tools, and to working out how
this might mediate the learning. Further, the fact that software can perform some of
the mathematical processes can be confusing; if the computer does the mathematics,
what learning is there for the students to do? For example, whereas plotting a
quadratic graph is a valid activity in a mathematics classroom as an end in itself,
generating the same curve using software is perhaps less valid as an end in itself.
To sum up: although the importance of the intended learning of a task seems
to be obvious, to understand what it is that the task is meant to 'teach' requires careful
analysis of the mathematics that might be provoked by the task, of the tools used to
mediate the activity of the students and - crucially - the prior learning of the students
(as argued in the introductory section above).
Obstacles
As discussed above, students will do only what is necessary to complete the
task. It follows that the design of the task needs to 'force' the students to identify,
adopt and adapt strategies to complete the task in order to reach target knowledge
(Brousseau, 1997). Adaptation may take place, Brousseau suggests, if the students
encounter and overcome 'obstacles' as they work through the task. He describes an
obstacle as:
'a previous piece of knowledge which was once interesting and successful but
which is now revealed as false or simply unadapted'. (p 82)
Obstacles can take a variety of forms; Brousseau, for example, identifies
obstacles of ontogenic, didactical and epistemological origin. The first of these relates
to the 'student's limitations' (p 86), including 'developmental' limitations (Swan,
2006) such as the lack of prior learning which is an obstacle because the student is in
some way not ready for the mathematics required to complete the task (Love &
Mason, 1992). For example, suppose a task requires students to generate graphs using
computer software and to 'notice' some feature or other. For students unfamiliar with
'noticing' tasks , this presents an ontogenic obstacle.
Obstacles of didactic origin 'are seen as obstacles for the students because of
ill thought out presentation of subject matter, or 'the result of narrow or faulty
instruction' (Harel & Sowder, 2005, p 34). Harel and Sowder give the example of the
didactical practice of teaching students to look for 'key words' in mathematics
problems (such as 'altogether' signals that addition is required). Theme A - M. Joubert
72
Both ontogenetic and didactic obstacles should be avoided (Brousseau, 1997,
Harel & Sowder, 2005). The third type of obstacle, however, the epistemological
obstacle, should not be avoided and is key to the design of 'good' tasks.
Epistemological obstacles are perhaps most clearly explained by Balacheff
(1990, p 264) who discusses how mathematical concepts are learnt through their use
as tools in the process of problem solving with some content; this content is supported
by the students' prior knowledge. However, although the old knowledge is a
necessary basis for the content, it may cause problems for the students as they work
through the problem; in other words it becomes an obstacle which causes the students
to stumble. If, in order to overcome the obstacle, the students are required to construct
the meaning of the new piece of knowledge, then this obstacle is an epistemological
obstacle. Harel and Sowder (2005) suggest that 'MMB' (multiplication makes bigger)
can often be seen as an epistemological obstacle and Sierpinska (1987) identifies a
complete mapping of epistemological obstacles with respect to limit; scientific
knowledge, infinity, function, real number.
As discussed at length in Joubert (2007), it is not always easy to distinguish
between didactical and epistemological obstacles and what may be epistemological in
one context may be didactical in another. A key consideration is the development and
prior learning of the students and the design of any task will need to take these into
account when designing the task.
Student activity and mathematical learning
In completing the task, the students interact with the milieu, described by
Balacheff and Sutherland (1994) as 'the specific part of the environment of the learner
which is accessible and relevant to his or her actions' (p 141). However, each student
experiences the milieu differently, depending on, for example, their prior learning.
The interactions of students can be conceptualised as a 'dialogue' between
the student and the feedback from the milieu. The feedback from the milieu can take
many forms; Brousseau includes verbal feedback from other students and the teacher,
an outcome of a game and drawings produced by a pantograph as examples. The
importance of feedback should not be underestimated;
'The pupils' behaviour and the type of control the pupils exert on the solution
they produce strongly depends on the feedback given during the situation. If there
is no feedback, then the pupils' cognitive activity is different from what it could
be in a situation in which the falsity of the solution could have serious
consequences' (Balacheff , 1990, p 260).
When computers are used, feedback from the milieu will also include
feedback from the computer. The general conception of computer feedback seems to
be that it is beneficial in teaching and learning mathematics; it can be seen to provide
opportunities 'to quickly test ideas, to observe invariants … and, generally, to be
bolder about making generalisations' (Hillel, 1992, p 205). However, students
sometimes interpret feedback from the computer in unexpected ways, which may
have a negative or distracting impact on developing the understandings the teacher
intended (Hoyles & Noss, 2003, Sutherland, 2007), and which may lead to the
development of strategies which are at odds with the intended learning, such as trial
and error, trial and improvement and 'intellectual passivity' (Hillel, 1992, p 217).
A range of different types of interactions between students and feedback
from the milieu may take place. For example, the TIMSS study (Hiebert et al., 2003)
classifies interactions in terms of public and private interactions, and then goes on to Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
73
categorise the mathematical processes for solving problems as 'Giving results only',
'Using procedures', 'Stating concepts' and 'Making connections'. Frobisher (1994)
provides a more detailed categorisation, including processes such as guessing,
pattern-seeking, predicting, hypothesising and proving. However, these do not take
into account the dialectical
9
nature of the student interactions with the milieu which,
as explained above, may be important in understanding and explaining the students'
progress through the task.
Modes of production
Brousseau (1997) uses the notion of 'modes of production' to describe the
different types of dialectic interactions between students and the milieu; he suggests
that as they work through a mathematical task, they will engage action dialectics, in
which the students know how to proceed; they implement a procedure or choose it in
preference to another or apply a knowing (the object of a student's construction
activity), all of these with or without communication. In the context of my research,
an example of an action dialectic was to generate a graph using software and to copy
the computer-generated graph onto a worksheet. In action dialectics within, the
student does not need to extend her mathematical knowledge or understanding to do
so; 'simple familiarity, even active familiarity … never suffices to provoke a
mathematization' (Brousseau, 1997 p 211). Some action dialectics are necessary

within any didactical situation; and Brousseau suggests that it is when the action
dialectics are motivated by the mathematics rather than the didactics, these actions
may lead to a sequence of mathematical dialectical interactions which could include
the development of hypotheses, alternative strategies, justifications and proofs.
Dialectics of formulation occur when students meet a difficulty or problem
as they engage in mathematical activity; Brousseau explains that when a solution to a
problem is inappropriate, the situation should feed back to the students in some way,
perhaps by providing a new situation. The means that the student may become
conscious of her strategies and begin to make suggestions. Brousseau includes in this
category 'classifying orders, questions etc....' (p 61). He goes on to say that in these
communications students do not "expect to be contradicted or called upon to verify …
information' (p 61). When the didactical intention is that the student should make
some observations, or to 'notice', it is likely that the students will begin to formulate
choices; noticing requires the student to make conscious choices about what to notice,
which aspects to attend to, which to suppress (Mason, 1989) and how to express and
articulate these. 'Noticing' can therefore be seen as a key formulation activity and in
some cases noticing may lead to making suggestions or to conjecturing. When
computers are used, an important implication of the computer's ability to 'do the
mathematics' is in the opportunities which can be developed for the students to work
inductively rather than deductively as is more usual in mathematics classrooms. For
example, when computers are used to draw graphs, students may be able to notice

9
This is the term Brousseau uses to emphasise the notion that the student interactions can be
seen as a 'dialogue' with the milieu. Sierpinska discusses the term in detail, referring to its roots in
philosophy, and concluding by remarking that, in Didactique, it means the method by which the
student manages contradictions between the expectations from the milieu and the feedback. Feedback,
she explains, is just communication of information; the dialectic turns the information into knowledge.
See Sierpinska, A. (2000) Theme A – M. Joubert
74
characteristics of families of graphs, develop conjectures based on their observations
and test their conjectures on the computer.
Both action and formulation involve manipulating 'moves in the game' or
mathematical objects; validation however involves manipulating 'statements about
the moves' (Sierpinska, 2000). Validation therefore takes place when an interaction
intentionally includes an element of proof, theorem or explanation and is treated thus
by the interaction partner (or interlocutor) 'this means that the interlocutor must be
able to provide feedback…' (Brousseau, 1997 p 16). Dialectics of validation include
justification (perhaps of a procedure, a word, a language or a model), organising
theoretical notions, 'axiomization' (ibid p 216), and a range of proofs. An example of
a validation dialectic might be an explanation to justify a prediction that a computergenerated graph will have particular intercepts by noticing a relationship between the
intercepts and the equations of graphs generated previously.
Brousseau, while suggesting that all three modes of production are 'expected
from students', (ibid p 62) argues that it is through situations of validation that
genuine mathematical activities take place in the classroom. Romberg and Kaput,
(Romberg, Kaput, Fennema, & Romberg, 1999) amongst others (for example,
Lakatos, Worrall, & Zahar, 1976) echo Brousseau's sentiments.
Brousseau suggests that situations of validation do not occur very often and
are unlikely to occur spontaneously and it is probable that validation will not take
place unless it is explicitly called for. This has important implications for task design.
Working across different 'fields'
It can be that the mathematical activity of the students relates only to the
physical or concrete characteristics of the mathematical objects they work with. On
the other hand, students may relate their activity to mathematical notions
underpinning the objects. For example, on the one hand students using dynamic
geometry software may construct a tangent to a circle by rotating a straight line so
that it touches the circle, and on the other hand they may use the geometrical property
that the tangent is perpendicular to the radius to construct the tangent (Laborde,
2005).
These different ways of working in different contexts are described in a
variety of ways; for Laborde (1998) the distinction is between 'spatio-graphical' and
'theoretical', for Fischbein (1993) and Mariotti (1995) it is between 'figural' and
'conceptual', for Tall (for example, 1996) it is between 'visuo-spatial' and
'verbal/logical'. While the authors' varying theoretical perspectives imply variations
on these ideas, the point for all of them is that it is useful to make the distinction and
this paper uses the terminology adopted by Noss, Healy, & Hoyles, (1997)
pragmatic/empirical' and 'mathematical/systematic' to make the distinction.
In addition to the perceived need to distinguish between the
'pragmatic/empirical' and 'mathematical/systematic' fields, there seems to be a
consensus that a movement between the two fields is required for mathematical
learning to take place (Balacheff, 1991; Brousseau, 1997, Dörfler, 2000; Laborde,
2005; Noss et al., 1997). Brousseau, for example, describes different types of proofs,
including contingent and experimental proofs and proofs by exhaustion. These, he
suggests, relate to implicit models students hold and therefore they are likely to take
place in the pragmatic/empirical field and not relate explicitly to theoretical
mathematical knowledge. However, for 'mathemization' to take place, according to
Brousseau, mathematical proofs which relate to the theoretical mathematics involved Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
75
in the situation, are required. Similarly, Mariotti (op cit) claims that the solution of
geometry problems requires continuous moves between the two fields and Laborde
(op cit) suggests that there is a need for interactions between images and concepts.
The implication, in terms of the relationship between the students' dialectics
(particularly of formulation and validation), and student learning is that, where these
dialectics remain in the pragmatic/empirical field, mathematical learning will be
limited.
When computers are used, very often the task students are given requires
them to construct an artefact on the screen, such as, for example, a graph or a
geometric transformation and they begin by working in the pragmatic/empirical field.
It seems that frequently the task does not require movement between this and
mathematical/systematic fields and mathematical learning is limited (Joubert, 2007).
In terms of implications for task design, the theoretical discussion related to
student dialectics above suggested that a task should provoke students to engage in
dialectics of action, formulation and, crucially, validation. Further, the students should
move between the pragmatic/empirical field and the mathematical/systematic field in
order to reach the goal of the task.
Concluding comments
This paper has made an argument that task designers should pay attention to
the mathematical learning a task addresses, emphasising the need for a task to
provoke student activity that does not merely look like mathematics, but actually is
learning mathematics. The task should be designed in such a way that it provides
situations for action, formulation and validation dialectics, so that students begin by
adopting a strategy and, in the course of stumbling over the epistemological obstacles
built into the task, they adapt their strategy and eventually reach the goal of the task.
The importance of understanding the role of the computer software in
classroom tasks was also made. In particular, the paper has suggested that the
designers of tasks need to be clear about what the work of the computer is, and what
the work of the students is. As explained, computer software is able to do the
mathematics that is frequently, in traditional classrooms, seen as the end point of a
task (such as creating a graph), and if computers are used in this role, then teachers
and designers of tasks need to be clear about what mathematics they want the students
to do. Further, because of the potential power of feedback from the computer,
designers need to take into account the meanings students read into this feedback.
The point was also made, several times, that the context and prior learning of
the students is a crucial concern. The implication of this is that no designed task can
be "set in stone" as teachers will frequently want to adapt the task to the needs of their
students (as discussed, for example, by Kieran, Tanguay, & Solares, 2012). My
concluding suggestion is that task designers should therefore take teachers' need to
adapt tasks into account in their design of tasks.

The interaction between task design and technology design in
creating tasks with Cabri Elem
Kate Mackrell
Institute of Education, University of London, UK
Michela Maschietto

Sophie Soury-Lavergne

Institut Français de l'Education, ENS Lyon, France
Both the design of tasks and the design of technology have been identified as important factors in the effective use of technology-based tasks in the classroom. By analyzing both the design of a sequence of tasks (based on didactical principles from Brousseau's (1998) theory of situations) and the affordances of Cabri Elem software it will be shown that technology can be designed in such a way as to enhance the implementation of didactical principles.
Keywords: Task design, technology, instrumental genesis, feedback, didactical variable
Design of the technology and design of the task
The potential for the contribution of Cabri II Plus and Cabri 3D to student learning is well known. However, Laborde and Laborde (2011) note that there is a gap between situations used in research and everyday teaching practice and suggest the provision of ready-made resources to help teachers take more advantage of dynamic mathematics environments. Sinclair (2003) studied pre-constructed files in a dynamic geometry environment and concluded that the design of the files was critical to their potential to support or impede student learning. There is an increasing concern about the design of technology itself. "Design detail counts" states Jackiw (Butler et al., 2009, p. 431). Research on resources and the problematic of quality indicates the importance of the question (Gueudet et al. 2011; Trgalova et al. 2011). Mackrell (2011) has shown that particular dynamic geometry technologies may have unclear interfaces, a lack of affordances and poor mathematical representations, all of which will hamper the use of such technology as an environment for the design of resources. The above concerns, together with the perceived need to create a version of Cabri that was suitable to the needs of primary students has led to the development of the Cabri Elem technology. A key difference with earlier versions of Cabri is that the focus of the technology is on creating an environment for task design, acknowledging the importance of both the design of the technology itself and of the design of tasks using the technology.
Tasks in Cabri Elem are presented in "activity books" which consist of a succession of pages incorporating a sequence of tasks. Once an activity book has been
created in the Cabri Elem Creator task design environment, it can be used directly by teachers and students in the more restricted environment of Cabri Elem Player. In this paper we will analyze a particular Cabri Elem activity book in order to illustrate the interconnections between the affordances of the technology and the ability to implement particular didactic principles.
Part I. Theories of Task and Software Design
The theory of didactical situations (Brousseau, 1998) offers a theoretical framework and a number of conceptual tools to study and also to design tasks. In this theory, knowledge is a property of a system constituted by a subject and a "milieu" in interaction. Learning occurs through this interaction: the subject acts within and receives feedback from the milieu. But there is an added requirement. The signification of the knowledge that can be constructed in the interaction depends on the existence of a space of uncertainty and freedom for the subject about appropriate action and strategy. If the student has no choice, the learning outcome may have no mathematical meaning. Together with criteria for success or failure, the goal, whether teacher or student determined, is made clear, unlike in the common dynamic geometry task "drag this point and observe" where the student has no choice of action and is uncertain about what is relevant to observe. In the case of mathematical learning with technology, the relation between the technology and the milieu is complex. The milieu cannot be reduced to the technology. Technology may be one component of the milieu, (Laborde and Capponi 1994) but only the part of technology relevant to the mathematics concerned (Brousseau 1998). The same technology will also not constitute the same milieu for every subject. The milieu related to a student changes as student knowledge, both technical and mathematical, develops.
The mathematical problem and the task are key elements of a didactical situation. In the context of this contribution, we characterize a "task" by the following requirements:
• a task involves learning objectives; when a teacher proposes a task to a student, he assumes that achieving the task will cause learning;
• it involves the student encountering a mathematical problem;
• it is performed by concrete and conceptual student actions;
• it corresponds to phases of the didactical situation (in the sense of Brousseau) and is related to different values of a set of didactical variables.
Didactical variables are parameters of the situation, with values that affect solution strategies. The effects can be of three kinds: (i) a change in the validity of a strategy, where a strategy that produces a correct answer with a certain value of a didactical variable will produce an incorrect answer with another value, (ii) a change in the cost of the strategy (for example counting elements one by one is efficient for a small number but much more costly for a larger number) (iii) the impossibility of using the strategy. A combination of the different didactical variable values contributes to the task definition. The learning situation is a choice of different tasks that lead the students to construct the appropriate strategy. Thus task design will consist, for a part, in identifying the didactical variables of the situation and then choosing the succession of appropriate combinations of didactical variable values. This will be one of the foci in describing the task design process.
When creating a learning task in a computer environment, the author has to create all the elements the student will deal with: the objects the student will Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

manipulate, the possibilities of actions on these objects and the feedback provided by the environment. The elements chosen will determine the possible milieu and the potential for learning. The feedback given by the milieu will be a second focus in describing the task design process.
Instrumental genesis involves the processes of instrumentation whereby a person builds personal utilization schemes for an artefact and instrumentalization whereby a person adapts an artefact to their own purposes, with the result that an artefact becomes an instrument to be used in the pursuit of a goal (Rabardel and Bourmaud, 2003). Instrumentation is clearly relevant to task design using tools, as it has been found to be problematic (Trouche, 2005). However, instrumental genesis is also highly relevant to the design of the technology itself. In the human computer interaction literature, "design is perhaps the most common issue addressed within the approach" (Kaptelinin and Nardi, 2006, p. 110):
"artefacts should be designed to enable efficient transformation into instruments. […] the importance of designing flexible, open artefacts that can be modified by users and adjusted for various tasks, including unanticipated tasks and the need for designers to take into account the actual transformation of practices and the real needs of users over the course of appropriating an artefact".
The most important design principle in the development of Cabri software is that of direct manipulation (Laborde and Laborde, 2011), which involves both action and feedback on action. This is a fundamental concept of human computer interaction, developed in the 1980's when the current almost-ubiquitous graphical user interfaces were replacing interfaces requiring text commands (Kaptelinin and Nardi, 2006, p. 82). The general principles below (Shneiderman and Plaisant, 2010, p. 196) are illustrated by examples from dynamic geometry.
1. Continuous representations of the objects and actions of interest with meaningful visual metaphors. Geometric objects and tools.
2. Physical actions, or presses of buttons, instead of complex syntax. Dragging to move objects, constructing a custom tool or macro.
3. Rapid, incremental, reversible actions whose effects on the objects of interest are visible immediately. The response of any geometric object when one of the points on which it is dependent is dragged.
Some of the benefits claimed for systems designed using these principles are that novices can learn basic functionality quickly, users can immediately see whether their actions are furthering their goals, users experience less anxiety and gain a sense of confidence and mastery (Shneiderman and Plaisant, 2010, p. 196) This has obvious implications for instrumentation.
However, Rabardel (2002, p. 148) suggests that direct manipulation may not always be the most appropriate means of interaction with an artefact in a learning situation. The aim, rather than making the action easier, may be to construct constraints that lead the subject to use and elaborate cognitive constructions of knowledge (p. 148). An implication is that the task designer in a technological environment must have the facility to vary the type of action required and response received as appropriate.
An important additional principle for mathematics educational software is "epistemic fidelity" in which the representations of mathematical objects must avoid any contradictions with the abstract objects they represent, both in appearance and in behaviour when manipulated (Laborde and Laborde, 2011). Rabardel (2002, p. 160) also warns that while instruments may be designed to favour the construction and manipulation of conceptualizations these impose a "world view" on users. This has
consequences for design at many levels, ranging from the choice of perspective (to ensure that a cube does not appear to "pulsate" when moved) in Cabri 3D to the importance of distinguishing geometric labels and variables (Mackrell, 2011).
Laborde and Laborde also feel that physical action is preferable to pressing buttons: that by directly acting on the representation of mathematical objects the user eventually perceives the abstract object itself.
Part II. Analysis of a Cabri Elem activity book
In what follows, we will look at an activity book and discuss the task design decisions and the technology affordances, which enable these decisions.

84
learning objectives: in a version of the activity book used with younger students the
scoreboard regions only gave values of one or ten. The score is always displayed in
some pages, but displayed only after a specific sequence of actions in other pages.
The score is generated by means of the point counter tool a new tool, which
counts the number of points within geometric shapes (in this case the three regions of
the scoreboard
11
). The idea for this tool was initiated by a primary teacher educator
for work with early number: she wanted a means of creating and counting a collection
of objects using technology. Other affordances used in this page are the ability to
evaluate expressions (the total score being calculated from the number of points in
each region), and the ability to reset the position of points.
Page 3: evaluation feedback
On page 3 the student is given a specific task: to reach a score equal to a
target number, randomly generated between 1 and 999 (see Figure 2). Clicking on the
reset button now in addition generates a new target number. Another new action is
that the student may, in addition to comparing whether the score matches the
scoreboard, click on a new button for evaluation feedback: a red frowning face if the
answer is wrong, and a yellow smiling face if the answer is correct. In case of failure,
the student can continue to drag counters and ask for a new evaluation: a new smiley
will appear to the right of the previous one. It is important that new feedback is only
generated at the student's request: otherwise a trial and error strategy not stemming
from mathematical considerations could lead to success.
The key new software affordance used in this page is the Boolean function,
which enables a comparison between the student response and the target number.
When the feedback button is pressed, the value of the resultant Boolean (TRUE or
FALSE) will determine which of the faces is shown.
Pages 4 to 7: suppression of a direct manipulation feedback and evolution of
the task
From page 4 to 7 students are no longer given the direct manipulation
feedback of seeing the score. They hence need to take into account the value of the
counters in the different regions of the scoreboard to determine the score. "Score" was
identified a priori as a possible didactical variable, with two values: visible or hidden.
All objects may be either visible or invisible in Cabri Elem, enabling the author to
control the level of direct manipulation feedback given.
In page 5, the number of counters is reduced so that, if the target number is
over 27, a strategy that consists in placing counters only in the green units region will
fail. A strategy which takes into account that a single counter can have another value
than 1, i.e. using the inside regions of the scoreboard, is necessary. Therefore, another
potential didactical variable is identified: the number of available counters, with two
values, 3x9=27 and =27. In page 6, the target number is a multiple of ten, between 10
and 990. As there are enough counters to either leave the green region empty or to fill
it with multiples of ten counters, a change of strategy is not necessary. In page 7,
however, a single counter is fixed in the green region. Therefore, new strategies are
required, involving the placement of a multiple of ten counters into the units region of

geometrical shape, the authors have created non-convex polygons with touching sides. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
85
the scoreboard. The "fixed counter" didactical variable is identified, with four values:
no fixed counters, or fixed counters in the units, tens, or hundreds region.
Page 8 contains input boxes for the student to enter the values of a counter in
each region of the scoreboard. The aim of this task is to summarize the key idea of the
activity book, i.e. that the value of a counter depends on the scoreboard region.
Other pages of the activity book not devoted to student tasks

The first page is designed with the aim of attracting teachers and students to
the activity book with an iconic representation of some of the main objects.
Pages 9 and 10 contain commentaries for teachers, reporting the main aspect
of the task, the evolution from one page to another, possible student strategies (correct
or not) and also the solution. The structure of the pages of the activity book was used
to organise these notes and the didactical variable analysis helped to determine what
information was useful. Trgalova et al. (2011) also points out that teachers find
teacher notes of value.
Part III. Feedback from the school
The "Target" activity book was trialled in the spring of 2012 in two primary
school classes: CE1 with the version presented here and CP (six year old students)
with a version where the target number size was limited to 99. Teachers used the
activity book as one resource for learning about place value and instrumentalised the
book by printing pages to construct related paper and pencil tasks. They were
enthusiastic about student engagement, mathematical reasoning and the evolution of
strategies, but raised a number of issues. We present here some findings related to
instrumentation by teachers and students, instrumentalization, strategies feedback and
didactical variables.
It was expected that the strong metaphor between the task situation and real
situations involving a scoreboard would, as well as providing a meaningful context,
minimize the need for instrumentation: however, students expected that, as in the real
situation, moving a counter would require tossing it in some way and were initially
uncertain about how to do this using the software. Teachers also proposed that
instrumentation would be enhanced by modifying page 2 to include a target number
chosen either by the teacher according to the constraints of the class, or chosen by
students in order to challenge each other.
Some students used the target number update not only to get a new number
after finding a previous target but also, unexpectedly, to get a number they knew they
were able to deal with. They were able to diagnose their level of expertise and this,
important ability to the learning process must not be ignored by the environment. It is
planned to modify pages to provoke problem resolution, but also to locally enable this
usage. This example of students' instrumentalization of a functionality to adapt it to
their level of expertise is a new, generalizable element in activity book design.
The number of available counters was not a didactical variable for most CE1
students, who used each region of the scoreboard and limited the number of counters
they needed to drag. Many of them did not notice the reduced number of counters on
page 5 and were surprised to apparently have to solve the same task again. However,
for a few CE1 students and many of the younger CP students who used only the units
region of the scoreboard and placed as many counters as the target number the
number of available counters was indeed a didactical variable. The status of page 5
will hence be changed in further developments of the book. Instead of being Theme A – K. Mackrell, M. Maschietto & S. Soury-Lavergne
86
automatically displayed to CE1 students, it will only be displayed as necessary, i.e. if
the unit region is repeatedly filled with many more than 10 counters. The strategy
feedback, resulting from our analysis in terms of didactic variables, will consist in
reducing the number of counters and choosing a target number over 50.
Conclusion
In this paper the following elements have been considered: task design,
construction of milieu in the context of a particular technology, didactical variable,
feedback, and instrumental genesis for authors and students. In order to discuss tasks,
we tried to show their mutual relationships. We have shown that software affordances
and theories related to task design together enable the effective creation of resources
for learning and their introduction into the classroom.
However, many elements remain to be controlled and articulated in the
analysis of tasks and task design. This paper, drawn from the initial stages of a study,
attempts to illustrate some of these and to suggest theoretical means to study the
whole process. On the one hand the analysis has shown the potentialities of Cabri
Elem, but on the other hand it has shown the complexity of the process: different
instrumental geneses are involved, subjects' knowledge comes into play, didactical
constraints are present, etc. However, we have also shown that there is not a distinct
divide between software affordances, task design and classroom implementation:
Cabri Elem affordances are based on theories of software design, but also come from
the requests of researchers and educators. In turn, designing a task in the Cabri Elem
environment enables a greater awareness of the potential of different didactical
variables. Feedback from the classroom suggests ways in which the task may be
improved.
The next stage in our study is to explore ways in which activity books could
be usefully modified by any teacher. The Cabri Elem task design environment
12
will
enable us to consider this new level of instrumental genesis.

Designing Tasks to Foster Operative Apprehension for
Visualization and Reasoning in Dynamic Geometry Environment
Anthony C. M. OR
Education Bureau, The Government of the Hong Kong Special Administrative
Region.
This paper presents how to design tasks in dynamic geometry
environment (DGE) to foster operative apprehension for visualization and
reasoning in Duval's model of geometrical reasoning. The meaning and
significance of operative apprehension in DGE would first be proposed,
and the principle of using soft constructions to design tasks to foster
operative apprehension would then be discussed, illustrated by some tasks
designed in the DGE GeoGebra. Finally a model of task design in DGE to
foster operative apprehension for visualization and reasoning is proposed
for further discussions in future research of task design in DGE.
Keywords: Task design, Dynamic Geometry Environment,
Visualization, Reasoning, Operative Apprehension, GeoGebra
1. Introduction
One of the important aims of the Hong Kong Secondary Mathematics
Curriculum is to develop students' ability to conceptualize, inquire, reason and
communicate (Curriculum Development Council, 1999 p.4). Hence the terms
"explore" and "justify" appear in the learning objectives of many topics. For example,
it is expected that students could "explore the formula for the area of circles" (ibid
p.20), or could "explore and justify the methods of constructing centres of a triangle
such as in-centre, circumcentre, orthocentre, centroids etc" (ibid p.23).
However, it seems that the learning tasks proposed in Hong Kong textbooks
could not always fulfil this aim. For instance, when constructing the circumcircle of a
triangle, students are told directly to first construct the perpendicular bisectors of the
three sides using rulers and compasses, and then use their intersection as a centre to
draw a circle passing through one of the vertices, and finally see that this circle also
passes through the other two vertices (Figure 1). In this task students are neither
provided the opportunity to explore nor asked to justify how the circumcircle could be
constructed, but instead just to verify the correctness of the procedures to construct
the circumcircle given by the textbooks. Figure 1: Construction of the circumcircle in textbooks

91
gives insight into the solution of a problem. He emphasizes that operative
apprehension is crucial and teachers have to identify factors triggering or inhibiting it
so as to make visualization possible and gives rise to various transfers.
With regard to the use of dynamic geometry software (DGS), Duval states
that DGS provides enormous possibilities of visualization through the introduction of
the aspect of movement, and allows manipulations of geometric objects and hence
true explorations of geometrical situations. However, the construction-centered design
of DGS does not develop all functions of visualization, in particular the operative
apprehension.
Duval's theory emphasizes the importance of operative apprehension to
facilitate visualization and also reasoning in the teaching and learning of geometry. In
view of his comments on the uses and limitation of DGS in visualization, I shall
discuss how to design tasks in DGE to foster operative apprehension for visualization
and reasoning. I would first define what operative apprehension means in the DGE,
and how the use of soft constructions proposed by Healy (2000) could be an effective
approach of designing task to foster operative apprehension.
3 Operative Apprehension in DGE
A task is a set of pre-designed, environmentally situated materials aims to
engage learners in activities that could transform the ways they see and do
mathematics (Leung, 2011). A task has to be pre-designed in the way that through
these pre-designed means, learners are guided to construct insights and the meaning
of the mathematics knowledge. A task is also environmentally situated in the sense
that the qualities or tools of the environment have been made use to empower learners
with extended or amplified abilities to acquire knowledge which could not be
acquired in the same ways in other environments (Leung, 2011). In what follows, I
shall discuss how to design tasks situated in DGE to foster operative apprehension for
visualization and reasoning in Duval's framework. In particular, I will focus on predesigned DG figures and interpret Duval's operative apprehension as the following:
Operative apprehension of a mathematical concept or problem in DGE is the
insights into the concept or the solution of the problem revealed by operating on a
pre-designed figure in the environment through dragging.
Let me illustrate the significance of operative apprehension in DGE using a
task I designed in GeoGebra (a free DGS). This task originates from the following
problem in a textbook.
A quadrilateral is dissected by a line joining the mid-points of one pair of
opposite sides, and the perpendiculars to this line from the mid-points of the other pair
of opposite sides. (See Figure 3(a) below.) What shape can you get from this
dissection?
A task is designed in GeoGebra to help learners to explore this problem
(http://www.geogebratube.org/student/m3459). In this task, a quadrilateral is
dissected into four pieces as described in the problem. Each piece can be rotated
through dragging the red point at the vertex. In this way we can see that how the four
pieces could form a rectangle (Figure 3). Also, the operation gives us the insights to
reason why this dissection gives a rectangle, by, for instance, thinking about why the
four angles at the vertices give a sum 360˚ (Figure 3(d)).
Theme A – A. C. M. OR
92
(a) (b)
(c) (d)
Figure 3: The GeoGebra task of dissecting a quadrilateral into a rectangle
Besides rotating the four pieces, learners can also operate on the shape of the
quadrilateral. After checking the "Change the shape" box, four green points appear at
the vertices of the quadrilateral and the shape of the quadrilateral could be changed by
dragging them. Through dragging the vertices, I see that the dissection would give a
square for some shapes of the quadrilateral (Figure 4).
Figure 4: Some shapes of the quadrilateral that give a square after the dissection
This problem reminds me the famous Haberdasher Puzzle composed by
English mathematician Dudeney (Dudeney, 1907). This puzzle shows how an
equilateral triangle could be dissected into a square (Figure 5). Although I know this
puzzle for a long time, I never understand how Dudeney could think of this method of
dissection, nor have any idea how to generalize his method to dissect an arbitrary
triangle into a square.
Figure 5: Dudeney's Haberdasher Puzzle of dissecting an equilateral triangle into a square
When I try to compare the quadrilateral problem with Dudeney's puzzle, I
suddenly realize that if I drag a vertex, say the upper-left one, to a position at which it
is collinear with the other two adjacent vertices (Figure 6(a)), the quadrilateral would
be degenerated into a triangle which is dissected into a rectangle. Furthermore, if I
drag this vertex along the side of the triangle (Figure 6(b)), since the shape of this
triangle is unchanged the area of the rectangle is kept constant while its length and
width are decreasing and increasing respectively through dragging. Hence I should
get a square somewhere on this side (Figure 6(c)). Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
93
(a) (b) (c)
Figure 6: Dissecting a triangle degenerated from the quadrilateral into rectangles or a square
After the above exploration I see how an arbitrary triangle could be dissected
into rectangles of various sizes, and there should be a particular dissection that gives a
square. Through operating on the shape of the quadrilateral, I get important insights of
comprehending how a general triangle could be dissected into a rectangle, and
investigating when the dissection would give a square.
This example illustrates the advantage of fostering operative apprehension in
DGE. If we use a paper quadrilateral, although we could cut it to see how it could be
dissected into a rectangle, it is impossible for us to operate on its shape. In DGE we
can operate on the shape of the quadrilateral so that we can degenerate it to a triangle
to get the insights of how a triangle could be dissected into a rectangle.
4 Operative Apprehension for Visualization and Reasoning: Soft
Construction
At the beginning of research in dynamic geometry, tasks in robust
constructions, i.e. constructions preserve relationships upon dragging, were
recognized as promoting for the learning of geometry. However, Healy (2000)
discovered through observation that, rather than robust constructions, students
preferred to investigate constructions "in which one of the chosen properties is
purposely constructed by eye, allowing the locus of permissible figures to be built up
in an empirical manner under the control of the student". Healy called these
constructions soft constructions.
Healy differentiates the roles of dragging in robust and soft constructions. In
a robust construction, dragging provides a visual verification of the validity of the
construction through dragging. In a soft construction, dragging is not verification but
part of the construction itself. Through dragging, the general can emerge from the
specific by searching empirically for the locus of figures fulfilling the given
conditions. Soft constructions offer a transition from an empirical approach to a
theoretical approach in solving a geometry problem.
In the lens of Duval's model of geometrical reasoning, tasks in robust and
soft constructions can be considered as operative apprehension on figures serving
different functions of visualization: a robust construction provides a verification of the
construction, while a soft construction provides heuristics or insights through an
empirically searched locus which mediates reasoning. I shall illustrate this point with
two GeoGebra tasks of drawing the circumcircle of a triangle, one in robust
construction and one in soft construction.
In the robust construction task, perpendicular bisectors of the three sides are
first constructed using the "Perpendicular Bisector" tool . A circle centred at their
intersection (found by the "Intersection" tool) and passing through either one
vertex (say A) is constructed using the "Circle" tool , and it could be seen that Theme A – A. C. M. OR
94
this circle also passes through the other two vertices (B and C). By dragging the
vertices of the triangle, learners can check the validity of the construction by seeing
that the circle always passes through the vertices. They can also see that the
circumcentre lies outside the triangle when the triangle is obtuse (Figure 7).
(a) (b) (c)
Figure 7: A robust construction task of finding the circumcircle of a triangle
In the soft construction task (http://www.geogebratube.org/student/m3958),
learners are first given the triangle and a circle which can be moved by dragging its
centre (in red) and a blue point on its circumference (Figure 8(a)). Learners first drag
the blue point to either one vertex, say A, and a dotted line joining A and the centre
would then be shown (Figure 8(b)). Then they drag the red centre to different
positions at which the circle also passes through another vertex B, and when this
happens a dotted line joining B and the centre would be shown. These positions of the
centre are marked in red, and learners can see that the locus of the centres of circles
passing through A and B is a straight line (Figure 8(c)). Learners can then be asked
what this line of locus should be, and the two dotted lines from the centre to A and B
providing hints for them to reason that this line is the perpendicular bisector of AB
(through looking at two congruent triangles). Once they recognize that the locus of
the centres should be the perpendicular bisector, they can find empirically the loci of
the centres when the circle passes through A, C (Figure 8(d)) and B, C (Figure 8(e)),
and finally visualize that the circumcircle should centred at the intersection of the
three loci, i.e. the intersection of the perpendicular bisectors of the three sides (Figure
8(f)).
(a)

(b) (c)
(d) (e) (f)
Figure 8: A soft construction task of finding the circumcircle of a triangle Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
95
The above example illustrates how a task in soft construction could foster
operative apprehension by recording the loci of positions at which the eye
construction satisfies the given conditions. These loci of positions provide insights to
solve the problem, and also mediate the reasoning of why the problem could be
solved in this way. I now propose the following principle of using soft constructions
to design task fostering operative apprehension for visualization and reasoning in
DGE.
Principle of using soft constructions to foster operative apprehension
Learners are provided opportunities to perform soft (eye) construction by
dragging. The loci of the dragging satisfying the given conditions, together with the
other elements supporting their visualization and reasoning, would be shown to the
learners so that theoretical elements could emerge from the empirical evidences.
I further elaborate the above principle using a more sophisticated task of
finding the incircle of a triangle (http://www.geogebratube.org/student/m4363). In
this task the triangle and a circle of centre I and passing through P are given, and the
radius IP is also shown. Learners are first asked to drag P to the side BC, then another
dotted line would be shown to indicate that there are two intersections (Figure 9(b)).
By dragging P towards the other intersection learners would visualize that for the
circle to touch BC, the two dotted radii should overlap to form one radius IP
perpendicular to BC (Figure 9(c)). I also anticipate that this process of dragging,
together with the overlapping of the two radii, would help learners to reason why the
tangent of a circle should be perpendicular to the radius.
(a) (b) (c)
Figure 9: A task of finding the incircle of a triangle – touching one side
Once the circle touches BC, P can no longer be dragged and learners are
asked to drag the centre I to different positions so that the circle would also touch AB,
and the locus of I is marked in red (Figure 10(a)). Learners are prompted to identify
this line of locus as the angle bisector at B, and could explain this by looking at the
congruent triangles IBP and IBQ. Similarly learners identify the locus of I at which
the circle touches BC and AC as another angle bisector at C (Figure 10(b)), and see
that the circle would touch the three sides when I is at the intersection of the angle
bisectors (Figure 10(c)).
(a) (b) (c)
Figure 10: A task of finding the incircle of a triangle – finding the incentre
Finally, the three vertices of the triangle are made draggable to the learners
and they are asked to drag the vertex A to change the shape of the triangle, and see that the original circle no longer touches the three sides (Figure 11(a)). They are then
asked to perform robust construct of the incircle by constructing the suitable lines in a
triangle using the given tools (median
perpendicular bisector
can then check the validity of their construction by dragging the vertices (Figure
11(c)).
(a)

5 Discussions and Implications
Based on the above illustrations, I propose a model of task design in DGE to
foster operative apprehension for visualization and
model of geometrical reasoning as follows:
Task Design Model in DGE to foster Operative
Visualization and Reasoning through Dragging

Discussions and Implications
Based on the above illustrations, I propose a model of task design in DGE to
foster operative apprehension for visualization and reasoning by modifying Duval
reasoning as follows:
Task Design Model in DGE to foster Operative Apprehension for
Visualization and Reasoning through Dragging
Task design in this model consists of two phases. In Phase 1, the
using Soft Construction to foster Operative Apprehension is applied so as to foster
operative apprehension through soft construction, i.e. to use the
solutions satisfying the given conditions. In the process of soft
of the locus of validity (Leung and Lopez-Real
other support elements that mediate reasoning would be shown. Use my in
as an example (p.7), the dotted radii and their overlapping through dragging (Figure
9) are the support elements which are shown to students to mediate the insight and
reasoning of perpendicularity of the radius and the side when the circle touches it.
Similarly, the traces and the radii shown by the software in Figure 10 support the
that the original circle no longer touches the three sides (Figure 11(a)). They are then
asked to perform robust construct of the incircle by constructing the suitable lines in a
, altitude and
(Figure 11(b)). They
can then check the validity of their construction by dragging the vertices (Figure

97
reasoning that the traces are the angle bisectors of the triangle and in-centre lies on
their intersection.
In this phase dragging and tracing are the cognitive tools (Leung, 2011) to
start a recursive cycle between visualization and reasoning until a solution and its
explanation is reached. In the design of the in-circle task, students are guided to first
visualize through dragging that the radius has to be perpendicular to the side when the
circle touches it. Then with this property students are further guided to visualize
through dragging and tracing that centre of the circle must lie on a certain line when
the circle touches two sides of the triangle. They are then guided to reason, using the
trace and the dotted radii, that this line is in fact the angle bisector. Finally they
further visualize that when the centre lies on the intersection of the two angle
bisectors, the circle would touch all the three sides and at this stage they should be
able to explain why this happens.
When the solution and its explanation are reached in Phase 1, the task is then
transited to Phase two in which students are required to use the construction tools
given by the software to do a robust construction to verify the solution and
explanations they obtained in Phase 1. This is done by releasing the shape of the
figure in the problem so that students observe that the soft construction in Phase 1 no
longer works when the shape of the figure is changed (Figure 11(a)). Students are
then asked to use the tools of the software to construct a robust in-circle that always
touch the three sides (Figure 11(b)(c)). In this phase dragging is a tool for visual
verification of the construction.
This model shows how the different roles of robust and soft constructions
could foster operative apprehension, through which the synergy of visualization,
reasoning and construction can be facilitated. If we agree with Duval that developing
visualization and reasoning abilities to favour the synergy of the three cognitive
processes is of crucial importance for the teaching of geometry, designing tasks to
fostering operative apprehension for visualization and reasoning in DGE effectively
would then be very promising to promote the teaching of geometry. This is also a
great challenge to all teachers, educators and researchers. It is hoped that the principle
and the model of task design in DGE proposed in this paper could provide a useful
initiation for further discussions, challenges and refinement in future task design
research.

Dynamic representations for algebraic objects available in
AlNuSet: how develop meanings of the notions involved in the
equation solution.
E. Robotti
DIDiMa srl spin-off ITD-CNR Genova (Italy).
This article presents a research work aimed to study the impact of
new representations for algebraic objects handled by AlNuSet, an artefact
of dynamic algebra recently developed. In particular this article focus on
equations and identities. Traditionally, conceptual construction of
algebraic equality is pursued through solving equations using techniques
of symbolic manipulation. Several researches have highlighted that this
approach does not favor the construction of an appropriate sense for the
notion of algebraic equality, identity or for that of solution of equation.
To this aim, teachers need new tools that provide effective representations
for algebraic objects. Thus, this article presents new semiotic
representations available in AlNuSet that support both students in the
conceptualization of algebraic objects and teachers in the design of
innovative educational sequences of tasks allowing to tackle algebra not
only in syntactic aspects but also in the semantic ones.
Keywords : dynamic algebra, representations, dynamic representations,
equation, identity, existential quantifier, universal quantifier
Introduction
With a significant percentage of students, the current teaching of algebra
seems not to be sufficient to effective develop skills and knowledge to master this
domain of knowledge (Sfard & Linchevski, 1994; Kieran, 2006).
To clarify students' difficulties in algebra I refer to Chevallard's (1985)
para-mathematical end proto-mathematical notions.
On the base of these definitions, the algebraic concepts taught at school are
mathematical notions. However, Chevallard highlights that there are some notions,
called para-mathematical notions (i.e. variable, parameter, unknown, universal or
existential quantifier, algebraic expressions, ...) that have a name and that can be
defined in class, but often no educational activity is performed about them. Moreover,
there are proto-mathematical notions (for example, recognize a simple factorization in
an expression of the second degree or the equivalence between expressions), that are
not explicitly defined in class, but they live in educational practice and students are
not aware of their existence. The development of para-mathematical and protomathematical notions, seem to be very important to give meanings to the algebraic
objects and to better control the algebraic manipulation activities. Students'
difficulties in algebra to develop para-mathematical and proto-mathematical notions,
seem to be due to the fact that these notions can be grasp by the control on their Theme A - E. Robotti
100
algebraic meaning (Arzarello, Bazzini, Chiappini, 1995). To make explicit protomathematical notions and to ensure that students grasp meaning of para-mathematica
notions, teachers need new artifacts, which make available new algebraic objects'
representations. Our research hypothesis is that AlNuSet (ALgebra on the NUmerical
SETs), can be effectively used to mediate conceptual development necessary to
master the notion of algebraic equality.
AlNuSet was developed in the context of ReMath (IST - 4 - 26751) EC
project and is designed for students of lower and upper secondary school (yrs 12-13 to
16/17). It was developed by the research group of ITD (Istituto per le Tecnologie
Didattiche)-CNR (Centro Nazionale di Ricerca) of Genoa (Italy) that I belong.
Alnuset allows, through visual-spatial approach and dynamic representations, to built
meanings of para-matematical and proto-mathematica notions.
In this article I show how this kind of representations implemented in
AlNuSet can support the teaching and learning algebra making explicit paramatematical and proto-matematical notions involving in equality and equation process
solution. The sequence of tasks was designed in collaborations with teachers involved
in ReMath project and it was experimented with them. This article focus on a
sequence of two tasks, aimed to presents a new educational approach to equation and
identity, which is part of a more completed Teaching Guide for teachers that I have
designed with my group of research (authors of AlNuSet) and experimented in
ReMath project context.
Short description of AlNuSet
Alnuset is constituted of three strictly integrated components: Algebraic Line
component, Symbolic Manipulator component and Functions component. Since this
paper concern tasks where only the first two components are used, I will describe in
the following only the Algebraic Line component and the Symbolic Manipulator
component (for more details see www.alnuset.com).
The main educational characteristics of these components are:
making available, through a visuo-spatial approach, dynamic representations
of expressions and algebraic propositions (in Algebraic Line component);
making available, through an operative and deductive approach, axioms and
rules to transform and manipulate algebraic expressions/propositions (in Manipulator
component).
The main characteristic of Algebraic Line component is the possibility to
represent an algebraic variable as a mobile point on the line, namely, a point that can
be dragged with the mouse along the line. Dragging the mobile point along the line,
the letter associated to that point assumes the values of numerical set instantiated.
This new visuo-spatial approach which exploits dynamic representations, allows to
make explicit the notion of variable as mobile point on the line that assume, in
numerical set instantiated, all its possible values. When dragging the mobile point on
the line, all algebraic expressions containing such a variable move accordingly. This
feature has transformed the number line into an algebraic line where it is possible to
operate with algebraic expressions and propositions through techniques of
quantitative and dynamic nature. This visuo-spatial approach to algebra allows
student to handle dynamic representations as new semiotic representations of
algebraic objects in Algebraic Line. This makes a dynamic algebra possible and
supports students in the conceptualization of algebraic objects. The most important Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
101
new semiotic representations available in Algebraic Line of AlNuSet that are involved
in the tasks presented in this paper are:
The post-it (see Fig 1b). The belonging of two expressions to the same post-it
can be connected to the notion of equality and equivalence between expressions.
Color of the dot associated to a proposition and/or to the numerical set
constructed by the user (see Fig 1a and 1b). The color accordance between the dot
associated to a proposition and that associated to the numerical set constructed by the
user, can be connected to the notion of truth set of the proposition and can be used to
validate the constructed numerical set as the truth set of the proposition.
The main characteristic of Symbolic Manipulator component is the
possibility to transform algebraic expressions and propositions through a set of
particular commands. These commands correspond to basic properties of operations,
properties of equality and inequality, logic operations among propositions, operations
among sets. Another characteristic is the possibility to create a new transformation
rule once it has been proved. These characteristics support the development of skills
regarding the algebraic transformation and they contribute to assign a meaning of
proof to it. Note that not all the commands are available in the same time: only the
commands that can be applied on the selected part of expression are available. The
user can easily control the whole process of algebraic transformation exploiting
feedback given by the system. Moreover, the user can verify the preservation of the
equivalence in the transformation representing the transformed forms on the
Algebraic Line.
Mediation provides by AlNuSet is profoundly different from that proposed
by the software used for the traditional teaching of algebra: both new dynamic
representations, based on visuo-spatial approach, which allow to reify semiotic
representations and its strictly integrated components, allow students to link semantic
and symbolic nature of algebraic objects. Moreover, AlNuSet's components allow

teachers to make explicit these links and, in particular, to make explicit paramatematical notions (i.e. variable, unknown, universal or existential quantifier, algebraic expressions,...) and proto-matematical notions (for example, choose the appropriate rule to transform an expression to obtain another; reconizing a factorization in an expressions...) involved in equality and equation notions.
Several researches (Chiappini, Pedemonte, B Robotti, 2008; Chiappini, Robotti, Trigalova, 2010;) highlighted the educational potentialities of this software showing how the approaches described above are effective in order to understand the basic mathematical concepts (fractions, expressions, equations,...)
Some particular tasks of the Teaching Guide
Note that, the standard teaching approach to algebra is to find, within the algebraic formalism, the meanings of algebraic notions (for instance, the manipulation of an equation allows to find values that, replaced in the initial equality, make it true; thus, the meaning of solutions of equation is found in the algebraic manipulation itself). The new approach to algebra offered by AlNuSet enables teachers to change this sequence: at first construct the meanings of algebraic notions (for instance, what does mean solving an equation) and, only then, deal with the formalism, finding in it the meanings previously built. This new approach is possible using dynamic representations that are available in AlNuSet, as I will show in the following sessions concerning the sequence of two tasks. Theme A - E. Robotti
102
The tasks aim to exploit operative and representative possibilities of the Algebraic Line component to design explorative activities that address the construction of meanings for the notions involved in the solution of equations and identities. Then, tasks aim to consider formal and syntactical aspect of algebraic manipulation involved in the solution of equations and identities. These algebraic manipulations are performed in Manipulator component by the application of rules and axioms available on its interface. The equivalence of the expressions obtained by these transformations can be verified on the Algebraic Line. In this way, the links between semantics aspects and syntactic aspects can be made perceptively evident.
The sequence of tasks presented in this paper is composed of different activities that focus on the solution of a first-degree equation and the comparison between equation and identity. For each activity, I will present the task assigned to the students and I will discuss how we have designed task taking into account the dynamic representations available in Algebraic Line of AlNuSet and the rules and axioms available in Manipulator component of AlNuSet. Finally, I will describe the mediation role of AlNuSet in teaching-learning process of the algebraic notions taken into account.
I underline that Teaching Guide aims to offer indications to better exploit the potentialities of AlNuSet in order to improve teaching and learning algebra (Chiappini G., Pedemonte B., Robotti E., 2010; for more details see Educational Activities in www.ainuset.com).
Linear algebraic equation
In order to master algebraic equality, the conceptual development of notions of equation, identity, truth-value and truth set is necessary. Moreover, to express the way in which a letter can condition the truth-value of an equality, you must be able to consciously use universal and existential quantifiers, even though in implicit way (that is, as para-mathematical notion). For this reason, the sequence of tasks presented in this paper aims to answer the following questions concerning equations, their process resolution and identities:
What does solving an equation mean? What could we intend for truth-value of an equality? What is an algebraic identity and what differentiates it from a conditioned equality?
In order to promote the construction of meanings for the notions of equation, identity, truth-value and truth set involved in answering these questions, the sequence of tasks promotes the para-mathematical notions of unknown, algebraic expressions, variable, universal and existential quantifier, equality. Similarly, it makes explicit the proto-mathematical notion concerning equivalent expressions.
To this aims, I show how the use of Algebraic Line's functionnalities and Manipulator's functionnalities allow students to approach the notions of equation and identity in different ways: perceptive way (by a visuo-spatial approach mediated by dynamic representations) in Algebraic line component, and syntactic way (by operative and deductive approach) in Manipulator component.
To make explicit the connection between AlNuSet, as tool for teaching and learning algebra, the representations and the task design, I highlight that, the design of the following tasks is based on integration of these two different approaches (perceptive and syntactic), which are possible only in the AlNuSet's components, in order to promote the development of semantic competences and operational competences engaged in the solution of equations and identities. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
103
Task 1
Consider the following two polynomials: x+2; 2*x+3.
Explain what does it mean putting the equal sign between them, or, in other words, explain how you interpret the following writing x+2=2*x+3.
Now, represent on the Algebraic Line of AlNuSet the two polynomials: x+2 and 2*x+3 and drag the mobile point x to verify your hypothesis. Insert in Manipulator the equality x+2=2*x+3 and solve it using the appropriate commands. What does it obtains?
The first part of the task is aimed to make explicit students' conceptions on the notion of algebraic equality. As matter of fact, on the semantic plan, equality denotes a truth-value (true/false) related to the statement of a comparison. When the expressions composing the equality are strictly numerical, it is easy verifying their truth-value through some simple calculations (e.g., 2*4+2=10 is true while 2*3+1=10 is false). Experiences with numerical equality contribute to structure a sense of computational result for the "=" sign. This sense can be an obstacle in the conceptualization of algebraic equality as relation between two terms, as highlighted by several researches (Kieran 1989, Filloy et al. 2000). Coherently with this meaning, we expect that the equal sign between two expressions could suggest that the computation related to the two terms of the equality has to produce the same result whatever the values of the variable x is.
The second part of the task aims to discuss this misconception and to construct the idea that the equality between two members (polynomials) is conditioned by the value of x. As matter of fact, when the expressions composing the equality are literal, the equality can present different senses because the value assumed by the letter can condition differently its truth-value. In this cases the "=" sign should suggest to verify numerical conditions of the variable for which two terms are equal. In others words, the equality is conditioned by the values of x.
To make explicit this condition, usually teachers have recourse to substitution of truth-values in the literal equality in order to obtain a true equality. This kind of approach does not seem very effective to grasp the sense of conditioned equality. For this reason, we designed the second part of the task asking students to use Algebraic Line of AlNuSet: by exploiting dynamic representations of the Algebraic Line it is possible to built the meaning of "=" sign between the expressions as conditioned equality in perceptive way. Thus, these representations allow students to grasp the meaning of conditioned equality by means of a visuo-spatial approach rather than a computational approach.
Solution in Algebraic Line component
On the Algebraic Line, students insert the mobile point x, that represent a variable, and the expressions x+2 and 2*x+3. Dragging the point x along the line, students can observe that there is only a value of x for which the points of the two expressions assume the same value. This dynamic representation contributes to build the meaning for the equal sign between the expressions as conditioned equality. As matter of fact, when student try to verify the equality between expressions, the drag of x is made with a specific aim: to ensure that the two expressions take equal values, that is, they are associated to the same point on the line and they belong to same postit (yellow square). If dragging is realized with this aim, then the variable can assume the meaning of unknown expressions have equal value and equality is true.
In Figure 1, two moments corresponding to the drag of x along the line represented (Fig. 1a, Fig. 1b)
2*x+3 are on the same point corresponding to the value 1 and they belong to the same post-it. The expressions are equals so that the equality is true.

107
Dragging x along the line it is possible to verify that the expressions 2x+3x
and 5x refer, for all values of x, to the same point and they belong to the same post-it.
The equality is verified for all values of x.
Note that the colour of the dot associated to the equation 2x+3x=5x is always
green so that the equality is always true and it is an identity. Instead, the expressions
2x+3 and 5x refer to the same point and they belong to the same post-it only for x=1.
This is a conditioned equality that is true for the only value 1 of x. This kind of task
and the support of the Algebraic Line, allow teachers to explicitly speak about
universal and existential quantifiers.
The dynamic representations available on the Algebraic Line allow teacher to
promote meaning of universal and existential quantifiers exploiting the perceptive and
visuo-spatial approach.
Conclusion
The sequence of tasks proposed in this article shows the impact of new
representations performed in Algebraic Line and Manipulator components of AlNuSet
in the solution process of equations and identities. The efficacy of visuo-spatial and
dynamic representations available in Algebraic Line, to built algebraic meanings of
notions involved in solution of equations and identities, is presented. Moreover, in
this paper I described how the formal procedure of equation' solution, performed in
Manipulator component, can be linked effectively to the meanings developed by by
perceptive approach in Algebraic Line component. The algebraic transformations
performed in Manipulator allow students to focus on the educational aim concerning
the equivalence between algebraic propositions. This equivalence is performed on the
base of rules and axioms that have to be chosen among that presented on the interface.
Moreover, the proof of the equivalence is not charged of calculus. The sequence of
tasks in which the use of Algebraic Line of AlNuSet is required, shows how it is
possible to promote the para-mathematical notions of unknown, algebraic
expressions, variable, universal and existential quantifier, equality. Moreover, the
tasks show how the use of Manipulator can support proto-mathematical notion
concerning equivalent expressions. Finally, the sequence of tasks performed by means
of AlNuSet' functionalities shows how teachers were able to innovate the teaching
learning algebra starting with the development of the meanings of algebraic notions
before moving to the formal aspects related to syntactic manipulations. The
discussion of tasks shows that this is possible by means of new dynamic
representations available in AlNuSet.

Designing Tasks for Use With Digital Technology
Michael O. J. Thomas
The University of Auckland, New Zealand
Catherine Lin
The University of Auckland, New Zealand
In this paper we use a research-oriented approach to describe
some of the features of technology-integrated tasks with epistemic value.
Some examples of the construction of these tasks are given along with
teacher factors required to employ them. A brief case study of the
collaboration of the authors, a researcher and a teacher, in the
development and implementation of tasks addressing Riemann integration
is presented.
Keywords: Tasks, Technology, Epistemic value, Pedagogy, Teachers
Background
Many educators promote digital technology as having a role to play in
helping students to develop mathematical thinking. However, some of the key
affordances arising from technology use emanate from the tasks we use with it. In
turn the implementation of these tasks depends in large measure on the knowledge
and orientations (Schoenfeld, 2010) of the teacher. Thus while engagement with
digital technologies may change or challenge traditional student learning trajectories
(Anthony & Walshaw, 2007), it can, and will, also challenge teaching trajectories.
Hence, one of the central issues in the use of technology
13
is the design and
implementation of tasks that will encourage the learning and understanding of
mathematics, and in particular mathematical thinking (ibid). To design these tasks we
have to consider how this mathematical thinking is mediated by the tasks that are
employed with the technology. In this paper we address the design aspects of such
tasks from a theoretical standpoint, present a brief case study and then discuss some
implications for teachers.
We take a relatively broad view of the idea of a task and take it to mean an
activity that students are asked to attempt (or choose to) in a mathematics lesson (and
possibly complete at another time). It may be short, as in solving a single linear
algebraic equation, or long, such as a structured or semi-structured investigation of
the graphical properties of polynomial functions of degree one and two. Solving the
tasks they are given will require certain techniques from students, which depend on
the task and, in the words of Artigue (2002), may go beyond routine actions to include
a complex combination of reasoning and routine work. To generate a wide range of

13
The term technology should be read as meaning digital technology throughout this paper. Theme A - M. O. J. Thomas & C. Lin
110
such techniques tasks need to take students beyond the 'routine', placing the task at
centre stage. These classroom tasks will require students to exhibit techniques that
have either epistemic or pragmatic value (Artigue, 2002). In the former the focus is
on the production of knowledge of the mathematical object under study, whereas in
the latter the techniques are perceived and evaluated in terms of their productive
potential. Techniques with pragmatic value alone include what are often termed
procedural tasks. In a technological classroom setting Thomas (2009a, p. 152)
suggests that procedural tasks such as:
1. Solve
3 2 0
2. Draw the graph of

1
2
3. Differentiate
3
9
4. Find
3 2

have little or no epistemic value, since solving these with 'black box'
technology use does not assist students to focus on, or understand, the constructs of
mathematics.
Other tasks that do have well known by-hand techniques can quickly assume
the character of procedural tasks when technology is used. One example of this is
when a well-known by-hand scheme is transferred to a technological tool, with a
subsequent change of technique. Using the scheme for finding the inverse of a
function given as y = f(x) that makes x the subject of the formula and then replaces x
with y can be partly executed on a CAS instrument using the technique of solving the
equation for x. Figure 1 shows two examples of how students given the task of finding
the inverse function by hand have integrated the use of CAS into this scheme,
employing a direct command to perform the first step of making x the subject of the
equation. The use of the CAS is indicated by the ♦ symbol, as requested. We note
that in each case the student writes down precisely the form given by the CAS, and
the first student (top) has also written down the details of each step of the scheme.
Neither student has used the technique of entering the function and simply using the
CAS to provide the inverse function, but instead have integrated it into their by-hand
method.
Figure 1. Integration of CAS in the task:
Given f(x) =
6x+ 1
2x− 3
is invertible (x≠1.5), find f
−1
(x).
What should be considered when constructing tasks employing technology
that have epistemic value? Based on a consideration of the benefits of a TaskTechnique-Theory (TTT) approach (derived from the anthropological theory of Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22
didactics of Chevallard), Kieran and Drijvers (2006) suggest a number of features of a
task with epistemic value.

(left) and bx (right) to both sides of an
equation.
Another example of a task that exemplifies using technology to engage
students with a mathematical concept in the manner described above is presented in
Heid, Thomas and Zbiek (2012, in press). This requires a consideration of a linear
ng for the algebraic form a function f would take when its graph is
k, for some real k. Assuming that students do not know a
procedure for writing this down, and may not even have a mental scheme for a
suitable technique, technology, such as a CAS calculator or computer program, can
help them solve the general problem inductively through specific examples. This may
start with reflecting the graph of, say, y = x
2
+ 3x in the line y = 2. The
an be used to draw the graphs, possibly linking the algebraic and graphical
representations in a dynamic way. In Figure 3 we see an example of how a slider is
used to vary the function (left) and then the value of k (right) and the program is set
lect the function. The first step shows that the points of intersection of
= 2 are invariant under reflection, and hence all lie on the line
and the second that all the points of intersection lie on the graph of the fun
value of the vertex is invariant under reflection in both cases.
The algebra view of GeoGebra also gives access to the algebraic form of the reflected
function. It is hoped that students may develop a technique for the ref
ating the graph vertically by -k, then reflecting in the
hen translating vertically by +k. This means linking translation
s across representations, relating graphs to algebraic forms f(x
Figure 3. Dynamic reflection of graphs in the line x = k using GeoGebra.
Of course a key feature of the task is the encouragement to generalise
algebraically for any function and the line y = k. Since g(x) is a reflection of

right-hand sum (Accuracy Difference) as the number of rectangles increases?; As we
increase the number of rectangles drawn between t = 0 to t = 10 hours, what did you
notice about the relationship between the rectangles and the area under the curve?
How does this feature relate to the accuracy of the area approximation?; and Can you
think about other methods to approximate the area to produce a better estimate? A
method using trapeziums followed. This prepared students for presentation of an
algebraic generalisation of the limit of Riemann sums.
Overall the mean improvement of the class based on tests before and after the
teaching was significantly better than that of a second group of students who covered
the same ground but did not do the computer tasks ($t = -2.9095$, $p < 0.01$), and the
students had an improved understanding of Riemann sums and numerical methods
graphically, although they were less able to carry out the method numerically. The
teacher talked to six of the 23 students in the class and when asked how the program
had influenced their understanding. All six commented that they liked the dynamic
graphics view of GeoGebra and that the visual aspect of the software really helped
them learn and understand the integration topic better. Two of their comments were:
Student 1: I think the visual display and the dynamic image of the program
help my understanding of seeing where the formula is derived from. By looking at
the different shapes…I understand better how we found the area using different
shapes and how it is related to the definite integral.
Student 2: I really like it [GeoGebra] when we were learning about the area
approximation using rectangle and also trapezium. I can see it on the graphics
view instantly that the approximation is better when you started changing the
number of rectangles or trapeziums…it is easier for me to understand because it is
not just graphical, it is also instant.
It appears from their comments that the task using GeoGebra particularly
helped these students understand better how the concept of integration can be seen to
begin with area approximations that improve if we increase the numbers of rectangles
or trapeziums, matching more closely the actual area under the graph. This idea can
be difficult to illustrate and explain without the aid of such technology. With regard to
the way their overall understanding from the module of work improved they said:
Student 2: I think my knowledge of the relationship between integration and
area has changed. It [GeoGebra] probably enhances my knowledge of area and
improves it. I mean before I see integration just as a technique or a formula
opposite to differentiation. But now…I understand more why we use integration
for area.
Student 3: Before I think integration just a formula that is opposite to
differentiation. But now I know more why you do integration, like it is for finding
out the area. Basically I see more connection between differentiation and
integration now.
Student 4: At Year 12, I just think integration as a simple algebra algorithm.
Now after you taught us the topic with the computer program, I think I have
learned more about integration such as how it relates to the area. I understand it
better graphically now.
The teacher enjoyed using the approach developed in her lessons, was
confident in doing so, and has continued to use it since. Her growing PTK is partly
evidenced in her comment that: "Teachers need to use GeoGebra…for investigative
activities in order to increase the interactions between students and the software. More
importantly, teachers need to pose interesting and meaningful problems [tasks] so that
students can be actively engaged, and try to answer questions and re-formulate
concepts in their own terms…an ideal way of using GeoGebra is where students
investigate mathematical ideas with the software by making conjectures and testing Theme A - M. O. J. Thomas & C. Lin
116
them out." She also comments that although the experience of writing the tasks with
GeoGebra was initially not easy, it improved her understanding of Riemann integral
since she needed to understand the concept thoroughly before she could use all the
program functions available in GeoGebra to achieve what we wanted to show the
students. Overall she felt "It was a very good experience for me collaborating with
[the researcher] trying to write tasks that can improve students' understanding."
In this paper we have taken a theoretical stance to making suggestions on the
kind of features that tasks incorporating technology use might need in order to have
epistemic value. These have been exemplified with several tasks that have their basis
in the research of the first author. We suggest that the development of tasks like these
is not a trivial matter for classroom mathematics teachers and have described how a
teacher-researcher collaborative effort is one possible way to assist teachers to build
the PTK they need to become confident task designers.

Designing mathematical modelling tasks in a technology rich

secondary school context
Vince Geiger
Australian Catholic University
Trevor Redmond
A. B. Paterson College
The potential of digital tools to enhance student learning is well researched, however, the potential of technology to promote students' engagement with mathematical modelling tasks has received limited consideration. This paper draws on a research study that aimed to investigate the possibilities that exist for student learning when teachers from six secondary schools designed tasks that anticipated for the use of digital tools within mathematical modelling tasks. The paper describes and analyses the collaboration which took place in identifying principles of design for such tasks.
Keywords: Mathematical modelling and Applications; Digital tools; Technology
Introduction
While there are strong research traditions in the fields of mathematical modelling and applications and the use of digital tools in mathematics classrooms, few studies have explored the potential of the nexus which exists between these two powerful approaches to thinking (Geiger, Faragher and Goos, 2010). Mathematical modelling is often described as a process involving the formulation of a mathematical representation of a real world situation and then using mathematics to derive results, interpret the results in terms of the given situation and if necessary, revising the model. The purpose of models is to interpret real world situations and/or make predictions about the future or past states of modelled systems (English, Fox, & Watters, 2005).
There is now a large corpus of literature devoted to the way in which digital tools can enhance teaching and learning opportunities in mathematics classrooms. Studies, however, have tended to report on advantages to instruction in mathematical thinking and learning within content specific domains such as number (e.g., Kieran & Guzma

n, 2005), geometry (e.g., Laborde, Kynigos, Hollebrands & Straesser, 2006), algebra and calculus (e.g., Ferrara, Pratt & Robutta, 2006) or social aspects of classroom practice such as collaborative investigative practice (e.g., Beatty & Geiger, 2010). Thus, there is little research on how digital tools can be used in tandem with mathematical knowledge to work on problems that exist in the real world, as

While such innovations [ICTs] have been useful in enhancing understandings of school mathematics, less is known about the transfer of such knowledge, skills and dispositions to the world beyond schools. Given the high tech world that students will enter once they leave schools, there needs to be recognition of the new demands of these changed workplaces. (p. 99)
Given this identified need for students to be provided opportunity to use digital tools when working on real world problems consideration needs to be given to the nature of the learning experiences, and the tasks at the centre of these experiences, students should encounter within school mathematics classes. The aim of this paper is to explore an approach to the design and implementation of tasks which focus on the a mathematical modelling approach to teaching and learning that is supported by digital tools. In doing so, the paper will address Theme A, Tools and Representations, through the following research question.
What are the principles of design for technology rich modelling and applications tasks that result in effective learning experiences for students?
Artefacts as mediators of mathematical learning
In developing principles of design for technology integrated modelling and applications tasks the role of artefacts, in this case the task and the digital tool(s), must be examined. Verillon and Rabardel's (1995) iconic work on the distinction between an artefact and an instrument provides insight into the role of artefacts in mediating learning by distinguishing between an artefact, which includes both physical and sign tools that have no intrinsic meaning of their own, and an instrument in which an artefact is used in a meaningful way to work on a specific task. Different tasks make different demands on the user and their relationship with the artefact. The development of this relationship, and thus how the artefact is used, is known as instrumental genesis. Instrumental genesis is a complex process in which, firstly, the potentialities of the artefact for performing a specific task are recognised which transforms the artefact into an instrument (instrumentalisation), and, secondly, there is a process that takes place within the user in order to use the instrument for a particular task (instrumentation) (Artigue, 2002). Instrumentation generates schemas of instrumented action that are either original creations by individuals or pre-existing entities that are appropriated from others. An instrument, therefore, consists of the artefact and the user's associated schemas of instrumented action. The process of instrumental genesis is also dynamic between the instrument and the user as the constraints and affordances of the artefact shape the user's conceptual development while at the same time the user's perception of the possibilities of the artefact during instrumentation can lead to the use of the artefact in ways that were not originally intended by the designers of a tool (Drijvers & Gravemeijer, 2005).
Instrumental genesis has been used to explain how digital tools are transformed into instruments for learning through interaction with teachers and students (e.g., Artigue, 2002). A teacher's activity in promoting a student's instrumental genesis is known as instrumental orchestration (Trouche, 2005). This process recognises the social aspects of learning as it allows for the sharing of schemas as of instrumented action that individuals have developed within a small group or whole class. A teacher can facilitate the appropriation of these schemas by other students by making the nature of these schemas explicit by orchestration classroom interaction around the schemas through careful and selective questioning
More recently, others have attempted to extend our understanding of an instrumental approach to the role of artefacts in mediating learning by recognising Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

that the genesis of an artefact into an instrument takes place within highly interactive environments, such as school staff rooms or mathematics classrooms, where a number of artefacts are used simultaneously. Gueudet and Trouche (2009) extend the definition of artefact by introducing the term resources to encompass any artefact with the potential to promote semiotic mediation in the process of learning. Resources include entities such as computer applications, student worksheets or discussions with a colleague. A resource is appropriated and reshaped by a teacher, in a way that reflects their professional experience in relation to the use of resources, to form a schema of utilisation - a process parallel to the creation of a schema of instrumented action within instrumental genesis. The combination of the resource and the schema of utilisation is called a document. The process of documental genesis is an ongoing one as utilisation schemas will be reshaped as a teacher gains more experience through the use of a resource.
A modelling task oriented research project
Six teachers were recruited from six secondary schools; three from each of two different Australian states. Schools were drawn from across different schools systems (government and non-government) and were representative of a range of socio-economic characteristics. Teachers were invited into the project because of their reputations as highly effective teachers with particular skills in the use of digital tools in mathematics learning and their commitment to improving the learning outcomes of their students. The project was managed by two university based researchers - one in each state. The researchers were primarily responsible for the: conceptual development of the project; classroom data collection including lesson observations, teacher and student interviews, and collection of student samples. Teachers were primarily responsible for the development and implementation of technology demanding mathematical modelling tasks. Researchers played a vital role in providing feedback about the effectiveness of tasks trialled in teachers' classrooms. Together teachers and researchers developed principles of design for effective tasks based on their shared experiences while trialling tasks in mathematics classrooms.
This paper reports, specifically, on the work of one teacher and on his students in a Year 11 (15-16 years of age) mathematics class. The curriculum context in which he taught mandated the teaching, learning and assessment of mathematical modelling as a key objective of a state-wide syllabus (educational authorities are state based in Australia). The use of technology in mathematics teaching and learning was also prescribed in the Mathematics B program (incorporating the study of functions, calculus and statistics) in which his students were enrolled. Students had almost unrestricted access to digital technologies including: powerful handheld digital devices with mathematical facilities such as data and function plotters and Computer Algebra Systems; computers with mathematically enabled applications; the internet; and electronic white boards.
The research design consisted of three components: (1) two whole day teacher professional learning meetings which took place at the beginning and middle of the project; (2) three classroom observations for each teacher; and (3) a focus group interview near the end of the project that involved all teachers. The detail and purpose of each of these activities is outlined in Table 1. Further detail on the research methodology can be found in (Geiger, Faragher and Goos, 2010). Theme A – V. Geiger & T. Redmond

Time Activity
Sept-Dec
Year 1
Teacher workshops in each state: research team outline the aims of the project; offer prototype tasks; discussion of principles which underlie prototype tasks.
Jan-April
Year 2
Lesson observations ; teacher and student interviews; collection of student work samples; feedback on effectiveness of trialed tasks in relation to modeling and the use of digital tools.
April-June
Year 2
Lesson observations; teacher and student interviews; collection of student work samples; feedback on effectiveness of trialed tasks in relation to modeling and the use of digital tools.
July
Year 2
Teacher workshops in each state: teachers share exemplars of digital tool and modelling tasks; discussion on principles which underlie teacher developed tasks; research team offer accounts of practice from classroom observations.
Aug-Sept
Year 2
Lesson observations; teacher and student interviews; collection of student work samples; feedback on effectiveness of trialed tasks in relation to modeling and the use of digital tools.
Oct-Dec
Year 2
Final project meeting and focus group interview in each state; teachers share exemplars of modelling and digital tool tasks; further discussion on principles which underlie teacher developed tasks.
Table 1: Research design
Principles of task design in technology demanding modelling tasks
The teacher (the co-author of this paper) who is the focus of this paper, proved to be an effective designer of technology demanding modelling tasks while, at the same time, demonstrated keen insight into his own design processes and how these developed through the duration of the project. This teacher, in particular, contributed to the development of principles for designing modelling tasks. These principles and their descriptions are presented in Table 2. While these are useful insights they confirm rather than extend what is widely accepted as approaches to designing effective modelling tasks or general advice on good teaching practice.
Principles Description
Syllabus compliance The task must meet the requirements of the syllabus for content knowledge and the dimensions related to applications and technology.
Authenticity and relevance
Tasks must be set in an authentic or life-related context. The task must be of interest to the teacher and be of potential interest to the student.
Open-endedness The mathematics necessary to solve the problem set up in the task should not be immediately apparent. The task must be open-ended in nature providing for opportunity for multiple solution pathways.
Connectivity Ideally the task must make links to different content areas within the syllabus.
Accessibility The task must provide opportunity for students to link to their previous learning. There should be provision for multiple entry and exist points. The task should allow for the introduction of scaffolding prompts or hints.
Development The task must provide challenge and so encourage students to go beyond what they presently know and can do through the modelling process.
Students' engagement with the task should provide feedback to the teacher about the development of their understanding.
Table 2: Characteristics of effective modelling tasks
The teacher also provided valuable input into the role technology played in the design of modelling tasks, and indicated that digital tools served as an enabler of each of the identified principles. He provided comment on the role of digital tools in

The use of digital tools is a mandatory element of the state-wide senior secondary mathematics syllabuses. Genuinely authentic problems are mathematically complex. The representational capabilities of digital tools allow students to accommodate this complexity and thus provide access to authentic problems that otherwise might be considered beyond the scope of their capabilities.
If we didn't have the CAS calculators we couldn't do half the stuff that we do. From my perspective it is the integration of the whole lot together. We have a set of data and we try and build a model from that. We do a scatter plot and we make decisions about the model. We build a model and make some sorts of predictions. Digital tools also provide the means for students with gaps in their content

knowledge to access challenging problem scenarios.
Lower achievers may be struggling with differentiation or integration at that particular point in time…but they can still have access to the problem. My lower achieving kids can still engage in the problem and still make some meaningful contributions. If they don't get caught up in all that manipulation they can still be thoughtful about it.
The nature of authentic open-ended problems means there is no clear solution pathway and students need to evaluate options as they progress toward a solution. The teacher argued that digital tools offer facilities that are essential for exploring possible solution pathways. Technology also provides the means for connecting different types of mathematical knowledge, for example, data representations and functional relationships that modelled patterns in the data.
Selecting authentic, open tasks to model generally implies the students will need to make use of technology. Even if the teacher has scaffolded the task to facilitate access to the context, there is a requirement that the task be sufficiently open for there to be multi-representations of the solution and perhaps different solutions.
The authenticity and open-endedness of a problem is enhanced if students are required to collect data relevant to a problem from an original source; a capacity provided by digital tools in his classroom.
There is often a need to collect data and then to determine whether a relationship exists within that data. Students may need to collect primary data, through the use of probes, or from a video that is then analysed using the technology or use secondary data collected from a newspaper, magazine, web site or some other source.
Used effectively, digital tools provide immediate feedback to students about their initial attempts to build models and solve problems thus progressing students' understanding of the underlying mathematics at the core of the task and hence their mathematical development.
Technology has a significant role to play in the provision of feedback to the student in the first instance, about the models they have built and how well they fit the context being investigated. In mathematical modelling it is important to look for consensus between the mathematics and the context, hence, it is necessary to consider the validity of the conclusions in terms of the context.
Exemplar task and commentary
The principles for design of technology demanding modelling tasks are evident in the following description of a task developed and then implemented by the teacher in his Year 11 mathematics classroom – the Algal Bloom Problem outlined in the Figure 1. In developing this task, the teacher had expected his students to build a Theme A – V. Geiger & T. Redmond
124
mathematical model for these data by first creating a scatterplot using their CAS active calculator. A plot of this data suggests a piecewise function (one part linear and one part power function) would be appropriate. The teacher anticipated that students would then use the plot to determine the general form of the functions that would best fit the data and, in due course, develop an equation that would best fit the data. Students were then expected to use the model they had created to respond to the question at the end of the task and also to list any assumptions they made in developing their model and also comment on any limitations they believed were inherent in the repose they provided.
In observing the lesson in which this task was used, the researcher noticed that while every student was able to produce a plot of the data using their handhelds, few had drawn the conclusion that a piecewise function was necessary to model the data. Most students attempted to model the data using a single function, generally by trying to generate a model for the data using the digital handhelds regression model facility. When their single functions were plotted on their screens with the original data points it was obvious that their various functions were a poor fit. When students asked the teacher for assistance he simply encouraged them to have a closer look at their data and explore a wider range of possibilities for fitting a model to the data. After a period of time, two students, working together near the researcher, attempted to fit a piecewise function to the data, and after performing fine adjustments to each part of their function were happy with the result. Their success prompted a subdued celebration by the two students which attracted the teacher's attention. After discussing their conjectured model with the teacher students went on to complete the task. A short period of time after his discussion with these students, the teacher called for the attention of the class and asked them about their progress. The two students near the researcher volunteered and were asked to outline their attempt at the task. When they announced they had decided to make use of a piecewise function, sections of the class responded in different ways. A small number of students indicated agreement with the approach the pair of students were proposing even though the details of the functions other students had used differed. Most students, however, expressed exasperation that they had not noticed what was now an obvious feature of the plotted data. These students then returned to the task and were able to develop a piecewise function that fitted the data for themselves. A small minority of students needed more direct help from the teacher but were also able to develop a model based on a piecewise function by the end of the lesson. The lesson concluded when the teacher asked the students to work further on their assumptions and limitations for homework.
The CSIRO has been monitoring the rate at which Carbon Dioxide is produced in a section of the Darling River. Over a 20 day period they recorded the rate of CO2 production in the river. The averages of these measurements appear in the table below.
The CO2 concentration [CO2] of the water is of concern because an excessive difference between the [CO2] at night and the [CO2] used during the day through photosynthesis can result in algal blooms which then results in oxygen deprivation and death of the resulting animal population and sunlight deprivation leading to death of the plant life and the subsequent death of that section of the river.
From experience it is known that a difference of greater than 5% between the [CO2] of a water sample at night and the [CO2] during the day can signal an algal bloom is imminent.

Discussion and conclusion
This task satisfies each of the principles developed during the project for mathematical modelling tasks and for the use of digital tools within tasks. The use of modelling tasks and digital tools are consistent with mandatory requirements of the relevant state syllabus. As national scientific bodies monitor the blue-green algae in the various river systems because of the effect on aquatic wildlife this represents a task set in a near authentic life-related context. The task is open-ended in that a variety of mathematical models are plausible and the use of different models will lead to different, but still valid, responses to the problem. The available digital tools provided the facility to trial a range of functions to fit a complex underlying pattern and offered immediate feedback on the appropriateness of a conjectured function allowing students to develop specific solutions from a wide range of possibilities.
Different types of mathematics were necessary to explore the data (data representation, different forms of function) and so, students were expected to make connections to different types of mathematical knowledge. The available technology provided the option of viewing different types of mathematical representations (e.g., scatterplots and function graphs) on a screen at the same time, so enhancing the connecting between these types of mathematical knowledge. Students found the task to be accessible as it linked to mathematical knowledge they had studied in previous classes and the teacher made use of progress made by other students to provide a prompt when many were experiencing difficulty. The opportunity to trial a function against the data and receive immediate feedback provided an entry point to most students and so made the problem accessible. As the task required students to make use of mathematical knowledge they had already studied in previous lessons within an unfamiliar context it provided opportunity for students' development in mathematical knowledge and their capacity to apply this knowledge in real world contexts. Here, digital tools acted as a catalyst for this development by providing feedback which indicated students' first single function conjectures were not consistent with the data. As outlined above, there is an inseparable interplay between the task and digital tools. The teacher has created the task by drawing on principles for developing effective technology active modelling tasks. These principles are based on the Theme A – V. Geiger & T. Redmond
126
potentialities of both types of resource – the task and the digital tool. In implementing the task, the teacher anticipated how students would interpret the potentials of the task for learning and of the digital tool to act as a resource. The relationship between student, teacher, task and digital tool represents a documental genesis as each element within this genesis transforms the other in some way. The task is transformed, from the perspective of the students when they realise they need to make use of a piecewise rather than a single function in order to model the data presented in the problem. This transformation occurs as a result of an attempt by the students to use a single function and receiving feedback via the digital device that this was an inappropriate model.
The use of the digital tool changes from that of a device that provided a specific solution for students once they had made a decision on the general form of the function to model the data into a tool used to explore the data and eventually find a model that fitted the data to their level of satisfaction. Students' learning is also transformed during this same process as they realise the purpose of the task and the digital tool is not to algorithmically implement prior learning but to apply their knowledge and understanding in an original way. The teacher had to transform his approach to the lesson when students took a path he had not anticipated – attempting to fit a single function to the data. He changed his approach by orchestrating the resources at his disposal, in this case the two students who had eventually solved the problem, to provide an insight into the problem other students were yet to see.
At the same time, nearly all of the teacher's principles of design, the characteristics of effective modelling tasks, acted as enablers of the process of instrumental genesis of both digital tools and of the task. The principle of authenticity and relevance requires students to recognise the potential of the available digital tools to assist them in exploring and solving the problem described in the task from within both purely mathematical and real world contexts. There was a necessary duality about the schemas of instrumented action required to accommodate the purely mathematical and contextual demands of the task. Students needed to recognise that the real world context demanded the development of a piecewise rather than single function to model the inhalation and exhalation of CO2. This required a specific use of the digital tool that was different from the development of a single function to model the provided data. Having decided that two functions were needed to model the data, a specific instrumentation of the digital tool was needed to find the most appropriate functions for each section of the piecewise function. This second process takes place within a purely mathematical context.
The open-endedness of the task placed students in a position where they were challenged to make choices among multiple potential solution pathways. Thus, students were required to make choices among existing schemas of instrumented action or to generate new schemas. To generate new schemas students must firstly recognising the potential of the digital tool for meeting the challenge defined by the task and then, secondly, develop processes for the use of their digital tool that are specific to the set task.
The principle of connectivity designed into this task required students to generate schemas of instrumented action that were inclusive of different types of mathematical content. The CAS active calculator students used while working with the task included the capacity to link statistical plots with the graphs of specific functions, and these functions could be developed using the regression facility of the calculator. With these facilities available, students needed to find ways of taking advantage of the capabilities of their digital tool in engaging with the demands of the Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
127
task and pursuing a solution. This is a type of instrumental genesis in which the potential of an artefact is only realised through its instrumented action.
The task was designed to link the demands of the activity to students' previous learning as the separate functions required to build an appropriate piecewise function had been studied and applied to real world contexts in earlier classes. Thus, the task was created to be accessible to students but, at the same time, required students to apply this previous learning in a more complex context – one in which multiple functions were needed to model a phenomena rather than a single function. This meant that students' existing schemas of instrumented action required adaptation in order to accommodate a more complex scenario. The CAS enabled calculator was the tool the teacher believed would mediate this adaptation through the provision of a medium that provided for the representation of multiple functions against complex data.
The development aspect of the design is most apparent in the way the way the teacher invited the pair of students who had found that an appropriate solution required a piecewise function to offer their solution to the whole class and the subsequent realisation by most of the class that this was an insight they had missed.

This revelation changed both the ways in which these students used the available
digital tools and also the way they viewed the task. In this circumstance the teacher
orchestrated changes in students' schemas of instrumented action related to both the
digital tool and also the task
The episode included in this paper demonstrates it is possible to design for
effective technology demanding mathematical modelling tasks, and so the approach
offers direction for curriculum designers, teachers and teacher educators. While the
teacher had designed an engaging task based on principles developed during the
project, students took an approach that was not anticipated by their teacher. The
teacher, however, was able to take advantage of students' original but inappropriate
approaches, generating a dynamic learning environment where students' knowledge
of using mathematics within real world contexts was transformed. This raises a
challenge for teachers in how such triggers can be deliberately embedded in planned
learning experiences in a way that provides space for the type of documental genesis
described in this paper. This also indicates that further research is necessary to
investigate how to take advantage of unanticipated events in a well planned lesson
and in turn for how teacher educators provide advice about task design and
implementation in pre-service and in-service programs.

Optimizing through geometric reasoning supported by 3-D
models: Visual representations of change
Walter Whiteley
Department of Mathematics, York University
Ami Mamolo
Faculty of Education, York University
The representations, tools and task discussed were designed as a
response to a pedagogical challenge: How can rate of change be
investigated meaningfully at stages and ages below calculus? The task
involves 3-D models of volume and surface area, to represent and explore
differences in volume between pairs of open-topped boxes, as well as an
exploration of a 2-D representation with dynamic geometry software.
Reasoning during the task, with the affordances offered by the tools,
learners as young as 14 were able to decide when and why an optimum
volume was reached. Through the lens of conceptual blending, we discuss
what mathematical insight, activity, and understanding is available to
learners via engagement with our task. We further suggest that the
representation of change developed through this task extends as an
accessible spatial reasoning technique applicable in a range of other
problems in 2-D and 3-D.
Key words: task sequence design, optimization, visual spatial
reasoning, 3-D model exploration, dynamic geometry software
Background
In this paper, we report on research about the design of a tool and task
intended to develop concepts of change and rate of change with secondary students,
pre-service and in-service teachers. The mathematical focus of the task is on
geometric reasoning – developing the concept of rate of change through visual spatial
reasoning, without reliance on calculation or computation. We will illustrate how
different types of tools can afford different mathematical activities, representations,
and interactions between representations, as well as how specific tools – in our case 3-
D models supported by dynamic geometry software (Geometer's Sketchpad) – can
impact student learning and understanding of mathematics. Our understanding of
'task' in this case is in line with the definition offered by Theme A: a teacher
designed purposeful 'thing to do' using tools for students in order to activate an
interactive tool-based environment to produce mathematical experiences. This task,
developed by Whiteley and researched by Mamolo and Whiteley, offers a means to
address the following problem: Theme A - W Whiteley & A. Mamolo
130
The Popcorn Box Problem
Given a square sheet of material, cut equal squares from the corners and fold up
the sides to make an open-top box (see Appendix A). How large should the square
cut-outs be to make the box contain maximum volume?
A version of this optimization problem was initially developed by the
Ontario Association for Mathematics Education (OAME, 2005) for grade 9 and 12
students (ages 14 and 17), as an introduction to optimization prior to calculus,
primarily with numerical calculations to compare overall volumes of boxes. Our task
affords an avenue of richer investigation of this problem through visual and
kinesthetic reasoning prior to the development of algebraic/symbolic reasoning of
calculus. It includes the use of 3-D models (pictured in Appendix B) made from clear
plastic sheeting and pieces of coloured foam, as well as a dynamic geometry
exploration via Geometer's Sketchpad (sample screens of which are provided in
Appendix C and D). The original tool, task, and an associated novel representation
presented here were designed as a 'proof of concept' that deep, effective reasoning
with change, and rate of change, could be enabled for students prior to symbolic
manipulation and the algebraic techniques of calculus. This was part of the response
by one of the authors (Whiteley) to a challenge during recent curriculum writing in
Ontario: Can we being reasoning about 'change' down to earlier years, with minimal
algebraic load and a focus on big ideas? In addition, do these tasks support unpacking
of concepts of change and optimization by pre-service and in-service teachers?
In what follows, we outline the design principles and development of the
task, highlighting the mathematical epistemological goals and principles to the design,
as well as the pedagogical considerations and modifications which resulted from
implementing the task with diverse sets of learners. These considerations speak to
how different types of tools may afford different learning possibilities for learners –
providing them with different types of experiences and activity, as well as different
ways to represent ideas and concepts. We then go on to address how experience with
this task may impact learners' understanding of optimization and, more generally,
problem solving. We use as a lens of analysis the framework of conceptual blending
developed by Fauconnier and Turner (2002), and offer suggestions of different
possible blends afforded to different participant groups from secondary school pupils
to their teachers.
Design Principles and Task Development
The initial task was to visually/spatially reason about the optimum shape of
an open-topped box (see Whiteley & Mamolo, 2012 for details of the task), enriching
a simple investigation geared for pre-calculus students. This investigation required
developing a new tool of 'paired boxes with physically represented changes' (see
Appendix B). Working with this tool, with a variety of participants from in-service
teachers and curriculum writers, through pre-service teachers, senior high school
students and students just completing elementary school (14 year olds) pushed the
development of the task and associated tools and representations in multiple
directions. In this section we describe specifics of the task, how participants engaged
with the tools, and the emergent principles which informed the task design.
The 3-D models included manipulative tools of paired boxes, with inserts of
foam for volume lost and gained (see Appendix B). The tools were designed, and redesigned after testing, to encourage a visual spatial way of reasoning about rate of
change that could emerge naturally via their use. The task was designed to scaffold Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
131
from exploring changes in volume with physical models, into reasoning supported by
visual representations through the dynamic geometry software GSP (see Appendix C),
and finally to the important idea of how geometric features can identify non-optimal
objects (leaving the optimal objects as the only remaining choice!).
Testing the design
Given that there were analogous examples in both 2-D and 3-D, and that the
physical models were more difficult to make for the 3-D situation, in the initial pilot,
with a group of classroom teachers, we first presented the 2-D problem in a GSP
sketch. The problem involved optimizing the area of a rectangle along a fixed barrier,
given a fixed perimeter (the fence on the river) and participants worked in pairs on the
computer to solve this. Then a demonstration with the physical model (Appendix B)
was presented, during which attention was directed to the materials filling in
'between' the two boxes as physical representations of the change in volume (and not
the size of the particular individual volumes). The participants took turns examining
the models, taking the 'change in volume' pieces out and comparing them by
overlaying the pieces of foam, and concluding which volume was larger. The
response of these adults was that the 3-D model was more effective in directing their
attention to the change in volume, than the analogous 2-D model had been. As a
result, further models were constructed so that every pair of learners could explore a
pair of physical boxes for themselves.
All subsequent testing and teaching with the task has started with the 3-D
activity, and occurred with high school students (14 and 17 years old), pre-service
teachers, in-service teachers. The novelty of this setting invites more attention to the
physical representation of the change in volume, and less attention to efforts to
convert the problem to symbolic or numerical formulas. The focus on spatial
reasoning provoked discussions of important curricular ideas and the accessibility of
mathematical concepts when lifted from their symbolic representations. In addition,
the unusual appearance of the pairs of models focussed the participants' attention on
key built-in 'errors' to the first-approximation of the change in volume (such as the
visibly missing 'corner volumes', see Appendix B) and away from incidental defects
in the cutting and model construction. This particular feature of the tools (the missing
volume in the corners) triggered a discussion of the roles and implications of
estimation and refinement in a meaningful and concrete way. This discussion led to
the suggestion that the size of the difference in cuts could be reduced by using
different materials – e.g. using Bristol board in addition to foam allows exploration of
thin differences in cut-size (where the Bristol board illustrates instantaneous rates of
change, while the foam illustrates average rates of change).
A bonus of starting with the 3-D tools was that participants made an initial
guess about the optimal shape (the echo of folklore that "the cube has the maximum
volume for a given surface…"). This was quickly found to be incorrect, just through
participants' own viewing of a pair of models. We found during these testing stages
that participants approached the task with the sense that there was a puzzle to be
sorted out that they 'owned', and were now motivated to understand why and what
the maximum might be. In addition, we found that younger students who are less
channelled into 2-D situations, brought stronger memories and naïve intuitions about
3-D settings, were less distracted by one-variable algebra (or any algebra), and posed
novel questions for exploration. As a result they were more willing to engage in the Theme A - W Whiteley & A. Mamolo
132
'play' that got them started along a trajectory reasoning with the affordances built into
the models.
Mathematical ideas represented in the task
Via engagement with the task and models, several mathematical ideas and
observations emerge in a manner accessible to learners of various ages and
mathematical sophistication. Here we identify a few key ones:
i.Volume and surface area can be physically represented.
ii.Change in volume is equal to surface area for the gains minus the surface
area for the loss, and these changes in volume (loss and gain) between
pairs can be compared qualitatively by naïve overlay strategies (see
Appendix B).
iii.Reasoning about 'change of volume' shifts to comparing surface areas and
recording the loss and the gain – with a visual focus, not with numerical
calculation.
iv.If the surface area of the loss from one box does not equal the surface area of
the gain of the other box – i.e. the pieces of foam do not overlap
completely – then the volume of the smaller box is clearly not the
optimum (i.e. we have a non-zero average rate of change).
v.Equivalently, the optimum occurs at the shape when the Bristol board

representing 'volume lost' completely covers the Bristol board
representing 'volume gained' (i.e. we have a zero instantaneous rate of
change) - which occurs by creating a box with a "corner cut" of 1/6 of
the way along an edge (or 1/3 of the way to the centre).
vi.Errors are reduced, and then vanish, as the size of the changes in the cut
corners is reduced (a hands-on way of passing to the limit and
representing this limiting value).
vii.The invariance of the optimal shape under scaling (proportional reasoning)
for the optimum is immediate to people working with this tool.
viii.Geometric optimization of other shapes can be explored by the 'geometric
loss-gain' variational paradigm.
ix.For students taking calculus, these steps in the task can then be connected to
algebraic reasoning, including a model-based introduction to the basic
conceptual layers of differential calculus (e.g. average change or secants
(thick foam); small differences as limits (Bristol board); optimal volume
as rate of change equal to zero).
x.For pre- or in-service teachers, this exploration supports unpacking of the
process steps and the big ideas of optimization with differential calculus.
Extending the Task
To the designer, and to the teacher, other questions for investigation arise.
Here are some that we have explored with at least some of the groups of participants:
a.Is there a 2-D analogue? Yes: a 2-D variant starts with a fixed perimeter
seeking maximum area, e.g. the "fence on the river" problem where three
sides of a rectangle must be fenced to produce a maximum area, or
variants;
b. A 3-D qualitative variation: Does the volume get bigger if we tilt the
sides of the box out (as is done in theatres)? Yes: initially the volume Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
133
increases – explored by a cross-sectional comparison, supported by
dynamic geometry software (see Appendix D);
c.What if we cut corners from a triangle, or a hexagon or…? (There is a
delightful general principle: if the edges of the paper are all tangent to an
in-circle – cut 1/3 of the way to the centre!);
d. If prompted, a deeper puzzle arises within the more common 2-D variant
with all four sides included: Why would the plane shape giving
maximum area when constrained by a fixed perimeter (a square) also be
the shape with a minimum perimeter when constrained to a fixed area?
Interestingly, people anticipate this duality will work ("it sounds right!")
- but the supportive reasoning, linked to a fundamental duality principle
in operations research, requires further shift in representation to points
on an area/perimeter graph, accessible only to the most adept problem
solvers.
We are reminded that problems become 'similar' in the mind of the problem
solver when the representation, or more generally, the reasoning, is transferred. One
key to transferring this geometric 'change in pairs' or 'geometric loss-gain' reasoning
is to provide other problems where it can be applied either quantitatively, or
qualitatively. The above list provides some starting points for exploring this transfer.
In the remainder of the paper, we turn our attention to how engagement with
our task can impact student learning and understanding of mathematics. For our
analysis, we use the framework of conceptual blending (Fauconnier & Turner, 2002),
and offer different possible blends that emerged from participants' engagement with
the task. The blends afforded differ based on learners' mathematical background and
sophistication, along with their own learning goals. We highlight some of the
important blends available for a variety of learners.
Conceptual Blending: A Framework for Analysis
Conceptual blending (Fauconnier & Turner, 1998, 2002) is a theory which
describes how new inferences can arise when two representations and associated ways
of reasoning (or 'input spaces') are brought together in a 'blended concept'. The
"blend" can be thought of as a mapping which combines certain features of the two
input spaces and projects them onto a third (newly formed) mental space. (In the
blend, other features are not mapped, shifting the focus and reducing the cognitive
load for further reasoning.) Blending processes are used to conceptualize actual things
such as computer viruses, fictional things such as talking animals, and impossible
things. Although blends may sometimes be bizarre, "the inferences generated inside
them are often useful and [can] lead to productive changes in the conceptualizer's
knowledge base" (Couson & Oakley, 2005, p.1513). Blending is not a metaphorical
or analogical map, but rather it is a specific way to combine and infer from and about
information from two or more mental spaces (Fauconnier & Turner, 2002). The
partial representations from an individual's perceptions and concepts that are
contained in the prior mental spaces blend by "the establishment and exploitation of
mappings, the activation of background knowledge, and frequently involve the use of
mental imagery and mental simulation" (Couson & Oakley, 2005, p.1513).
The emergent blended space arises in three ways: "through composition of
projections from the inputs, through completion based on independently recruited
frames and scenarios, and through elaboration" (Fauconnier & Turner, 2002, p. 48,
emphasis in original). Specifically, composition creates new relations not previously Theme A - W Whiteley & A. Mamolo
134
existent in the separate input spaces, while completion allows the composite structure
in the blended space to be thought of as part of a larger structure in the blend, and
elaboration, or "running the blend" consists of cognitive work performed within the
blend to exploit and elaborate upon the composite structure (Fauconnier, 1997, p.150-
1). The blend continues to offer the individual ways to access each of the original
representations, in a flexible manner. For instance, in our case, the three input spaces,
are (i) the word problem of maximum measured volume, (ii) the classical approach to
optimization through calculus and rate of change (often held as a symbolic procedure
with formulas), and (iii) the spatial reasoning (i.e. the variational exploration of
change in volume represented physically with pieces of foam, and then Bristol board
see Appendix B). Such a blend would allow an individual to:
i.compose - to explore change physically by starting with a pair of
representative examples (e.g. boxes) and focus primarily on the change
in volumes (ΔV for the secant in symbols);
ii.compose - to conceptualize change in volume physically by considering
surface area for loss and gain (ΔV in symbols, pieces of foam in the
model);
iii.complete - to focus on the sign of the change, with a simple physical
comparison via foam inserts, to determine which changes will make the
volume larger;
iv.complete - to consider sources of error – and minimize them (an informal
invitation to a limit process, which is natural in the physical model);
v.elaborate - to consider what boxes cannot be the optimum and why (rate of
change is not zero in both the models and the symbols);
vi.elaborate and combine - to eliminate the boxes with non-zero rates of
changes and determine the single box shape which remains as the
optimum (in both the model and the symbols).
We note that a blend is both an internal cognitive process and a cultural
artefact. Once achieved by someone and shared – this new blend becomes a possible
cognitive approach requiring less cognitive load for others who have the appropriate
parts to develop their own internal blend. Our task provides support for such
transmission because the tools are external and the task focuses attention on key
features listed above. The use of an external representation further supports shared
conversations about the blended concept, the process and the reasoning.
The original background to such model-based visual reasoning was scattered
reflections by Whiteley which evolved over several decades of classroom teaching
practice, observing patterns of deep, but often hidden, connections between: perimeter
and area; and between surface area and change in volume, trying to anticipate why at
answer would be what the symbolic computations produced. The goal was to have
both a symbolic answer and a visually sensible answer that matched! Implicitly – the
key blend was being developed and repeatedly explored in pedagogical contexts.
However, that form of reasoning was not part of shared experiences or curricular
practices, and therefore was not accessible, or even communicable, without the
external support provided by our task. The physical models as tools and
representations provided an essential support for communicating, for refining the
representation, for reasoning, and then for embedding this one clear example into a
widening mix of problems and solutions that fit with the new representation, and the
larger conceptual blend. Whiteley (2011) provides a more extensive discussion of
how the framework of blending gives insight into this modelling and model building
process, illustrated with the task presented here. We turn our attention now toward Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
135
different blends created by prospective and practicing teachers, university students,
and secondary school students.
Emergent blends from engagement with the popcorn box task
The representation of change and optimization in the model(s) is 'sensible'
to a wide variety of problem solvers. The key steps with the model are similar for a
very wide variety of users. The conceptual blends and the context, however, are very
different:
a.For practicing teachers, we interpret both a completion and composition of
a blend. Specifically, the task allows an opportunity to un-pack the basic
processes of calculus and optimization in an unusual context, supporting
careful reflection on the steps (completion), and an alternative visual
way to reason through the problems (composition). The teachers create
a new blend between a well-grasped symbolic sense of the processes of
calculus, and a novel spatial sense of optimizing in geometric problems.
The 'aha' moment when the 'loss-gain' representation is also found in
the symbolic derivative set to zero is exciting to witness.
b. For prospective teachers, a similar situation arises. The task is also an
opportunity to un-pack the concepts of calculus, and invites reflection to
develop a more flexible and "thicker" conceptual basis for the study of
change and optimization (completing a blend). Individuals are creating
(composing) a new blend between a sometimes fragile symbolic sense of
the processes of calculus, and a novel spatial sense of optimizing and
checking optima in geometric problems, which will strengthen both
(elaboration).
c.Alternatively, for practicing and prospective teachers, the geometric
paradigm available through our task can be blended with the prior
formula-based procedural calculus knowledge, to re-infuse it with sense
and visual estimation that grounds the algebraic solutions to geometric
optimization (elaboration and completion).
d. For senior secondary students or university students starting calculus, or
doing an initial review, the task affords a blend where key processes are
experienced twice, in two representations, supporting an initial
development of both procedural steps and conceptual reasoning.
Students are creating an "immediate" balanced blend which supports
flexible approaches to solving problems (composition and completion).
e.For younger secondary students, even down to age 14, this task provides
an accessible tool to solve problems they had heard about but had not
been able to approach (e.g. why does a square have the maximum
volume for a fixed perimeter?). The task affords a reasoning power, and
a representation, which solves optimization problems and lays an initial
foundation for a later mature blend with the second symbolic / algebraic
approach, with sufficient parallels in the reasoning to make the calculus
'make sense' (composition).
Concluding Remarks
The task and task design are intimately linked to a novel visual
representation of loss-gain in geometric optimization, and to reasoning processes that
provide an alternative to symbolic manipulations – an alternative accessible to young Theme A - W Whiteley & A. Mamolo
136
students. The task and activity emergent from the task can be analysed via the lens of
conceptual blending, which can inform the teacher/researcher about both the
conceptual development of his/her students as well as the possibilities or deficiencies
of the tools and models. The task also offers a context in which the actions and
expressed reflections of students/research participants can give insight into spatial
reasoning, and the possibility of new rich blends, given initial procedural symbolic
ways of solving problems. The task was carried out in pairs (and then debriefed in
larger groups), which encouraged development of shared blends, and allowed the
researchers to observe more of the student activity and reasoning. There are many
questions that arise when observing how participants act (and fail to act) with the
materials, which can lead to an enriched understanding of what mathematical
experiences are necessary for the learner.
The tool representing loss and gain, the associated visual representation of
volume changes and the associated task provided a way "to change what we see"
(Hoffman 1998) and "how" we see. With the directed "seeing" flowing from the
affordances in the task, such as the "missing corners", the colour coded pieces of
foam, and the clear plastic sheeting. This change in "seeing" / change in "thinking"
would otherwise not have been accessible to, or at least noticed by, most participants.
With practice, the problem solver internalizes the representations, and can reason
"spatially" in the mind – imaging and imagining situations, and changes, which carry
on the reasoning internally. In the language of Fauconnier and Turner (1998, 2002),
the task affords an opportunity for composing a blend from a physical input space –
the models – and a mental input space – the procedural knowledge of calculus – to
create a newly formed understanding of optimization. This may allow completion or
elaboration of a blend for individuals well-versed in calculus, such as prospective and
practicing teachers. In the blended space, each "visual step" in the task has an
algebraic representation, and each key step in algebraic reasoning has visual support
to confirm that the "solution makes sense". In our view, variants of this intended
blend support a flexible problem solving cycle.

second one. These graphic ostensives evoke or even "say", the geometrical properties
used to build the perpendicular bisector of the segment. In the left-hand drawing, the
pupil has traced the perpendicular with the segment passing by his midpoint, whereas
in the right-hand drawing, the second pupil has built the whole points equidistant
from the ends of the segment.
These graphic ostensives do not evoke only the geometrical properties that
they incarnate but also others ostensives, materials now: graduated ruler and set
square in one case, ruler (not graduated) and compass in the other case. Resorting to
the ostensives is thus controlled by objects that have no materiality, no perceptibility,
but that are only evoked by the ostensives. In return, depending on the
characterization of the perpendicular bisector used by the pupil, he uses different
geometrical tools and draws lines and signs characteristic of the properties used. The
ostensives embody and reveal the property of the perpendicular bisector underlying
the geometrical construction. Thus, the concept of ostensive is linked in a
consubstantial way to the concept of non-ostensive - notion, concept, idea - which
cannot be handled but only evoked through the associated ostensives. As Chevallard
(1994) emphasized, every implementation of a technique assumes the resort to two
kinds of objects: ostensives and non-ostensives.
We can see through this small example how the tools used to perform a task,
but also the way they are used, lead to a different mathematical activity. Therefore,
the didactical knowledge on the relationship between ostensive and non-ostensive
objects is essential for the teacher when he designs a mathematical activity. In this
example, if a teacher wants the pupils to use a geometrical property instead of
another, he privileges some tools rather than others. Thus, the first stage for
understanding and analysing the task-design, teaching, learning triad is to reveal
ostensives and non-ostensives in each technique used to perform a task. The notion of
ostensive was introduced in Anthropological Theory of the Didactic, (Chevallard
1994, Bosch 1995, Bosch & Chevallard 1999) to describe and analyse the
mathematical activity. A very broad definition is: "One calls ostensives, the objects
which have for us a material form, sensitive, notwithstanding unspecified"
(Chevallard, 1994, p.4, our translation). Therefore, any object which can be handled
concretely by the body, the voice, the vision is an ostensive: material object, gesture,
language, diagram, drawing, graphics, formalism, etc. Then non-ostensives are the
objects which "cannot, strictly speaking, be handled: they can only be evoked,
through the handling of ostensives associated." (Chevallard, 1994, p. 5, our
translation). Thus for example, the concept of quantity related to a thumb, an index
and a major raised is a non-ostensive that is not accessible by perception apart from
its representation by an ostensive like the fingers which were raised, the figure "3",
the word "three", or a drawing like "". Consequently any work of conceptualization
seems the fruit of a work on ostensives which gives access to non-ostensives. The
analysis and the design of a task to teach and learn mathematics go through the
identification of everything that makes signals and "speaks" in the situations, i.e. the
whole ostensives and associated non-ostensives.
The aim of this text is to present how in ATD the artefacts are analysed in
their two dimensions of tool to act and tool to think within task design for the
teaching and learning of mathematics. In the first section we come back on the
concepts of ostensive and non-ostensive as element for describing the mathematical
activity from ATD point of view. In the second section, we clarify the concepts of
instrumental value and semiotic value of ostensive starting from an example; these are
essential concepts for the design and the analysis of mathematical activity. In the third Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
143
section we show how an ostensive can stop being a tool for taking an action because
the non-ostensive that it evokes is not operational and does not make sense any more.
Then, in the fourth section we show how the *choice* of an ostensive for designing a
task is based on a dialectical play between the instrumental and semiotic values.
Lastly, we will show how the notion of praxeology, developed in ATD, can be a
useful tool to understand the relationship between ostensives and non-ostensives
evoked in a mathematical activity.
1. Ostensives, institution and praxeologies
Let us consider now the following problem
15
: if 8 lollipops cost 10 €, how
much are 3 lollipops? Until the middle of the 20th century in France, the expected
answer was based on the theory of the ratios and proportions: "8 is to 10 as 3 is to x".
It results symbolically in writing the proportion "8: 10:: 3: x" and is calculated by
using the fact that the product of the extremes terms is equal to the product of the
middle terms: 8 × x = 10 × 3 thus x = 10 × 3/8 = 3.75. In the 1970's, the reform "of
modern mathematics" has modified the curriculum. Then, the modelling of the
situations of proportionality by a linear function is expected: if f(8) = 10, then f(3) =
f(3/8 × 8) = 3/8 × f(8) = 3/8 ×10 = 3.75. In the 1990's, such problems are solved with
"the cross-product" starting with writing the values in a "table of proportionality" (see
figure 2): x = (10 × 3)/8 = 30/8 = 3.75.
Number of lollipops 8 3
Price of lollipops (€) 10 x
Figure 2 – Table of proportionality
Nowadays, at the primary school the pupil must use the "rule of three" which
uses the return to the unity: if 8 lollipops cost 10 €, then 1 lollipop costs 10 €/8 =
1.25 €. The price of 3 lollipops thus equals 3 × 1.25 € = 3.75 €.
Thus, the techniques used to solve a task and the discourses that justify them
depend on the institutions within which they are used. However the institutions
generate practices and discourses on the practices that are specific because, as
Radford (2002) underlines, the artefacts/ostensives contain within themselves the
culture of the institution that produces them but also the culture of the institution that
resorts to them.These are the two founder points of the Anthropological Theory of the
Didactic. The model of the mathematical activity can be built in terms of praxeologies
within institutions, like any other human activity. The personal relationship with an
ostensive is regulated by the institutional relationship with this ostensive, inside the

institution where it has been activated. In ATD, a praxeology is structured into two components. The praxis component contains techniques to achieve a kind of tasks. The logos component includes the theoretical discourses, called technology, that describe, explain, justify or develop the techniques used, and the justification of technology, called theory. Thus, the mathematical activity is carried out through the handling of ostensives whose instrumental value is perceived through the praxis component whereas the semiotic value nourishes the logos component of praxeologies.

15
We borrow the idea of this example from Chevallard (1994). Theme A – F. Wozniak
144
2. Instrumental value and semiotic value of an ostensive
In a "classe de CP" of a primary school – children between six and seven
years old – pupils try to calculate the result of the addition "12 + 6". A pupil counts
12, 13, 14,.. 17, 18 and raises an additional finger each time. The fingers that raise
during the counting constitute a gestural ostensive. Raising a finger at the same time a
number name is enunciated allows controlling how much numbers names were
enunciated. Thus the gesture makes the achievement of the task possible: it is an
element of the implementation of the technique. But the fingers that raise gradually
say what the pupil does: he continues the counting from 12. The same ostensive, the
gesture of the fingers raising gradually, has two values: an instrumental value that
expresses what has been carried out by the ostensive and a semiotic value that allows
seeing what is made by the ostensive and reveals the evoked non-ostensive. In the
same way, the number name enunciated when the fingers raise is a linguistic
ostensive which lets us see (or rather understand) the technique used by the pupil: the
counting. But the declamation of number names has also an instrumental value: the
last number name enunciated is the result of the addition. The work made by the pupil
on the words is an element of the technique of addition. Thus the language does not
have only a communication function for describing, for instance, a technique. It is
also an ostensive like another: it is simultaneously a tool which makes possible to
achieve a task and makes apparent the meaning of what is made.
Instrumental and semiotic values of an ostensive "appear, within a given
technique, linked like the recto and back of a sheet of paper" (Chevallard 1994, p.6,
our translation). The mathematical activity is carried out through the handled
ostensives and of the non-ostensives thus evoked. Then, a didactic analysis, in ATD,
takes into account what the ostensives make possible to do, their instrumental value,
and what they let us see of the work done, being done or to be made, their semiotic
value. In this example, we have seen how the efficiency of the process gives sense to
what has been done: the instrumental value of an ostensive nourishes its semiotic
value. With the next example, we observe the case where the loss of sense makes an
ostensive loses its instrumentality.
3. The loss of instrumentality of an ostensive
In a "classe de CM2" of a primary school – pupils between ten and eleven
years old – pupils solve a proportionality problem (Wozniak, 2012). It is asked to
determine the height of a giant in an amusement park from a photograph
16
of 16.1 cm
horizontally by 12 cm vertically (see figure 3).

eah! On the sheet of mathematics. It is like the sheet we have made
durations. You are right, Ouiam
we have done a… we have made several small problems where it was necessary
ice of 5 kg,
resorting to a table of
which reveals to pupils the kind of problems they solve. At the next Theme A – F. Wozniak
146
session, the teacher becomes even more precise to give some meaning to the numbers
arranged in the (proportionality) tables that pupils are obviously not able to make use
of: "How many times we need the size of an human foot to obtain the size of an
adult man? " (our translation). And to make sure of the understanding of the question,
the teacher makes a drawing. Finally, a solution is collectively found and the teacher
concludes: "To calculate the size of the giant, one takes the size of his foot and
multiplies it by six" (our translation). Then pupils must redo individually the work
which was made collectively by using only the photograph given at the beginning.
The analysis of these last writings allows noting that the pupils did not understand
what have occurred: one third answers nothing on the sheet and only another third
gives the good answer (with a badly filled out table for two of them).
If we report this episode, it is in order to illustrate how much an ostensive –
here, the table of proportionality – has lost of its instrumentality when it has lost its
semioticity. A single table of proportionality is not enough to solve the problem
given. However it seems that, for this teacher, the presence of a table of
proportionality alone must be enough to make understandable for the pupils that they
have to solve a problem of proportionality and how to proceed. Thus the teacher has
got rid of the genuine challenge of the learning: recognizing that a situation has to get
modelling by the proportionality. The table of proportionality can become an
instrument only if the pupil has recognized the situation of proportionality: the
instrumentality of ostensive also depends on its semioticity.
With these two last examples – add 12 + 6 or determine the height of a giant
– we observe that instrumental value and semiotic value are inseparable and how they
nourish one another. An ostensive is efficient only if the non-ostensive evoked makes
sense for the mathematical activity. But in the same way, the efficiency of the
technique that uses an ostensive makes sense about what has been done. Therefore,
tool and representation are embedded and the ATD modelling of mathematical
activity as a praxeology allows clarifying the relationships by means of the praxis
component and the logos one.
4. Choose an ostensive for a design task: study the values according to
the learning objective
Now, we illustrate with an example how the concepts of instrumental and
semiotic values make possible to answer two essential questions to design a
mathematical activity: – What mathematics epistemological considerations are taken
into account when designing tasks using tools? How do different types of tools afford
different mathematical activities/tasks, different representations and/or discourses,
and different interactions between representations? –
Let us consider a teacher of a "classe de CP" of a primary school who wishes
to introduce an ostensive representing the integers as a reference tool. This teacher
hesitates between a linear or tabular presentation (see figures 5 and 6).

40 41 42 43 44 45 46 47 48 49
Figure 5- Tabular presentation of integers from 0 to 49
Which ostensive must be chosen? The linear presentation, or number line, is
present in pre-primary school – children between three and six years old – and is
found in various board games where it is necessary to push or to move back a pawn
according to a dice throw. It is a familiar representation whereas the table of numbers
is a tool which belongs to the school culture. The number line enforces the continuity
of the series of numbers and makes possible the association between cardinal number
and ordinal number. It also allows determining for each number what is the previous
and the next number, bounding it between two whole tens, adding or subtracting two
numbers while moving forth or back by analogy with games. They are there the
ingredients of its instrumental value. The same techniques can be used with a table of
numbers. However the tabular structure arranges the numbers according to their

figures of tens and units, and breaks somehow the continuity of the number line. Then it is less easy to perceive than 19 is between 18 and 20 or 10 and 20 with a table of numbers than with a number line.
If the aim of the teacher is to obtain the result by counting, he can consider that the instrumental value is more important for the number line. Of course, the same technique of counting can be used with both ostensives, but the table of numbers makes easier the use of the decomposition of tens and units because of its structure. For example, to add 5 + 12, the pupil can advance of 12 boxes on the number file from 5 (see figure 5). With the table of numbers, it is possible to find the result by moving down from a line from 5 and then by moving forth by two boxes (see figure 6). This last technique is based on the decomposition of 12 into 10 + 2. Obviously, a moving on the number file by a jump of ten boxes and then by two jumps of one box is possible. Nevertheless, this technique is easier to use with the table of numbers than with the number file. If the goal of the teacher is to develop a work on the numeration and the decomposition of the numbers rather than counting, he can consider that the instrumental value is more important for the table of numbers. Therefore, the choice of the representation will be determined by the mathematical praxeologies that the teacher wishes to make alive in the classroom: the greatest instrumentality and the greatest semioticity are then estimated according to the aim of the study. It is finally noteworthy that the semiotic value of ostensive is not "already there". It is a work around the structure of the table which reveals 26 as being at the crossing of the line of 20 and column of 6 and led to the decomposition 26 = 20 + 6. It is because the table of numbers is transformed into a tool making easier the use of the decomposition of the numbers that its semiotic value, connected with the numeration, develops. The instrumental genesis (Rabardel, 1995) does not facilitate only the use, and thus the instrumentality, of an ostensive. It develops also its semiotic value: an increase of the instrumental value allows also an increase of the semiotic value.
We have discussed above that the instrumental value of the table of numbers, from a didactic point of view, is to make easier the transition from techniques relying on counting to techniques based on numeration and additive decomposition. The teacher will determine his choice between the number file and the table of numbers according to the non-ostensives that it evokes and thus techniques that it makes Theme A – F. Wozniak
148
possible to implement. The instrumental value of an ostensive from the point of view of the teacher's activity to design a teaching situation is thus based on the semiotic value of this ostensive from the point of view of the pupil's mathematical activity. But not only, because the semiotic value of an ostensive is also built starting from its instrumentalization. Thus, the choice of a particular artefact for a design task is determined according to the analysis of its semiotic and instrumental value to develop particular mathematical praxeologies. The notion of praxeology is thus central in ATD to design a mathematical activity. The teacher must consider the techniques he wants to make alive in the classroom to perform a specific task; he must consider the technological discourses he wants the pupils to develop for describing, explaining, justifying and developing the techniques used. In the above example, the choice of tools is determined by the questions on the kinds of praxeologies that the teacher intends to make alive in the classroom.
Conclusion
Any ostensive is an instrument to do something and the representative of a non-ostensive that allows thinking what is made or has to be made. It is this bivalence that is recognized through the concepts of instrumental value and semiotic value of an ostensive which are inseparable and nourish each other within praxeologies that activate the ostensive. In fact, an ostensive can acquire a higher instrumentality thanks to a technological or theoretical work giving a higher intelligibility to new technical uses. Reciprocally an ostensive can acquire a greater semioticity thanks to a work on instrumentation.The identification of the instrumental and semiotic values seems an essential didactic gesture for the teacher during the design of a teaching situation. It is based on an epistemological analysis of mathematical praxeologies that he wishes to make alive in his classroom depending on the learning challenge. The example in the fourth section illustrates this point of view.
What happens when the instrumental and semiotic values of ostensives are insufficiently taken into account during the design of a mathematical activity? In this case, the milieu of the situation (according to Brousseau, 1997) is insufficient to create a dynamics that allows the construction of the knowledge. In Bulf, Mathé, Mithalal, Wozniak (in press) we show how a teacher in this case uses a specific ostensive, the language. In fact, he resorts to maieutic as a driver of the mathematical activity which cannot start from the others ostensives and non-ostensives of the situation. The teacher intervenes directly with pupils in order to guide them in their activity. Thus, through the questions he asks, he finally ends by suggesting the expected answer. This kind of situation is named by Brousseau (1986) the Topaze's effect.
In fact, the instrumentality of the notions of instrumental and semiotic values of an ostensive to design a mathematical activity is born from the anthropological point of view which we adopted: identification, interpretation and description of the instrumental and semiotic values of an ostensive depend on the studied practices and the institutions in which they are activated. ATD is an epistemological approach and its main theoretical tool is the notion of mathematical praxeology as model of mathematical knowledge. The notion of praxeology allows analysing the tool-driven relationships within the design, teaching and learning triad. What type of techniques does the teacher want the pupils use? What kind of technological discourses does the teacher want the pupils develop? These are fundamental questions to design a mathematical activity and analyse its teaching and learning. Any mathematical Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
149
activity activates ostensives and evokes associated non-ostensives. Then, the analysis of the instrumental value and the semiotic value of the ostensives allows to choice the tools for performing the task in function of techniques or technological discourses the teacher wants to be used in the classroom. In conclusion, it seems that the notions of praxeologies, instrumental value, and semiotic value of an ostensive, are useful theoretical tools to study task design.

Theme B
Accounting for student perspectives in task design
Janet Ainley
School of Education, University of Leicester, UK
Claire Margolinas
Laboratoire ACTé, Université Blaise Pascal, Clermont Université, France
It is obvious that tasks or sequences of tasks are designed to embody mathematical knowledge in ways that are accessible to students, and to improve students' mathematics thinking. However, if we look beyond the intentions of those who design and select tasks, the actual impact on students' mathematical learning raises important questions. One of the aims of this thematic group is to gain insights into students' perspectives about the meanings and purposes of mathematical tasks, and to better understand how appropriate task design might help to minimise the gap between teacher intentions and student mathematical activity.
There is a tacit assumption that the completion of mathematical tasks chosen or designed by the teacher will result in the student learning the intended mathematics. This view is persistent despite research that suggests that this is not a direct relationship (Margolinas, 2004, 2005). This can result in completion of the task (rather than mathematical learning) becoming the priority for students and even sometimes for teachers. This can be particularly true for younger and lower achieving students, who are "helped" by the teacher to complete the task in order to 'keep up' with their peers. Teachers are encouraged to differentiate tasks for different students in order to facilitate learning. However, changes that make it easier for the student to complete the task may have the effect of undermining the designers' intentions, and reinforcing students' attention of completion as the priority.
Research about learners' perceptions of the use of contexts in mathematical tasks has suggested that these can differ considerably from intentions of designers (Cooper & Dunne, 2000). Whilst designers may choose contexts to offer real world models to think with or to illustrate the usefulness of mathematical concepts in real life, pedagogic practice may lead students to adopt 'tricks' to bypass the contextual elements (e.g. Gerofsky, 1996), Verschaffel, Greer, & Torbeyns, 2006)), or fail to appreciate the extent to which everyday knowledge should be utilised in the mathematical task (Cooper & Dunne, 2000). Tasks or sequences which draw on real world contexts, but which do not reflect the purposes for which mathematics is used in the real world, may be perceived by students as evidence of the gap between school mathematics and relevance to their everyday lives (Ainley, Pratt, & Hansen, 2006).
Another issue is a methodological one. One possibility for measuring the impact of tasks or sequences on students' learning is the use of pre- and post-tests. However, since it is highly likely that any teaching may result in some outcome on posttests, it is not so obvious what should be considered as a significant posttest outcome. For instance, if we consider only the mean value of an entire cohort of students, we may not understand whether the low achieving students (as determined Theme B – Introduction
152
by the pretest) have really benefited from the task or sequence. Moreover, the goal of the task or sequence may not be easily (or even possibly) assessed in a written test. Often, it is only by observing the evolution of students' strategies that we can understand the effect of a task or sequence (Brousseau, 2008). Task design is generally initially implemented in favourable contexts: the teachers are members of the research team or closely linked to the designers. In this context, the impact on students is not only linked to the tasks but also to the impact on teacher or students of a collaborative way of dealing with teaching (Arsac, Balacheff, & Mante, 1992).
These methodological issues are only examples of those that can be addressed in our group. An aim of this thematic group is therefore to reflect on methodological issues related to studying task impact on students.
Possible questions might be:
• How is it possible to assess the impact of task or sequence on students' mathematical learning?
• What is the intended and actual impact of a task or sequence on low achieving students?
• What do students actually do and attend to when confronted with tasks?
• How do students understand the purposes of tasks they are given in the classroom?
• How do students' reactions influence teachers' adaptation of the task?
• Might what appears to be 'only' a change in presentation convey a different meaning to the student, and result in different mathematical activity?

Emergent tasks--spontaneous design supporting in-depth learning
Angelika Bikner-Ahsbahs
University of Bremen
Thomas Janßen
University of Bremen

In this paper the concept of emergent tasks is presented. It has
been developed through empirical investigations of interest-dense
situations comparing them with situations where learning opportunities
were not taken up and enables teachers to shape learning opportunities in
everyday lessons in an effective way. Three forms of emergent tasks, their
conditions of success and possible uses are discussed.
Keywords: Interest-dense situations, learning opportunity, social
interaction, epistemic process
Introduction
Interest-dense situations provide epistemic and interest-supporting learning
opportunities to the students by the adaptive behavior of the teacher (Bikner-Ahsbahs,
2003; 2005). So far, we have understood how these situations can be built through
social interaction but we did not exactly know in what way the teacher aligns his
behavior to the students' needs. Investigating this problem brought to the fore a new
task format which is not designed beforehand and hence accompanied by the
problems of given tasks described in the call of ICMI Study 22 (ICMI, 2012) but is
constructed instantaneously deepening mathematical thinking. In the long run, this
investigation has the potential to answer some notable problems of task design, for
example "to better understand how appropriate task design might help to minimize
the gap between teacher intentions and student mathematical activity" (ICMI, 2012,
15) or how tasks developed in favorable contexts can be made more accessible in
ordinary classrooms.
Regularly in mathematics classrooms, tasks designed beforehand are
implemented to initiate learning activities. In this process, time is needed to
understand the task affordances, especially when they are complex and the students
are unfamiliar with their forms. The time on task and with it the possible outcomes
are reduced when a considerable amount of time is needed for understanding its
requirements (Caroll, 1989). However, time on task alone does not induce sucessful
learning, but must be supported by sophisticated teacher instruction (Caroll, 1989, 30;
Christiansen & Walther, 1986, 261). For instance, Prediger and Scherres (2012) show
in a case study that with so called self-differentiating tasks optimal learning takes
place only if it is supported by a teacher intervention that transforms the mathematical
learning potential into a fruitful epistemic situation. The two problematic aspects Theme B – A. Bikner-Ahsbahs & T. Janßen
154
discussed so far—the reduction of learning time needed to understand the affordances
of tasks and the necessity to take learning opportunities in the classroom—are
addressed effectively by the concept of emergent tasks presented in this paper. More
aligned to the specific situation than in ad hoc tasks (Christiansen & Walther, 1986,
296), in emergent tasks the teacher conceives the mathematical potential of a learning
opportunity and translates it into a task, so that
1. the students' interest present in the situation is taken up and
2. acute mathematical problems and questions are addressed adaptively.
Investigating emergent tasks and their supporting conditions may elucidate
how the gap between the students' experiences and the given purposes of tasks can be
bridged through the adaptive character of these tasks. In this paper the concept of
emergent tasks will be worked out based on qualitative data. Forms of emergent tasks
and necessary conditions are presented. Furthermore, based on an empirical example,
influences of emergent tasks on further learning processes are illustrated.
Theoretical background and research questions
Given the immediate perceivability of emergent tasks they can contribute to a
more effective use of time in class. With their adaptive character, they are embedded
in an understanding of mathematics learning that places it in the social togetherness of
learners and teacher (Jungwirth, 2003). Both align to the mathematical and situational
requirements not only of the teachers' goals, but especially of the students' learning
processes. This very condition characterizes the social interaction in interest-dense
situations (Bikner-Ahsbahs, 2005). Hence, we assume emergent tasks to be a means
to initiate and sustain interest-dense situations and with it deepened mathematical
learning.
Interest-dense situations can be described by three characteristics: the
learners are deeply involved in working on mathematical questions, they construct
successively deep mathematical meanings, and they explicitly or implicitly see the
mathematical object as important in the situation (Bikner-Ahsbahs, 2003; 2005).
Common to all interest-dense situations is the scheme of students' epistemic actions:
Starting from the gathering of smallest bits of knowledge via the connecting of
mathematical knowledge students get to structure-seeing (GCSt model). Structureseeing can refer to known mathematical structures that are seen in new contexts, but
also includes the development of new structures. Hence, interest-dense situations can
be considered mathematically rich learning processes. The teacher puts aside fixed
answer expectations in favor of the developing situation. The students do not try to reproduce the teacher's expected answers but concentrate on their own learning
processes. They try to grasp the mathematical content in the social interaction with
their peers.
The content-related driving force of such situations is the students' general
epistemic need (GEN) (Kidron et al., 2010; 2011). It is often only implicitly visible in
epistemic actions. Together with a mathematical gap experienced by the learners it
can lead to more specific needs, for example to formalize. In this case, the need can
be satisfied by specific actions. These then lead to epistemic steps, hence to the
experience of competence and a stabilization of the situational interest (Krapp, 2005),
which in turn reproduces the GEN. Thus, a situation-apt emergent task reacting to the
needs of a student should be suitable to bring forward epistemic processes.
However, it remains unclear what characteristics emergent tasks account for
and how exactly they come about. This study tries to clarify the following questions: Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
155
1.Under which conditions do emergent task come about and are there
specific forms to be identified? More precisely, we look for conditions of
classroom situations and the requirements the teacher must meet to
design useful emergent tasks.
2.What is the use of emergent tasks?
Methodological considerations
The research questions are investigated focusing on processes by the use of
qualitative methods. As emergent tasks seem to be an attendant phenomenon to
interest-dense situations, data from a project dedicated to this subject is used. We
identify scenes where teachers translate learning opportunities into tasks and examine
how these tasks guide further epistemic processes. We consider these processes
successful when students get to mathematical insight regarding the underlying
problem. The GCSt model helps in this process: Success in this sense can be stated
whenever students see structures (which is the case in all interest-dense situations)
and this can be ascribed to the emergent task.
We assume with Brousseau (2008, as quoted by ICMI, 2012, 16) that "it is
only by observing the evolution of students' strategies that we can understand the
effect of a task or sequence", and aim at answering the question what students
"actually do and attend to when confronted with task" (ICMI, 2012, 16) - even more
so as emergent tasks by definition can only occur in everyday classroom interaction
and not in artificial laboratory setups. Thus we ground our ongoing study on the video
transcripts from 16 interest-dense situations of 8 lessons. 5 of the lessons are still to
be analyzed. They are taken from a total of 89 lessons dedicated to fractions that were
conducted for half a year in a 6th grade class. The transcripts are analyzed focusing
the question how the teacher deals with learning opportunities marked by the
students' GEN. By comparison with scenes where a similar learning potential is not
used in an emergent task, fostering and hindering conditions of emergent tasks are
gradually worked out. These may vary depending on the form of emergent tasks and
thus express a teacher-dependent typing. We reconstruct this typing by first analyzing
one rich situation containing an emergent task. In each scene subsequently analyzed a
contrasting permanent comparison to the previous scenes is conducted (Jungwirth,
2003). This leads to a typing of emergent tasks regarding the situational conditions.
To describe the tasks designed by the teacher in the situation we use the
definition of tasks by Bruder (2000). It describes tasks as calls to action with an initial
state I consisting of given information, conditions, etc., a final state F meaning the
solution, conclusion, etc., and a transformation T between the initial and the final
state. Based on this definition we can describe in each situation what is given in the
students' utterances, what the students struggle with, and what is translated by the
teacher.
The method of analysis follows the rules of the interpretative approach
(Jungwirth, 2003). It assumes that subjects act towards things (here: mathematical
content, learning environments, other persons, etc.) according to the meanings these
things have for them, and furthermore, that these meanings are built in social
interactions through interpretation (Blumer cited by Wagner, 1999, 32). Analyzing
then means re-interpreting the interpretations of the subjects. As we work on everyday
classes, we can adopt the reflexivity assumption from ethnomethodology: the reasons
for acting are visible in acting itself (Lamnek, 1995, 51 ff). Regarding the tasks this
means that the persons involved make clear through their actions (i) how the learning Theme B – A. Bikner-Ahsbahs & T. Janßen
156
opportunity comes about, (ii) if, why, and how the teacher formulates an emergent
task, and (iii) how this task influences the epistemic process.
Exemplary data analysis
In the following exemplary display of results we will first describe a situation
where the teacher does not see the potential of the learning opportunity and present a
first hypothesis regarding possible reasons. Then one successful emergent task is
presented and its conditions are worked out. Finally these considerations are
completed by a look at the following task sequence which leads from the initial
problem to a learning result for many students.
A missed learning opportunity
The students are asked to find one third of a slip of paper. Rosa proposes to
tentatively fold the slip in three layers. Some students cannot follow this idea as they
have problems implementing it. The teacher, Mr. Kramer, is not content and says:
167 T: ah is there (.) is there yet another
possibility (.) some took (..) the view ,one
could also fold in the middle
168 /S: no
169 /T: and does that work in the middle
170 S: no
171 S: doesn't work.
172 Mira: Yeah ,it works (.) yes
173 Mira: yes but that would only ,work
well. if one would fold it here
174 T: yes'
175 S: uh
176 Mira: and then one would have to
fold once more then there would be four
pieces ,and ,the one piece one would have
had ,to throw that away then that would
work
177 S: ooh
178 T: ah like that yes.
179 S: ooh
180 T: yes so it works yes (...) there one
would have given away one piece right (..)
well okay
181 Eric: but one can also divide the last
piece by three (.) if one then divides by four
and one divides one piece by three then
again
182 /T: yes but then one has the same
problem again one piece divided by three
183 /S: yes exactly
184 /T: right
Transcription key:

exact' raising the voice
,exact with a new onset
EXACT with a loud voice
(.)/(..)/... 1, 2, ... sec pause
/S: interrupts the previous
speaker
T: teacher
The open question of the teacher stimulates the students. They discuss the
question whether it "works" to divide the strip in the middle (168-172). Mira proposes
to bisect twice and to "throw away" one of the four pieces (173-176). According to
the teacher one would have "given away" one piece in this case. He makes clear that
this is a good idea but that not using the whole paper slip is unfortunate—he thus
clarifies the initial state and the final state. In fragile speech, Eric proposes to divide
the surplus piece by three (181). With this proposal Eric starts an approximation Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
157
process. But the teacher does not take up this idea. Once more he marks the situation
as unfortunate, as one would have the same problem again. "Yes exactly" is the
supporting reaction in the class which in turn gets appreciation by the teacher (182-
184). Eric sees a different final state than the rest of the class. He does not try to get
exactly one third in just one step, but looks for a successive approximation. And his
initial state is different, too: While Mira and even more explicitly the teacher mark the
surplus piece as unfortunate, this very piece constitutes the starting point of Eric's
idea.
Eric's view constitutes a learning opportunity: If one repeats the process of
dividing one of the four pieces by 4 and puts three of the resulting smaller pieces next
to the three remaining larger ones, one is again left with one small piece that can
again be divided. The result is an approximation algorithm for the division by 3.
Fig. 1: The first two steps of the approximation algorithm for the division of the paper slip
by 3
However, the potential of the situation remains unused. Why does the teacher
not adapt to Eric's view and hence does not use this learning opportunity? He is
familiar with approximation algorithms, for example with the bisection method,
because he also teaches calculus. In fact, in another lesson he initiates a similar
method in the very same class to show the density of rational numbers, albeit by
dividing fractions by 2 and not as an approximation. In this case there are some

possible reasons to not follow Eric's idea: Either the teacher really does not see the mathematical potential of the situation, or he does not expect such a complex algorithm at the beginning of grade 6. Anyway, he does not show interest in Eric's idea, possibly also because he has different plans for the class.
An example of an emergent task
Previous to the scene presented here the students had worked on the question how to divide a round licorice stick evenly among three persons. Among other techniques the students discussed the possibility to cut the stick in length, so that the cross sectional area would be divided in three sectors of 120° each. Because angles had not been introduced before the meaning of 360° was presented using two set squares. The division of a circle by 3 was illustrated with a round trash can where the middle was marked by the cast. This is the point where Anji asks her question.
139 Anji: Mister Kramer I have a question here. they have divided it from the top but how do they know what 120 DEGREES are.
140 T: ah okay' you want to go back to the set square once more.
141 /Anji: no (.) well but when they ,that is such a stick and how do they know that because ,they can't do that with the set square.
142 /S: yes that's round now right
143 /Ernst: that is round right
144 /S: it's round right
145 T: Tom yes. that is kind of a practical problem right' how do I do that when it is such a very small one and not such a BIG circle eh'
146 Tom: one has to put the zero in the central point and then it works nevertheless I think (.) then one only has to imagine the lines from the 120 until one can draw.
147 T: ah yeah I ,there must additionally ,we will exercise that
148 /S: yes but how Theme B – A. Bikner-Ahsbahs & T. Janßen
158
149 /Rahel: yes Mister Kramer once more a stupid question ,how does one GET the central point how did they GET that. because that is so small.
150 S: that is just
151 /T: that's another problem right. that's a practical problem (..) oh no ,how does one even find the central point in such a small circle right' (.) exactly. those are questions'
152 Anji: a very small compass right'
153 T: yes one can find out with the compass ,only when one is just drawing the circle' one has the central point. but when one has the circle already right'
154 Rahel: yes
155 T: that's exactly what geometry works with.
156 /Rahel: I know that
157 T: there are possibilities to find out a-n-d you can puzzle at home maybe someone finds a possibility'
158 /S: ah I know-
159 /S: one just puts the thing in there
160 /S: one stings in there
161 T: one puts it in
162 S: what'
163 S: oho
164 T: yes but one can act as if one wouldn't have it. how can one find it then. right maybe there's a possibility right maybe you find something. right and then you just try try to divide in thirds. (..) so first draw a circle' then act as if one wouldn't have the central point' one can't find it anymore and then how can one find it again. and when one has it how can one divide in thirds.
The initial question by Anji shows her GEN. The teacher tries to understand and thus shows interest in her learning process (140). The reaction of the teacher seems imprecise as Anji's does not agree and specifies her question (141). Her question is how the division of the circle in three equal parts can be accomplished in practice as the diameter is very small (ca. 1cm). Some students do not see the problem, i.e. the initial state, which Anji and the teacher have agreed upon. They only see the form of the profile as relevant, which is "round" (142-144). So the teacher once more points out Anji's problem by comparing the profile to the larger circle they had worked with before (145). Tom offers a solution. He describes how to measure angles even on very small objects using the set square (146). At this point the teacher probably notices already that the missing central point poses an additional problem and wants to postpone it to an exercise (147). But the students insist on an immediate clarification by asking "but how" (can we exercise that) (148). Rahel reacts by naming the difficulty in dividing the circle without knowing the central point (149). She grasps the epistemic gap and thus sees the mathematical structure. Now the teacher summarizes the two problems: How does one even find the central point in such a small circle? Commenting "those are questions" he documents wonder about the deep involvement of the students that he tries to take up (151). Anji proposes to use a "very small compass" (152). Mr. Kramer tries to reformulate the problem: If one draws the circle the central point is known. But how can the central point be found if the circle is already given (153)? The teacher probably does not know yet how he can work with this situation. He situates the students' questions as problems of geometry. Again, the students react driven by their epistemic need: "I know that" (this is what geometry works with) is a comment that makes clear that the students do not care about the general context, but about their specific problem (154-156). Now the teacher starts drafting a question that picks up the problem and the epistemic need of the class (157). But for some students the initial state is still unclear: they assume the central point to be known, as one can just put the compass there (158-163). The teacher feels prompted to specify his thoughts and poses the following task as a Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
159
homework assignment: Draw a circle, pretend the central point were unknown, find out how it can be rediscovered (164).
In this situation we see more than just an adaptation of an existing task as a consequence of the students' reactions (ICMI, 2012, 16). Rather, a task emerges as a reaction of the teacher to a central problem of the students. The teacher is the designer taking up the students' epistemic need (Kidron et al., 2010; 2011) that he transforms into an action program. The social interaction is fed by the different views the subjects have of the situation. Initially, there are questions, but a clear initial state for the task is missing. This changes when Rahel asks for the central point. A brief clarification of I and F leads to an emergent task that may seem "to be 'only' a change in presentation" (ICMI, 2012, 17) but proves to be particularly fruitful: At the beginning of the next lesson the teacher asks who has worked alone on the task and gotten to a solution. According to the log of the lesson, 20 of 26 students had tried to solve the task on their own, and 16 students got a solution. Some of the students' solutions are presented. Five different methods can be identified which represent structure-seeing at different levels of abstraction:
1. Two maximal, perpendicular chords are found tentatively, they intersect at the central point.
2. To find the maximal chord, a sampling system with nested measurements is presented.
3. The maximal chord is found using the set square. It is placed in the circle so that the circle line passes through the same numbers, which are then maximized. Finally, the central point is marked by the zero.
4. By twofold, perpendicular use of a ruled transparent the central point is found.
5. Two parallel tangents are applied to the circle. Half of the distance is taken as the radius of two circles with their central points on the circle. Their intersection marks the central point of the initial circle.
The last solution, which is presented by Andy, is closest to the one that is part of the curriculum in grade 7. However, it seems too complex for many of his peers. Hence, the teacher encourages the class to ask Andy about his procedure. The crucial question is why he gets the diameter and the central point this way. The teacher then disseminates prepared paper circles without marked central points and asks the students to use and check Andy's method. The students now focus on the question how one can know where on the circle the compass must be placed. They find out that it is irrelevant as all points have the same distance to the central point (structure-seeing). Only two points on exact opposite sides would be inconvenient. In the end, the teacher gives a homework assignment as an emergent task, which demands an expanded use and application of Andy's method and induces an institutionalization: Andy's and two other methods are to be put down in writing "so we don't forget that". Andy's method is not only used to find the central points of the circles, but also incomplete circles are to be reconstructed. The institutionalization contains both, repetition and consolidation of the method. From our analysis we derive five possible design principles that allow for a sequencing based on an emergent task about learning a method: Theme B – A. Bikner-Ahsbahs & T. Janßen
160
Principle Description of the step
Emergent task reacting to a student problem
Presenting and questioning students' solutions to the task are presented, questions are asked
Using and checking an interesting method is used and checked by the students
Expanded use and application the potential in use is evaluated by an expanded task
Institutionalization (individual) textualization
Tab.1: Five principles for a task sequence about lerning a method
What was the difference between this situation and the one presented before? The teacher tried to grasp the problem from the perspective of the students. Posing questions he makes clear what he has yet understood and thus provokes the students to specify and to make the problem (i.e. the GEN) more visible. This does not necessarily bring clarification. But as soon as the teacher has understood the mathematical problem of the students he can translate it into a task: "how does one find the the central point of a circle"? The task is adapted to the students' situation: they have already shown a GEN, and the question is already clear in the situation. The teacher takes the students' situation and their need seriously and makes it the basis of a longer learning process through the emergent task.
Summary of results and concluding remarks
Emergent tasks can be designed whenever the students' epistemic interest can be translated into a task. In most cases both the initial state and the final state are not clear for all participants. It is the teacher's role to translate and thus clarify. Based on the analyses of four interest-dense situations we were able to identify three different forms of emergent tasks. When the students' epistemic need is explicated the teacher can react to it immediately. We presented a case where an emergent task initiated the learning of a method through a task sequence. When the students' need is implicit their problem may be visible to the teacher or not. In the first case emergent tasks may consist of smaller prompts reacting to a student's problem. In the latter case the teacher may help making the problem visible by asking questions like: "show us what you mean", "take the chalk and write (or draw) what you mean". In our data, the students' managed to explicate their problems in this way and especially communicate to the teacher what they were struggling with. On the other hand, we showed how such an opportunity was missed and Eric's idea remained unused. Besides the translations of explicit and implicit problems we also found emergent tasks that unveiled an epistemic gap that initially remained unnoticed by the students.
On the part of the teacher our studies point at three necessary conditions that enable her or him to see situations, where an emergent task is suitable, and to then perform the appropriate translations. The teacher must
• have mathematical knowledge that extends the content of the lesson,
• show interest in the students' learning processes,
• and be open for unusual ways on the part of the students. She or he must be willing to abstain from the planned course.
So far, we have only investigated emergent tasks in one class and the study is still ongoing. Further research investigating interest-dense situations and emergent tasks in other classes and other areas is needed. In addition, it remains an open question whether this task format can also be found outside interest-dense situations, and if yes, how this happens and how it influences learning processes. Emergent tasks can be a powerful tool for the teacher to adapt his behavior to the students' actions Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
161
and interactions in a given mathematical problem situation. However, the implementation of this tool is yet to be investigated.

Mathematical Investigations: The Impact of Students' Enacted Activity on Design, Development, Evaluation and Implementation

James Calleja
St Clare College, Malta and Faculty of Education, University of Malta

This paper is based on a year-long action research study that I conducted in a Form Four mathematics class in a girls' state secondary school in Malta. The focus is on presenting the framework that was used to plan, develop, design, classify, implement and evaluate investigative tasks. This framework hence provides principles and guidelines on examining the differentiation between the tasks as designed and foreseen by the teacher and the actual instructional activities as undertaken by the students. For the teacher-researcher, students' perspectives become crucial within the developmental cyclic process of designing, modifying, implementing and evaluating tasks. The study reported in this paper shows that when students' contributions (students' classroom experiences, responses and understandings) are valued, the teacher-researcher gains more informed knowledge and improved understanding about the design and implementation of investigative tasks.

Investigations; active learning; reflective practice; students' perspectives; task resources

Introduction

This paper draws upon an action research study which I conducted with a Form Four (i.e., 14-year-olds) mathematics class during the scholastic year 2008-2009 that explored the integration of a set of 18 investigations within the mathematics syllabus (see Calleja, 2011). Since then, I have moved to a different state school and have also assumed the responsibilities of Head of Mathematics Department. The focus of this paper is to present a view of didactical goals, guidelines and frameworks that may be useful for collaborative design research projects that are specifically aimed at integrating tasks that promote active learning practices (see Anthony, 1996). The embedded understanding is enlightening my current collaborative project, which commenced in September 2012, on promoting the design and implementation of inquiry-based mathematical tasks with all the Form One students (i.e., 11-year-olds) in my new secondary school. As head of mathematics department, I am coordinating this year-long pilot project and acting as a teacher-mentor within a team consisting of the four other mathematics teachers. At present, we are busy selecting, planning, designing, implementing and evaluating a variety of inquiry tasks, including a range of resource materials (e.g., worksheets, measuring instruments, etc.). Working within our community of practice, we follow a teacher-researcher perspective of 'learning-Theme B – J. Calleja 164
to-develop-learning' (Jaworski, 2006) while implementing our task-driven pedagogy (Walls, 2005).

The Research Area and Methodology

At the time of the action research study in my former school, I undertook the role of a reflective practitioner (see Schön, 1983) in the belief that "good research is not about good methods as much as it is about good thinking" (Stake, 1995, p. 19). This involved taking a reflective stance towards planning, designing, implementing, modifying and evaluating a set of mathematical investigations that I integrated within my scheme of work. Data collection included multiple sources. Apart from writing field notes of my classroom observations, I occasionally discussed classroom situations with a critical friend and kept a reflective journal to give my own interpretations as the events unfolded. However, I also valued students' reflections, thoughts and suggestions. Thus, I encouraged students to keep a learning log book through which they could write about their learning experiences, feelings and learning environment. Moreover, midway through the study, I conducted semi-structured qualitative interviews with the students. Data analysis was then an on-going process of searching for themes as these emerged and resurfaced. This sense-making journey was a search for 'some' truth through qualitative triangulation, namely, an account that presented the classroom situations from three different perspectives: those of the teacher-researcher, the students and a critical friend (McKernan, 1996). My qualitative account emerged as an informed story highlighting the salient features of the classroom community while engaged with a range of investigative tasks as an approach to learning mathematics. At the same time, this study offered me the possibility to better understand and eventually improve my practice.

Conceptual Framework

Reform-oriented approaches claim that doing mathematics should involve sense-making activities by using tasks that provide students with a variety of challenging experiences through which they can actively construct their mathematical meanings (Bishop, 1991). Within this 'active learning' approach – which is associated with experiential, collaborative and inquiry-based learning (see Anthony, 1996) – students gain autonomy and take control over the direction of their learning. Referring to the pedagogical implications, Ernest (1991, p. 288) proposes that the role of the teacher
is understood in ways that support this pedagogy, as manager of the learning environment and learning resources, and facilitator of learning.
Thus, it is within the teacher's remit to include cognitively demanding tasks for their students, encouraging them to work together and to justify their solutions. Learners are thought of in turn as subjects who are responsible for learning, for making decisions and also for their behaviour (Teong, 2002). Put differently, whereas students are trusted and respected as responsible learners of mathematics and as constructors of their own meaningful knowledge, the teacher assumes the role of a facilitator who assists students' learning by observing, listening, questioning and challenging their inquiries.
Learning through active participation also carries an important social dimension. For as Fosnot (2005) claims, learners can negotiate meanings when they engage in cooperative social learning activities. This social constructivist dimension is Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford. 165
based on the understanding that students should be active participants in their own learning by communicating and exchanging ideas with the teacher and other students. Learning is believed to occur by being part of and interacting within a social environment. Discussion with peers can assist learning as students develop conceptual understanding when they articulate their thoughts and points of view, when they learn to listen to others and when they ask questions (Orton & Frobisher, 1996). It follows that learning opportunities arise when student contributions are encouraged and when discussions invite students to challenge, argue and offer explanations.

Defining Tasks as Investigations

Mathematical tasks are an important vehicle through which classroom instruction can enhance students' learning. The tasks teachers present students with and the way in which students negotiate mathematical meaning by working on the set tasks largely determine students' classroom experiences and their learning of mathematics (Hiebert, et al., 1997; Shimizu et al., 2010). As Doyle (1983, p. 161) argues, tasks "influence learners by directing their attention to particular aspects of content and by specifying ways of processing information" and are "defined by the answers students are required to produce and the routes that can be used to obtain these answers". Hence, a key decision for teachers lies in their choice of tasks (Sullivan, 2011). In my action research study, I had chosen investigative tasks. The selected investigations required students to participate actively in their learning as a way of constructing mathematical knowledge within a social setting.
In this paper, an investigative task or investigation is defined as an inquiry into a mathematical situation presented by the teacher, but which can also initiate from a statement or a question posed by a student (Greenes, 1996). The topic of the investigation could arise from real-life or from a mathematically designed problem (e.g., Investigate the sum of angles in polygons). Again, an investigation can be a very open exploration or it can take the form of a more structured task that guides the learner into discovering mathematics (Yeo & Yeap, 2010).
Investigations offer opportunities for students to be more active in their learning. When students engage with such work they are involved in processes of exploration and explanation (Skovsmose, 2001). Students are expected to engage with finding ways to unravel the task assigned and be able to justify their work by presenting their method/s to the whole class. In the process, students engage in thinking critically, learning to ask, sharing ideas and communicating mathematically.

A Framework for Reflection on Design and Implementation

Integrating investigations takes into consideration how different mathematical processes and strategies can be embedded within the core topics which make up the content of a mathematics curriculum (Frobisher, 1994). Consequently, in planning and designing my 18 investigative tasks, I set out to achieve two aims. The tasks had to: (i) be related to the mathematics content prescribed in the Form Four syllabus; and
(ii) engage students in mathematical inquiry, that is, thinking about, developing, using and making sense of mathematics (Breen & O'Shea, 2010). While a number of the selected investigative tasks integrated mathematical topics in order to allow students to experience different areas of mathematics, other tasks were intended mainly to help consolidate mathematical concepts and skills. Furthermore, in the belief that tasks should provoke curiosity in and be meaningful to students, the selection and creation Theme B – J. Calleja 166
of tasks and resource materials took into account the students' interests, mathematical ability and needs. However, when I came to setting future goals I took into consideration the responses/feedback that the students had provided during the study.
Within this conceptual framework, investigative tasks were classified according to the mathematics embedded within the activity, the degree of structure/guidance provided to students and the time devoted for students' activity. The main reason behind the decision to use investigations of varying levels was to smooth the transition for students from working on traditional exercises to engaging in more challenging tasks (Orton & Frobisher, 1996). Moreover, the spread of tasks along this classification helped to gradually introduce students to the cognitive processes of making and doing mathematics. In other words, the different levels offered graded entry points for students to familiarise themselves with the social experiences of mathematical inquiry, discussion and communication.
At the basic level, the investigations were structured tasks that lead students to mathematical discoveries. The given instructions guided students, who worked individually or in pairs, to use particular pre-determined mathematical concepts and apply them to arrive at a solution. At the next level, the investigations were semi-structured. This meant that they were either less structured or students were initially given some guidance in their work but were then free to explore and engage with the task using their own conceptual mathematical understanding and reasoning. Believing that learners benefit from discussing ideas and solutions when working on these more challenging tasks, the students were instructed to work in small groups of two or three. At the third and higher level, the students encountered unstructured investigations that were more process-oriented activities. These required students to investigate the problem posed or the situation presented in as many different ways as they wished and through different methods. These investigations placed greater demands on students to think through a solution, to make inferences and to test their own conjectures. As this type of investigation required students to challenge, argue about and justify their reasoning, the unstructured investigations were set as a group activity involving between three to four students.
Other than the level of structure, the investigations were also classified along the three 'reality levels' identified by Skovsmose (2001). Skovsmose sees mathematical investigations as a landscape that ranges across three levels of real-life contexts. These are: (i) pure mathematics which simply involves working with numbers or geometric figures; (ii) semi-reality which refers to an everyday-life problem that is rendered artificial as it is tackled in a classroom situation where variables can be controlled; and (iii) real-life situations where students are directly involved in carrying out the exercise in the actual setting.
Combining these two classifications, I came up with a rubric consisting of nine different types of investigations. Initially, the main purpose was to produce a template along which I could select and position the investigations (see Table 1). The matrix was eventually also useful in exploring how tasks were enacted in class and whether the students' actual engagement shifted the nature of tasks along the rubric.

Investigation	structured	semi-structured	unstructured
pure mathematics	Type 1	Type 4	Type 7
semi-reality	Type 2	Type 5	Type 8
real-life	Type 3	Type 6	Type 9

Table 1: The nine types of investigationsMargolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford. 167

Investigations of types 1, 2 and 3 were structured tasks that varied according to the level of reality involved. While 'type 1' tasks resembled typical traditional exercises that are similar to those found in mathematics textbooks, 'type 2' and 'type 3' tasks were situated in a context of more practical mathematical experiences. Investigations of types 4, 5 and 6 were semi-structured tasks that again varied from a purely mathematical context to a real-life situation. The unstructured nature of investigations of types 7, 8 and 9, which again differed by context, placed the greatest cognitive demands on students as they were presented as more 'open-investigations'.

Selecting and Planning Investigations within Hypothetical Learning Trajectories

My quest to select tasks with goals in mind (Hiebert et al., 1997) involved thinking about how investigations would provoke inquiry and stimulate learning. As Simon and Tzur (2004, p. 93) argue:
The tasks are selected based on hypotheses about the learning process; the hypothesis of the learning process is based on the tasks involved.
Along these lines, the day-to-day classroom experiences were vital in informing future planning that sought to integrate the learning goals with the trajectory of students' mathematical thinking and learning. This reflective process

included the notion of 'hypothetical learning trajectory' (HLT) through which the teacher considers the learning goals, the instructional activities, and the thinking and learning in which the students might engage (Simon, 1995). A key aspect of this learning trajectory concerns a prediction of how students' thinking will evolve as they participate in the instructional activities. Actually, in classifying the tasks, I always started off with a HLT based on my expectations about students' explorations in learning – indicating the hypothetical learning trajectories from the syllabus (see Table 2). However, the actual learning trajectory cannot be known in advance as it depends on how the teacher and the students enact the tasks throughout the implementation process (see Stein et al., 2000). This eventuality of having students' task-inquiry leading to different learning trajectories than those anticipated by the teacher is indicated in Table 2, which shows a segment of my task-delineated scheme. More precisely, in my study, this occurrence rested upon how students actually went about working on the task and, in particular, their decisions regarding the use of the resources provided. This realization is crucial for the success of my current collaborative project. For I have come to appreciate that designing and implementing tasks requires teacher-decisions not only the number of resources, but also on the type and range of resources to be made available to students. The possibility of differentiating the resources that accompany tasks presents an opportunity for teachers to assign the same tasks to students of different abilities (discussed further in the following section).

Table 2: A section showing how the scheme of work evolved

The scheme of work thus becomes a crucial reflective document for the teacher. By being responsive to students' inquiries, the teacher can occasionally finetune it as he or she re-plans and re-designs tasks and instructional practices. It is worth mentioning here that tasks might shift horizontally along the rubric presented in Table 1. In my case, a shift from structured to semi-structured to unstructured (or vice-versa) may results from the way students engage with the task.

Incorporating Students' Perspective in Design and Implementation

Reported and used extensively in research literature is the Mathematical Tasks Framework developed from the QUASAR (Quantitative Understandings: Amplifying Student Achievement and Reasoning) project team (Stein et al., 2000). This framework defines mathematical tasks as they unfold from design into implementation. In the framework outlined, mathematical tasks pass through three distinct yet related phases: as written by curriculum developers, as presented by the teacher in class, and as negotiated by students during classroom instruction. The framework is also useful in studying changes in task features and cognitive demands as instruction passes between any two successive phases.

As one might understand, depending on their beliefs, attitudes and experience, mathematics teachers are likely to implement the same task in different ways. For example, during the task presentation phase, different teachers may provide different kinds of instruction (information, guidelines and hints) to students about the task. I would argue that providing instruction towards the process rather than the product of students' inquiry is less likely to influence or modify the cognitive demands within the task. During this phase, teachers also tend to attribute titles to the tasks they assign. Reflecting on an incident from my research, I have come to understand that the task title might convey meaning to students about the kind of mathematical content involved in their investigation. Perhaps this focus indirectly provides unwarranted closure to the activity, thus directing students' attention to specific lines of inquiry and possibly shifting the intended 'open' nature of the task. I believe that presenting 'open' titles, such as, 'Investigate Right-Angled Triangles' rather than 'Investigate Pythagoras' Theorem' may offer more 'open' learning opportunities for students. In this case, a few students who attended private lessons already knew the theorem whereas others seemed puzzled by the title. These students, hence, offered resistance and lacked engagement. Apparently, the kind of title presented altered students' learning dispositions since they had 'good' reasons not to investigate. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

169

During the presentation phase, teachers usually also provide students with resource materials to support task inquiry. Teachers might adapt tasks for students of lower ability by opting to provide more appropriate resource materials possibly without unduly reducing the cognitive demands within the task. As in my current collaborative project referred to earlier, teachers are investigating the possibility of designing and implementing inquiry-based learning tasks, on a weekly basis, along a whole scholastic year. These tasks are accompanied by a range of resource materials (including worksheets and instruments) with the intention to cater for students in our ability classes. For example, for the task 'Classifying Triangles' students in a high ability class are provided with a worksheet, scissors and glue, while students in a lower ability class are provided with cut-out triangles, glue, protractor and a ruler. Although students in the two classes are expected to classify different triangles, the ones in the lower ability class are provided with additional material to support their mathematical inquiry. Within this design principle, the 'process help' provided by a range of resources makes it possible for teachers to adapt tasks for all students. This prospect also offers students multiple entry points in engaging with the task. I therefore contend that, within a research task design project, incorporating a range of resources may be crucial in minimizing the gap between the intended and the enacted activity and in engaging all students in cognitively demanding mathematical inquiry. Students may nevertheless interpret and negotiate tasks in ways that may be different from those intended by the teacher – the process of inquiry may either be undermined or sustained/improved during instruction. Occurrence of the latter trait is more likely to manifest itself in environments where students become truly responsible autonomous learners working within social norms of collaborative learning. When students become independent self-regulated learners, their activity might generate different mathematical trajectories to those intended by the teacher. The 'young mathematician' might be confident enough to choose what resources to use and to consider different lines of inquiry. Alternatively, as a number of studies show, teachers have a propensity in reducing the demand level of the task related to classroom norms, task conditions, and teachers' and students' dispositions (Henningsen & Stein, 1997). For example, Desforges and Cockburn (1987) report this tendency occurring when students are struggling or when they give up. Likewise, during my action research, I faced situations where a particular student continuously asked for help when she fell behind compared to the others. During our interview, this student reported that I usually made it easier for her to finish tasks. My task enactment evidently avoided the student's frustration and speeded up task completion. Bound by time constraints, I occasionally reverted to forms of telling to move on the class to the next phase, namely, the whole-class presentation and discussion. Such teacher interventions direct students' attention towards priority in task completion – at times at the expense of more meaningful and deeper understanding. With hindsight I argue that help directed towards the outcome of the activity hinders the process of learning by investigation and inhibits students' cognitive development.

Concluding Remarks

Implementing investigative tasks essentially involves four-phases: tasks as planned and designed by the teacher; tasks as presented to the students; tasks as negotiated by students; and tasks as concluded by the students and the teacher (Ponte, Segurado & Oliveira, 2003). The study of these inter-related phases has informed practitioners, researchers and academics about design issues originating from Theme B – J. Calleja

170

students' engagement with a range of tasks (see Stein et al., 2000). Of foremost importance here is the formulation of principles, guidelines and reflective frameworks for effectively exploring how students negotiate and engage with tasks. As I see it, this awareness is based on a reflective framework that includes: (i) a clear understanding of the purpose of tasks – one that resonates well with active learning; (ii) a classification within which different types of content-related tasks could be fitted – this alignment would be useful in examining how different tasks are designed and presented by the teacher and eventually enacted by students in class; (iii) a taskdelineated scheme that defines the teacher's hypothetical learning trajectories and accounts for students' learning trajectories – this scheme hence also defines the didactical approach undertaken by teachers in class; and (iv) an account of the range and type of resources provided to students in order to render tasks more accessible to all students – this also provides a basis for investigating how students make use of the resource materials supplied and consequently on the ensuing activity.

Writing the Student into the Task: Agency and Voice
David Clarke
International Centre for Classroom Research, University of Melbourne
Carmel Mesiti
International Centre for Classroom Research, University of Melbourne
In this paper, we characterize tasks with respect to intention,
action and interpretation to generate insight into student agency and voice.
It is our contention that a written mathematical problem cannot be
seriously discussed as a mathematical task without specification of the
intended purpose, participants, and product. In addition, differences
between social, cultural and curricular settings, together with differences
between participating classroom communities, shape the performative
realization of a mathematical task. This challenges reductionist attempts
to characterize instructional tasks independent of these considerations.
Given this contextual dependence, any commonalities across context carry
significant weight. Central to an understanding of "mathematical task" as
enacted in classroom settings is the social distribution of responsibility,
agency and voice. Our research shows that competent teachers in several
countries utilize mathematical tasks in a way that maximizes student
agency and voice. We propose that the prioritisation of student agency
and voice should be one of the principles of task design.
Keywords: Task Design, Agency; Voice; Didactical Triangle
Introduction
The classroom performance of a task is ultimately a unique synthesis of task,
teacher, students and situation. The activity that arises as a consequence of a student's
undertaking a task is itself a constituent element of the learning process and the
artefacts (both conceptual and physical) employed in the completion of the task serve
simultaneous purposes as scaffolds for cognition, repositories of distributed cognition
and cognitive products. Task selection by teachers initiates an instructional process
that includes task enactment (collaboratively by teacher and student) and the
interpretation of the consequences of this enactment (again, by teacher and student).
In the context of Theme B, this paper addresses the question: How do students'
reactions influence teacher adaptation of the task? We argue that this question does
not adequately portray the fundamental reflexivity by which the actions of teacher and
student are mutually informing during the performance of a task. There is no doubt
that student response influences the teacher's incremental and iterative adjustment of
the task as performed in the classroom, but, equally, these progressive adjustments by
the teacher iteratively influence the nature of student responses to the task, while
continually re-constructing the task itself in the act of its undertaking. Something of Theme B – D. Clarke & C. Mesiti
174
this dynamic reciprocality may be captured by the inclusion of other Theme B
questions as contributing considerations: "What do students actually do and attend to
when confronted with tasks?" and "How do students understand the purposes of tasks
they are given in the classroom." In combination, these questions provide our focus.
Marx and Walsh (1988) identified three essential elements to any
consideration of the role of 'academic tasks': the conditions under which the tasks are
set; the cognitive plans students use to accomplish tasks; and the products that
students create as a result of their task-related efforts. This conception either ignores
the role of teacher intentionality and mediation, or it relegates this to just another
element in the social context in which the task is undertaken. There is a further danger
that student agency and authorship are identified solely with the products of the task
and their role in the performative realisation of the task itself goes unrecognised.
Our conception of the teacher /student /task triad is highly interconnected and
accords significant agency to each in the determination of the actions and outcomes
that find their nexus in the social situation for which the task is the pretext. It is our
contention that a written mathematical problem such as "Find the average of 13, 15,
17, 19, and 21" cannot be seriously discussed as a mathematical task without
specification of the intended purpose, participants, and product. Even with this
specification of intention, the performative realisation of the task is a collective
mathematical performance by the teacher and students in a particular context for a
particular purpose, generating particular products. "Find the average of 13, 15, 17, 19,
and 21" could be referred to as the task statement or the task stimuli, but it is only one
component of the task as enacted by particular people at a particular time and place
for a particular purpose. Even the imprecision of "average" cannot be either praised as
a well-intentioned attempt to elicit information about student understandings of mean,
median and mode, or criticised as mathematical sloppiness, until we know the
teacher's intentions for the task.
We have examined the function of mathematical tasks in classrooms in five
countries. A three-camera method of video data generation (see Clarke, 2006), was
supplemented by post-lesson video-stimulated reconstructive interviews with teacher
and students, and by teacher questionnaires and copies of student work. Our analysis
characterized the tasks employed in each classroom with respect to intention, action
and interpretation and related the instructional purpose that guided the teacher's task
selection and use to student interpretation and action, and, ultimately, to the learning
that post-lesson interviews encouraged us to associate with each task. In this paper,
we draw on some of the findings from that analysis.
Our analysis employed 'function' as the combination of intention, action and
interpretation to examine the functionality of mathematical tasks in classroom
settings. Of particular interest were differences in the function of mathematically
similar tasks when employed by different teachers, in different classrooms, for
different instructional purposes, with different students. The significance of
differences between social, cultural and curricular settings, together with differences
between participating classroom communities, challenges any reductionist attempts to
characterize instructional tasks independent of these considerations. Of equal interest
were differences in learning outcomes arising from the use of fundamentally different
mathematical tasks, such as highly decontextualised or abstract tasks (see the Chinese
examples below) in comparison with contextualized or so-called 'real world' tasks.
In relation to the related advocacies of relevant and authentic mathematics,
Kirschner, Sweller and Clark (2006) make the insightful observation that Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
175
It may be an error to assume that the pedagogic content of the learning experience
is [should be] identical to the methods and processes (i.e., the epistemology) of
the discipline being studied (p. 84).
In particular, their assertion that "The practice of a profession is not the same
as learning to practice the profession" (p. 83) highlights a critical issue in the design
of instruction in mathematics. How is classroom mathematical activity related to the
activity of the mathematician? While we may classify the tasks of the mathematics
classroom in a variety of ways, we should not confuse those tasks with the tasks of the
mathematician: they are fundamentally different in purpose.
Mathematical tasks employed in educational settings have been variously
categorised under designations such as 'authentic,' 'rich' and 'complex.' The
classification 'authentic' has particularly emotive overtones – suggesting that some
mathematical tasks might be classified as 'inauthentic.' The most common usage of
the term 'authentic' in this regard seems to refer to an assumed correspondence
between the nature of the task and other mathematical activities that might be
undertaken outside the classroom for purposes other than the learning of mathematics.
The value attached to 'authentic mathematical tasks' seems to appeal to a theory of
learning that measures mathematical understanding by the capacity to employ
mathematical knowledge obtained in the classroom in non-classroom ('real-world')
settings and which constructs the process of mathematical learning as 'legitimate
peripheral participation' (Lave & Wenger, 1991) in the mathematical activities of a
community larger than a mathematics class. Such apprenticeship models deny or
ignore the significance of the students' role as agents in their own learning, actively
shaping classroom activity through their participation and progressively becoming
more skilled, not as mathematicians, but as mathematics students.
The eighth-grade mathematics classrooms that provided the sites for our
analysis were drawn from the data set generated by the Learner's Perspective Study
(LPS) (Clarke, Keitel, & Shimizu, 2006). Our initial goal in the analysis of
mathematical tasks undertaken in these classrooms was the selection of tasks that
could legitimately be described as distinctive because of the character of the
mathematical activity or because of the teachers' didactical moves in utilising the
tasks to facilitate student learning. In this paper, we will use a small selection of very
different examples to make two points that we suggest should be central to task
design in mathematics education:
(i) The competent teachers that we studied prioritised student agency in the
classroom performance of mathematical tasks;
(ii) In promoting high quality mathematical activity, the teacher's capacity
to choreograph sophisticated classroom discourse was as important as
the mathematical sophistication of the task statement or question.
Sample Task One: Japan School 1 – Lesson 1 (the Stairs Task)
[For reasons of brevity, 15 minutes of data record has been omitted from the
middle of the table]
Theme B – D. Clarke & C. Mesiti
176
Educational Context of the Task
This was the first lesson in a sequence of lessons concerned with functions, relations and patterns,
where particular emphasis was placed on the special terms used in mathematics. The teacher identified
her global aims for the entire lesson sequence of about sixteen lessons, as: i) identifying functions and
their relationships to everyday life; and ii) understanding how to solve equations using a table, a graph
or formal algebraic techniques. This particular lesson was designed by the teacher to focus on: i)
different variables and their relationships with one another; ii) understanding the form of a linear
equation; and iii) understanding that the investigation of the nature and function of equations is of
utmost importance.
Social Performance of the Task
Teacher Mathematical Task
as presented
Student
The teacher states her goal to the
class, "I'd like to think about
change using these figures."

The teacher asks students to work
on drawing the next two figures in
the sequence.
The Stairs Task
1) The first three figures
have been drawn for you.
Draw the next two figures
by stacking one cm sided
squares on top of each other
(Students attentive)

Nou is invited to the board to
draw the next two figures.
The teacher invites students to
present ideas on identifying what
aspect of the figures is changing.
The teacher invites students to
work in small teams to identify as
many aspects as they can.
2)What changes when the
number of steps changes?
Jitsu immediately suggests, "the
number of steps."
Nobo and Nou add "size" and
"area" respectively.
Taka adds "height."
(The teacher roams the classroom
and speaks with individual
students)
The teacher addresses the class and
invites further suggestions on
"what changes?"
Students working in small
groups)
Nii adds "number of sides" and
"number of squares."
Mika adds "circumference."
Taka says, "shape."
Nou responds with "the length of
the base."
Jitsu adds "the time it takes to
draw the figures."
Nobo adds "sum of the interior
angle" and "the number of
vertices."
The teacher invites students to
suggest how they might go about
examining the relationship between
the number of steps and the
circumference.
The teacher reiterates Mawa's
mention of the use of a table and
reminds students that mathematical
expressions are also useful in
examining relationships.
She proceeds to draw up a table:
3) Examine the relationship

between the number of steps
and the circumference.
Some students suggest,
"graphs."
Mawa mentions "table." Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
177
She asks students to complete the
table and to identify a
mathematical relationship
(The teacher roams around the
room assisting students)
(Students go to the board
and complete the table or
write an equation)
(~15 minutes)
(Students work on the assigned
task at their desks, while some of
their classmates go to the board)
The teacher asks for other
interpretations - other methods for
getting the answer.
The teacher highlights this method
graphically with Nobo's help:
Nii responds that you can add
four to the previous answer, so
that to get the circumference for
six steps, one adds four to 20.
The teacher assigns the homework
task:
4) Show that 'multiplying by
four' works.
5) Examine the relationship
between the number of steps
and another feature of the
diagrams.
(students attentive)
The Stairs Task is well-known and used by mathematics teachers in many countries. This teacher offered students several opportunities to exercise agency while undertaking the task. For example, the students were able to identify a large number of differing variables. The discussion then converged on the particular connection between the number of steps and the circumference and began to model a mathematical approach to defining this relationship. The teacher's focus on the students and the partnership she had formed with them in their learning was further evidenced by students' contributions at the board: Nou drew steps four and five; Yama traced one of the figures with his finger to illustrate the concept of circumference; Ume completed the table, while Taka wrote the relationship in algebraic terms; and Nobo shared his various conjectures of relevant variables. Once the relationship (y = 4x) was proposed, the teacher's attention turned to how to demonstrate the correctness of this equation, "Think about how to show that multiplying by four works." Her recurrent emphasis was on the collaborative exploration of the problem in the interest of promoting student reflection and learning.
Task Two: China School 2 - Lesson 8 (the Numbers task)
The class was learning about the system of linear equations. The students have spent previous lessons working with inequalities, the relationship between the concept of linear equations in two unknowns and their solution, the transformation of equations and solution methods involving substitution and elimination. This was the eighth lesson in this topic and one of the teacher's goals for this lesson was for students to learn to solve some special linear equations in three unknowns. The task statement consisted of: Theme B - D. Clarke & C. Mesiti
178
There is a three digit number. The sum of the three digits is 12. The sum of the hundreds digit and the tens digit is greater than the ones digit by 2. Three times the hundreds digit equals the sum of the tens and the ones digits. Let the hundreds digit be x, and the tens digit be y and the ones digit be z. Set up the equations according to the question.
The teacher's purpose in using this task was to introduce students to the underlying structure of algebraic representations and to assist them to develop appropriate mathematical language. The task was presented to the class and three students were able to correctly provide the individual equations to form the entire system. At this point, the teacher spent some time identifying the exact nature and definitive characteristics of a system of linear equations in three unknowns. The students were not encouraged to actually solve the equations, algebraically or by other means. The task consisted entirely of setting up the system of equations. Students were then presented with the following system to solve:
x + y = 11
y + z = 17
x + z = 10
□
□
□
□
□
Our interest in this task lies in the significant devolution of responsibility to the students to generate solutions and the prioritisation of the development of student facility with the technical language of mathematics.
Task 3. Japan School 3 - Lesson 1 (the Long Task)
In this task, the seemingly simple pair of simultaneous equations 5x + 2y = 9 and -5x +3y = 1 engaged the class for a fifty-minute lesson (and indeed was the discussion point for the first fifteen minutes of the following lesson). A feature of the performance of this task was the extent to which student suggestions, responses and the articulation of their thinking were regarded as instruments for developing understanding.
The teacher, when asked about his aim for this lesson responded, "It's not that I just wanted them to just solve the problems but also, um, I wanted to teach them that there is a need to think about it a little - what solving equations is all about." The emphasis on prompting student reflection, enacted in this class through social interaction, rather than merely on the solution of a fairly trite mathematical problem distinguished this task performance and this teacher's practice.
This third task provides a stark illustration of the crucial nature of the teacher's role. It also problematises the characterisation of a task as a "good task" independent of the social setting and actions through which the task is undertaken. Our analysis prioritises consideration of the social interactive aspects of task performance and, in particular, interactions that constitute the progressive restructuring or reconception of the task itself.
Theoretical Alternatives in Analysing Classroom Task Performance
There are many different theories currently being employed in mathematics education. Activity Theory, for example, is an obvious contender in considering how the classroom use of mathematical tasks might be situated theoretically. Recent developments in the conceptualisation of Activity Theory (eg Engestrom, 2001) have increased the breadth of phenomena and contexts able to be addressed using Activity Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
179
Theory. In particular, mathematical tasks can be situated naturally within the tools available for use in pedagogic activity systems.
Gellert (2008) usefully contrasts 'interactionist' and 'structuralist' perspectives on mathematics classroom practice. In the consideration of the classroom use of mathematical tasks, the interactionist perspective offers insight into the negotiative processes that interact with individuals' use in classroom settings for the socially-mediated constitution of learning. The structuralist perspective potentially offers very different insights into the deployment and function of mathematical tasks in classrooms. Focusing attention on differentiated participation, a structuralist analysis aspires to explain such differentiation in terms of hierarchies and power relationships. In the case of mathematical tasks, these hierarchies reflect the enactment of an entrenched social order and the privileging of particular forms of knowledge. Within the structuralist perspective, particular pedagogies can be seen as embodying systems of social and academic privilege (Bernstein, 1996) and in the mathematics classroom it is primarily through the performance of mathematical tasks that these pedagogies are enacted.
The choice of the theoretical lens focuses analytical attention on some aspects of the role of mathematical tasks and ignores others. This is inevitable. Another entry point employs the three related issues of Abstraction, Context and Transfer. In some discussions, abstract mathematics seems to be treated as simply decontextualised mathematics. Clarke and Helme have argued that there is no such thing as decontextualised mathematics (Clarke & Helme, 1998), since all mathematical activity is undertaken in a context of some sort. If abstraction in mathematics is to have any legitimacy or relevance, then it must reside in some form of generalisability of the mathematical matter under consideration, in the sense that the principle, concept or procedure can be thought of as transcending any particular context or instance. But, to argue that an exercise in Euclidean geometry or in pure number is an abstract task is to deny the social situatedness that has become accepted even from the most cognitivist of perspectives (Lave & Wenger, 1991).
In relation to mathematical tasks, Clarke and Helme distinguished the social context in which the task is undertaken from any 'figurative context' that might be an element of the way the task is posed. In this sense, the task:
Siu Ming's family intends to travel to Beijing by train during the national holiday, so they have booked three adult tickets and one student ticket, totalling $560. After hearing this, Siu Ming's classmate Siu Wong would like to go to Beijing with them. As a result they buy three adult tickets and two student tickets for a total of $640. Can you calculate the cost of each adult and student ticket?
(Shanghai School 3, Lesson 7, Train task)
has a figurative context that integrates elements such as the family's need to travel by train and the familiar difference in cost between an adult and a student ticket. The social context, however, could take a wide variety of forms, including: an exploratory instructional activity undertaken in small collaborative groups; the focus of a whole class discussion, orchestrated by the teacher to draw out existing student understandings; or, an assessment task to be undertaken individually. In each case, the manner in which the task will be performed is likely to be quite different, even though we can conceive of the same student as participant in each setting. Theme B - D. Clarke & C. Mesiti
180
The Three Tasks
The three tasks were selected for their disparity across the key attributes: mathematics invoked (both content category and level of sophistication); figurative context (real-world or decontextualised); resources utilised in task completion (diagrams and other representations); and the nature of the role of the task participants. Students were given a significant "voice" in the completion of each task, but the nature of their participation reflected differences in the extent and character of the distribution of responsibility for knowledge constructed in the course of task completion. This distribution of responsibility (or enhanced agency) is a consequence of each teacher's strategic decision, moment by moment, of how best to orchestrate student work on the task. In seeking to understand task performance as the iterative culmination in the joint construction, not only of the task solution, but of the mathematical principles of which the task is model and purveyor.
If we take 'transfer' not as a description of a particular cognitive process, but as a metaphor for a skill developed in one context being used in a different context, then it is reasonable to ask, "Under what conditions (and through the instructional use of what tasks) will the likelihood of transfer be maximised?" A cognitivist might direct attention to the selective variation of task attributes with the intention of successively focusing student attention on salient aspects of the mathematical concept or procedure to be learned. Variation Theory (Marton and Tsui, 2004) identifies learning with an increasing capacity to discern relevant attributes in the object of learning. From such a perspective, particular tasks and particular sequences of tasks can be critiqued as more or less conducive to directing student attention appropriately and thereby to the optimal promotion of the discernment that is identified with learning.
Distributed Cognition (Hutchins, 1995) and other theories with a material semiotic character accord significance to artefacts as participating in cognition. Rezart and Straesser (2012) have expanded our conception of socio-didactical situations in mathematics classes, and include artefacts in addition to the teacher, the students, and the mathematics. Once representational forms are included in the broad class of artefacts, then mathematical tasks cease to be either the objects to which we apply our cognitive tools nor merely the social catalysts for their deployment. Rather, mathematical tasks become the embodiment of performed cognition, integrating, as they do, representational forms, socio-cultural imperatives and mathematical entities. We find it useful to portray mathematical tasks performatively in order to examine the role each task plays in affording or constraining agency and voice in the social settings in which the tasks are communally performed. Our conception of the teacher/student/task triad accords significant agency to each in the determination of the actions and outcomes that find their nexus in the social situation for which the task is the pretext.
In each of the three tasks shown, the teacher prioritised student agency in task completion, but in very different ways: The Japanese teacher opened Task One by stimulating student discussion of what had noticeably changed during the recent holiday break. This discussion, drawing on student personal experience, situated the mathematical activity in relation to out-of-class contexts with which the students would be familiar. In Task Two, the teacher's purpose was to introduce students to the underlying structure of algebraic representations, and the task as posed was stripped of any elements that might invoke a figurative context. However, even lacking any sense of familiar context, other than the classroom setting itself, student Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
181
active participation in the task performance was still prioritised. Task Three was chosen because of the fascinating use by the teacher of a relatively pedestrian pair of simultaneous equations to scaffold students' developing understanding of the general attributes and properties of systems of linear equations. In the performance of this

task, student suggestions, responses and the elicited articulation of their thinking became instruments for developing understanding.
Conclusions
Tasks have long been recognized as crucial mediators between mathematical content and the mathematics learner. Of particular interest in our analysis were differences in the function of mathematically similar tasks, dealing with similar mathematical content (those relating to systems of linear equations), when employed by different teachers, in different classrooms, for different instructional purposes, with different students. The "entry point" for our analysis was a tabulation of the details related to the social performance of the task (as shown for Sample Task One). Using these tables, our analysis drew on the video-stimulated, post-lesson interview data to identify intention and interpretation and relate both to social performance of the task.
The conception that the community-at-large holds of the mathematics classroom is intrinsically bound up with the type of tasks that characterise such settings. And this conception is not in error. Mathematical tasks are the embodiment of the curricular pretext that brings each particular set of individuals together in every mathematics classroom. In other contexts, individuals come together to engage in musical performances or dramatic performances. The performances of the mathematics classroom are largely the performance of mathematical tasks and if we are to understand and facilitate the learning that is the ostensible purpose of such settings then we must understand the nature of the performances that we find there.
The thread that we pursued through the examples discussed has been that of the social distribution of responsibility, agency and voice. We commenced our analysis disposed from other studies to believe that these issues were important. Our exploration of responsibility, agency and voice in the context of the classroom performance of mathematical tasks suggests to us that competent teachers of mathematics (within the constraints of culture and curriculum) share a belief in the importance of these elements. The valuing of agency and voice is evident in the task performances in the classrooms of these teachers, rather than in any explicit articulation by them in classroom video data or in interview.
If we are to find pattern and structure in the profound diversity of "welltaught" mathematics classrooms around the world, then the attention given by competent teachers to student voice and student agency, and the mathematical tasks that they employ to catalyse that voice and agency, support our belief that the maximization of student agency and voice in the performative enactment of a mathematical task should be recognized as a key principle of task design and delivery.

Making distinctions in task design and student activity

Alf Coles
University of Bristol
Laurinda Brown
University of Bristol

In this article, we articulate design principles that have developed, during the time of the authors' collaboration, over a period of fifteen years. The principles are drawn both from the enactivist theory of cognition and learning (Varela, Thompson and Rosch, 1991) and the pedagogic ideas of Gattegno (1987). We exemplify how task design centres around activities that provoke differences in student response, allowing the opportunity for students to make distinctions and for teachers to introduce new skills. We illustrate how the principles operate to inform teacher planning, teaching actions in the classroom and students' mathematical activity. The fact the principles operate on these three levels means that student activity closely matches teacher intentions.

Keywords: task design principles, mathematics teaching, student activity, enactivism, Gattegno, distinctions

Introduction

In this article we draw out implications of task design principles for our understanding of how teacher intentions and student mathematical activity may begin to converge. We address the questions: what do students actually do and attend to when confronted with tasks? how do students' reactions influence teachers' adaptation of the task?

Our design principles have developed over the fifteen-year period of our collaboration; they arise from our epistemological commitment to enactivism (Varela, Thompson and Rosch, 1991) and the pedagogical influence of the work of Gattegno (1987). Following this introduction, we offer a brief sketch of these perspectives, we then set out and exemplify our design principles and present evidence from the practice of two teachers to analyse the students' mathematical activity.

The particular community that is the focus of this article centred around one school (School S) in the Bristol area of the UK, that was in 'partnership' with the University of Bristol, meaning that the mathematics department took student-teachers from the PGCE course on an annual basis. Alf Coles joined this department in 1996, having already begun a research collaboration with Laurinda Brown. Alf became a school-based mentor for the PGCE course and, in 2001, head of the mathematics department. Between 1996 and 2003, Laurinda made this school her main research site and visited, where possible, weekly. During these visits (often for a day) she would work in Alf's classroom, observing, sometimes co-teaching and always Theme B – A. Cole & L. Brown
184
reflecting on events afterwards. This collaboration led to publications (e.g., Brown and Coles, 1997, 2010) and research projects (e.g., Brown et al, 2001).

We take, as our definition of task, the one suggested in the discussion document of this study group, 'a task is anything that a teacher uses to demonstrate mathematics, to pursue interactively with students, or to ask students to do something. Task can also be anything that students decide to do for themselves in a particular situation' (Watson and Ohtani, 2012, p.4). In any task, as well as learning some mathematics, students are learning about what learning mathematics is like in this classroom; for us, the choice to use of any task cannot be dissociated from a choice about ways of working.

There is a significant problem, identified in the literature, around the student experience of tasks, compared to the intentions of the designer or teacher. Mason, Graham and Johnston-Wilder (2005, p.131) raise the issue of how an expert's awarenesses get translated into instructions for the learner that do not lead to those same awarenesses. Mason et al (2005) connect this issue to Chevallard's didactic transposition (1988), the problem of moving from the knowledge used in a sphere, such as mathematics, to the knowledge to be taught. The contexts in which mathematical knowledge is used can never be faithfully replicated in a classroom. We see a similar issue being highlighted by Tahta (1980) when he distinguishes 'outer' and 'inner' aspects of tasks. The outer task is what is made explicit by the teacher, the inner task is the relationship or awareness the teacher hopes students will gain. The problem for teachers is that the more the desired behaviours in students are specified, the less these behaviours are likely to emanate from students' own awareness. We see essentially the issue again being described by Watson and Mason (2007):

Engaging learners in activity is important, but in order to learn from that activity they need to experience some kind of shift or transformation in what they are sensitised to notice and attend to mathematically. (p.209)

We also agree with Watson and Mason's (2007) emphasis on:

the importance of developing ways of working, a classroom rubric in which the learners are drawn into patterns of thinking, in which some transforming action takes place (p.210)

In other words, one solution to the problem of how to connect teacher intentions and student activity, is to focus on developing particular ways of working, or patterns of thinking with students. In this article, through analysing examples of what students do when faced with tasks and how teachers respond, we suggest that the issue can also be addressed through a focus on the making of distinctions in task design. However, before getting to this argument, in the next sections we set out our epistemological and mathematical perspectives and the design principles that operated in School S.

Enactivism

Enactivism entails a commitment to the inseparability of thought and action (Varela, Thomson and Rosch, 1991) and a rejection of the view that we operate in the world via making use of inner representations of objects, with thoughts about these representations leading to actions. Rather, we are closed to the world, from an informational point of view. All the world can do is 'trigger'; how we respond is determined by our structure, that is, by the particular relations and physical components that make up ourselves. All living beings are, in this sense, "structure determined" (Maturana 1988, p.12). Through a recursive process of acting in the Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
185
world and the world acting back we learn to co-ordinate our actions with others, as we 'co-evolve' (Varela, Thomson and Rosch, 1991, p.201) in a process labeled 'structural coupling' (Maturana & Varela, 1987, p.75). In each interaction my structure changes, as does the world. It is our history of structural coupling (both as a species and in each individual lifetime) that accounts for the smooth functioning of so much of our life. Varela writes, on the enactive view, 'perception is perceptually guided action' (1999, p.12), i.e., perception is not a passive receipt of information (which we represent) but part of an active (on-going and recursive) process of structural coupling with the world. Over time, how we act can change how we perceive (an example being the wine taster, who is able to make distinctions literally imperceptible to the untrained palate).

Within enactivist epistemology, practical knowledge linked to action is fore grounded, with more propositional knowledge arising from awareness of action. Maturana and Varela (1987), key enactivist writers, state, 'cognition is effective action, an action that will enable a living being to continue its existence in a definite environment' (1987, p. 29). So an action is effective if it allows me to continue operating in a specific context. Knowledge, which requires cognition, is therefore also equated with effective action. Knowing cannot be separated from the knower nor the context in which the knower acts, hence, '[a]ll doing is knowing and all knowing is doing' (Maturana and Varela, 1987, p.27).

The palate of the wine taster offers a metaphor for the enactive view of learning, in the making of ever-finer distinctions in a sphere of action. If learning is seen as the development of knowing, then learning is equated with being able to act differently (in new ways), which is also the same as saying that learning is equated with being able to perceive differently.

Enactivism also carries implications for how learning can occur, which arise from the notion of structural determinism. In a classroom, the most significant features of the 'environment' for any individual are the other individuals in the room. Any interaction between teacher and student or between student and student must alter the structure of both, in the process. Enactivism is a profoundly social theory, we are quite literally changed through interaction with others, or more precisely, we change ourselves through interaction with others who likewise change themselves. We cannot not change, however minimally, in every encounter. Equally, we cannot specify any change we want to provoke in others. It is in this sense that we understand Stewart (2010), in a book on enactivism, when he writes, 'instruction, in the strict sense of the word, is radically impossible' (p.9). All we can do, as teachers, is provoke, stimulate, trigger; how students respond will be a function of their own structures and histories and cannot be determined by us.

Mathematical thinking

Our view of mathematics has been influenced by Gattegno (1987). Gattegno saw mathematics as the awareness of relationships (1965). Awareness was a technical term for Gattegno, whose purpose is, 'to illuminate our fields of action' (1987, p.25). He turned "awareness" into a countable noun – we can enumerate awarenesses. We are being algebraic whenever we step back from a procedure, or a dynamic, to become aware of it. Writing something as simple as x+y, entails a stepping back from the process of addition, to represent that dynamic. In fact, for Gattegno, all mathematics was algebraic, since awareness of relationships and awareness of dynamics are intimately linked, 'all is algebra in mathematics, because to say Theme B – A. Cole & L. Brown
186
"algebra" is to say the awareness of the mind at work on whatever content' (Gattegno, 1965, p.22). Gattegno privileged the visible and the tangible, in the learning of mathematics. He worked with imagery and another quotation of his that we have both lived with, is that mathematics 'is shot through with infinity' (1984, p.20). The connection we make here is that, once we become aware of a relationship (i.e., once we are mathematizing, or thinking mathematically) then it becomes possible to imagine that relationship iterated and hence to infinity. Gattegno also distinguished

'powers of the mind' (1971) that he believed all humans possess, which mean all
humans are able to think mathematically. These powers (also referred to in Brown
and Coles, 2011, p.866) are:
1) extraction, finding 'what is common among so large a range of variations'; 2)
making transformations, based on the early use of language 'This is my pen' to
'That is your pen'; 3) handling abstractions, evidenced by learning the meanings
attached to words; and 4) stressing and ignoring, without which 'we can not see
anything' (paraphrased from Gattegno, 1971, pp. 9-11).
Making distinctions play a role in (1) and (4), linking to our enactivist stance.
Principles of task design
Arising directly from the epistemological and mathematical perspectives
above, the design principles that operated in School S included the following list,
which we will unpack and exemplify. This list is not presented as a finished product
and was not made explicit within the department. However, over the course of the last
fifteen years, within the community around School S, various of these principles were
spoken about and worked on as a group. Two mathematics teachers from School S
have moved to be Heads of Mathematics in different schools, and have established
their own curricula based on similar principles for activities. The principles are:
1.starting with a closed activity (which may involve teaching a new skill).
2.considering at least two contrasting examples (where possible, images)
and collecting responses on a 'common board'.
3.asking students to comment on what is the same or different about
contrasting examples and/or to pose questions.
4.having a challenge prepared in case no questions are forthcoming.
5.introducing language and notation arising from student distinctions.
6.opportunities for students to spot patterns, make conjectures and work on
proving them (hence involving generalising and algebra).
7.opportunities for the teacher to teach further new skills and for students to
practice skills in different contexts.
Principles 2, 3, 5, 7 come from the enactive view of knowing and learning,
which is linked to the making of distinctions. By working with at least two examples,
we support students in sharing distinctions and, through this sharing, making new
distinctions, which is tantamount to learning from the enactive perspective. Language
and notation is introduced to label distinctions students make, to support new ways of
seeing. By 'examples' (principle 2), we mean to capture a wide range of possibilities,
including images, animations and procedures. Principle 6 comes from our view of
mathematics as being essentially about the activities of conjecturing, no matter what
content is being covered. Principles 1, 4 and 7 derive from Gattegno. The closed
activity will, where possible, involved something visible or tangible and which all
students can do. The challenge and opportunity to teach skills in different contexts are Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
187
linked to the power humans have of extraction. When we do something in different
contexts, it is more likely we can extract the skill are retain it for use another time.
In the next section we exemplify these principles, first with a task in the
scheme of work of School S and then two tasks that arose in lessons.
Principles exemplified
Equable shapes
One exemplification of these design principles, is a task (we call it 'Equable
Shapes') that begins with the shapes in Figure 2 drawn on the board. The origins of
this task are obscure. The version of the task presented below was developed at
School S, from an idea Laurinda had used in her teaching. Often, in School S, tasks
would be borrowed from elsewhere but worked on, by Laurinda and Alf in the earlier
years of our collaboration, and as a department when Alf became head of
mathematics. There was a scheme of work in the school which specified certain
'common tasks' (such as 'Equable Shapes') had to be done in a certain time slot with
a certain year group. Discussion amongst teachers often led to changes in task
beginnings, which were written up for the following year. What follows is a
condensed version of the kind of write up that would be in the scheme of work, for
teachers. We have analysed the write up against the seven design principles above.
10 cm
2.5 cm
3 cm
8 cm
Figure 2: Two contrasting examples
These shapes are 'two contrasting examples' (principle 2). With this image
on the board, the teacher asks students, 'what is the same and what is different'
(principle 3). Generally, in the UK, students will at some point begin to comment
about the different sizes of the rectangles. Students may or may not need support in
remembering that mathematicians use the ideas of 'area' and 'perimeter' to judge the
size of rectangles. This awareness leads the teacher to invite the students to find the
area and perimeter of both shapes (a closed task, principle 1). The results are:
10 by 2.5 cm rectangle: Area = 25cm
2
, Perimeter = 25cm
7 by 3 cm rectangle: Area = 21cm
2
, Perimeter = 20cm
Again, the offer from the teacher is for students to comment on anything they
notice that is the same or different. A student will usually notice that for the first
rectangle, the value of the area and perimeter is the same. At this point, the teacher
introduces the label 'equable' (principle 5) as a name for the 10 by 2.5 rectangle. The
teacher can then ask students what questions they could pose (principle 3) and gather
ideas on the board. The teacher-prepared challenge is: what other equable rectangles
can we find? are there equable shapes that are not rectangles? (principle 4). Just the
work on rectangles, offers opportunities for pattern spotting, generalising, algebra and
conjecture (principle 6). In working on generalising what they notice, students are Theme B – A. Cole & L. Brown
188
using skills of distinguishing area and perimeter and, depending on the direction in
which the activity goes, skills may need to be taught to support students in solving
linear equations, using Pythagoras' theorem, using trigonometry, while focused on the
idea of finding equable shapes (principle 7).
In keeping with our own design principles, we now offer contrasting
examples of tasks that arose more or less spontaneously in the practice of two
teachers. These examples allow us to address the questions, when using the design
principles above: what do students actually do and attend to when confronted with
tasks? and, how do students' reactions influence teachers' adaptation of the task?
Transcript 1: Fractions of quantities
The transcript below is from a video recording of a lesson, taken as part of
one of the research projects (Brown et al, 2001) that involved teachers at School S
(among other schools). Laurinda directed the project and Alf was a teacher and
researcher. The transcript shows the emergence of a task spontaneously within a
lesson of Teacher A, who worked in School S. This kind of sequence in a lesson often
occurred in School S, evidenced in video recordings of lessons, discussions amongst
teachers and visitor observations. The original problem for students had been to find
rectangles with area 12. Three examples were on the board, when Student 2 was given
the pen. The students were in year 7 (aged 11-12) and the examples on the board were
a 3 by 4 rectangle, a 2 by 6 and a 12 by 1 (Teacher A refers to these examples in line
42).
[Student 2 takes the board pen and board ruler and draws a half square by 24
square rectangle, giving it the label
1
/2 by 24.]
39 Students: Half a square?
40 Student 2: Half a square.
41 Student 8: Half of 44, half of 48, sorry.
42 Teacher A: Excellent. Oh, lovely. Well done. [Students applaud] So, 3 times 4
is 12, 2 times 6 is twelve, 1 times 12 is twelve and a half times 24 is also 12.
43 Student: And do we do that as well.
44 Teacher A: Pardon.
45 Student 8: And a quarter times 48 is twelve.
46 Teacher A: And a quarter times 48 ...
47 Student 8: And an eighth times ...
48 Student: Three quarters.
49 Teacher A: And an eighth times ...
50 Student: I'm not saying.
51 Student: You can actually go on.
Following this exchange, the teacher then wrote ¼ x 48 and got two students
to confirm the answer. Teacher A then wrote on the board (see boxes) as the
conversation developed.
57 Teacher A: What about a third?
58 Student: What? 1 x
59 Student 9: 36. 3
60 Student: No, you can't really draw a third.
61 Teacher A: Why, how do you work it out
for those that are struggling a bit. [Directed at 1 x 36
Student 9.] How do you know? He's right, it is 3
36. How do you know it's 36?
Two students responded to this question, and then Student 10 said, '3 twelves
are 36'. Teacher A picked up this idea and asked what 4 twelves are, pointing to the ¼
x 48 written on the board. Teacher A asked (line 69), what
1
/6
th
would be, a student Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
189
responded '72'. Another student asked (line 72), 'What about 100? How could you
draw it though?' and three turns later, a student asked (line 76), 'Sir, what would just
a straight line be?'.
In this short episode, that was not planned, we see the design principles in
action. The questions the class were initially working on are closed (principle 1), for
example, line 49, 'And an eighth times'. The teacher wrote up ¼ x 48 and
1
/3 x 36, so
there were two examples for students to see (principle 2). Students were patently the
ones posing the questions and sometimes answering them, for example in lines 45, 47,
72 and 76 (principle 3). The teacher contributed to posing challenges in lines 57, 61,
69 (principle 4). It is the students who first introduced the language of fractions,
Teacher A provided the notation (e.g., ¼ x 48) to describe the rectangles they were
considering (principle 5). There is clearly scope for spotting patterns in this task, as
many students did; generalizing came with the awareness that you could take any unit
fraction as the height and still make a rectangle of area 12, taken to its limit by a
student in line 76, 'what would just a straight line be?' (principle 6). Part of what
students were doing, in this short episode, was practicing a relatively mundane skill of
finding fractions of quantities, but they were doing it in a novel context and with their
attention on the area of the resulting rectangle (principle 7).
There are sections of the transcript (lines 45-51) where, if names were
removed, it would be impossible to tell if students or teacher were speaking. This
exchange was prompted by a student drawing a shape with a fractional side length.
One connection that is made by a student (Student 10) is that to answer,
1
/3 ? = 12,
you can work out 3 12. We interpret this statement from Student 10 as an example
of the kind of shift in attention that Watson and Mason (2007, p.209) describe as
being central to learning mathematics. Student 10 articulated an awareness of a
relationship that then supported other students in extending the implied pattern (
1
/6
? = 12, means 6 12=?, etc), this awareness of relationship is mathematical thinking.
What is significant for us, in this lesson, is the way the design principles of
the department appear to have influenced how Teacher A adapts in an episode that
arose spontaneously from an unplanned student response to an activity. Teacher A
was creating the task as the lesson unfolded. Perhaps even more striking is the way
the students played a role in creating the task, with Teacher A allowing discussion of
student ideas to run and focusing the whole class on certain questions (e.g., lines 49
and 57). We know, from interviews carried out as part of the ESRC project, that
'going with' student ideas in the way we see in this transcript was something Teacher
A was, at that time, just beginning to experiment with.
Transcript 2: Both Ways
The transcript below is from a video taken in 2008 (as part of an ESRC
Studentship) of a teacher (W) who had been in the department for several years and
who had worked with this group of (aged 12-13) students for a year and a half. The
task we called "Both Ways", W had drawn the image in Figure 3 and invited students
to suggest a number to go in the top left circle.
Figure 3. Both ways
×
×
×
=Theme B – A. Cole & L. Brown
190
A student had suggested 74 as the starting number, which the class then
worked through, getting answers of 740 in both circles in the bottom right. Teacher
W looked at these answers on the board as she said the first line of the transcript.
Transcript notation: (.) indicates a small pause, (2) a 2 second pause, ( ) undecipherable
speech
1 Teacher W: oh right (.) okay
2 Student: yeah but why (.) why does it come to that
3 Student: is that meant to happen miss
4 Student: yeah it is
5 Student: no
6 Student: oh yeah miss
7 Student: because if you do seventy four times ( )
8 Teacher W: um (4) any comments (.) any comments (.) yeah

9 Student: cos it can't be seven hundred and forty which is the bottom one (.)
because seventy four times five is three hundred and seventy and then (1) no (1)
no ignore me
10 Student: it (.) the two answers in the little circles no matter what you start up
there will always be the same (.) because if you start there no matter what (.) if
it's times five times two it's like times ten
A little later in the lesson, Teacher W drew a second "Both Ways" image, it
was the same as Figure 3 except the "x5" arrows were replaced by "÷2".
33 Teacher W: okay I've changed the number machine (.) you may not have
noticed (.) okay can we have any thoughts at the moment (1) about what's going
to happen in these two circles (1) any thoughts (.) Student 1 yeah go on
34 Student 1: might be (.) still going to be the same
35 Teacher W: same (1) anything else (1) any other comments
36 Student: I think they're going to be different because they're different order um
(4) what's it called when
37 Teacher W: order of operations
38 Student: ( )
39 Teacher W: so you think it's different (.) timesing by two and adding two is
different to adding two and timesing by two (1)
40 Student: yeah
41 Teacher W: okay so because they're different operations
42 Student: I think it's going to be the same as well (.) because both numbers are
times five and added by two (.) so it's kind of the same thing you're doing
43 Student: I reckon they're going to be different (.) because if you start with one
again (.) if you times by five and plus two it's going to be seven (.) and if you add
two first it'll be three and then you times five which is fifteen (.) so plus-ing on
two first will make it a bigger number
44 Teacher W: okay everybody can you draw that back of your book (.) don't
worry if it's a mess (.) just draw circles squares and two more circles (.) put those
in and I want you to choose your own starting number
This activity meets the design principles presented earlier, however, we offer
this transcript to focus on what students do. In line 2 and 3 we see students asking
questions having made the, perhaps surprising, distinction that there is no distinction
to be made between the final circles of Figure 3. In lines 7, 9 and 10 all the student
comments include the word "because" and in line 10 a statement of proof is offered as
to why the answers at the end are the same. When W sets up the second problem she
asks students what they think will happen. All the responses that follow use the
language of similarity and difference, commenting about reasons the answers at the
end might be the same or different. As in transcript 1, we see evidence here that
students in this department responded to tasks by making distinctions that lead to Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
191
them asking questions, noticing pattern and generalising. In the classroom of Teacher
W, some students' generalisation has taken the form of mathematical proof.
Discussion
We have demonstrated how our design principles are linked to both
enactivist and Gattegno's ideas about learning. Both perspectives see the making of
distinctions as one of the basic mental functions and a key to learning. The design
principles (2) starting with contrasting examples, (3) students comparing/contrasting
and (5) naming the distinctions that students make, are all linked directly to the
making of distinctions and hence, to learning. We see the principles operating in (at
least) three ways. Firstly, the principles inform teacher planning, for example in the
activity 'Equable Shapes'. In this task, the examples of the two rectangles inevitably
focus students on the distinction between perimeter and area, from which questions
and challenges can be generated that provoke further work with that distinction.
Secondly, transcript 1 provides evidence that, over time, these principles can also
inform teacher actions in the classroom, in adapting tasks in the light of student
responses. We are not suggesting there was necessarily any conscious decision
making on the part of Teacher A, linked to the principles; we see evidence that the
principles have become part of his practice of teaching, as analysed above. Thirdly,
there is evidence in transcript 1 and 2 that the principles can inform (again, implicitly)
student actions in the mathematics classroom. In answering what, given the use of our
design principles, do students do and attend to in response to tasks, the evidence from
these transcripts is that through making distinctions, students notice and extend
patterns, they ask questions and generalise.
In Teacher A's lesson (transcript 1) we see a snapshot of a way of working in
which the design principles of School S have become part of what students see
themselves doing in mathematics lessons. Student 2 offers ½ x 24, and another
student immediately offers ¼ x 48. In this context, the activities that Teacher A
chooses to offer students become less important, as students can make distinctions
and generate questions without prompting. We interpret the students in this short
excerpt as exhibiting 'inquiry as a form of engagement' (Watson and Mason, 2007,
p.213) rather than inquiry being structured into the task. We suggest one reason the
design principles are able to operate on three levels (to influence teacher planning,
teacher actions in the classrooms and student activity) is that they are based on a
theory of learning. The design principles embody how, as a department, we viewed
mathematical thinking; our stated aim, as a department, was to develop students'
mathematical thinking. These design principles helped close the gap between our
intentions for students to be thinking mathematically and what students did in
classrooms. By making distinctions about mathematical objects, which was an
inevitable part of tasks in this department, students were thinking mathematically.
In transcript 2, there is evidence of students posing questions spontaneously
however we see a difference compared to the spontaneity of transcript 1. It was clear
from subsequent discussion with Teacher A that the task students ended up engaging
with in transcript 1 was not planned. In contrast, Teacher W had crafted her two
starting examples on the 'Both Ways' task and there was no surprise in how the
students responded and that the distinctions they made lead to a motivation to explore
different starting numbers and then later different operations on the 'arms'.
We want to suggest that the making of distinctions within mathematics can
become a habit and a normal way of engaging in tasks for students. Creating Theme B – A. Cole & L. Brown
192
opportunities for students to make distinctions within mathematics can also become a
habit for teachers and a normal way of both planning activity and informing decisions
in the classroom. When this happens, there is a convergence of planned and actual
activity. With a focus on distinctions, there is a potential route out of the problems
highlighted by Mason et al (2005) around the divergence of teacher intention and
student activity. With a focus on distinctions, the expert (teacher) can plan, initially
via the choice of examples, to support students in making the same distinctions as a
mathematician, leading to the same awarenesses. It is of course no easy skill to be
able to 'run' a discussion in the manner we see Teacher A or W doing in the
transcripts and we are not suggesting that task design is the end of the story; but we
do see evidence that task design based on making distinctions supports teachers in
working to support and develop the responses (distinctions) of their students.

Applying the Phenomenographic Approach to Students'
Conceptions of Tasks
Kimberly Gardner
Kennesaw State University
Tasks serve a communicative purpose between teacher and
student. The student's perception of the task's purpose is communicated
in the approaches used and work produced. By applying the descriptions
of an outcomes space from a phenomenographic inquiry to student work
samples, an assessment of what students tended to focus on and the
meaning they assigned to the task were analyzed to determine the depth of
student learning. The findings show that the meaning and purpose a
student assigns to a task are aligned with the student's meaning of
learning, approaches to learning, and capabilities sought as a result of
learning.
Keywords: Focal awareness, learning, phenomenography, student
conceptions, tasks
Introduction
Tasks are an important component of any unit plan for learning. They serve
a communicative purpose between teacher and student, by conveying the teacher's
intent for learning and the student's conception of that intent (Crabbe, 2007). Often,
responses or work produced from a task reveal a disconnect between the teacher's
learning expectation and the true depth of knowledge attained by the student.
Attributing to the gap between expected versus actual learning outcomes is that
people experience learning differently, and therefore will conceptualize the object of
learning differently.
Phenomenography is a research methodology with its own theoretical
framework that accounts for the qualitatively different ways people experience
learning. From this theoretical stance, the impact a task has on learning may be
analyzed using the outcome space of student conceptions about the task. The purpose
of this application of phenomenographic inquiry is to present an approach to gauge a
task's impact on learning, solely from the student's perspective. By analyzing a
student's conception of, and approach to learning, the relationship between focal
awareness and task performance is further documented. The analysis is guided by the
following questions: a) what do students attend to when assigned a task, b) how do
students understand the purpose of an assigned task, and c) how is it possible to assess
the impact of the task on students' learning. Theme B – K. Gardner
194
Theoretical Framework
Learning
Phenomenography is an empirical approach to studying the various ways
people experience a particular object of learning. The learner's perspective is the unit
of analysis. Learning achievement is based on the quality of the learner's description
of the object of learning, which has often been categorized as ranging from surface
learning to deep learning (Marton & Booth, 1997). Learning is defined as perceiving,
conceptualizing, or understanding something in a new way by discerning it from and
relating it to a context (Marton & Booth, 1997; Pramling, 1996). Furthermore,
learning involves two aspects: i) what is to be learned, and ii) how one goes about
learning (Marton & Booth, 1997). The learner's perspective of what is to be learned
is derived from the student's definition of the direct object of learning. How the
learner assigns meaning to the learning object is determined by the learning strategies
the student recommends for meeting personal learning goals. Since these aspects of
learning will vary, a hierarchical non-linear structure of the qualitative differences is
formed, and is called the outcome space (Marton, 1986).
The outcome space in Table #1 used in the study characterizes the learners'
perspectives of statistics, and it originates from research by Gardner (2007; 2010).
The outcome space has been iteratively refined based on further accumulation of
student responses to the phenomenographic inquiry in various levels of statistics
courses. Phenomenographic studies on the conceptions of statistics conducted by
Gordon (2004) and Petocz & Reid (2003) have yielded outcome spaces with similar
conceptions.
Conception 1: Statistics as facts or algorithms
Definition:
Statistics is a class in which one states terms, evaluates expressions and formulas,
solves equations, and makes and describes graphs.
Approach:
Write and study examples or facts the teacher presents, memorize formulas and
procedures, manipulate a calculator, solve problems the way they are done in class
Capabilities:
Do well on a statistics test, remember formulas and facts after a long period of
time.
Conception 2: Concepts about and procedures for handling data.
Definition:
Statistics is the study of contextualized techniques for collecting, representing, and

analyzing data.
Approach:
Write or state a contextual interpretation of graphs and numerical summaries, execute procedures with and without technology, relate personal experience and knowledge to statistical concepts, determine the appropriate statistical method for a given scenario.
Capabilities:
Explain or teach statistics to another person, read and understand statistics in media, use technology, know when it is appropriate to use a particular procedure or method.
Conception 3: Summarize, estimate, infer and predict
Definition:
Statistics is the study of processes used to estimate population attributes and to generalize or predict trends.
Approach:
Use multiple approaches, utilize technology to differentiate or discover trends, recognize when data need to be collected, explain assumptions, procedures and results to others, assess the reliability of results, provide support for conclusions drawn or estimates made.
Capabilities:
Write or present a detailed analysis of an inference, estimate, or prediction that includes an assessment of assumptions, interpret statistical output from software, appreciate the practicality of statistics. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
195
Conception 4: Adapting, restructuring, changing viewpoint
Definition:
Statistics is a way to acquire knowledge about a population and illuminate trends to improve the quality of life, inform decisions, and change one's outlook of the world. It also comes with the responsibility to use and monitor ethical practices.
Approach:
Adapt to the variable nature of statistics, question the ethical treatment of subjects in studies involving humans or animals, employ the highest ethical standards and design principles, disseminates results of studies to illuminate attributes and inform decisions
Capabilities:
Devise a plan of action to change policies or perceptions based on reliable study results, redefine one's understanding of statistics as new processes are learned, formulate theories, re-structure one's view of the world.
Table 1. Outcome space for conceptions of statistics
Task
Traditionally, a task is defined simply as the work given to the student by the teacher to direct the student towards a specified learning goal (Doyle, 1988). To remain consistent with the phenomenographic definition of learning, a task is further characterized by its relationship to the structural and referential aspects of the learning experience, as defined by Marton and Booth (1997). A task is a situation requiring the learner to experience the object of learning in such a way that the learner must discern components of the situation and how they are related (structural aspect), then assign a meaning to the situation (referential aspect).
Prior knowledge, understanding, skills, and connections reside in the structural domain, and they surface to the foreground as a result of a perceived situation to address, or equivalently complete an assigned task. An analysis of the work produced gives some indication of how knowledge and skills were choreographed to complete the task. The application of multiple approaches or applying and honing skills to tasks with increasing degrees of complexity require students to hold more aspects of the learning object in their focal awareness, therefore they discern more properties of the object of learning and how they are connected (Kirshner, F., Paas, & Kirschner, P., 2011; Runesson, 2006). Therefore, students' work is a depiction of their approach to learning, which reveals structural aspects of their focal awareness.
The referential domain is the learning outcome as perceived by the student, which may be communicated through various forms of assessment. A student's conception of learning informs what is attended to when undertaking an assignment. Therefore, the meaning or purpose of the task assigned by the student is directly related to the student's definition of learning. A student's personal learning goals are made evident by the capabilities they seek to acquire as a result of learning. These capabilities are demonstrated in the product of work. Thus the student's meaning or purpose assigned to the task provides evidence of the depth of learning. The collective structural and referential aspects of students' focal awareness are descriptive evaluations of group performance and learning.
Student Conceptions
Since the student's conception is the unit of analysis, an explanation of what a student is attentive to when engaged in a task is warranted. The basic components of awareness are apprehension, discernment, and simultaneity (Marton & Booth, 1997; Uljens, 1996). Apprehension refers to being conscious of a perceptual or sensual experience in the presence of concrete or abstract entities; discernment involves Theme B – K. Gardner
196
recognizing a foreground-background structure of a situation; simultaneity means knowing how the discerned parts are related to the whole structure. The structure of a student's focal awareness directly informs the way the student understands content, which leads the student to perceive that something has been learned. The capacity of focal awareness for an individual is limited, which accounts for the different ways people experience the object of learning (Marton & Booth, 1997).
Methodology
Task Description
Data were collected from one section of a graduate course in data analysis and probability for pre-service and in-service teachers. The task in Figure 1 is an item from the course mid-semester examination. The item assessed the student's performance level on analyzing and reporting summarized data.
Figure 1. Assessment task on descriptive statistics
Four weeks prior to the assessment, students engaged in a five day lesson introducing the data investigation process and data analysis techniques. One of the unit objectives was to recognize the need to generate and analyze data to gain insight to a specific problem. To motivate the lesson, students identified data specific problems, formulated questions, and then generated data from various statistical experiments. Recording the students' scores from the Bop-It game was one such activity, and the dataset was used only for the assessment task. Other experiences students had during the unit lesson were technology labs on producing graphs and numerical summaries of univariate data, and small work groups in which datasets with various features were analyzed and then reported to the class. The lesson activities were informative in determining and expanding the precision and depth of the students' analyses. The Bop-It activity provided a contextual understanding of the assessment task. All student item responses were sorted based on conceptions in the outcome space. One item from each conception was randomly selected for the study, to demonstrate applications of phenomenography. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
197
Approach
To begin the analysis, characteristics of a student's written responses were noted and matched to items in the approach list. The response was categorized by the conception that had the most advanced approaches noted. A grading rubric was applied to rate the performance level (not met, beginning, advancing, accomplished, exceeds) of the response. The conception and performance level were then used to describe the student's focal awareness while engaged in the task, and to explain what the response revealed about the student's understanding of the purpose of the task.
Results and Discussion
Anna
Anna's response to the descriptive statistics task is provided in Figure 2. The performance level was classified as "Beginning" and the approaches used by Anna are aligned with Conception 1.
Figure 2. Anna's task response
Anna's response indicates a focus on surface level capabilities. Her approach to the task is a partial recitation of the written distribution summaries presented in the introduction of the learning unit by the teacher and in the textbook. Based on her use of intervals, "…between 35 – 40.", and approximations, "close to 14", it is evident that Anna fixated on providing visual interpretations of the histogram. She did not state features of the histogram used to conclude the distribution is skewed right, although this response is correct. She also was aware of the effect of a high outlier on the mean, but she did not apply the formula for determining specific outliers. Finally, she did not refer to the table that gave the exact mean of the distributions, and only focused on where she perceived the scores clustered, presumably based on frequencies. She did not provide an overall assessment of variability, nor a summative statement about the contextual meaning of the distribution. The capabilities illustrated by Anna suggest she discerned the purpose of the task to be an assessment of her ability to describe features of a histogram. Anna was able to recall facts about histograms that helped her to properly identify the shape of the distribution, sense the presence of outliers, and approximate the center. As demonstrated by her response, to Anna the purpose of the task is to determine whether she can recall facts about statistical summaries.
Byron
Figure 3 is Byron's response to the task. The response was rated as "Advancing" and the most advanced approach resides in Conception 2. Although Byron approached the task similarly to those presented in the class, he used more than one summary in his response, providing some indication that he could determine Theme B – K. Gardner
198
appropriate methods. By referring to the data as scores, he was also able to relate the features to the task context.
Figure 3. Byron's task response
His attention is focused towards two graphs and the table of moments provided in the task. Coming to the forefront is an undisclosed feature of the box plot that lead him to conclude the distribution had "uneven" spread, which to him is not a characteristic of a normal distribution. But the meaning of this is not further clarified. Similarly, an unidentified feature of the histogram informed Byron's description of the distribution shape. His comparison of the mean and median indicates he knew facts about the effect of high outliers on resistant and non-resistant measures of center. He demonstrated correct application of the outlier formula and correctly interpreted its results. Byron's learning is still considered surface level, but advancing towards a higher conception. His conception of the purpose of the task was a means for him to communicate his understanding of concepts about data.
Charles
Charles' task was rated as "Accomplished" because there were a few points deducted for minor misconceptions revealed in his explanations. Based on his approach in Figure 4, Charles attended to all of the summaries provided in the task, thus incorporating multiple approaches to summarize the distribution. He also annotated each graph, thereby utilizing technological output to differentiate or discover trends and to provide support for conclusions drawn. These approaches are in Conception 3. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
199
Figure 4. Charles' task response
Charles' response is a strong indication of his deep understanding of descriptive statistics as demonstrated in his capabilities to write a detailed summary of a distribution and interpret statistical output. Charles' conception of the task is best described as a means for him to demonstrate his ability to summarize data and support the conclusions drawn.
Conclusion and Implications
This research demonstrates a method for determining what students attend to when assigned a task, how they understand the purpose of a task, and what their responses reveal about learning, through the applications of phenomenography. The individual student responses contribute to the collective of varying levels in students' understanding. An analysis of their work through the lens of the outcome space communicates the depth and quality of collective learning, thereby informing the degree to which the task or task sequence impacted learning.
The task used in this research assessed student understanding of descriptive statistics and data analysis. Collectively, the various levels of performance in the class are summarized by the first three conceptions of statistics in the outcome space. The presence of student responses in the three conceptions allow for reflection upon and evaluation of the selection and sequencing of tasks throughout the unit lessons. For example, the lesson task sequence was identifying data problems, formulating questions, generating data, using technology to produce summaries, writing an analysis, and reporting the analysis. A lesson requiring students to first design a statistical activity, and then teach it to the class could be contrasted with the results of the lesson for this study to determine whether more students attained higher Theme B – K. Gardner
200
conceptions. Furthermore, since none of the students responded in ways described by Conception 4, supplementing the lesson sequence with complex tasks requiring the compilation of numerous approaches to learning and demanding deeper cognitive focus may enthusiastically move students towards this level. A response indicative of Conception 4 would have included an illuminating effect or call to action based on the analysis. For example, a reflective statement on the Bop It activity explaining the high frequency of 0 scores, or a statement extending recommendations to the manufacturer based on the findings would have been evidence to categorize a response at this level. It is noted that in the researcher's other statistics courses, some students reach perspectives of Conception 4 in reports where they had to design and conduct comparative studies.
This research also shows that the meaning and purpose a student assigns to a task are aligned with the student's meaning of learning, approaches to learning, and capabilities sought as a result of learning. Lau, Liem, & Nie (2008) discuss similar findings in which the value students assigned to task was shown to be associated with the goal of learning. Students may be asked at integral points in a unit to define the object of learning, so that when or where changes occur from task to task can be noted. To encourage students to aim for conceptions that indicate deep learning, the teaching model, Learning Study (Runesson, 2006) provides methods immersed in the phenomenographic perspective.
The Learning Study model begins with planning a lesson aimed at depicting

the critical points of departure in the various ways students understand the object of learning; the lesson is then designed to exploit the patterns of variation to give students multiple ways of experiencing the object of learning (Runesson, 2006). Variation and repeated practice are viewed as effective teaching methods to encourage students to practice varying their perspective. Repeated practice in this context does not mean mundane, rote repetition. Instead, it means to create, invent, adapt, and progress in the light of previous practice where students get numerous opportunities to challenge their perspectives, vary their approaches, and extend or hone the skills they employ (Fazey & Marton, 2002; Runesson, 2006). Designing lessons from the Learning Study perspective inherently leads to developing tasks that provide authentic experiences and require simultaneous, structural focus on multiple details of the learning object.

On what epistemological thinking brings (or does not bring) to the analysis of tasks in terms of potentialities for mathematical learning

Pierre Job
University of Liège, Belgique
Maggy Schneider
University of Liège, Belgique

As recalled by the proposed framework text, the relationship between the completion of tasks by students and the effectively achieved mathematical learning must be questioned. The present contribution will develop and illustrate that this relationship may be adequately analysed by adopting a praxeological perspective (Chevallard, 1999), supported by an epistemological study. Indeed, such a view allows to highlight the fundamental character of the task with respect to the targeted knowledge, and to identify the praxeological level adapted to the level of teaching (Schneider, 2011). Therefore, it allows a certain understanding of the behaviour of students, allowing to assess the impact of the tasks on the learning processes, beyond a possible methodology based on pre/post tests.

Keywords: epistemological obstacle, fundamental task, praxeology, praxeological level, pre/post test

Introduction

Teachers, researchers and the mathematical community in general have an interest in designing tasks to help students, pupils … acquire mathematical knowledge. This goal in mind, a first methodological problem arises regarding their efficiency. A common practice to evaluate the impact of a task is the use of pre/post tests, mimicking procedures found in (hard) sciences like biology and chemistry. The work of Brousseau (Brousseau, 1998) issues a strong warning towards such practices. Although they may be sound in other contexts, in the setting of mathematical education they are subject to great concerns because of sociological considerations pertaining to human behaviour in learning institutions. Brousseau have shown how a teacher and his pupils may engage in some sort of role playing where pupils decode, from the behavior of the teacher, or other hints not drawn from the knowledge they are supposed to acquire, how to answer the given task and how the teacher, consciously or not, gives credit to his pupils doing so, giving an overall illusion of knowledge acquisition. Those initials analysis have been shown to carry over different levels of education (Calmant, 2004, Job, 2011, Rouy, 2007).

Though it puts into perspective the pre/post tests methodology, the sociological viewpoint used by Brousseau might led some people to believe that Theme B – P. Job & M. Schneider 204 mathematical understanding ultimately only relies on considerations where mathematical knowledge doesn't need to be analysed e.g. an epistemological study of the targeted knowledge isn't required. Far away from this conclusion, Brousseau, again, shows, thanks to the concept of epistemological obstacle, how much the inner peculiarities of mathematical knowledge are at the very heart of mathematical difficulties encountered by students and pupils, and, moreover, that the "toughness" of these difficulties leads, to some extent, to the aforementioned role playing between a teacher and his pupils, as a way of trying to do some mathematics despite the encountered difficulties. As a conclusion the work of Brousseau shows beyond any reasonable doubt that an epistemological analysis of the knowledge of concern cannot be bypassed in the design of mathematical task. But what kind of tool do we have to convey such an inquiry? How can we give credit to a task if the pre/post tests methodology is unsound? Those questions can be addressed, at least to some extent, using the praxeology concept.

Praxeologies, a model of (mathematical) knowledge

The work of Chevallard (Chevallard, 1999) extending some parts of Brousseau's work endow us with the concept of praxeology, a model of what (mathematical) knowledge is, whose great strength is to address in a single coherent framework both anthropological and epistemological concerns mentioned above. According to that theory, any activity, including mathematical ones, can be conceptualized as a task, something to do, a technique used to solve it, and a justification of the technique used to solve the task that can be split into a technology and a theory, a theory being a more abstract level of justification than the technology. We will show in the sequel how praxeologies can be put to good use and among other things shed some more light onto the distinction between technology and theory. But before that we should emphasize that one breakthrough permitted by this approach is to allow mathematical knowledge to gain a form of relativism. This doesn't mean that Pythagoras' theorem will sometimes be true and other times false, but that different institutions may have different views on the same knowledge e.g. a given knowledge may be a simple technique in one institution, like the limit concept in many Belgian secondary schools, or a theory developed to give analysis a Euclidean architecture as has been done by Cauchy who in many ways can be considered the father of analysis and the creator of the modern concept of limit (Job, 2011).

Two different praxeological levels

This institutional relativity of mathematical knowledge has led Schneider (Schneider, 2009) to distinguish between two different kinds of praxeology, modelling ones and deductive ones, allowing us, as we shall explain, to understand the dynamic behind some hard to teach concepts like the limit one (Job, 2011), but also to design tasks that transcend the pre/post tests pitfalls.

In the first kind of praxeology, modelling ones, the fundamental task is to compute features of objects like areas of surfaces, volumes of solids whose existence doesn't rely yet on a formal definition. Those objects exist as mental constructions shared, or believed to be, by some institutions. Justifications given in those praxeologies to techniques developed to address the fundamental task often rely on pragmatic arguments. A technique is validated if the results obtained are in accordance with results derived using other valid techniques that may even belong to Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford. 205 other fields of sciences. For instance, early infinitesimals techniques where used and recognized based on the accordance with results obtained using physical arguments of cinematic nature.

In the second kind of praxeology, deductive ones, the fundamental task consist in defining those mental constructions, to make explicit what was left in the shadow in the first kind of praxeology and built a deductive theory. Often the techniques used in modelling praxeology are used in deductive ones as definitions. The definition of integral given by Cauchy is a good example of such a procedure: an approximation procedure is turned into a definition that, in turn, is used to prove theorems about integrals (existence, uniqueness …).

The two kinds of praxeology are distinct but closely related, the second kind often taking place after the first one. With these two concepts we don't aim, nor claim to encompass the whole mathematics, but important parts of its growth like the birth of analysis from calculus. Indeed, it can be showed that calculus can be roughly speaking represented as a modelling praxeology and analysis a deductive one (Job, 2011). These two praxeologies take into account the institutional relativity of various concepts like the limit one and the derivative that may otherwise be seen as concepts that somehow where born at some place in time almost as they appear nowadays whereas they evolved under the guidance of very different viewpoints. The calculus period was mostly guided by the will to be able to compute areas… and analysis was created out of the will to purge calculus from geometry and physics, forge a new area of mathematics whose rigor would equal that of the ancient Greeks.

Epistemological thickness and fundamental character of a task

The praxeological levels introduced above allow us to get back to our initial asking. How do we assess a task? A partial answer given by Brousseau (Brousseau, 1998) is to consider a task fundamental with respect to a given knowledge if the knowledge takes places in a praxeology as a technique where the task cannot be solved without that knowledge. The knowledge is thus seen as a kind of optimal answer to the proposed task. This requirement is legitimated by what we have said earlier in this article about the role playing pupils, students and teachers are prone to engage. It shouldn't be possible to solve the task used to teach a certain knowledge only using hints external to the knowledge like the teachers eyebrows indicating if the students are running along the required lines.

This understanding of the fundamental nature of a task has been shown to be effective to introduce concepts likes the rational numbers (Brousseau, 1998) but doesn't seem to translate well to concepts like the limit one. Indeed, it is one of the twentieth century achievements to have shown with the work of Abraham Robinson that a sound basis could be given to infinitesimal concepts so far rejected as a sound basis for calculus. The limit concept is thus by no means necessary to cast the calculus into a deductive mould.

Anyway, the very heart of Brousseau's idea can be adapted is the following manner, taking into account the institutional relativity of knowledge introduced above. A task is said to be fundamental (in a broad sense) with respect to a given knowledge and a given institution if that institution takes for granted the knowledge is optimal to solve the task. In this new definition there is no more necessity in a "mathematical" way but an anthropological necessity that an institution gives to itself.

At this point, we are now able to understand the leading role played by praxeological levels. The structure of a fundamental task and even the fundamental Theme B – P. Job & M. Schneider 206 character of that task with respect to, for instance, the limit concept depend on what kind of praxeology we place ourselves in. A fundamental task for the limit concept in a deductive praxeology won't be the same as a fundamental task in a modelling one. Before we dive into some characteristics of these tasks, let us first give an example of the consequences of not being able to clearly state whether a task belong to one praxeological level or the other.

The consequences of blurred praxeological levels in secondary school

In (Job, 2011) we study the teaching of the limit concept in secondary school and are able to support the following views. Secondary school tries to teach the limit concept but fails to do so, unable to identify the praxeological level where it should belong.

Secondary school tries to teach this concept giving students elements that belongs to the deductive praxeology of analysis mathematicians use nowadays in order to place itself under the supervision of that institution from which it draws its legitimacy. This deductive praxeology being out of reach to students of that age, the school praxeology mainly consists of elements acting as blazons, that is, parts of the original praxeology that are able to support the illusion of a real teaching of the limit concept from an outside perspective.

Among these blazons, the definition of a limit plays a key role. Secondary school tries to teach this definition using various tricks to make believe students this definition is a somewhat complicated (mathematical) way of saying something very natural. For instance, it gives students tables with values of x and f(x) for a given

function, waiting for the students to recognized some sort of behaviour that should be put into sentences like "as x tends to … f(x) approaches …". Starting from such sentences, teachers gradually turn these into the required forms "f(x) can be made as close as one wishes to …" using arguments that belong more to rhetoric than mathematics.
Such an approach is misleading in nature for the definition of the limit concept was designed by Cauchy to conduct proofs and define other key concepts of analysis like the derivative. But except for a few trivial ones, proofs in secondary school are left aside. So the very use of the limit concept in the deductive praxeology where it belongs is left aside. The school praxeology thus bears no fundamental character whatsoever.
Such a fool's game isn't the consequence of any malicious thoughts on the side of secondary school but the resultant of antagonist constraints. On the one hand, it has to teach the limit concept in a way mathematicians would recognize as valid, which is a daunting task. On the other hand it must succeed in that task. The only way secondary school has to its disposal to conciliate the two is to take the deductive praxeology, strip it from most of its content and wrap it in a discourse that can be accepted by students even if the cost is to propose tasks that have no fundamental character. This wrapping is partly a consequence of its unawareness of the existence of another praxeology (a modelling one) where the limit concept is legitimate.
So secondary school's praxeology with respect to the limit concept lies in a no man's land, not being in a deductive or in a modelling praxeology. Similar conclusions are drawn in (Rouy, 2007) regarding the derivative also based on praxeological considerations. This analysis sheds a new light on the pre/post-tests methodology. How could we give credit to a task succeeding a sequence of pre and post tests if that task isn't epistemologically consistent? Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
207
What praxeological level for secondary school?
The section above asks a crucial question. Is there a place left for the limit concept in school that would be mathematically legitimate? The answer might be positive if we place ourselves in a modelling praxeology. Although Schneider is critical towards some of the tasks they designed (Schneider, 2001), AHA (AHA, 1999) has proposed a fundamental task for the limit concept in a modelling praxeology, which is declined at the various levels of application of the concept in sub-tasks (areas, speeds, tangents).
On the other hand, Job has studied the teaching of the limit concept in a deductive praxeology (Job, 2011). Its results show how much a deductive approach to the limit concept is a very demanding task. In a few words, the students were asked to propose definitions of a certain behaviour of sequences of real numbers and then to proof properties related to this behaviour. The students were mostly unable to make their definitions evolve. They stayed stuck with definitions that are "descriptions" of what they see of the studied behaviour. They couldn't possibly envision their definitions as something to be chosen to allow proofs despite the many contradictions pointed out by the teacher. This inability is related to epistemological obstacles. Students see definition as a description of some mental concept they believe everyone of them share. They therefore don't understand the rules of the game they are asked to play, feeling they are asked something unnecessary complicated because "everyone agree with the found properties", "nothing has to be proved". This situation seems like a dead end because the teaching school has given them tends to reinforce their vision of mathematics, depriving them from the need to cast theories into a deductive mould.
Different understandings of the task concept
Let us give a second example of the use of praxeologies that will put the task concept itself into question, showing it should sometimes be understood at a different level than is usually done, thus clarifying the concept of a fundamental task understood in a broad sense.
We shall illustrate our views through a task used by our team (Job & Schneider, to be published) to teach negative numbers and specifically the multiplication rule to 12 years old pupils. Being as concise as possible, pupils are asked to devise a single formula that allows them to encompass the motion of two vehicles, being flashed by a radar, driving different roads, but at the same constant speed of 2km/min. A first formula p=2t emerges for positive times where p denotes a location and t a time
17
. They are then asked to elaborate a formula that would also be valid for negative times e.g. times before the two cars are flashed. This requirement of a single formula brings pupils face to face with expressions like -6=2 x (-3) and therefore to an extension of the multiplication rule for positive numbers to negative ones. Pupils are then asked to deal with cars driving in the direction opposite to the one the first two where driving. This introduces "negative" speeds, the minus sign telling which direction the car is driving. The same requirement of a single formula leads in turn to expressions like 6=(-2) x (-3) a completes the multiplication rule for negative numbers.

17
Aside the multiplication rule, the task allow us to make pupils distinguish between distance and position among many other things we have no space to elaborate on. Theme B – P. Job & M. Schneider
208
Such an introduction of negative numbers and their multiplication meets pupils' global assent but what we are trying to emphasize lies somewhere else. The peculiarity of our task doesn't rely so much on the pupils' assent, but on a characteristic where they are not involved in the first place. This task tries to expose pupils to a choice made by mathematicians/physicists to allow them to model with a single formula the various incarnations of the same motion, in terms pupils should be able to understand. Pushing the structure of our task to the extreme, it doesn't matter so much if the pupils agree with the decision made by mathematicians/physicists as long as they understand there is a choice to be made and its consequences, because it is not their assent we are seeking. We simply try to make as explicit as possible choices made by some institution they have no impact on. Learning mathematics and physics also means learning the conventions of those institutions whether we agree or not with them. It is not to say that pupils have nothing to understand. On the opposite, there is something to understand which is located at a level that is subtle to explain, not to pupils who are living the task, but to the mathematical learning community: if you want to learn mathematics you have to accept its conventions whether or not you agree with them as long as you understand why those conventions have been adopted.
Conclusion
We have argued that a pre/post-tests methodology is unsound to assess the efficiency of a task and that the distinction between two kinds of praxeologies (modelling and deductive ones) plays a key role in designing tasks and understanding the dynamic of ordinary lessons. A task should clearly identify whether it belongs to one praxeology or the other in order to be meaningful. A task that doesn't belong to any of those two levels should be handled with great care, its fundamental character being dubious. Being able to state to what kind of praxeology we belong allow us to interpret students' work in the light of a solid epistemological background, therefore giving us tools to avoid misinterpretations that pre/post-tests a prone to commit due to their very structure: a post test result better than a pre-test one isn't obviously a sign of better understanding but may only be the result of an accommodation from the students that have understood how to answer the tasks without using the targeted mathematical knowledge. Taking advantage of the distinction made between modelling and deductive praxeologies and the relativity of knowledge, we have put into question the very concept of a task showing how much its understanding can be and should broadened as soon as we are dealing with the teaching of concepts like the limit one or the negative numbers. Those tasks should be understood in a broader sense than usual, as a way to highlight choices made by an institution and the reasons underlying these choices.

Designing Covariation Tasks to Support Students' Reasoning about Quantities involved in Rate of Change
Heather L. Johnson
University of Colorado Denver
This paper articulates theoretical and practical considerations for designing a sequence of covariation tasks to support students' reasoning about quantities involved in rate of change. Adapting the well-known bottle problem during two iterations of implementation and analysis, this researcher-developed task sequence incorporates dynamically linked geometric and graphical representations of covarying quantities and prompts fostering students' coordination of quantities that are changing together. Taking into account students' perspective of quantities involved, this task sequence is designed to support students' progression in using nonnumerical quantitative reasoning to make predictions and create representations indicating how one quantity might change in relationship to another changing quantity.
Keywords: Task design, Reasoning, Quantity, Covariation, Rate of Change
Researchers using mathematical tasks involving dynamic representations of covarying quantities have supported middle and high school students' consideration of relationships between quantities involved in rate of change (e.g., Johnson, 2012b; Monk & Nemirovsky, 1994; Saldanha & Thompson, 1998; Stroup, 2002). In this paper I articulate theoretical and practical considerations for designing a sequence of covariation tasks to support middle school students' reasoning about quantities involved in rate of change. The design of this task sequence accounted for students' perspective of quantities involved to support their progression in using nonnumerical quantitative reasoning to make predictions and create representations indicating how one quantity might change in relationship to another changing quantity.
Background
Drawing on Sierpinska's (2004) characterization, by mathematical task I mean a purposefully designed problem intended for a particular audience. By problem, I mean a situated problem (Gravemeijer, 1994) involving a particular context. I take an interpretive stance on context, drawing on Van Oers' articulation of context: "What counts as context depends on how a situation is interpreted in terms of activity to be carried out" (1998, p. 481). Acknowledging that individuals for whom a task is intended can interpret the task in myriad ways, I assume that an individual's perspective on the nature of the problem to be solved can influence an individual's reasoning about mathematics he or she perceives to be involved in the task. Theme B – H. Johnson
212
I consider mathematical reasoning to be an individual's purposeful mental activity situated within a particular context. The purposeful activity includes making sense of how a mathematical situation holds together (Simon, 1996), making relationships between objects involved in a situation (Thompson, 1996), and engaging in operation that involves carrying out actions both mentally and physically (Piaget, 1970). When characterizing reasoning as quantitative, I consider a quantity to be an individual's conception of the measurability of an attribute of an object (Thompson, 1994). Because individuals do not need to determine actual measurements to reason quantitatively, quantitative mental operations are nonnumerical (Thompson, 1994). By articulating that the object of the reasoning is quantities involved in rate of change, I do not assume that individuals will reason about rate of change as single entity. Focusing on covariation (Carlson et al., 2002), I attend to how individuals make sense of and make relationships between quantities that are changing together.
Adapting the well-known bottle problem to design covariation tasks
I designed covaration tasks by adapting the well-known bottle problem developed by the Nottingham University's Shell Centre (Swan & the Shell Centre Team, 1999). Given the context of a bottle filling with liquid being dispensed into the bottle at a constant rate and a picture of a bottle, the bottle problem requires students to sketch a graph of the changing height of the liquid as a function of the changing volume. Researchers have used the bottle problem to investigate the reasoning of undergraduate and graduate mathematics students (Carlson et al., 2002) and prospective elementary (Carlson, Larsen, & Lesh, 2003) and secondary (Heid, Lunt, Portnoy, & Zembat, 2006) mathematics teachers. My adaptations to the bottle problem have had two iterations of implementation and analysis. The task sequence reported in this paper is from the second iteration.
In the first iteration I developed a covariation task by adapting the bottle problem in two ways: (1) Providing students with a graph and asking students to sketch a bottle that the graph could represent, and (2) Using a graph that represented the changing volume of the liquid as a function of the changing height. Prompts included in this covaration task were: (1) How is the volume of the liquid in the bottle changing as the height of the liquid in the bottle increases? (2) Sketch a bottle that the graph could represent. Intending to implement the task with high school students who had not yet taken a calculus course, I provided students with a graph because previous

research (Carlson et al., 2002; Heid et al., 2006) found that even students with extensive mathematics background have difficulty creating graphs. I chose to represent volume as a function of height in part because preservice elementary teachers working on the bottle problem operated with the independent variable, volume, as if it were time (Carlson, Larsen, & Lesh, 2003). I hypothesized that representing volume as a function of height might reduce the likelihood of students treating the independent variable as if it were time.

In the second iteration I adapted Thompson, Byerly, and Hatfield's (in press) version of the bottle problem that dynamically links a pictorial representation of a filling bottle with a graph relating the volume of liquid in the bottle to the height of liquid in the bottle. Key to Thompson et al.'s adaptation was the use of a dynamic environment linking pictorial and graphical representations. I hypothesized that such an environment could foster students' reasoning about covarying quantities by explicitly linking a change in one representation with a change in another representation. Hence, I adapted Thompson et al.'s bottle problem (implemented with Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
213
beginning calculus students) for use with 7
th
grade pre-algebra students. Anticipating that 7
th
grade students might have limited conceptions of volume, I altered the context of the task from a filling bottle to a two-dimensional shape being filled with area. In making this change, the two dimensional pictorial representation would represent a two dimensional rather than a three dimensional quantity.

The adaptation for 7
th
grade pre-algebra students resulted in a sequence of four tasks. Accompanying each task was a dynamic sketch I developed using Geometer's Sketchpad software (Jackiw, 2009). The filling rectangle sketch (see Fig. 1) linked a rectangle with a graph that related the amount of shaded area to the height of the shaded area. Students could vary the height of the rectangle by animating or dragging point H. Students could drag point F to vary the width of the rectangle, then predict and create corresponding graphs representing the amount of shaded area as a function of its height. The filling triangle sketch (see Fig. 2) linked a right triangle with a graph that related the amount of shaded area to the height of the shaded area. Students could vary the height of the triangle by animating or dragging point D, then predict and create a corresponding graph representing the amount of shaded area as a function of its height. By affording students' manipulation of dynamically linked representations, the dynamic sketches seem to foster students' consideration of relationships between covarying quantities.

Figure 1. Filling Rectangle Sketch Figure 2. Filling Triangle Sketch

Task sequence

The task sequence is designed to support students' progression in using nonnumerical quantitative reasoning to coordinate covarying quantities. The description of the task sequence includes: (1) Statement describing the context for the task sequence (2) Identification of dynamic sketch used with each task (filling rectangle or triangle), (3) Quantitative reasoning (QR) objective for each task (italics), and (4) Prompts fostering students' coordination of quantities that are changing together. The context for the task sequence describes the situation on which the tasks are based. A QR objective is distinct from a learning objective because it indicates purposeful activity intended to support a way of reasoning rather than an intended mathematical understanding. These QR objectives indicate purposeful ways of making sense of and making relationships between covarying quantities. Prompts refer to questions and directives designed to foster students' making of relationships between quantities and predictions about characteristics of linked representations. Theme B – H. Johnson
214

Context for task sequence

Imagine that a shape (rectangle/triangle) is being filled with area.

Task #1: Filling Rectangle Sketch

Create and use non well-ordered tables of values indicating measurements of related quantities to predict characteristics of graphs relating those quantities.

Press Animate Point to run the animation of the filling rectangle. What changes and what stays the same?

Given a non-well ordered table of heights for a rectangle with a given base, determine the different amounts of area. For example:

Imagine the side length of EF was 4 cm. Complete the table:

Length of Side EH 1 cm 3 cm 5 cm 7 cm 10 cm

Area of Rectangle EFGH

Imagine you created a graph relating the side length of EH and the filling area of EFGH. Would the graph be linear? Explain why or why not.

Repeat bibc for bases of different lengths. How would the graphs be similar/different?

Task #2: Filling Rectangle Sketch

Use an amount of change in one quantity to predict an amount of change in a related quantity.

Given a non-well ordered table of heights for a rectangle with a given base (e.g., the table in 1b), determine the different amounts of area.

Determine at least two different ways to complete this statement: When the height increases by _____, the area increases by _____. How many ways can this statement be completed?

When given the two different heights for the same base, determine the amount of increase in area. For example,

Imagine the side length of EF was 3 cm. Complete the table:

Length of side EH 14.5 cm 16.5 cm

Amounts of increase in area of rectangle EFGH

Task #3: Filling Rectangle Sketch

(1) Use a graph relating two quantities to predict a measure for a third, related quantity (not represented explicitly by the graph). (2) Use a relationship between two quantities to predict characteristics of a graph relating one of those quantities to a third quantity.

Given graphs representing the amount of filling area as a function of the length of side EH, predict the length of the base of the rectangle.

Given a relationship between changing area and changing height (e.g., As the length of EH increases by 2 cm, the area of rectangle EFGH increases by 3 cm
2
),
predict what a graph relating area and the side length of EH would be like.

What would a graph be like for a rectangle with (1) a very short base, (2) a very long base? Why? Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
215

Task #4: Filling Triangle Sketch

Use a dynamic geometric representation of covarying quantities to predict characteristics of a graph relating the quantities.

Press Animate Point to run the animation of the filling triangle. What changes and what stays the same?

How does area change as the height increases?

Imagine you created a graph relating the side length of AD and the filling area ABCD. What would the graph be like?

Press Animate Point to sketch the graph. Was it what you expected? Why do you think it looks that way?

Design principles

Three principles guided my design of the task sequence. Central to each of these principles was my consideration of how students might perceive the nature of the quantities involved and how students' perspectives might influence their consideration of relationship between those quantities.

(1) Anticipate students' perspectives on relationships between changing quantities

Drawing on results of analysis of students' work on the first adaptation of the bottle problem, I anticipated two distinct perspectives students might have on relationships between change in the covarying quantities involved in the task sequence: (a) Quantities can change simultaneously with change in one quantity being independent of change in a related quantity (Johnson, 2012a) and (b) Change in one quantity depends on change in a related quantity (Johnson, 2012b).

(a) By relating covarying quantities as if each quantity were changing independently of the other quantity with respect to time, students can make comparisons between amounts of change in each quantity (Johnson, 2012a). For a filling rectangle, if 7
th
grade students could determine amounts of area for given amounts of height (The height being the length of EH – see Fig. 1), they could make comparisons between amounts of change in area and amounts of change in height. By sequencing filling rectangle tasks that afforded calculation of amounts of area prior to a filling triangle task that problematized calculation of amounts of area, I intended to support students' gradual move away from making numerical calculations.

(b) Reasoning about change in one quantity as being dependent on change in a related quantity can support students' attention to variation in the intensity of a change (Johnson, 2012b). If 7
th
grade students were able to envision the area of the filling triangle as varying in relationship to the height (The height being the length of AD – see Fig. 2), they could make claims about the area of the triangle increasing more slowly as the height increased. By requiring students to predict how area would change as height increased when manipulating dynamically linked geometric and graphical representations, I intended to support students' reasoning about variation in area as being dependent on variation in height. Theme B – H. Johnson
216

(2) Incorporate key aspects to support students' attention to covarying quantities

The task sequence incorporated three key aspects: (a) Tables that were not well ordered, (b) Questions supporting students' attention to covarying quantities, and (c) Questions supporting students' making of predictions about change.

(a) In the filling rectangle tasks I incorporated tables that were not well ordered. By indicating that a table is not well ordered, I mean that the independent variable contained in the table (in the case of the filling rectangle tasks, the length of EH) does not increase by a uniform amount. When working only with well ordered tables, secondary students did not necessarily attend to change in both independent and dependent variables (Lobato, Ellis, & Munoz, 2003) and tended to pay attention to numerical patterns (Ellis, 2007). I anticipated that including tables that were not well ordered could promote students' attention to and making of relationships between covarying quantities.

(b) Both the filling rectangle and the filling triangle tasks incorporated prompts supporting students' attention to and making of relationships between the changing quantities of area and height. The prompt "What changes and what stays the same?" provided an entry point into the task and fostered students' attention to different quantities involved in the task. Subsequent prompts supported students' making relationships between quantities that were changing together. For example, in task 2b, completing the statement "When the height increases by _____, the area increases by _____" in multiple ways supports students' consideration of multiple relationships between amounts of increase in height and area for a rectangle with a given base. Once students could begin to focus on relationships between quantities, it seems reasonable that students could then draw on those relationships to engage in related activity.

(c) Each task supported students' activity of making predictions about (1) characteristics of a linked representation (tasks 1, 3, 4) or (2) a related amount of change (task 2). Making predictions can foster students' use of nonnumerical reasoning by supporting students' envisioning of running through calculations without actually making the calculations to make relationships between the changing area and the changing height. For example, task 2c required students to predict amounts of change in area given two different heights without actually determining amounts of area. If students determined amounts of area, subtracted those amounts, then arrived at amounts of change, it could indicate that students were not yet relating changes in height with changes in area. By requiring students to predict characteristics of graphs representing rectangles with differently sized bases, task 3c supported students' use of relationships between area and height. Such predictions were intended to support students' attention to relationships rather than to results of calculations.

(3) Sequence tasks to support students' progression from numerically based reasoning to nonnumerically based reasoning

I sequenced the filling rectangle tasks prior to the filling triangle task based on two research hypotheses related to students' perspectives on quantities involved: (a) Students can use numerical calculations (with or without actually engaging in calculations) to make comparisons between amounts of change in covarying quantities, and (b) By focusing on covariation, students can attend to situations Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
217
involving constant rate of change in ways that can support their attention to variation in the intensity of change in situations involving varying rates of change.

(a) While numerical calculations can be an entry point into the filling rectangle tasks, the design of each filling rectangle task is not intended to support students generalizing from numerical calculations. In contrast, intent is to support students' engagement in the nonnumerical operation of linking a changing area with a changing height. Students working from numerical calculations could begin to imagine running through calculations (without actually completing the calculations) to relate the changing area to the changing height.

(b) The filling rectangle tasks incorporate constant rates of change, and the filling triangle task incorporates a rate of change that increases at a decreasing rate. Although it may seem obvious to position tasks involving constant rate of change task prior to a task involving varying rate of change, research has questioned whether situations involving constant rate of change are sufficiently complex to engender students' reasoning related to varying rate of change (Stroup, 2002). Filling rectangle tasks incorporating constant rate of change supported students' focus on the covarying quantities of volume and height. I anticipated that such tasks would contain sufficient

complexity to support students' consideration of situations involving varying rate of change because they could foster students' coordination of covarying quantities.
Task implementation and analysis
During May 2012, I implemented the filling rectangle tasks with 4 sections of 7
th
grade students at an urban middle school in a large Midwestern U.S. city. The district has identified the school as high performing based on students' academic performance, with approximately 45% of students identified as English Language Learners and over 90% of students receiving free or reduced lunch. I implemented tasks 1-3 during three consecutive days of whole class instruction. Following the lessons, I conducted 40-minute task-based interviews with 7 pairs of students, selecting at least 1 pair of students from each of the 4 sections. I purposefully chose student pairs based on the students' participation in classroom instruction and on evidence of reasoning about quantities involved in rate of change. During the taskbased interviews I followed up with task 3 and presented task 4. For this paper I report results of analysis of students' work on task 4.
Analysis of students' work during task-based interviews revealed two main findings: (a) Students may depend on numerical calculations to make claims about how quantities are changing together, and (b) Students may create graphs relating covarying quantities (not including time) as if one quantity were elapsing time.
(a) Students who depended on numerical calculations had difficulty making predictions about how the area of the triangle would change as the height increased. The responses of two students, Navarro and Myra (who participated in different interview pairs), provide insight into the kind of difficulty students might have. When Navarro and Myra were presented with the filling triangle task, both of them attempted to determine amounts of area. Even after prompting to not worry about making calculations, Navarro's persistence in trying to calculate amounts of area made it seem as if he depended on calculating amounts of areas to make such predictions. Unlike Navarro, after my prompt to not worry about how to calculate the area, Myra smiled and exclaimed "Oh, I get you now!" When I asked her to explain, she said "the area is getting bigger, but how much it increases is getting smaller." By

variation in how the area was increasing. Future iterations of implementation and analysis could provide further explanation as to how students' nonnumerical reasoning develops when making relationships between quantities.
(b) Although the filling triangle sketch related area with the length of AD, when predicting features of a graph some students seemed to operate as if AD represented time. I designed the animation (See Fig. 2) so that the graph would begin to be sketched from a point when the triangle was partially filled. When predicting the shape of a graph relating area and side length for the filling triangle, Tomas sketched a graph in the air, indicating the graph would curve and then begin to increase again (which is not consistent with the graph shown in Fig. 2). When asked to explain why, Tomas said that area would fill more slowly and then start filling more quickly again. Even though Tomas attended to both area and side length when using the animation, he seemed to sketch the graph as if it were relating increasing area with elapsing time. Future tasks dynamically linking multiple graphs relating changing quantities to a single geometric representation might support students' consideration of the independent variable as something other than time.
Implications for task design in research investigating students' reasoning
Designing a sequence of tasks to support students' reasoning involved theoretical considerations including how students might make sense of and coordinate covarying quantities and practical considerations including how students might manipulate quantities represented with dynamic geometry sketches. The task sequence supports students' progression in using nonnumerical quantitative reasoning to make predictions and create representations indicating how one quantity might change in relationship to another changing quantity. Researchers could draw on and expand design principles underlying this task sequence to develop other task sequences focusing on quantity and covariation. Future research involving implementation of this and other task sequences could support development and expansion of frameworks articulating progressions in quantitative and covariational reasoning.

This paper presents a research framework for a design research approach to constructing creative learning opportunities and some related empirical studies.
Keywords: Learning difficulties, rote learning, creative reasoning, task design.
Introduction
A central problem in mathematics education is that we want students to understand mathematics and to become efficient problem solvers, but even after 30 years of research and reform many students still do inefficient rote thinking (Hiebert, 2003; Lithner 2008). This can be seen as one of the main reasons behind learning difficulties in mathematics. The reason that the rote learning problem is (largely) unsolved in many countries is a combination of several factors related to the immense complexity of mathematics learning (Niss, 1999) and to the lack of research insights concerning the effectiveness of different teaching designs (Niss, 2007).
This design research addresses some of the most central mathematics learning goals, which we (teachers, researchers and other actors in the educational systems) largely fail to help students to reach: problem solving ability, reasoning ability and conceptual understanding. Problem solving is defined as "engaging in a task for which the solution method is not known in advance" (NCTM, 2000, p. 51) and includes identifying, posing, and specifying different kinds of problems and solving them, if appropriate, in different ways (Niss 2003). Reasoning is a fundamental aspect of mathematics (NCTM, 2000). It goes beyond constructing reasoning, and includes abilities like following and assessing chains of arguments, Theme B – J. Lithner et al

knowing what a proof is and how it differs from other kinds of reasoning, uncovering the basic ideas in a given line of argument, and devising formal and informal arguments (Niss 2003). The notion of understanding is very complex (Sierpinska 1996), and will not be pursued here beyond noting that several of the theoretical constructs denoted understanding concern relations between rote learning and deeper understanding, e.g. Skemp (1978) and Hiebert & Lefevre (1986). The notion will here be used in a relatively intuitive way, referring to insights in the origin, motivation, meaning and use (Brousseau 1997) of a mathematical fact, method, concept or other idea.
Rote learning
Rote learning is "the process of learning something by repeating it until you remember it rather than by understanding the meaning of it" (Oxford Advanced Learner's Dictionary). The characteristics, causes, and consequences of rote learning in mathematics can to a large extent be connected to an unwarranted and far-reaching reduction of complexity in terms of an algorithmic focus (Skemp, 1978; Hiebert & Carpenter, 1992; Tall, 1996; Vinner, 1997; Hiebert, 2003; Lithner, 2008). Referring to "massive amounts of converging data" in studies from USA, Hiebert (2003) suggests that the baseline conclusion is that students are learning best the kinds of mathematics that they are having the most opportunities to learn, which is simple calculation procedures, terms and definitions through memorization. Similar opportunities to learn were found in a Swedish large-scale study including observations of 200 mathematics classrooms (Boesen et al., 2012).
Memorising facts and procedures, sometimes without understanding, is a central aspect of mathematics learning. The problem is when rote learning becomes dominating since it is not possible to develop other central competencies like problem solving ability and conceptual understanding by rote learning alone. For example, it is well known (e.g. Schoenfeld, 1985) that there is no transfer from rote learning of basic facts and procedures to the ability to solve non-routine mathematical problems. From literature reviews (e.g. Hiebert, 2003) and from the empirical studies exemplified below, it is reasonable to draw the conclusion that rote learning is one of the main causes behind the difficulties to learn mathematics that large groups of students of all age levels encounter.
Creative reasoning
This and the next section consist of a summary of selected parts of a research framework (Lithner, 2008) that is based on the outcomes of a series of empirical studies on the relationship between reasoning and learning difficulties in mathematics. Reasoning is defined in this paper as the line of thought that is adopted to produce assertions and reach conclusions when solving tasks. Reasoning is not necessarily based on formal logic and is therefore not restricted to proof; It may even be incorrect as long as there are some sensible (to the reasoner) arguments supporting it. A basic assumption is that the design of the students' tasks (and of the classroom context) affect the reasoning the students will activate which in turn affects their opportunities to learn. A "task" includes most of the work requested from students in classrooms, such as exercises, tests, group work, etc. Arguments can be anchored in either surface or intrinsic properties, and the relevance of a mathematical property can depend on context. In deciding if 9/15 or 2/3 is largest, the size of the numbers (9, 15, 2, 3) is a surface property that is insufficient to resolve the problem (a conclusion Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

based on this property alone is that 9/15>2/3 since 9 and 15 are larger than 2 and 3), while the quotient captures the intrinsic property. The intrinsic/surface distinction was introduced because one of the reasons behind students' difficulties was found to be the anchoring of arguments in surface properties (Lithner, 2003). The aspect of creativity that is emphasized in this framework is not 'genius' or 'exceptional novelty,' but the

creation of mathematical task solutions that can be modest but that are original to the individual who creates them (Silver, 1997).
The discussion above leads to a definition of Creative Mathematically Founded Reasoning (CMR) that fulfils all of the following criteria. i) Creativity; a new (to the reasoner) reasoning sequence is created, or a forgotten one is re-created, in a way that is sufficiently fluent and flexible to avoid restraining fixations. ii) Plausibility; there are arguments supporting the strategy choice and/or strategy implementation explaining why the conclusions are true or plausible. iii) Anchoring; the arguments are anchored in the intrinsic mathematical properties of the components that are involved in the reasoning.
Imitative reasoning
The empirical studies that form the basis of this framework have identified three main types of mathematically superficial imitative Algorithmic Reasoning (AR), which may lead to rote learning. The term 'algorithm' includes all pre-specified procedures (not only calculations), such as finding the zeros of a function by zooming in on its intersections with the x-axis with a graphing calculator. "An algorithm is a finite sequence of executable instructions which allows one to find a definite result for a given class of problems" (Brousseau, 1997, p. 129). The importance of an algorithm is that it can be determined in advance. The n:th transition does not depend on any circumstance that was unforeseen in the (n-1)st transition - not on finding new information, any new decision, any interpretation, or thus on any meaning that one could attribute to the transitions. Therefore, the execution of an algorithm has high reliability and speed (Brousseau, 1997), which is the strength of using an algorithm when the purpose is only to produce a task solution.
However, if the purpose is to learn something from solving the task, the fact that an algorithm is independent of new decisions, interpretations or meaning implies that all of the conceptually difficult parts are taken care of by the algorithm, and thus only the easy parts are left to the student. This may lead to rote learning. In particular, the resultant argumentation is normally superficial and very limited, as seen in the main AR types that are found in studies: Familiar AR includes a strategy choice that can be characterized by attempts to identify a task as being of a familiar type with a corresponding known solution algorithm or a complete answer. In Delimiting AR, the algorithm is chosen from a set of algorithms that are available to the reasoner, and the set is delimited by the reasoner through the included algorithms' surface property relationships with the task. For example, if the task contains a second-degree polynomial p(x), the reasoner can choose to solve the corresponding equation as p(x)=0 even if the task asks for the maximum of the polynomial. In Guided AR, the reasoning is mainly guided by two types of sources that are external to the task. In person-guided AR, a teacher or a peer pilots the student's solution. In text-guided AR, the strategy choice is founded on identifying, in the task to be solved, similar surface properties to those in a text source (e.g., a textbook). Argumentation may be present, but it is not necessary because the authority of the guide ensures that the strategy choice and the implementation are correct. Theme B - J. Lithner et al
224
In students' attempts to resolve problematic task solving situations, the CMR criteria i-iii were found to capture the main differences seen in reasoning characteristics between AR (where i-iii are absent) and constructive CMR (Lithner, 2008). Students often use superficial imitative reasoning of the types presented above in laboratory tests and when working with tasks (e.g. textbooks or assessment) in regular classroom contexts, which is a major obstacle both when it comes to learn and to use mathematics (e.g. Lithner, 2000; 2003: 2008; 2011, Bergqvist, Lithner & Sumpter, 2008; Boesen, Lithner & Palm, 2010). In addition, teaching, textbooks and assessment mainly promote rote learning in the sense that Guided AR is provided by teachers and textbooks, and that most practice and test tasks can be solved by AR (e.g. Bergqvist 2007; Palm, Boesen & Lithner, 2011; Bergqvist & Lithner, 2012; Boesen et al., 2012). Judging from the quote by Hiebert in the introduction this may be the case also outside Sweden, for example as found in common American calculus textbooks (Lithner, 2004).
Design research and the theory of didactical situations
The ongoing research described below can be characterised as design research which in this paper refers to the use of scientific methods to develop theories, frameworks and principles of innovative educational designs. Although the meaning of design experiments have not been settled in the literature (Schoenfeld, 2007) Plomp (2009) argue that authors may vary in the details of how they picture design research, but they all agree that design research comprises of a number of stages or phases: preliminary phase (development of framework), prototyping phase and assessment phase. A key characteristic of design research is thus that it is strongly aligned with effective models linking research and practice (Cobb et al. 2003), which, according to Burkhardt and Schoenfeld (2003), "the traditions of educational research are not". According to Gravemeijer & Cobb (2006) "the purpose of the design experiment is both to test and improve the conjectured local instruction theory that was developed in the preliminary phase, and to develop an understanding of how it works."
The underlying characterisations of students' reasoning in this paper emanate from a cognitive psychology perspective, but extend into sociocultural considerations when addressing potential causes and consequences. The theoretical foundation for the attempts to design better learning opportunities is Brousseau's Theory of Didactical Situations (1997), which is a theory of how mathematics can be learnt through non-routine problem solving. It emphasises "the social and cultural activities which condition the creation, the practice and the communication of knowledge" (p. 23). One central construct is the devolution of problem. The student has to take responsibility for a part of the problem solving process, but she cannot in general learn in isolation. The teacher's task is to arrange a suitable didactic situation in the form of a problem. Between when the student accepts the problem as her own and the moment when she produces her answer, the teacher refrains from interfering and suggesting the knowledge that she wants to see appear. This part of the didactic situation is called an adidactical situation. The student must construct the piece of new knowledge and the teacher must therefore arrange not the communication of knowledge, but the devolution of a good problem.
The teacher may (e.g. to reduce complexity) try to overcome learning obstacles and force learning by devolving less of the problem to the student. Brousseau exemplifies this by the Topaze effect (p. 25) when the teacher lets the Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
225
teaching act collapse by taking responsibility for the student's work and letting the target knowledge disappear (as in Guided AR). Telling the student that an automatic method exists relieves her of the responsibility for her intellectual work, thus blocking the devolution of a problem. If this is the normal didactic situation the student meets then the didactical contract is formed accordingly, which may not be the teacher's intention. The teacher expects the student to learn problem solving reasoning, while the student expects that an algorithm should be provided that relieves her of the responsibility of engaging in the adidactical situation.
The key issue with respect to this paper is to find a suitable devolution of problem, with the aim of providing learning opportunities through CMR instead of AR. It is in general easy to design AR tasks, since the structure of the task is based on repeating the algorithmic procedure and follows therefore directly from the procedure. For example, after the procedure to solve linear equations (ax+b=cx+d) is described then a large number of AR tasks are obtained trivially by just formulating different equations. If the purpose is just to design any mathematical non-routine problem suitable for a particular student group, then the situation is a bit trickier but the literature and the Internet is full of good mathematics problems. However, if the purpose is to design a problem that can help the student to construct a particular target knowledge then the design becomes much more complicated. In addition, the central target knowledge within mathematics curricula is often such that a set of tasks (and adidactical situations) rather than a singular task is required. For example, if the goal is that the student shall by herself construct a general method for solving linear equations it is unrealistic that this can be done in a single adidactical situation.
A design experiment
This design experiment is a part of a larger project that studies teaching designs that give students different opportunities to learn with respect to imitation or construction of knowledge. In this experiment two ways of teaching are compared: I) An algorithmic method for solving a type of tasks is presented, and students apply this method on a set of practice tasks. The structure is founded in the framework for AR and the tasks have the same structure as common textbook tasks. II) Guiding the individual into by herself constructing a solution method. This structure is founded in the devolution of problem and in the framework for CMR. See below for examples.
In order to be able to compare these two ways of teaching, it is prioritised a) that similar target knowledge can be reached by both ways and b) that the target knowledge may be learnt both by rote and by CMR. A suitable form of target knowledge is task solving methods that can be economised as mathematical procedures. This is a central aspect of mathematical knowledge (Kilpatrick, Swafford & Findell, 2001). The teaching of such procedures seems to constitute some 50-100% of mathematics teaching (Lithner, 2008; Boesen et al., 2012), at least in Sweden but maybe also in other countries (Hiebert, 2003). Thus the overall background question posed is: 'how to best learn mathematical task solving procedures'? Is it to practice standard algorithms by large amounts of drill exercises, or by the students' own construction of the procedures? Concerning this issue the discrepancies between research and practice, and between different research perspectives seem large (Arbaugh et al., 2010). In addition, there seems to be little empirical evidence backing the rather few theoretical claims made.
The teaching mode I is hypothesised to lead the subject into rote learning of algorithms by AR without understanding the foundations of the algorithm. In the Theme B - J. Lithner et al
226
mode II the subject is not given a method that can be directly applied to solve the tasks. Instead, a sequence of exploratory tasks is given. This devolution of problem is intended to make pure rote learning impossible and the subject has to understand the method in order to solve the task. One argument behind the hypothesis that tasks that require CMR will lead to a constructive adidactical situation with a real devolution of problem is related to the three defining criteria of CMR: i) Novelty, that the task cannot be solved by familiar imitative reasoning, ensures the devolution of some kind of reasoning that the student has to be responsible for. ii) The presence of arguments, supporting the plausibility of the conclusions, is necessary to guide and verify the construction of new insights. iii) The necessity to anchor the reasoning ensures that the mathematical obstacles are addressed and that the resolutions are based on properties of relevant mathematical facts and concepts.
The research question of this experiment is: What are the characteristics of an adidactical situation that leads to a devolution of problem where learning through CMR is more efficient than learning through AR in the format common in school?
The present pre-clinical (Schoenfeld, 2007) experiment is in order to reduce complexity carried out without peer-peer or peer-teacher interaction, and serves to clarify basic phenomena as a preparation to pose the same question in a real classroom context. Several iterations and revisions of task designs have been carried out. In one of the designs two groups of students (n=99) are matched by grades and basic cognitive tests. An example of an AR practice task is given in Figure 1. The corresponding CMR practice task consists of the same introduction and same question at the end, but the sentence with the formula ("If x is…) and the solved example is removed. One week after the practice session all students from both groups take the same post-test.
When squares are put in a row it looks like the figure to the right. 13 matches are need for four squares:
If x is the number of squares then the number of matches y can be calculated by the function y=3x+1
Example: If 4 squares are put in a row then y=3x+1=3.4+1=13 matches are needed.
How many matches are needed to get 6 squares in a row?
Figure 1, example of an AR practice task.
One may note that compared the AR group could have an advantage since they are provided with more information. However, the empirical studies mentioned above show that if students are given an algorithmic solution method to a task, they will mainly apply AR to solve the task without considering the underlying meaning of the concepts, representations or connections. Thus they will probably not even try to understand meaning of the algebraic formula, which in this example is the relation between the figure of matches and the formula y=3x+1. Then the Theory of Didactical Situations implies that the CMR group may learn better. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
227
Figure 2
The results show that this is the case, in the sense that the CMR group on average has significantly higher test results and shorter response times (Figure 1). The test tasks "Formula" ask for recalling the formula, "Short numerical" for recalling and applying a solution method and "Long numerical" for (re)constructing a solution method.
In addition, the common belief that only the best pupils can benefit from learning through their own construction of solution methods is not supported by this experiment. On the contrary, in the 30% with lowest cognitive index (a composite grade and pre-test score) the difference to the advantage of the CMR group is even larger than for the whole sample (Figure 2).
Figure 3 Theme B - J. Lithner et al
228
Parallel to the experiment above, other complementary studies are carried out within the research project. One example is an ongoing study using functional Magnetic Resonance Imaging (fMRI) to compare brain activity for students (n=40) from AR and CMR training groups. This study is exploratory with the aim to analyse non-behavioural information about students' thinking processes. One question asked is if students from the two groups activate different neural networks, and how this relates to earlier research findings about the brain and the learning of mathematics. Another question is if students from one group show higher brain activity in specific regions, and what the causes may be. For example, brain activity in the CMR group could be higher if they have created some kind of richer neural networks or lower if they have developed more rational solution methods and/or more efficient understanding. Another example of ongoing research uses eye-tracking methods to compare the strategies used by students learning through AR and CMR designs.
The work reported in this paper has been presented in research journals (see the references), in a large number of Nordic teacher conferences, in international

research conferences (e.g. Kristiansand 2011, London 2012, Seoul 2012) and has
attracted some interest from national and local media (TV, radio, newspapers and
popular scientific journals). During the spring 2012 discussions with leading local
school administrators about collaboration in design research and educational
development has been initiated, and financial resources are allocated for this purpose.
The research is externally and internally financed and is carried out in
collaboration with researchers, teacher educators and teachers from different areas
(mathematics education, psychology, neuroscience) in Umeå, Falun and Karlstad. The
roles of the authors can be summarised as follows. Johan Lithner (Professor in
Mathematics education): Project leader, educational theoretical and conceptual
background, design principles, construction of initial task versions. Bert Jonsson
(Senior university lecturer in Psychology), psychological theoretical and conceptual
background, cognitive measures. Carina Granberg (Senior university lecturer in
Educational work) and Jan Olsson (School teacher, Licentiate research student),
designing ICT interactive tasks for the classroom. Yvonne Liljekvist and Mathias
Norqvist (School teachers, teacher educators, PhD students in Mathematics
education), construction of testable tasks. All are engaged in the cyclic designrevision-testing-evaluation-redesign of the tasks.
The ongoing research presented above reside in the pre-clinical stage
(Schoenfeld, 2007) and concerns the design of mathematical tasks that are suitable for
devolution of problems where students may solve the tasks by CMR. One aim is to
form a basis for clinical (classroom) studies. However, it is not just to take tasks
designed and evaluated in the pre-clinical phase into the classroom. Stein, Engle,
Smith & Huges (2008) argue that teachers who attempt to use inquiry-based, studentcentred instructional tasks face challenges that go beyond identifying well-designed
tasks and setting them up appropriately in the classroom. Thus one major challenge
for the further research is how the task and teaching designs can incorporate class
interactions. A second challenge is to design tasks that are more open to the students'
own initiatives, and a third to design adidactical situations that encompass wider and
deeper target knowledge than the algebraic formulas in the design experiment above.

Shortcomings in the milieu for algebraic generalisation arising
from task design and vagueness in mathematical discourse

Heidi Strømskag Måsøval
Sør-Trøndelag University College, Norway

This paper presents how the milieu for students' engagement
with an algebraic generalisation task is constrained by two factors: first,
by the task design; second, by the students' unawareness of the nature of a
mathematical statement, combined with the teacher's use of a generic
example without the students' awareness of it.

Keywords: Milieu, adidactical situation, algebraic generalisation,
mathematical statement, generic example.

Introduction

The formulation of a task, as well as its mathematical, social, psychological,
and didactic contexts, are important factors for students' responses on the task
(Sierpinska, 2004). This paper presents an analysis of three student teachers'
collaborative engagement with a task on algebraic generalisation of a shape pattern.
The task is designed by their mathematics teacher educator.

The author has had
influence neither on the design nor on the implementation of the given task. 'Task' is
here understood as an assignment given to students to which they are expected to
produce a solution. The paper deals with the question of how students understand the
purpose of the task they are given in a regular teaching situation (i.e., it is not the
result of didactical engineering, Artigue & Perrin-Glorian, 1991). I show how the
formulation of the task and the interaction between the teacher and the students about
the task constitute a gap between the teacher's intention with the task and the
students' mathematical activity.

Inspired by the writing of Whitehead (1947), Devlin (1994), and others, I
view mathematics as the science of patterns. A shape pattern in school mathematics is
usually instantiated by some consecutive geometric configurations in an alignment
imagined as continuing until infinity. Radford (2006) provides a useful
characterisation of algebraic generalisation of patterns when he proposes that
generalizing a pattern algebraically rests on the capability of grasping a
commonality noticed on some elements of a sequence S, being aware that this
commonality applies to all the terms of S and being able to use it to provide a
direct expression of whatsoever term of S. (Radford, 2006, p. 5)

In the rest of the paper, "students" is used to refer to student teachers, and "teacher" is
used to refer to a teacher educator. Theme B – H. S. Måsøval

Theoretical framework

In Brousseau's (1997) theory of didactical situations in mathematics, an
adidactical situation is a situation in which the student takes a mathematical problem
as his own and solves it on the basis of its internal logic without the teacher's
guidance and without trying to interpret the teacher's intention with the problem. The
devolution of an adidactical learning situation is the act by which the teacher
encourages the student to accept the responsibility for an adidactical learning situation
or for a problem, and the teacher accepts the consequences of the transfer of this
responsibility (Brousseau, 1997). The student cannot engage in any adidactical
situation; the teacher attempts to arrange an adidactical situation that the student can
handle.

In the devolution process, which is part of the broader (didactical) situation,
the teacher is faced with a system, itself built up from a pair of systems; the student
and a milieu that lacks any didactical intentions with regard to the student (Brousseau,
1997). The milieu is a subset of the students' environment with only those features
that are relevant with respect to the knowledge aimed at by the teacher in the
didactical situation. The concept of milieu models the elements of the material or
intellectual reality on which the students act and which may be an obstacle to their
actions and reasoning (Laborde & Perrin-Glorian, 2005). That is, the milieu of a
didactical situation is the part of the environment that can bring feedback to students'
actions to accomplish a task.

An adidactical situation is part of the didactical situation that is the broader
situation with the system of interaction of the students with the milieu arranged with
the purpose of the students' appropriation of the target knowledge without the
teacher's intervention (Brousseau, 1997). The teacher can act on the milieu by
providing new information or new equipment, for example by asking a question or
directing students' attention to certain factors in the classroom situation. When the
teacher acts on the milieu, she changes the knowledge needed to solve the problem
(Perrin-Glorian, Deblois & Robert, 2008). Whether the student can handle an
adidactical situation depends upon two conditions: first, that the student has prior
knowledge that enables him to engage with the situation; second, that the milieu
created by the teacher provides the student with knowings that enable him to develop
the knowledge aimed at (by the teacher).

Succeeding the devolution phase, the didactical situation consists of four
situations (or phases) in which the role of the teacher and the status of knowledge
change (Brousseau, 1997): Situations of action, formulation, and validation are
intentionally adidactical situations, whereas the situation of institutionalisation is not
adidactical. In the following paragraph, these situations are briefly described (for a
more elaborated explanation, see Brousseau, 1997, or Måsøval, 2011, Chapter 2).

The situation of action is where the students engage with the presented
problem on the basis of its internal logic without the teacher's intervention. The
students construct a representation of the situation which serves as a "model" that
guides them in their decisions. In the situation offormulation the students exchange
and compare observations between themselves, where the main purpose is to develop
language to formulate their observations and agree on some common meanings. Here,
the teacher re-enters the scene to chair the exchanges and make sure that all
formulations are made "visible" in the classroom. In the situation of validation the
students try to explain some phenomenon or verify a conjecture. Here, the teacher acts
as a chair in a scientific debate and intervenes only to structure the debate and Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI
encourage the students to use more precise mathematical concepts.

Institutionalisation is where the teacher
terminology and highlights definitions and theorems considered important for the

intention was not communicated to the students.
The data are Task 4 and a video-recorded observation of three students'
collaborative engagement with Task 4 (with teacher intervention). The students are
Anne, Helen, and Paul (pseudonyms), who were in their first academic year on a
teacher education programme for primary and lower secondary school in Norway.
The observed teacher (the one who had designed the task) is my colleague, an
experienced, male teacher of mathematics. My role during data collection was to be a
silent observer while video-recording the classroom interaction analysed in the paper.
The teacher interacted with the students during the observed episode on the basis of
the students' difficulty in understanding two of the concepts used in the task. The
video-recorded episode has been transcribed and analysed through a process of open
coding (using an adapted grounded theory approach, Strauss & Corbin, 1998) where
concepts from the theory of didactical situations (Brousseau, 1997) have been used to
make sense of what factors constrain the students' algebraic generalisation of the
actual shape pattern (in this way addressing the research question).
Analysis of students' engagement with a task on algebraic generalisation
Anne, Helen, and Paul have drawn the first three elements of a shape pattern
(Figure 2) which is a continuation of the element given in Task 4. They have found
that for the first element of this shape pattern (the 5x5 square given in the task), the
number of black components (represented by black x-es) is equal to the sum of the
first four natural numbers, and the number of white components (represented by
turquoise x-es) is equal to the sum of the first five natural numbers. The students have
observed that this is a regularity that applies also for the next two elements of the
shape pattern. That is, they have verified by inspection that for the second element (a
6x6 square), the number of black components is equal to the sum of the first five
natural numbers, and the number of turquoise components is equal to the sum of the
first six natural numbers, and likewise for the third element. They have, however, not
identified the sums of consecutive natural numbers to be triangular numbers.
Figure 2. Continuation of the shape pattern invented by Anne, Helen, and Paul (Task 4a)
When they come to Tasks 4b and 4c, they wonder what is meant by "figurate
number" and "mathematical statement", and get the teacher to help them. The teacher
explains that the question about figurate numbers is about being down on the
"bedrock" looking for standard numbers that it is common to have in one's "toolbox".
The teacher thereafter asks what the students recognise if they look at the first
element (given in the task) as a whole. The following exchange takes place:
591 Paul: Well, that it is five squared.
592 Teacher: Right.
593 Anne: Yes, it is indeed squares, and then [Pause 1-3 s]
594 Teacher: Yes, it is indeed squares, square numbers.
595 Paul: And then you have nine and sixteen as the numbers of
[Pause 1-3 s] no, ten perhaps? Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
235
596 Teacher: And then there are the black and white ones? Do you recognise
them?
597 Anne: Fifteen, twenty one [Pause 1-3 s] ehm
In turn 591 Paul focuses on the first element of the shape pattern (the 5x5
square). I interpret his words here to suggest that he continues to look at this element
in turn 595 and refers to its number of black and white components. The numerical
values he suggests at first are wrong, but he then makes a new suggestion which is
right for the number of black components of the first element. The teacher does not
directly respond to Paul's answer, and when the teacher asks if they recognise the
black and white components (turn 596), Anne responds by giving the number of black
and white components of the second element. This seems to make Paul insecure about
what the teacher asks for; he wonders whether it is only the first element or it is the
sequence of elements they are supposed to consider:
598 Paul: If we are supposed to see the connection, it is only this very shape we shall
look at now? [Draws a curve with his pencil around the element
given in the task] It is not the next shapes we have made [points
at the succeeding elements drawn in his notebook when he says
"next"]?
599 Teacher: You may well look at it as it stands there [Pause 1-3 s] uh [Pause
1-3 s] [indecipherable]
600 Paul: Not further, ok.
The teacher's response in turn 599 I interpret as confirming that it is
satisfactory that the students look at the element given in the task (a 5x5 square) as a
basis for finding answers to Tasks 4b and 4c. It is plausible that the teacher takes this
stance as a consequence of seeing the 5x5 square as a generic example. This element
of the shape pattern is an example which illustrates that the sum of the fourth and the
fifth triangular numbers is equal to the fifth square number. It is generic (Rowland,
2000) in the sense that it is a representative of a class of elements which have the
property that they are squares which (by the two colours) illustrate that the n-th square
number is the sum of the (n ––– 1)-th and the n-th triangular numbers.
These general properties are however not addressed in the classroom
situation. The teacher does not express to the students that he uses the 5x5 square in
the sense of a generic example, nor does he use the term "generic". What I interpret as
the teacher's implicit utilisation of a generic example contributes to vagueness in the
discourse: The stance taken by the teacher about the sufficiency of looking at one
element of the shape pattern (genericity of the 5x5 square) is consistent with the
formulation in Tasks 4b and 4c (reproduced below), a correspondence which may be
expected since the task is designed by the same teacher. Application of singular
number in the noun "the shape" indicates that the shape presented in the task is seen
as generic:
What kinds of figurate numbers do you find in the bright and the dark areas, and
in the shape as a whole? [Task 4b, emphasis added]
Express what the shape tells you about these numbers in terms of a mathematical
statement. [Task 4c, emphasis added]
After having observed that the 5x5 square contains ten black components and
fifteen white components, the students describe the structure of the next elements of
the shape pattern. They observe that the elements develop by adding to the white
components an extra row (at the top) with one more component, and that the number
of black components of a successive element is the same as the number of white
components of the present element. The teacher reminds the students that they have Theme B – H. S. Måsøval
236
earlier written ten as a sum of the first four natural numbers, and further, tells them
that numbers with this structure are referred to as triangular numbers. He refers to
what I interpret as (for him) a generic example when he continues:
640 Teacher E: So this is actually the clue here. That this element, I think I'll just
tell you, that this shape represents a kind of connection between
triangular numbers and square numbers.

This is succeeded by a comment by Anne that she had been insecure what
was meant by the concept of "figurate numbers". After some exchanges between the
teacher and her, she (re)turns attention to the concept of "mathematical statement"
which so far has not been addressed explicitly by the teacher:
651 Anne: Express what the shape tells about these numbers in terms of a
mathematical statement [recitation from the task]. Are we
supposed to write it as a formula or shall we formulate it?
Based on the students' conclusion on Task 4c (an explanation in natural
language of the structure of the first element of the shape pattern), it is plausible that
Anne in turn 651 is trying to figure out whether the teacher wants them to present the
solution to Task 4c as a formula (potentially in mathematical notation) or as a
formulation (potentially in natural language). The teacher responds by reinforcing
attention towards the first element of the shape pattern, which I suggest he continues
to use as a generic example:
652 Teacher: Well, then you can think of that one [points at the 5x5 square
presented in the task]. If you look at it as a whole, what square
number is it that it [Pause 1-3 s] shows us? What position?
653 Helen: Five or?
654 Anne: What number in the series or?
655 Teacher: What number in the series of square numbers, right.
656 Anne: Well, I can imagine it is [Pause 1-3 s] the fifth then.
657 Teacher: The fifth, right.
658 Anne: Because that would have been good for us [smiles]
659 Teacher: Yes. [Students laugh] Well, but here we don't have much choice,
really. It is the fifth, it is twenty five, it is square number five.
(Anne: uh huh). And if we think of it as composed by triangular
numbers (Anne: yes) then you can think of [Pause 1-3 s] what
position in the series of triangular numbers is that which these
black and white [components] represent?
I interpret the teacher's utterances in turns 652, 655, 657, and 659 as an
incidence of the Topaze effect (Brousseau, 1997): The answer that the students must
give is determined in advance (the theorem asserting that the n-th square number is
equal to the sum of the (n ---1)-th and the n-th triangular numbers); the teacher
chooses questions to which the answer can be given (turn 652). The knowledge
necessary to produce these answers changes, so does its meaning. Faced with the
student's continued difficulty in giving the answer, the teacher poses easier and easier
questions: It is possible to answer the teacher's question in turn 659 without having to
formulate the intended theorem. Hence the target knowledge has disappeared, a
phenomenon referred to as the Topaze effect.
There are features in the milieu which I interpret as giving rise to the Topaze
effect: First, the nature of the concept of a mathematical statement is not known to the
students and is neither explained to them in plain text. Second, the teacher's use of a
particular example in a generic sense, apparently without the students' consciousness
about it, contributes to the students' comprehension of the particular example as
representing a mathematical statement in its own right. The teacher leaves the Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
237
students after turn 659, and the students collaborate to find the positions of the
triangular numbers from which the fifth square number is constructed (the new task).
The outcome of their engagement with Task 4c is the expression in natural language
of the property of one particular shape: the fifth square number is constructed from
the fourth and the fifth triangular numbers. They make no attempt to generalise this
characteristic to apply to an arbitrary element of the shape pattern, neither in natural
language, nor in algebraic notation.
682 Paul: Well, a person who could figure out a formula for this, he would be good
[laughs].
683 Anne: No, but it is not written (Paul: no) that we shall have a formula
(Paul: right). We are supposed to express it as a mathematical
statement. We have done that now. It is not very good, but we
have emphasised what is relevant, I think.
Recall that Anne asked the teacher if they were supposed to write the
mathematical statement as a formula or just formulate it (turn 651). Paul's and Anne's
utterances (turns 682 and 683) indicate that they have interpreted the teacher's
response (turn 652) to Anne's question (turn 651) to mean that a mathematical
statement is a formulation (in natural language) about the numbers in the shape given
in the task. Further, Anne seems to conclude that a formula is different from a
mathematical statement in the way she claims that they are not asked to find a formula
(turn 683). It is likely that she by "formula" understands an expression in
mathematical notation.
Discussion
The students remain unaware that the aim of Task 4 is to establish a theorem
about a general relationship between numbers (or sequences of numbers). The
generalisation process is obscured by two interrelated factors, which are interpreted as
weaknesses in the milieu.
The first factor is about the design of the task: It is problematic that the task
presents only one element of an imagined pattern, combined with the use of singular
number ("the shape") when referring to the pattern. Further, there is a problem with
the design of the task because the students produce appropriate solutions to the first
two subtasks (with input from the teacher on the concept of figurate numbers); this,
however, does not afford them with knowings that enable them to formulate the
intended theorem. In the context of algebraic generalisation of shape patterns, the
knowledge at stake is algebraic generalisation of arithmetic relations mapped from the
elements of the pattern. For epistemological reasons, the focus in tasks on algebraic
generalisation of shape patterns therefore should be on those arithmetic relations; e.g.
in Task 4 (here efficiently represented in mathematical notation): that
2
4 5 T T 5 ,
2
5 6 T T 6 and so on, to subsequently encourage generalisation by algebraic thinking.
The second factor that constitutes a weakness in the milieu is about the
students' unfamiliarity with the concept of mathematical statement. The students had
identified the structure of the fifth, sixth and seventh elements, even if they had not
been explicit about their rank (that is, they had not made the point that the fifth
element is the sum of the first four natural numbers and the first five natural numbers,
and likewise for the next two). They had got the teacher to come to them because they
did not know what was meant by the concepts of figurate number and mathematical
statement. Anne's recitation of Task 4c and her subsequent question (turn 651)
indicates that the adidactical situation devolved to the students is not appropriate Theme B – H. S. Måsøval
238
because it depends on knowledge they do not have (the concept of mathematical
statement). The teacher, however, instead of explaining the nature of a mathematical
statement, directs attention to the 5x5 square. It is relevant here that the teacher
believes that the students know the concept of mathematical statement (articulated in
conversation with the teacher after the lesson). It is therefore plausible that the teacher
interprets Anne's question in turn 651 to signify a problem with seeing the invariant
structure of the elements of the shape pattern, and not a problem with the concept of
mathematical statement per se. For that reason, when he acts on the milieu, he tries to
help them discover the structure of the elements (by utilising a generic example) so
they can develop the knowledge aimed at: an equivalence relation between square
numbers and the sum of two triangular numbers. But, as described above, the
students' interpretation of the teacher's (generic) example as complete in itself,
without attention to general properties, terminates the generalisation process. The
milieu is changed, so is the knowledge needed to solve the (new) task. A gap has been
created between the teacher's intention with the (original) task and the students'
actions on the milieu.
Måsøval (2011) has identified that tasks on algebraic generalisation of shape
patterns are of two different types, based on the mathematical object they aim at: The
first type (arbitrary shape patterns) aims at a formula for the numerical value of the nth member of the sequence mapped from the shape pattern; the second (conjectural
shape patterns) aims at a theorem which asserts equality between two different
algebraic expressions for the n-th member of the sequence mapped from the shape
pattern. It is therefore important that those who design (or choose) tasks analyse the
target the tasks aim at, whether it is a formula for the numerical value of the n-th
element of the actual pattern (a functional relationship), or it is a general numerical
statement (a theorem) decontextualised from the actual pattern. This is in order for the
milieu to be designed such that the desired relationship can be explored and
explicated by the students (e.g. through decomposition of elements according to the
invariant structure of the pattern).

Order of tasks in sequences of early algebra
Pedro Palhares
CIEC, Institute of Education, University of Minho
Leonel Vieira
CIEC, Institute of Education, University of Minho
Joaquim Gimenez
Universidad de Barcelona
This paper is about the selection, construction and application of a
sequence of tasks involving patterns, in order to promote algebraic thinking,
in two classes, in the period starting in the last trimester of the 3
rd
year and
the first trimester of the 4
th
year of schooling. Each sequence was composed
by twelve tasks (six structural and six sequential). One class got the
sequential group of tasks first, and then the structural, while the other group
got the reverse order. One of the goals of the study was to ascertain the
cognitive suitability of designed sequences of tasks as a situated process.
Keywords: Algebraic thinking; sequence of tasks; patterns
1. About task design and algebra study
We consider task design as a crucial element of the learning environment, and
we propose to explore the role that it plays for learners without forgetting the potential
role of the teacher in encouraging whole class discussion around tasks. Our perspective
relates to one aspect of Realistic Mathematics Education, in which the designer
conducts anticipatory thought experiments by envisioning both how proposed
instructional activities might be realized in the classroom, and what students might learn
as they engage in them. Central instructional design strategies were task analysis and
the construction of learning hierarchies in order to identify reification development. Our
starting conjecture in terms of designing didactical sequences of tasks, is that we need
epistemic and cognitive analysis not only to criticize each task itself, but to adapt its
connections as best as possible to the students abilities, found by analyzing teaching
experiments as cumulative and with anticipatory purposes. It's important for our task
analysis to identify difficulty factors providing frameworks for hypothesizing
instructional designs inspired by developmental cognition.
We decided to use an early algebra task as an explanation for a situated study
supporting the perspective in which algebraic reasoning could be highly promoted
(Kaput, 1995; Malara & Navarra, 2002; NCTM, 2000) as a tool intertwined with
arithmetic (Lins & Gimenez 1997) building on their interconnection (Mason, 2008) to
promote success by developing together both arithmetic and algebra, one implicated on
the other. The study supporting this paper has been done with 8-9 years old students. Theme B – P. Palhares, L. Vieira, J. Gimenez
242
About the teaching experiment
The basis to build our sequence of tasks and test analysis, is to promote
algebraic thinking by overcoming relational apprehension (Smith, 2011) and the use of
patterns (Orton, 1999; Carraher, Martinez and Schliemann, 2008), used here in
connection with a search for order or structure and therefore regularity, repetition and
symmetry are frequently present (Frobisher et al., 1999), because of the relevance to the
development of abstraction, generalization and the establishment of relations (Lins &
Gimenez 1997; Mulligan et al., 2006).

The first part of the study consisted of the construction and validation of a questionnaire-task that later was used as pre- and post-test control strictly validated as it's usual in empirical studies (Vieira, Palhares & Gimenez 2012). Next step concerns the experimental process based upon a refined sequence of tasks. The principles for our task design are: (1) assuming the possibility of using arithmetic number sense related to algebraic reasoning; (2) assuming suitability criteria for analyzing mathematical activities; (3) mathematically inspired by using relations and diversity of representations but not letters for the unknowns; (4) hearing the voice of the students for analyzing and promoting mathematisation and retention.
A set of nineteen short tasks was designed, from which twelve tasks were chosen, six of the structural type and six of the sequential type. These separation is closely related to strands 1 and 2 within Core aspect A of algebraic reasoning (Kaput, 2008). In each type, half was figural and the other was numeric. In our sequence of tasks, the main aim is to reflect about the use of some knowledge to build and/or transfer to other mathematical knowledge. Our presentation leaves the problems from everyday life for a subsequent time. Therefore, we don't explain other algebraic activities more related to promote modeling processes. We are facing the problem of complexity and connection of tasks in designing sequences.
The tasks were meant to be diverse, some leading to an exploratory and investigative open activity to improve meaningful construction (Thompson, Carlson, & Silverman, 2007), and also as a problem solving approach (Arcavi & Friedlander 2011), some others involving structured generalization rules (Stacey, 1989). In the experiment, the teacher introduces always the problem by focusing heavily on exploring the situation, leaving the student a maximum degree of freedom for discussion.
About mathematic/epistemic suitability
The activities integrate various mathematical aspects. The tasks of the sequential type were characterized by the existence of the first terms of a sequence, asking for the next term or a more advanced as a kind of generalization. The tasks of the structural type include different processes and properties: equality and order properties, finding rules from examples, identify equivalences, assume relational identities, acting by assumption, particularization,… among others.
Cognitive suitability
The implementation sequence was such that numeric and figural were alternated, with an increasing mathematisation in the case of the sequential type. Figural aspects are interpreted as supported by images or pictures in the sense of Pallascio (1992). The patterns and questions are not usual in textbooks, but involve addition and multiplication and addition rules. Only in one case one pattern can be considered as a division. We now give one example for each subtype:Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
243
Task type 1 (structural and figural)
In such a task, the aim is to observe how the arguments reveal an algorithmic process (based on Femiano, 2003).
Observe carefully the four dish scales that are in equilibrium.
Substitute the question mark by the number that allows the scale to remain in equilibrium. All equal figures have the same value.
Explain how you have found the value to substitute the question mark. You can use words or calculations to describe what you have done.
It's expected that students find the value of a star, and after finding values, identify that the square and triangle sum is 8. Then they can use trial and error, or change the order and assume that two other variables have the same value. Four equal properties are used in this case. We must notice that in such figural tasks, the role of the teacher is to pay attention about the consideration of the same value for the same figure. The teacher asks suddenly the students to explain their ideas in order to focus on mathematical argumentation used.
Task type 2 (structural and numeric)
In such a task, it was planned that the most difficult aspect is the interpretation itself because the sequence of starting numbers is not in order and for the fact that it's not a usual class task.
Observe carefully the four 'number machine'.
Substitute the question mark by a number that follows the rule of the other three machines.
Explain how you have found the number to substitute the question mark. You may use words or calculations.
We already knew that the use of additive comparison tended to be somewhat challenging to students of this age.
Task type 3 (sequential and figural)
This task was proposed to initiate table representations to establish combined rules made by two operations. The idea is to identify the ways in reaching the rule, and the way to explain. This is similar to those explained by Radford for these ages (Radford 2010) to provoke the use of arguments based on numbers. In this case, the figure can help to find the answer for the first questions.
Observe carefully the sequence of figures below.
Fig. 1 Fig. 2 Fig. 3 Fig. 4 Fig. 5 Theme B – P. Palhares, L. Vieira, J. Gimenez
244
Construct the two following figures 4 and 5. Without drawing or constructing it, say how many squares of each colour will have the 8
th
figure. Complete the table.
Figure number 1 2 3 4 5 … 10 20
Number of white squares 2 6 …
Number of gray squares 1 1 …
Explain how you have got to the number of squares of each colour in the 8
th
figure, using the table. Is it possible to find in this sequence a figure with exactly 50 white squares and one gray square? Explain what your thoughts to answer the question were. Did you find any regularity in the sequence of white squares? And in the gray squares? Write a small text on the conclusions you have reached. Can you establish some relation between the number of the figure and the number of white squares? Justify your answer. What is the rule for this pattern?
Task type 4 (sequential numeric)
It's a typical task in which the students are required to identify the pattern
Observe carefully the sequence of numbers below:
6, 10, 14, 18, 22, ____, ____, ____, …
Place numbers on the lines. What will be the 10
th
term of the sequence? And what will be the 20
th
term of the sequence? Explain how you have found the 20
th
term of the sequence. Will the number 63 be a part of this sequence of numbers? Justify your answer.
The tasks have been answered in a group work setting. After the groups have solved, they had to present their solution with the justification to the whole class and a discussion followed, contributing to provide a sense of purpose and ownership (Ainley and Pratt, 2011). In these classes, one group was chosen from and followed from the start, with their dialogues being recorded. The second author participated as a second teacher, after obtaining permission from the school board and from parents.
These tasks have been introduced in two classes after the pre-test. In one of the classes, the students were confronted with the sequence of sequential tasks, and in the other class students were confronted with the sequence of structural tasks. This has happened near the end of the schooling year and it was followed by the application of the post-test, which happened in the end of May. After vacation time, in September, being the students already on the 4
th
year of schooling, the test was applied again. The intention was to check for retention. Then students were confronted with the sequence of tasks they had not solved yet. We had then one class solving six sequential tasks and then six structural tasks and another class solving six structural tasks and then six sequential tasks. All students in the two classes solved the same set of twelve problems. Finally, the test was applied one last time, in November.
2. Results and implication for redesigning
The main intention is to introduce a cycle of redesigning interpreting the students' answers both as qualitative and quantitative data. A systematic analysis of student work is not thoroughly described because of space limitation. Contrary to our expectations what these results show is that it is not indifferent to start with sequential or with structural tasks. Sequential tasks are better for starters and apparently provide a solid foundation for the work with structural tasks. As to the two groups that have been followed in more detail, the results have been these: Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

We have taped and later transcribed the dialogues in one group for each class.
We will focus on the first two tasks of each type and compare their resolution in the two classes. In terms of the designed tasks, both pairs reached, at the initial stage of predictions, generalizations expected by the designers. In particular, we found some inductive generalization based on the collection and analysis of data (as followed by the sequence of tasks in this activity), but nobody did any deductive reasoning. Let's explain some observations about the tasks above exemplified.
Concerning task 1 described above, which for the structural>sequential class (StSe) was the first task and for the sequential>structural class (SeSt) was the seventh both groups initially fell for attempting trial and error. Both groups easily found the value for the star. Group StSe had some difficulties in concluding that the triangle and the rectangle had to have the same value. The main reason apparently was that being the shapes different, they assumed the value had to be different. They made several attempts with different values. The researcher asked them if they had observed all the scales and from this prompt they returned to the observation of the scales and concluded immediately that the triangle and the rectangle had to have the same value and solved the rest easily. Group SeSt tried at first to guess the final scale value. But abandoned this strategy, found the value for the star and through the analysis of the third scale they found the values of the triangle and rectangle and solved the problem.
Concerning task 2 described above, it was the second task for the StSe group and the eighth for the SeSt group. Group StSe has approached this problem with a strategy based on the difference between the entry number and the exit number. As one of the machines presented the number 10, they started conjecturing with it, as calculations were easier. Eventually they perceived the strategy was not working. Next they tried to establish the difference between the exit number from one machine and the entry number of the following. They gave it up and tried two things: one was comparing the sum of entry and exit numbers of one machine and the entry number of the following, the other was to compare the sum of the three entry numbers of three machine and the exit number of the third. They continued attempting adding and subtracting numbers until they moved to a multiplicative strategy, but this move resulted from an ill constructed comment from the teacher, giving too much away. After this they revealed no difficulty in finding the relation or the rule. Group SeSt rapidly found the value that should be placed in the question mark. Therefore we could not conclude if that was due to the establishment of relations between the numbers or to luck on the first attempt. In the explanation that followed they just describe the calculations performed:
Theme B – P. Palhares, L. Vieira, J. Gimenez
246
Helen – it's 5 times 3.
Frank – 5 times 3?
Helen – plus 1.
Earnest – it's 5 times 3.
Helen – 7 and 7 is 14 plus 7, 21; 21 plus 1, 22… it's 28 (pointing with the finger to the question mark). 9 and 9 is 18, plus 9, 27.
Earnest – It's 28 (pointing to the question mark).
Helen – 28 (while pressuring Frank's arm, who is responsible for the writing).
Frank – calm down!
Helen – we have to write it down.
Earnest – now we have to explain why.
Concerning task 3 described above, it was the second task for the group SeSt and the eighth for the group StSe. In the group SeSt, one of the elements refers that it is always 'plus two' (speaking to the group partners) while the researcher was still presenting the task, adding that it was always one above and one below:
Earnest – Ah! Figure six has to have on the top 7. Figure…
Frank – eight…
Helen – it has to be 6 down here and the figure eight? Figure seven how much does it have?
Earnest – figure seven, figure seven, figure seven… ah, figure six has 7 here and 6 here and figure seven…
Frank – 8, it has 7 here and here 8.
Helen – 9 and 8
Earnest – what? Figure eight? Then write it.
They work line by line, interiorizing that the top line has one more square than the line below. They do not reveal any difficulty filling the table, establishing the relation 'double' between the figure number and the number of white squares, identifying the invariant (gray square). In the question about wherever there was a

figure with exactly 50 white squares and one gray square, one of the group elements refers immediately that it is possible, since they're even (white squares) plus one gray square. In the question about the relation between the figure number and the number of squares they find the relation and manage to establish a distant generalization in the oral conversation, referring that it is the double plus one, however they fail to say so in the written answer.
The group StSe identifies immediately the number of white and gray squares in figure 8, and they reveal no difficulty in filling the table. As to the question about the existence of a figure with 50 whites and one gray, they rapidly answer that it is figure 25. In the question about the relation between the figure number and the number of squares, they find a near generalization mentioning that "the number of whiter squares doubles is two more than the previous one and the gray stays". This group has no difficulty finding the relation between the figure number and the number of squares, but does not offer a justification.
Concerning task 4 described above, it was the fourth for the group SeSt and the tenth for the group StSe. Group SeSt have initiated solving this task by searching for a regularity between consecutive terms (plus 4 than the previous term) and later they found that to find a distant term they could multiply the term number by 4 and add 2. They justified that 63 was not a part of the sequence because it was an odd number. In the last question about the regularity found they wrote: "the order number times 4 plus 2 gives the number for the term. They are all even numbers". Group StSe does not reveal difficulties in finding that the difference between consecutive terms is 4. Meanwhile they discover they can multiply the term number by 4 and then add 2, and have written 20x4+2=82 to find the 20
th
term. However in the written explanation they show some Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
247
confusion and get into contradictions. As to 63 being part of the sequence, they claim that it is not multiple of 4 (omitting the ulterior adding of 2 units). They say: "all multiples of 4 are even". Last, in relation to the regularity, they write: "the quadruple of the number for a term plus 2 is equal to the number of the sequence of the term".
Conclusions
First of all, we know from many previous experiences that structured investigative activities indicate that they provide opportunities for meaningful learning of mathematical concepts. We also know that differences between a designer's planned actions and student work should be expected. One can argue that, these students were unfamiliar with structural algebraic tasks, and they answer them as open questions, making their own interpretation. Cognitive analysis seems not to be enough to decide about ordering. The study is considered as a first step for reconsidering the tasks for redesign in which a new cycle of testing could lead to small or big changes. Apparently, it seems that only because of epistemic values, we consider structural tasks after. It is however clear students that started with the sequential tasks seem to be capable of establishing distant generalization when the other group couldn't. And certainly the group that started with sequential tasks appears to retain their performance more robustly stable across time. This type of task design proved to be a rich starting point for significant classroom discussions on early algebraic situations.

A Task Design for Conjecturing in Primary Classroom Contexts

Pi-Jen Lin
National Hsinchu University of Education, Taiwan
Wen-Huan Tsai
National Hsinchu University of Education, Taiwan

The purpose of the study was to design tasks for conjecturing to support students engaging in the activities of proving in primary classroom contexts. A task involving perimeter and area of figures as an example was designed on the basis of nine principles of designing for conjecturing and proving suggested in F. L. Lin's team work (Lin, et al., 2012). Twenty seven third grade students' written work was collected for the main data of the study. It was found that the task was characterized as four features in accordance with students' justification, which were analyzed by three components of proofs suggested by Stylianides and Ball (2008) .

Key Words: mathematical conjecturing, proving, task design, primary,

Introduction

Mathematical tasks are recognized as the tool for teachers to shape a teaching design and for students to develop, utilize and understand a certain concept (Stein, Grover, Henningsen, 1996). Thus, mathematical instruction is generally organized and delivered through students' activities on mathematical tasks. Nevertheless, students respond to mathematical tasks very differently, depending on the structure and demands shaped by tasks enacted by teachers. This indicates that to reach high quality of mathematics instruction, mathematical tasks play a crucial role. Thus, selecting and designing appropriate tasks is essential to the success of teaching mathematics (Doyle, 1988; Stein & Lane, 1996).

Doyle (1983) defined academic tasks as (a) the products that students are to formulate, such as the answers to a set of questions; (b) the operations that are to be used to generate the product, such as classifying examples of a concept; and (c) the "givens" or resources available to students while they are generating a product. Doyle (1988) further argues that tasks with different cognitive demands are likely to induce different kinds of learning. According to this definition, tasks can vary not only with respect to mathematics content but also with respect to the cognitive processes involved in working on them. Only worthwhile tasks offer students the opportunity to extend what they know and stimulate their learning. Tasks that require students to solve complex problems can be considered to be cognitively demanding tasks. In contrast, cognitively undemanding tasks are those that give less opportunity for the students to engage in high-level cognitive processes. The conjecturing tasks require Theme B – Pi-Jen Lin & Wen-Huan Tsai
250
high cognitive demands because they are involved in three components: a set of true statements, valid modes of argumentation, and appropriate representation of modes of argumentation (Stylianides, 2007). Therefore, it is worthwhile to develop teachers' knowledge of conjecturing tasks design for enhancing students' proofs. Moreover, proof is a vehicle to enhance students' understanding of mathematics concepts and promote mathematical proficiency and reasoning (Hanna, 2000). Proving is an important means of exploring in mathematics. Research shows that engagement in proving can support students to explore why things work in mathematics and explain their disagreements in meaningful ways, thus providing them with a solid basis for conceptual understanding (Stylianides, 2007). The previous studies suggest that students should have early and appropriate opportunities to incorporate proof into their mathematical learning (Ko, 2010; Kilpatrick, Swafford & Findell, 2001;Stylianides, 2007).

Conceptual Framework for Designing Conjecturing Tasks

Conjecturing and proving can promote mathematical thinking and launch mathematical inquiry; therefore, tasks of conjecturing and proving should be designed to be embedded into any grade level of classrooms (Kilpatrick, et al., 2001). The tasks of both conjecturing and proving are involved in students' conjecturing, but F. L. Lin and his colleagues distinguished the distinction of the principles for conjecturing tasks design from those for proving task design (Lin, et al., 2012). The four principles for designing conjecturing tasks and the five principles for designing proving tasks are considered as the conceptual framework of the study, since they are achieved to two fundamental functions: relating to the learners' roles or hypothetical learning trajectories and the practical function of easily evaluating.

In the tasks for conjecturing, students are asked not only to generate conjectures according to the given information which could be ill-defined, but also search for proofs to verify or justify whether the conjectures they made are true or not. They further suggest that the designing efficient tasks for conjecturing should consider the provision of opportunities to: (1) observation, (2) construct, (3) transform, and (4) reflect. The observation-based conjecturing refers to activities that involve purposeful or systematic focus on specific cases in order to make a generalization about the cases. The construction is a principle that encourages students to construct new knowledge based on prior knowledge which may lead to conjectures. The transformation design principle means that the task gives students the opportunities to generate conjectures by transforming given algorithms or formula. The conjectures by transformation may lead students to incorrect or meaningless statements. Thus, the reflection principle is essential to design the tasks for conjecturing.

The tasks for proving can promote proofs and proving. The type of tasks for proving is characterized as to ask students to justify whether the given statement in the existing conjectures is true. The false or true statement is given by the instructor's. Lin and his colleagues suggest that the tasks for proving have different difficulties, depending on the sources of conjectures are either from instructor's or students' themselves (Lin, et al., 2012). In the case of conjecture given by the instructor, students may feel it is not necessary to prove it, because they accept the truth based on either epistemic values (Duval, 1998) or instructor's academic authority (Lin &Tsai, 2012a; Reid, 1995). In the case of conjecture given by students themselves, they may Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
251
have unclear distinction between conjecturing and proving. For instance, they may consider empirical arguments as deductive proof (Stylianides and Stylianides, 2009). The five principles for designing proving tasks suggested by Lin's team have to do with modes of argumentation and its representations. They include: classifying mathematics statements, expressing arguments in several modes, changing roles in a task, defining efficient and necessary proof, and creating and sharing proof. The first principle is to provide the opportunity for students understanding six possible types of statement between universal and existential statements. It could be always true, sometimes true, and never true for true or false statement, respectively. The second principle is to provide the opportunity for students to understand various modes of argumentation to be used appropriately for different types of statement, such as counter examples, supportive examples, deductive and inductive proof via various

representations. The third designing principle promotes the opportunities of switching the role of students as an instructor or an evaluator of the proposed justification from traditionally being seen as the learner. The fourth principle provides students the opportunities to be aware of the sufficiency and necessity for a legitimate proof. The final principle is to provide students the opportunity of creating a proof and then present it to the whole class in public for verifying its validity and truth.

A statement, existing in the tasks for proving, proposed by the instructor can be logically true or false. The existing empirical studies suggest that students at primary or secondary level do not accept counterexamples as refutation, rather, they offer more than one counterexamples for refuting a false statement (Reid & Knipping, 2010). Student even at high school level or undergraduates still have difficulty with mathematical proof in school mathematics (Lin &Tsai, 2012a; Ko, 2010). Some of them accept the truth of empirical induction from finite number of discrete cases for verifying a true statement. Besides, students or future teachers also perform better on false statement than true statement (Lin &Tsai, 2012b). The different difficulties may result from the nature of proving, because the verification of a false statement is easier than a true statement in that one counterexample is enough to refute a false statement. A true statement needs to be verified by inductive or deductive reasoning. The processes of proving a true statement demand rigor and complex argumentation.

On the basis of literature review, it could be a good start for the beginners at primary level for the study to learn proofs with a false statement instead of a true statement for designing proving tasks. However, it is new experience and knowledge that the task design for conjecturing are conducted by the primary teachers involving in the study, because their students have little experience with what conjecturing and proving looks like. Thus, the purpose of the study is intended to support teachers to design various conjecturing tasks in line with the mathematics contents to be taught in primary classroom contexts for student exploring the activities of proving. The paper describes not only the development of the task design but also the effect of conjecturing task on enhancing students' engaging in the activity of proving in the context of the relationship between perimeter and area in two figures. The task referred to in the study was the activities or artifacts such as teaching aids exploring in classroom contexts. Theme B - Pi-Jen Lin & Wen-Huan Tsai

252

Method

Participants and Context

The task involved in the study was designed by one of the teachers who participated in the first year of a three-year project that was designed to help teachers to create conjecturing tasks for engaging students in the activity of proving. Hence, the tasks design for students engaging in valid proofs is a new experience and novice learning for the teachers, but they were mutually supported in the professional team consisting of six teachers and two researchers, the authors of the paper.

Twenty-seven third grade students in the class have separately learned the concepts of perimeter and area of a figure before engaging the task. They engaged in several activities of conjecturing in the first semester. The task was conducted in the second semester, so that some of the students had slight experience of finding out a counter example to refute a false statement.

They were grouped heterogeneously in groups of 4 or 5. After given the task, the students first worked independently and jotted down their judgement and verification on B4 paper; then they came together in groups to compare their solutions, and finally they shared their arguments to the whole class. The lesson was videotaped throughout the entire class. Each student's written work was collected throughout the whole year.

Designing Conjecturing Tasks for Students Engaging in the Activities of Proving

The task designed by the teacher was to ask students to make a conjecture and verify whether it is true. The statement is that "In any two figures, if the area of one figure is bigger than the other, then its perimeter of the figure is greater than the other, too. Do you agree? Why? Show your work on the grid paper. " The task for conjecturing is initiated from a false statement. The task design was on the basis of the four principles of the task for conjecturing and five principles of the task for proving, suggested by F. L. Lin's team work (Lin, et al., 2012), since it is potential to launch the following activities for students engaging in conjecturing and proving: (1) The task provided students an opportunity to engage in observation through finding out a pair of two figures and making a generalisation about the cases; (2) The task provided students an opportunity to engage in construction. For instance, to solve the task, students needed to create two figures with different areas but same perimeter; (3) The task encouraged students an opportunity to transform prior knowledge of the perimeter and area of an irregular figure by counting the number of small squares on the grid paper; and (4) The task provided students an opportunity for reflection. For instance, "Show your work" as part of the task is to ask students to explain why they believe their conjecture is true for the given condition.

In addition, the task was also characterised as the following features: (1) The task promoted students classifying various statements, such as, the statement of same area in two figures result in same perimeter; (2) The task had the potential to require students to express same argument in several representations of modes of argument. The counter examples for refuting the false statement can be expressed by either "bigger area but smaller/same perimeter" or "same area but greater perimeter"; (3) The task engaging in the classroom provided the students as the role of an evaluator for the justification proposed by them; (4) After the false statement was proved, the students were asked to modify it and rephrase it as a true statement; and (5) The task Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

253

engaged in the classroom context provided students an opportunity with creating and sharing their own proofs.

Data Collection and Analysis

The result session was aligned to the Stylianides and Ball's (2008) three components of proof by using students' written work. Taking the consideration of students as mathematical learners, proof suggested by them can be defined as a set of accepted statements, known modes of argumentation, and accessible modes of argument representation to a classroom community. The three components of proofs as the framework of analyzing the data collected for the study, students' written solutions were first split into two piles and then a pile was assigned to each group of the two groups consisting of six school teachers studying in a master program. Afterwards, they took turns to review the other pile for increasing the validity and reliability of analysis.

Results

The Set of Statements Accepted by the Third Graders

After the task was explored, 8 (30%) students made incorrect judgment by accepting the teacher's statement, while 19 (70%) students judged correctly and verified successfully by finding out a pair of figures to reject the conjecture given by the teacher.

The set of statements referred to the statements accepted by the classroom community. Once they figured out a pair of figures, various accepted set of statements as part of their arguments were generated by 13 students, such as "bigger area but smaller perimeter", "bigger area but same perimeter", "smaller area but same perimeter", or "same area but greater/smaller perimeter". For instance, Ming, Jenny, Ron, and Huei, as the examples, successfully showed their accepted statements by their classmates, as shown in Table 1. Thus, possessing various types of statements for students' classification is the first feature of the task.

In addition, the statement "The bigger area in one figure, it is not necessary to be greater in perimeter." that 6 students used was another type of statement. Starting from the condition "bigger area in one figure than the other" given in the instructor's statement was the most common statements accepted by those who were in favor of the conjecture (in total, 68%, 13 out of 19). Theme B - Pi-Jen Lin & Wen-Huan Tsai

254

Table 1: The Set of Statements Accepted by the Third Graders.

Modes of Argument Known by the Third Graders

Modes of argument are the ways of verifying or justifying a statement.

Overall, the mode of argument for the task used mostly by the third graders was the use of counterexample. They seemly knew that one counterexample is sufficient to refute a false statement. Their modes of argument for this task were not like other tasks that students are used to offer more than one counterexamples for refuting a false statement (Lin & Tsai, 2012a). Thus, the task provided the best opportunity for promoting students' understanding on proving that a single counterexample is sufficient to refute a false statement. This is the second feature of the task.

For verifying or refuting the statement given by the teacher, the students needed to find out a pair of figures such that one area in one figure is bigger/smaller than the other. It is followed by observing the relation of their perimeters. To fulfil the work, students needed clear distinction between the two concepts: area and perimeter. Sometimes, they needed to attempt several times, as shown in Figure 1. The Figure 1 displayed that the task was not only providing students an opportunity for exploring the activity of conjecturing and proving but also for clarifying students' confusion of perimeter with area. This is the third feature of the task.

Figure 1: Student' Tries for Finding Out a Pair of Two Figures

Representations of Modes of Argument Accessible by the Third Graders

The representations of modes of argument are the forms of expression for communicating with the classroom community. This conjecture task involving the relationship of perimeter and area, word expressions with figures was the most popular form of argument accessible by the third graders. As shown in Table 2. Eighteen (67%) students verified the statement by drawing at least an irregular figure in the pair of figures on the grid paper. It seems that third graders readily draw an irregular shape on the grid paper. As a consequence, it made students successful in conjecturing and justifying the statement. This is the fourth feature of the task. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

255

Figure 2: Student' Representation of Figures

Conclusions and Discussions

The quality of task design was evaluated by students' justification on the basis of the three components of mathematical arguments, suggested by Stylianides and Ball (2008). It is said that the task maintained high cognitive demands while it was implemented into a third grade classroom, since the task was characterized as the following four features.

(1) The task provided students new experience that there were various types of statement instead of a single type for a counterexample to refute a false statement. It has to do with the first component of proofs: a set of statements. The students have developed knowledge of proofs for refuting a false statement by unique type of statement for a counterexample from prior tasks. This feature meets the first principle of task designing for proving suggested by F. L. Lin's team (Lin, et al., 2012).

(2) The second feature was that the task provided the best opportunity for promoting students' understanding of a single case as a counterexample to be sufficient to refute a false statement. This feature is documented from the second component of proofs suggested by Stylianides and Ball (2008). The task was beneficial for developing students' knowledge of the way of refuting a false statement. This was different from previous studies in which most of the students at primary or secondary level were used to utilize more than one counterexamples to refute a false statement (Lin &Tsai, 2012a; Reid & Knipping, 2010).

(3) The task, which provided students an opportunity not only engaging the activity of conjecturing and proving but also clarifying students' confusion of perimeter with area, was characterized as the third feature. The feature of clarifying students' misconception or confusion between concepts is not on the list of task design principles suggested in F. L. Lin et al.'s work. The result indicated that the task could be a powerful instructional approach via conjecturing for clear understanding on perimeter and area. However, the effect of conjecturing on learning the relationship of perimeter and area needs further study in the future.

(4) The final feature was that the provision of grid paper as part of the task has potential to make students' successful in conjecturing and proving. The pictorial representation in several modes of argument was matched with the second principle of task design for conjecturing suggested in F. L. Lin et al.'s work (Lin, et al., 2012).

The study suggested that knowledge of students' mathematics concepts and teachers' knowledge of proofs embedded in the conjecturing tasks were two essential factors affecting the quality of proving exploring in the conjecturing activity. Without solid mathematical concepts underpinning the arguments, it is impossible for students Theme B - Pi-Jen Lin & Wen-Huan Tsai

256

to produce logical proofs. The study also suggested that the provision of false statements instead of true statements made it more possible for students to learn successfully on acquiring the knowledge of conjecturing and proving.

Using Student Solutions to Design Follow-up Tasks to ModelEliciting Activities

Peter Radonich
Northcote College, New Zealand
Caroline Yoon
The University of Auckland, New Zealand

Model-Eliciting Activities (MEA) are open ended mathematical
tasks in which students develop a mathematical model to solve a real
world problem. Their open-ended nature often results in students
developing and articulating a great diversity of mathematical ideas. What
tasks can help students extend these ideas after the MEA has been
completed? We describe an innovative approach for designing Follow-up
tasks to MEAs, which requires students to analyse other students'
solutions to the MEA they have just completed. As students critique and
analyse the mathematical strengths and shortcomings in other students'
solutions, they simultaneously challenge and extend their own
mathematical thinking.

Keywords: Mathematical modelling; task design; model eliciting
activities

Introduction

Peter's story: As a teacher, I've often come across intriguing contexts and
wondered if I could turn them into mathematical tasks for the classroom. An
advertisement in the situations vacant column, asking for a chicken sexer: "An
extremely high level (98%) of accuracy is imperative. Speed is vital, sexing
approximately 1000 chicks per hour." Or the following description of a YouTube
video: "Alexander Overwijk draws a perfect freehand circle 1m in diameter in less
than a second." Experience has taught me that turning these contexts into effective
mathematical tasks is not an easy thing. Often, the context outshines the mathematics.
Other times, the mathematical content is too fleeting, trivial, broad or complex. I have
folders filled with this kind of raw material but for some time, I lacked the design
tools to craft them into mathematical tasks. I was intrigued when I heard Caroline
describe some task design principles she was using in her research, while I was on a
teaching sabbatical at a local university.
Caroline's story: In that talk, I described a sequence of four calculus tasks
that I had developed together with Tommy Dreyfus and Mike Thomas. Two of the
calculus tasks (described in Yoon, Dreyfus & Thomas, 2010) were created using wellestablished principles for designing special modelling tasks called Model-Eliciting
Activities (MEAs) (Lesh, Hoover, Hole, Kelly & Post, 2000). But the other two
calculus tasks were created without any specific guiding design principles. I had just Theme B - P. Radonich & C. Yoon
260
written a grant proposal to develop design principles for the latter kinds of tasks—
tasks that followed MEAs and extended students' thinking further. As fate would
have it, I was looking for teacher-designers to participate in the project at the same
time that Peter was looking for task design principles.
A team of designers: The proposal was funded, and we spent the next two
years (with two other teacher-designers, Anne Patel and Nikki Sullivan) designing,
testing and revising tasks and their underlying design principles. We applied Lesh et
al.'s (2000) design principles to the context of the perfect freehand circle YouTube
video to create an MEA we called the Giotto MEA (described below). When we
tested the Giotto MEA in classrooms, students typically developed and articulated a
diversity of mathematical ideas, but their written solutions often had numerous
shortcomings. Peter proposed that these imperfect student-generated solutions were
rich fodder for designing Follow-up tasks to MEAs. He proposed that students could
extend their own mathematical thinking by analysing the gaps and strengths in other
students' solutions to the MEA. We will describe how we used this approach to
design Follow-up tasks to MEAs, as illustrated in one Follow-up task to the Giotto
MEA. We identify with Theme B working group, which aims to "understand how
appropriate task design might help minimise the gap between teacher intentions and
student mathematical activity". Our Follow-up tasks address this aim as they are
designed around students' perspectives (indeed their very solutions) to the initial
MEA.

The Giotto MEA

Model-Eliciting Activities (MEAs) are a class of mathematical modelling
tasks where students develop a mathematical model in response to a real world
problem. MEAs do not stipulate what that model should look like, but only what the
model should be able to do. This open-endedness typically leads to MEAs eliciting a
diversity of mathematical approaches from students. Consequently, MEAs have been
used to identify creatively gifted mathematics students (Chamberlin & Moon, 2005)
and to investigate equity issues in undergraduate engineering courses (Diefes-Dux,
Hjalmarson, Zawojewski & Bowman, 2006).
We created the "The Giotto MEA" (see website http://icmi22radonich-yoonpaper.wikispaces.com/home) according to Lesh et al.'s (2000) principles for
designing MEAs, which are summarised in Table 1. The problem begins with a comic
that tells how the Renaissance artist, Giotto, gained the pope's attention by drawing a
perfect freehand circle (see Figure 1). After reading the comic, students are asked to
draw their own freehand circles and choose the best among them. Next, they watch a
short YouTube video of a mathematics teacher who professes to be the world's
freehand circle drawing champion and appears to draw a perfect freehand circle. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI

solutions
When analysing the mathematical approaches in students' solutions to
MEAs, we draw on theoretical perspectives that focus on the
that students attend to, such as modelling perspectives (Lesh & Doerr
Blum and Galbraith, 2007) and Mason's theory of the structure of attention (2004).
These perspectives characterise mathematical structure as consisting of
objects or elements (such as counts, measures, sets),
few, large, open), operations (e.g. combine, enlarge, invert), and relationships (e.g.
greater than, equivalent to). Accordingly, when analysing students' solutions, we
concentrate on identifying
and relationships that students perceive and work with.
Additionally, we
structures can only be identified through the observable signs the person produces and
works with. According to Arzarello, Paola, Robutti and Sabena (2009), these signs or
semiotic resources may involve spoken language, gestures, written text, symbols,
diagrams, graphs and physical artefacts. Consequently,
resources that students produce
students appear to be perceiving.

example, we found that the mistake in SJH's scoring system provided an opportunity
to explore ways of comparing actual measures of circularity to ideal measures.
Another advantage of using students' written work in Follow-up tasks is that
it shines the spotlight on student knowledge. Some of the Follow-up tasks we have
designed are more typical of teacher-led approaches, which reinforce circle properties
such as cyclic quadrilaterals and angles at the centre and circumference. Such tasks
run the danger of emphasising the already prevalent perception that teachers are the
source of mathematically correct solutions (English & Doerr, 2004), and students
could interpret such tasks as subtle hints that these properties of circles should have
featured in their solutions to the Giotto MEA. The use of student solutions to design
Follow-up tasks can help avert the danger of students thinking the teacher-presented
ideas are necessarily more correct than their own.
When other students read Sonya, Jun and Hayley's letter with its original
handwriting and diagrams, they may make what is essentially a cultural connection.
The Follow-up task is situated in the context of Sonya, Jun and Hayley: three
mathematics students who have struggled with the Giotto MEA. Students working on

the Follow-up based on SJH's solution may relate to them, as they too are
mathematics students who have just worked in groups on the same problem. This
connection may lead students to be more engaged and curious about exploring the
mathematical concepts that other students described, which in turn, could help
students reflect more deeply on their own method (Boaler 1993).
As part of our research, we obtained permission from students to use their
solutions in developing future tasks, and we used pseudonyms to protect their
identities. However, a teacher may wish to use their own students' work as a resource
for creating Follow-up tasks, possibly even with the intention of using those tasks in
classes where the students' identities may be revealed to their peers. In such cases,
teachers need to be sensitive to students' fears about making their work public. Effort
will be required to create a culture where discussing student work is a natural and safe
part of the teaching and learning process. Our experience is that students are often less
concerned about sharing group solutions with the class, and are more inclined to share
individual solutions if names aren't revealed. Even if students give permission to
share their solutions, however, teachers may not have enough time to prepare Followup tasks for the next lesson. In this case, we advocate using Follow-up tasks based on
student solutions from previous years or from other schools or even countries.
This paper has emphasised the diversity of mathematical ideas that are
evident in student solutions to MEAs. However, in our research we have found that
student solutions also reveal a range of competencies in other related areas, such as
mathematical modelling and communication. We have successfully used the same
approach of using student solutions to create Follow-up tasks whereby students
evaluate the strengths and shortcomings of other students' mathematical
communication and modelling as a way of improving their own. A valuable feature of
our design approach is that it enables us to create tasks that extend and develop a wide
range of mathematical competencies in students.

Tasks to Promote Holistic Flexible Reasoning about Simple
Additive Structures
Annie Savard
McGill University
Elena Polotskaia
McGill University
Viktor Freiman
Université de Moncton
Claudine Gervais
Commission scolaire des Grandes-Seigneuries
In this paper, we focus on an approach that promotes holistic
flexible reasoning with simple additive structures in arithmetic problem
solving in elementary school. We propose to distinguish two paradigms in
which additive problem solving tasks can be seen. We also propose an
ethno-mathematical model to analyze the tasks and their implementations.
In our experimentation, a new form of problem solving task was designed
and tested. The results of our experimentation show that the proposed
approach promotes the holistic additive reasoning in students.
Key words: elementary mathematics; problem solving; additive
structures; holistic reasoning
Introduction
The current math curriculum for elementary school in Quebec pays a special
attention to the development of students' problem solving skills. Some problems that
involve using one addition or one subtraction operation can be difficult for some
students until the age of 12-14 (Vergnaud, 2009). Many researchers (Carpenter,
Fennema, Franke, Linda, & Empson, 1999; Carpenter, Moser, & Bebout, 1988; De
Corte & Verschaffel, 1980; Gerofsky, 2004; Julo, 2002; Nesher, Greeno, & Riley,
1982; Riley, Greeno, & Heller, 1984; Vergnaud, 1982a) (to name few) studied the
subject from different perspectives and stated that students have difficulty in
acquiring a full and flexible understanding of addition and subtraction. Thus, it seems
relevant to look at how to improve students' learning by helping teachers to develop
new teaching practices.
Our team is conducting a 3-year research project funded by the Quebec
Ministry of Education on additive problem solving in early grades of elementary
school. The goals of the project are: 1) to develop a pedagogical approach that would
promote holistic and flexible reasoning about simple additive structures; 2) to design
and test a set of tasks and didactical scenarios that implements the new approach; 3)
to propose a related teacher professional development program. Our research team Theme B - A. Savard et al.
270
consists of two researchers (Savard and Freiman), a designer (Polotskaia), and a
school board consultant responsible for the teachers' professional development
(Gervais).
Answering to the request of Theme B of the study group, we would like to
clarify the following question. How can the task of additive problem solving
transformed the way to minimise the gap between teacher intentions and students
activity? First, we will discuss the nature of additive problems as mathematical tasks
to better understand their possible educative purposes. Then, we will provide a
theoretical framework to analyze students' and teachers' behaviours regarding this
kind of tasks in school settings. It will help us to see why students' actual problemsolving activity can differ from teacher's intentions. A short overview of alternatives
found in the literature will provide us with specific pedagogical recommendations for
the new ways of designing tasks related to word problems having additive structure.
As support to our principles for such design we briefly discuss some preliminary
findings from the first year of experimentations with elementary school teachers.
Two paradigms in additive problem solving
Nowadays, there are two paradigms in which additive problem solving can
be seen. The first one, which we will call the Operational Paradigm, puts the focus
on addition and subtraction as arithmetic operations. From this position, additive word
problems can be seen as exercises where the knowledge about arithmetic operations
can be applied or further developed. It corresponds to an order of teaching
mathematics where students first learn about operations (how to add and subtract) and
then try to solve different word problems to practice this knowledge and to get the
conceptual understanding of these operations. This paradigm is clearly formulated by
Brissiaud (2010) who argues that, "to have a conceptual knowledge of subtraction"
means "to have different senses of the subtraction operation" like: finding the
difference, finding the complement and take over. However, knowing what it means
to add or to subtract two quantities, or how to add or subtract two numbers, is not
enough to solve additive word problems (Vergnaud, 1982b). As follows from the
research (Carpenter, Fennema, Franke, Linda, & Empson, 1999; Gerofsky, 2004;
Nesher, Greeno, & Riley, 1982; Riley, Greeno, & Heller, 1984; Vergnaud, 1982) , the
senses of subtraction-as-finding-the-difference or subtraction-as-finding-thecomplement, are not easy to construct directly from the first and quite intuitive sense -
subtraction-as-a-take over.
Several studies conducted in 1980-90s aimed to understand students'
difficulties with word problems by proposing classifications of word problems
according to their semantic and mathematical structures (Carpenter et al., 1999;
Nesher et al., 1982; Riley et al., 1984; Vergnaud, 1982a). Contemporary research
(Barrouillet & Camos, 2002; Nunes, Bryant, Evans, Bell, & Barros, 2011; Pape, 2003;
Thevenot, 2010) shows that some problems are particularly difficult because they
require a flexible and holistic analysis of their mathematical structure while easy
problems do not require such analysis. Yet in the Operational Paradigm, additive
structures are not seen as a primary mathematical knowledge, but only as different
senses of two arithmetic operations.
A different paradigm, which we will name the Relational Paradigm, appears
in the works by Davydov (1982) and more recent studies (Iannece, Mellone, &
Tortora, 2009; Xin, Wiles, & Lin, 2008). According to Davydov (1982), the concept
of additive relationship is, "the law of composition by which the relation between Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
271
two elements determines a unique third element as a function" (p. 229). Davydov
(1982) advanced that an adequate understanding of the additive relationship is the
basis for the learning of addition and subtraction and should be taught prior to
counting. According to this view, arithmetic operations are not the mean to
understand a situation but serve as tools to modify the situation, one understood, in a
desired way.
In the Relational Paradigm, a problem solving task should be an occasion to
analyse the additive relationships present in the situation. This yields the following
task design principles.
1.The task should be based on a situation involving a simple additive
relationship between three quantities.
2.The task should involve students in the mathematical analysis of the
described relationship as a whole. It should help students to discover
different properties of the relationship, and to see how different
arithmetic operations can be used in the described situation for different
purposes.
Existing formats of presenting tasks with additive word problem usually
limits student's activity to the goal of finding a solution as final step of problemsolving process, and thus does not directly imply any in-depth analysis of the
problem's structure which would help to develop more holistic view. Furthermore,
problem solving as a school task has some psychological and social characteristics
that, themselves and together with the classroom norms (Bosch, Chevallard, &
Gascón, 2005), can potentially contribute to either widening or reducing the gap
between pedagogical intentions and students' activity. The socio-cultural analysis is
therefore needed to explicit teacher-student behaviour patterns during the activity and
related didactic tensions.
Modeling teaching and learning situations for developing mathematical
and citizenship competencies
A well-designed curriculum should help students develop profound
mathematical knowledge. Furthermore, students should develop competencies
applicable in an outside classroom context. To respond to these fundamental
requirements, a good mathematical task should be anchored in a socio-cultural
context, that reflects the culture and the society including the student's experiences
inside and outside the classroom (Savard, 2008).
In order to analyze learning situations, and related tasks as a socio-cultural
phenomena, we used an ethno-mathematic model - the Math and Citizenship
competencies learning model - created by Mukhopadhyay et Greer (2001) and further
developed by Savard (2008). According to this model, implementing problemsolving tasks should start with an analysis of the given "real world" situation
involving its socio-cultural context. Then, the focus should move towards the
mathematical context. The model compels students to take into consideration the
relationships between the quantities involved. Mathematical operations are used to
find a result. Then, the result should be evaluated and interpreted within the initial
"real world" context (corresponds to the cycle described by (Novotná, 1998)) and
eventually in a larger socio-cultural and political context to develop students' critical
thinking (Lipman, 2003). Completing the learning cycle real world-mathematics-real
world can potentially promote meaningful learning in students. Does the traditionally Theme B - A. Savard et al.
272
designed problem-solving task help the teacher to organize students' activity in this
cyclic way?
The explicit main goal of a problem solving tasks is finding the answer. As
described by Gerofsky (2004), very often the answer has no real value in the sociocultural context of the child. Therefore, students don't see problem solving as an
occasion for a meaningful discussion about real-world situations. They often see it as

an exercise of addition or subtraction operations. This students' perception of the task
prevents the learning cycle to be completed. The task is often finished at the moment
when the numerical answer is found and validated by the teacher. A special effort is
required from the teacher to organise the class work in a way where the learning cycle
can be completed.
Moving too quickly to finding an answer can provoke a specific didactic
contract (Brousseau, 1988) in students. For example, students might think that the
teacher's expectation is to find the numerical answer the easiest way possible. Under
the pressure of this contract, students can develop different strategies that help them
rapidly translate the text of the problem to a mathematical expression. According to
Hegarty et al. (1995), some students can recognize numerical data and key-words,
such as more, less, increase, take over, and construct a mathematical expression in a
straightforward way, translating these words to arithmetic operations. However, by
using this "direct translation" strategy (Hegarty et al., 1995), students move too
quickly to the arithmetic operation and do not pay attention to the underlying
mathematical concepts and relationships. This problem solving strategy is very
efficient for many problems but not for all of them. Yet, the success of using this
strategy can prevent students from acquiring a more profound understanding of the
mathematical structure of the problem.
The proposed above socio-cultural model (Savard, 2008) helps recognize the
difficulties teachers may have while implementing problem solving tasks and
obtaining the desired educational goal – a profound and flexible understanding of the
additive structures. Furthermore, based on this model, some more task design
principals can be deduced.
3.The task should use a socio-cultural context in which students can identify
themselves as active agents.
4.The task should not contain any explicit and immediate questions that
could be answered by finding one particular number. This criterion is to
prevent students from immediately calculating the answer. However, the
task should include an intriguing element, which would support students'
natural interest and commitment.
5.The goal of the task, which is learning to analyze the situation, should be
explicitly communicated to students.
The formulated task design principles do not correspond hundred percent to
the traditional word problem task organisation. What other organizations of such tasks
can we find in the literature?
Task organizations overview
As we mentioned earlier, in order to solve difficult or complex problems,
students should be able to see the mathematical structure of the problem in a flexible
holistic way. In the literature, we can find many approaches and methods potentially
supporting this ability development in students. Some of these studies (Bartolini
Bussi, Canalini, & Ferri, 2011; Ducharme & Polotskaia, 2008; Gamo, Sander, & Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
273
Richard, 2009; Julo, 2002; Nguala, 2005) concern the use of different representations
for the problems. Gamo et al. (2009) demonstrate that the comparison of problems
and the use of different representations can help students develop efficient problemsolving strategies. Any graphical or schematic representation potentially gives
students a rapid visual access to the entire system of quantitative relationships
described in the problem. Therefore, using diagrams should promote the holistic
vision of the problem in students. Comparison of problems (Bartolini Bussi et al.,
2011) and multiple wording of the same problem (Julo, 2002; Nguala, 2005) are also
shown to be beneficial for elder students. However, these tasks can be linguistically
difficult for very young students (Ducharme & Polotskaia, 2008).
Some other studies (DeBlois, 2006; Neef, Nelles, Iwata, & Page, 2003)
propose particular didactic management and class work organisation. Neef and her
colleagues (2003) have shown that learning about the roles of each data element in the
problem greatly improves the success in problem solving among students with
developmental disabilities. DeBlois (2006) suggests that a request for feedback on the
solved problem may provoke coordination between representations and procedures
and may lead students to reorganize their thoughts. Both approaches clearly reflect the
effort to reorganise students' reasoning about the situation in a holistic flexible way.
All mentioned above teaching approaches, explicitly or implicitly, promote
in students the ability to see the problem as a whole and to better coordinate
relationships between quantities involved. To reinforce this important aspect of the
problem solving activity in young students the following principles should be
followed.
6.The text of the task should be very short and should contain simple words
and expressions that the students are familiar with.
7.The mathematical discussion of the situation should integrate appropriate
graphical representations as a method of analysis.
Keeping in mind all formulated above principles, what concrete task
organization do we propose?
Task description
We provide here one example of the task that we named 360° situation to
highlight the main goal – holistic analysis of the mathematical structure of the
situation. This is an example of a text proposed to students.
Peter, Gabriel and Daniel are playing marbles. Peter says, "I have 5 marbles."
Gabriel says, "I have 8 marbles." Daniel says, "Peter has 4 marbles less than
Gabriel".
We introduce this text as a strange situation or as a situation where one of the
persons made a mistake. Students are invited to explain why the text is unrealistic and
how it can be corrected considering different quantities involved.
The objective of the first is to make explicit the fact that all three quantities
are related to each other and that the choice of two values implies one (and only one)
third value. At the next step, we invite students to construct a graphical
representation, which can support discovering of the appropriate arithmetic
operations. Each quantity should be evaluated to figure out a correct numeric value in
the condition where the other two quantities are fixed. At this step, the formal use of
arithmetic operations can be discussed. Finally, the numbers in the text can be
replaced with different ones to further generalise the initially discussed quantitative
relations. This will complete the 360° tour around the situation. Theme B – A. Savard et al.
274
Preliminary observation in the classroom
The first year of our project was implemented in rural public schools in
Quebec. We worked with two experimental groups of grade 2 elementary students (32
students, age 7-8 years). One other group of students of the same grade (14 students)
was observed as a control group. In the experimental group, teachers worked with
new and traditional tasks of additive problem solving. The teachers from the
experimental group received 6 follow-up sessions during the school year. In the
control group, only traditional problem solving tasks design was used and the teacher
did not participate in follow-up sessions.
Experiments with the 360° situation tasks started with manipulative activities
where we discussed with students some methods and sense of comparison of lengths
of two physical objects. We used coloured ropes and paper strips. The 360° tasks
were used then to organize the analyse-and-representation activities for students to
discuss different comparison situations. One of the central part of these activities was
the construction of an "Arrange-all" diagram (Ng & Lee, 2009; Polotskaia, 2010) – a
representation of the mathematical structure of the problem similar to the ropes we
have just manipulated with. These diagrams were used as an analytical tool to find
appropriate arithmetic operations for the given situation. In total, three 360° situation
tasks were worked with students prior to solving traditional problems. During our
sessions with teachers we recommended the use of similar discussions about all
additive problems till the end of the school year.
Although a detailed presentation and analysis of collected data lies beyond
the scope of this paper, we would like to share some observations made in the
experimental classrooms. Below is the partial script of the first lesson when the
described above task was proposed to students.
Teacher writes the story of Peter, Gabriel, and Daniel on the blackboard and asks
students to read it aloud. She explains that one of the three friends said something
wrong or made a mistake.
Teacher, showing the three affirmations on the blackboard: Who said something
wrong?
A: Gabriel
Teacher: You say Gabriel. Why?
A: There are 8. It's a lot. There are 5 and 4.
Teacher: Ok, Who agree with A that Gabriel is wrong? [Some students raised
their hands]
Teacher: Does anybody think differently? Is it another friend who made a
mistake? [Many students raised their hands]
Teacher: You B, what do you think?
B: I think it is Daniel
Teacher: You think it is Daniel who is wrong. Why?
B: Because… Because, let us take the 5 marbles of Peter. Daniel says that Peter
has 4 marbles less than Gabriel. Because, 4 plus 4 is 8, but 5 plus 4 will be 9.
…
Teacher: Ok. Now we will check each of your propositions.
The intention of the teacher for this part of the lesson was to engage students
in the discussion about additive relationship between three quantities. The semantic
meaning of the situation described in the task was in contradiction with the numerical
values indicated in the text. The numbers were small, so it was easy for students to
see this contradiction. We can see from the script that students, while giving their
arguments, tried to analyse the three numbers altogether. Therefore, the form of the
task helped minimize the gap between the teacher's intentions and the students'
activity. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
275
We should mention here that at the end of the year, students from the
experimental group have generally succeeded to demonstrate a progress in solving
problems in which the holistic and flexible mathematical analysis was really
necessary. At the same time, students from the control group have progressed more in
solving problems that could be solved without such analysis.
Regarding the implementation of the 360° situation tasks, we observed that
teachers have a tendency to return to the traditional teaching behaviours as soon as
they start to work with traditional problems. For example, once the numerical answer
was found for the problem, the discussion of the problem often ended abruptly. Thus,
the focus of the activity was often shifted towards the use of the correct (recently
discussed) representation or the calculation of the numerical answer.
Conclusion
As response to the call for contribution to the Theme B of the study, we
presented our theoretical perspectives on the new task design for problem solving. By
collaborating with teachers on the use of different types of tasks (we called them 360°
situation), we expected to minimize the gap between teachers' intentions and
children's mathematical activity. We are convinced that the Relational Paradigm can
be a powerful theoretical tool in didactic engineering and task designs. It helps to
construct tasks in which relational analysis is explicitly targeted. The tasks, having
this important property and implemented throughout the Math and Citizenship
competencies learning model, can play a major role in the reorientation of the
classroom work with word problems from operations-oriented toward relationsoriented. It can also help teachers and students to reconsider their immediate
teaching/learning targets in mathematical activities. While our preliminary data on
students' results and teachers' practices show some progresses, we agree with De
Corte (2012), that teachers need a closer follow-up in the new approaches for a
considerably long time in order to profoundly change their practice.

Theme C: Design and use of text-based resources

Denisse Thompson
University of South Florida, USA
Anne Watson
University of Oxford, UK

This theme focuses on the design of textbooks, downloadable materials, and
other forms of text-based communication designed to generate mathematical learning.
We recognise that most teachers use textbooks and/or online packages of materials as
their total or main source of tasks. Hence the design and use of tasks presented in
textbooks is central to many school students' experience of mathematics. The
scholarly study of task design should include consideration of theoretically-based
textbook development, and can take place at different grain-sizes from individual
tasks, through sequences of tasks, to a whole textbook series (Usiskin, 2003).
Some analyses of textbooks draw attention to differences in the use of
language, illustrations, cultural and social allusions and some focus more on the
mathematical and epistemological content (Askew, Hodgen, Hossain, & Bretscher,
2010; Haggarty & Pepin, 2001; Sutherland, 2002; Thompson, Senk, & Johnson, in
press). Significant differences have been found in the conceptual coherence,
mathematical challenge, consistency of images, and ordering of tasks between, for
example, UK and Singapore textbooks. For example, in some textbooks a new
concept is introduced through some everyday questions which are gradually refined to
focus on a formal presentation; in others, practice of a technique precedes application
through word problems (Ainley, 2010). The design of the order, development,
representation and presentation of content is therefore a suitable topic for this ICMI
study.
Another way to look at textual presentation is to analyse the content of
individual questions or sequences of questions, and variation theory has been used as
a tool both for design and analysis at this fine-grained level (Watson & Mason, 2006).
For example, control of variation among examples can be used to direct learners
towards inductive generalisations about concepts; example sequencing with
controlled variation can lead learners towards some cognitive conflict. Textual
presentation could be informed by research about how features of page and screen
layout affect learners' attention (Ainsworth, 2009; Poole & Ball, 2006).
A third way to look at textbook tasks is to view them as the shapers of the
curriculum rather than merely presenting a given curriculum (Senk & Thompson,
2003). The underlying commitments about the nature of mathematics, mathematical
activity, and how mathematics is learnt, vary between textbook series and between
countries. How these are promoted in the design and content of the tasks in the
textbook is an important area of study because a textbook series might have more
influence on learners and learning than a national curriculum. Different designers may
interpret national standards or recommendations in different ways so that
understanding the principles on which they instantiate these recommendations is an Theme C – Introduction
280
important area of study (Hirsch, 2007). Various components of mathematics will be
prioritised or marginalised differently through different kinds of tasks and there will
be legitimate debate about how students come into contact with mathematical
absolutes (if there are any) (e.g. Harel & Wilson, 2011).
Authors' intentions can be different from how tasks or sequences of tasks are
used in classrooms, and in this theme we could also look at pedagogic suggestions,
particularly for innovative or unusual tasks, and information about conceptual
intentions (Thompson & Senk, 2010). Many textbooks now refer users to online
resources and tasks, and there is a professional development element to their use.
There may be a difference between the adventurousness of students and the
conservatism of teachers in their use and vice versa. (See chapters in Reys, Reys, &
Rubenstein (2010) for issues related to curriculum and tasks in terms of intentions and
enactments.)
Throughout the following set of questions, we consider a textbook and/or
online resource to be a collection of tasks, generally sequenced in a given way, and
often surrounded by related narrative and/or questions:
• How do curriculum expectations influence authors' design principles?
• How does an intention to promote change influence design?
• How do designers' expectations of teacher knowledge inform the design of
dual purpose tasks: to teach students and to facilitate teacher learning?
• How can authors and teachers learn from alignments and misalignments of
teachers' adaptations and authors' intent, and the implications for
students' learning?
• How can or should new digital formats influence textbook design: e.g. use
of podcasts, twitter, and other social media; implications for design and
coherence of materials (either original digital design or transfer from
print) if teachers are able to select tasks in varied orders?
• How do cultural considerations about instruction and pedagogy influence
design: for example, whether teachers are seen as "facilitators" or
"givers" of knowledge?
• How can designers take account of the language of instruction not being
students' home language?
• What research about design of textbooks and other materials should be
undertaken to inform the next generation of designers? In particular, how
might design experiments (e.g., Clements (2007) or teaching
experiments (such as Japanese lesson study)) influence task design in
curriculum materials?
• How can design principles from software design, advertising, graphical art
and eye-gaze research be used to improve text-based materials?

Mathematical tasks aim at supporting students to engage in a
range of mathematical activities with specific didactical goals. Task
design has to take into account the specificity of these different didactical
goals (e.g., exploration, concept formation, practising skills). In this study,
we focus on tasks intended for the didactical aim of mathematical
knowledge organization ("organizing tasks"). In our learning pathways,
phases of knowledge organization usually follow a phase of open
exploration, of constructing individual concepts; they aim at regularizing
and systematizing the students' singular ideas and results. Because such
organizing processes conducted in whole-classroom discussion often fall
short of engaging every single student, our design research study sets out
to develop task formats that promote adequate cognitive activities and
formats for this organizing phase. The article describes the efforts in
constructing and evaluating organizing tasks and presents – as a result of

our study – a conceptual framework for the delicate balance between individual engagement and convergence.
Keywords: organizing tasks, organizing knowledge, regularizing and systematizing
The challenge of organizing knowledge
The construction of mathematical knowledge is a multistep process of "organizing fields of experience" as Freudenthal pointed out (1973, p. 123). In subsequent work of the realistic math education approach (de Lange, 1996), examples of organizing processes are abundant, comprising "horizontal" and "vertical" mathematization (Treffers, 1987, p. 247). Although these ideas lie at the heart of most contemporary approaches for mathematics education, it is undeniable that in mathematics classrooms such organizing processes can rarely be found explicitly (Hiebert et al., 2003). However, there is a need for development of activities which

promote systematizing, regularizing, and preserving the results of exploration with several goals:
• structuring the singular and divergent results and connecting them to other facets of knowledge (systematizing),
• transforming results into regular and consolidated mathematics (Brousseau, 1997, calls this phase the "institutionalization", we call it regularizing);
• writing down in a form that is accessible later (preserving).
When and how do such procedures of organizing knowledge occur? When observing German mathematics classrooms, we often find phases of discovery and individual problem solving. For the subsequent phases of regularizing, we actually encounter two different types of classroom procedures.
In the first type of procedure, the teacher conducts a whole-classroom discussion in a Socratic dialogue, collects and evaluates students' contributions, and leads the class to an organized and structured knowledge. This procedure requires whole classroom conversation techniques and proves precarious with respect to the cognitive activation of every single student. In the second type of procedure, the teacher may avoid whole-classroom discussion and instead refer students to the information boxes in the textbook where the correct mathematical concept or result is stated. This ensures a common basis, but there is a danger that the individually constructed knowledge cannot be integrated in this "ready-made-mathematics".
What are alternative options for supporting students in organizing their knowledge, in mastering the step from the singular and individual knowledge to the regular and commonly accepted mathematical knowledge while preserving students' engagement? In our design research study, we developed approaches and tasks on the basis of three premises: (1) Teachers predominantly work with textbooks, so the organizing tasks should be embedded into a comprehensive textbook curriculum; (2) Students must be actively involved in the learning processes; (3) Teachers are not supposed to give up their role in moderating the process of organizing with the whole class. We consider the communication processes within the class as extremely important for attaining a high level of mathematical insight.
Hence, our goals are to construct tasks that support students in actively organizing their knowledge and simultaneously support teachers in guiding this process in an effective manner. We call this task type "organizing task" or, when we need to avoid the misunderstanding of organizing as a purely external, administrative activity, as "knowledge organizing tasks". The guiding questions for our study are:
Q1. Specification of learning goals:
What elements of knowledge have to be organized and preserved?
Q2. Types of Task:s
Which types of tasks can support students' active knowledge organization?
Q3. Principles for the Task Design:
Which principles guide the construction of organizing tasks?
The framework: design research for a middle school curriculum
The study on organizing tasks is embedded in the long term design research project KOSIMA (2006-2016, cf. Hußmann et al., 2011). It is briefly presented here with its methodological framework and the conceptual framework for the design products. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

Methodological framework of the long-term design research project
The project KOSIMA (Hußmann et al., 2011) follows the methodology of Didactical Design Research (Gravemeijer & Cobb, 2006; McKenney & Reeves, 2012) with its dual aim of designing teaching-learning-arrangements for a complete middle school curriculum (grades 5 to 10 of German Realschule, Gesamtschule, Sekundarschule) and empirically researching the teaching-learning-processes and their conditions. The developed curriculum is published as the textbook Mathewerkstatt from 2012 to 2017 (Barzel et al., 2012 ff.) and a comprehensive teachers' manual.
All teaching-learning-arrangements of the textbook-to-be are developed in iterative cycles of design, evaluation (by expert discussions and classroom experiments), and redesign. Whereas the design and evaluation steps of the project refer to the entire implementation of the textbook, the deeper research is organized in several smaller design research studies that necessarily have to address more narrow research questions. These studies use different concrete research methods and designs (e.g., intervention studies in quasi-experimental designs, design experiments in laboratory settings with up to four cycles, e.g., Leuders & Philipp, 2012; Prediger & Schnell, 2013). An overall evaluation of summative effectiveness commenced in August, 2012. Results of the quasi-experimental intervention with pre-post-test over two years can be expected in 2014.
The community involved in these processes is a large group of people from different backgrounds who collaborate fruitfully:
• researchers (the four authors of this paper, being the editors of the textbook and leaders of the design research project, supported by many PhD students and student researchers)
• authors of the teaching-learning-arrangements (about 20 experienced reflective practitioners, together with the editors)
• the publisher (with 2-4 copy editors who finalize the design products)
• project teachers (about 10 teachers with their classes, who teach with the curriculum and the textbook material continually in their regular classes).
Conceptual framework for the design product
The design of the middle school curriculum is guided by certain design principles. We only state those which are relevant for the focus of this paper, that is for designing organizing tasks (cf. Hußmann et al., 2011; Prediger et al., 2011).
Following socio-constructivist theories of learning, we emphasize the importance of students' active engagement and sense-making by starting from meaningful context problems, and developing conceptual understanding (Leuders et al., 2012, following Wagenschein, 1977 and Freudenthal, 1973). For realizing these principles, every teaching-learning-arrangement (each for 2-6 sessions) is structured into four main phases: activation, exploration, organization of knowledge, and practice.
Activation of students' experiences. For including students' pre-instructional experiences into the learning pathways, every arrangement is situated in an everyday context that allows problems for ready-made mathematics to be reinvented and students to construct meanings for the intended mathematical topics.
The following is an example referred to throughout this article. "Constructing Packages" provides a context for students to think about solid figures and their

characteristics, such as parallel and perpendicular lines. To solve problems related to this topic, students put themselves in the role of a package designer who has to create new packaging for a toy. In considering a good design for a package, a designer has to think about what criteria are relevant to create a good package-box. Apart from price, other possible criteria are look, stackability, and ease of construction. Stackability specifically leads to the necessity of having packages with parallel and perpendicular lines.
Exploration. In this extensive phase, the problems are operationalized into open and rich exploration tasks (Fiewelling & William, 2001; Freudenthal, 1973). They allow students to actively and collaboratively re-invent ideas, concepts, procedures and relations in the sense of horizontal mathematization. Due to the openness and student-centricity of this phase, it often results in a large diversity of individual ideas, strategies, solutions, findings, pre-concepts, etc. The concrete design principles for exploration tasks that were developed or refined during the design research project are not reported here. Looking at our example in this phase: Students assume the role of the package-designer and they actually construct a package-box for a specific item, e.g. a toy. During this process of construction, many students realize that the "box must be straight and precise, not awry or askew". These experiences prepare the systemization of the concept of perpendicular and parallel in the next phase.
Organization of knowledge. The goal of the subsequent phase of organization (in German "ordnen" which also means "ordering", "arranging") is to establish a shared understanding of the core concepts, theorems and procedures and to preserve and document this understanding in the self-written "knowledge-storage" (in German "Wissensspeicher").
The packaging example highlights the kinds of activities required in this phase. Exploration often leads to a great diversity – in our example a lot of different boxes, ideas, images, and students' thoughts. All of these products and ideas have to be shared and compared in order to systematize the new knowledge. To stimulate students´ mental processes, we created focused cognitive activities (called acquisition activities) according to the new knowledge.
The type of acquisition activity depends on the types of knowledge. For the concept of perpendicular and parallel, one can differentiate between the following aspects, which have to be learned:
• Students must learn the technical terms "perpendicular" and "parallel". These words are names and just conventions, which cannot be discovered or explored. Students have to be informed about these new words. This has to be done in a language, which can be easily understood by students and with words which link to the experience of the exploration phase (see the first lines of the task in Fig 2).
• Another convention in our example is the marking of a right angle with a dot (a convention that differs throughout several countries). This is information that students must learn (see picture on the left side in Fig. 2).
• Students have to learn to recognize perpendicular and parallel lines. Task 2b (in Fig. 2) involves concretisation and distinction of the new concept. Pupils have to recognize which pairs of lines show parallel or perpendicular ones.
• The extent to which individual students can verbalise the new concept varies and can be described by the extrema: On the one side students Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

formulate a definition by themselves, a very ambitious task; on the other side students have to copy a given definition (see Fig 3). Choosing a correct definition from several given ones is an activity in between these extrema, and this is demonstrated in our example. (See (2b) in Fig 2.)
When inspecting regular lessons and textbooks, we have only rarely encountered tasks that were constructed for supporting such organizing processes (e.g., Swan, 2005). That is why we had to conduct a design research study for specifying principles for a systematic construction and composition of organizing tasks. The results are reported in the section on Findings.
Practice. In the fourth phase of practice (in German "vertiefen" = deepen, intensify), the students are supposed to render their knowledge and skills more stable and flexible by repeated practice and transfer. Our design principles for these tasks refer to didactical approaches of productive exercises, structured tasks and reflective practising (Büchter & Leuders, 2005; Watson & Mason, 1998; Winter, 1984; Wittmann & Müller, 1990).
It is important to note that the construction of "organizing tasks" as a "carrier of the organizing" phase has only become indispensable within our didactical approach that distinguishes these phases explicitly to give students space for more individual mathematical activities. Within a more integrated approach, concept exploring and organizing activities could be combined or integrated more flexibly.
Methods of the design research study on organizing tasks
The construction of "organizing tasks" and the development of an overarching didactical approach for the principled construction of the tasks are embedded in the larger design research project depicted previously. For the concrete study, the cycles of constructing and evaluating organizing tasks were passed through topic by topic, each in four cycles (mostly including further microcycles).
For each topic, the first and second cycle of design, evaluation, and redesign is conducted by expert discussions. After specifying the goals of the learning arrangements, the writing team (authors and one editor) suggests a first draft for the formulation of target knowledge that students are supposed to save in their "knowledge storage". After discussing the selection and priorities by the editor team with respect to didactical-conceptual considerations, the (exploration and) organizing tasks are formulated, discussed and further developed. The details of formulation are edited by experienced copy editors of the publisher who optimize readability and coherence. The third cycle of evaluation is conducted in classroom experiments with 3-10 teachers in their regular classrooms. The data base for the investigation consists of teachers' written and oral feedback, scans of students' written texts for tasks, knowledge storages and classroom assessments as well as some videos of classroom interaction and design experiments in laboratory settings on selected tasks. For the current study, the qualitative data analysis is conducted with respect to connections between forms of tasks and a) students' engagement within the processes, b) the convergence of the processes and c) the results of organized knowledge as stored and especially as performed in the assessments. In the fourth cycle of redesign, with theoretical feedback authors, editors and copy editors again are involved in finalizing versions for the textbook and the teachers' manual. The final version is ready for widespread implementation and effective everyday use.
During these four-step processes for many different mathematical topics, we iteratively accumulated the reflections and experiences, generalized from the specific

topics, and developed a conceptual framework for organizing task design. Whereas the answers for research question Q1 on the relevant kinds of knowledge were mostly generated in the first and second steps of theoretical and conceptual evaluation,

answers for Q2 and Q3 on effects of forms of tasks mostly rely on the empirical
investigation, involving deeper insights into the mechanisms of the teaching-learning
processes as well as practical experiences on robustness for different classroom
conditions. Out of the whole conceptual framework for designing organizing task, we
present two major aspects in the next section.
Findings
Specification of learning goals: modes and facets of knowledge
The didactical base of a systematic task design is the exact specification of
the intended learning goal, here concretely the mode of knowledge that is supposed to
be systematized, regularized, and preserved. For concretizing this specification
process for each mathematical topic, we developed a conceptual framework of
different knowledge elements as printed in Figure 1 (Prediger et al., 2011).
The horizontal dimension follows the classical distinction (Hiebert &
Carpenter, 1992) among knowledge about facts, concepts (e.g., numbers, operations,
relations), and connections as codified in theorems (conceptual knowledge) on the one
hand, and the knowledge about mathematical and technical procedures (procedural
knowledge) on the other hand. We added metacognitive knowledge which includes
problem solving strategies or steps in modelling processes.

Fig. 1. Conceptual framework for specifying learning goals (Prediger et al., 2011)
During the design research process, we realized the importance of specifying
a second (here vertical) dimension that we call facets of knowledge: Whereas a piece
of knowledge is often only represented by its explicit verbalisations (in definitions,
theorems or instructions for procedures) or underlying conventions (like the technical
terms), didactical research has often shown that knowledge acquisition must also
comprise concretization and distinction (like examples and counterexamples for
concepts, cf. Winter, 1984 and Fig. 2 Task 2a) or knowledge of possible errors in
procedures (cf. Vollrath, 2010)) and meanings and connections to other elements of Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
289
knowledge, given by visual representations and mental models, explanations and preformal proofs.
As mathematical understanding is conceptualized as individual construction
of relations, dependencies, or connections between mathematical ideas, procedures
and concepts (Hiebert & Carpenter, 1992), we promote that the organizing tasks and
the knowledge storage must always include various facets of knowledge. It is the first
step of the construction process of an organizing task to specify which cells of Fig. 1
shall be addressed in the task. These modes and facets of knowledge are then subject
for initiating the processes of systematizing (= connecting different facets of
knowledge systematically), regularizing (= transforming individual constructions
from the exploration phase into regular mathematical concepts, connections and
procedures), and preserving (= documenting facets in the knowledge storage so that
they can be recalled some months later).
Types of tasks: initiating acquisition activities in a balance between students'
engagement and convergence
As made explicit previously, students must be actively involved in the
processes of systematizing, regularizing, and preserving knowledge. The necessity of
active engagement is explainable within the socio-constructivist framework and
reconstructable in the empirical investigations, because simple inputs (e.g., teachers
dictating the information) were not suitable for activating students' mental processes.
That is why for each piece of knowledge (cells in Fig. 1 selected for a
specific topic) that is to be systematized and preserved, a focused cognitive activity
(acquisition activity) must be initiated that supports students' active acquisition of this
piece of knowledge.
Fig. 2 shows some formats for how such activities could be initiated. First the
technical terms (here parallel and perpendicular) are given - in the frame and context
of the experiences and discoveries which have been done before (here the context of
exactly folding straight boxes). In 2a), examples and counterexamples are to be
identified. In 2b), students shall choose between possible definitions. Independent
personal definitions would produce again very divergent solutions, but finding a
correct and fitting one among some examples allows an active engagement with
higher convergence. Theme C – B. Barzel et al.
290
Fig. 2. Examples and counterexamples in 2a), Finding a correct definition in 2b) (Barzel et
al., 2012)
The classroom experiments showed clearly that the balance between
students' engagement and convergence of the process is delicate. If the openness of
the activity is high, students can intensively engage with the content; like in the
exploration tasks, they develop very divergent ideas and entries for the knowledge
storage. These divergences produce either the need for the teacher to moderate the
processes in funnel-like patterns (Bauersfeld, 1988), or to give individual feedback to
each individual attempt to write a knowledge storage, which is too much work for
each task. If tasks are optimized only with respect to convergence, it might risk
students not being engaged enough. The adequate balance between convergence and
engagement depends on the concrete topic and the concrete piece of knowledge.
The result of the generalization process was the specification of a range of
acquisition activities for each piece of knowledge, as illustrated for two exemplary
pieces of knowledge in Fig. 3. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
291
Fig 3. Range of acquisition activities in the balance between convergence and engagement
Discussion
Due to the fact that our design research in the KOSIMA project results in a
new textbook, the design part of the work itself has important impact on several
communities. First of all, it affects the students, who get the chance to develop and
reinvent mathematical concepts by relating relevant contexts with individual,
sustainable conceptions. The developed learning arrangement offers structured tasks
so that the teacher can moderate the learning processes and can support students in
organizing their knowledge. It has to be mentioned that the Mathewerkstatt is one of
only a few textbooks in Germany that are put to the test and fully revised and
reviewed by sample classes for guaranteeing usability by teachers.
The research that was conducted in the iterative interplay with design,
evaluation, analysis and revision of the learning arrangements showed the potential of
the structure of activation – exploration – organization – practice. The insights gained
into the deeper structures of the initiated learning processes allow us to contribute also
to didactical theory. A further evaluation on the generated learning progress was
started in August 2012 for a two year study.

Developing Young Students' Geometric Insight Based on
Multiple Informal Classifications as a Central Principle in the Task
Design
Marita Barabash
Achva Academic College, Israel
Raisa Guberman
Achva Academic College, Israel
The geometrical (and more generally, mathematical) insight of
students, as defined in our previous research, is characterized by four main
parameters. Such insight should be, in our opinion, the focus of educators at
any level of mathematics. This implies the need for teaching/learning
materials designed to serve this purpose. In this paper we illustrate how task
design principles aimed at students' mathematical insight are implemented
in a series of geometrical textbooks for grades 2-6 of primary school.
Keywords: mathematical insight, teaching solids at primary school,
teaching geometry at primary school, informal classifications
Introduction: our model of mathematical insight as a conceptual basis for
the task design

In our past and present research, we follow previous studies (see e. g., Barabash & Guberman, 2008; Griffiths, 1971; Sternberg & Davidson, 1999) in the search for characteristics and ways of development of mathematical insight as a feature reflecting the depth of a person's mathematical thinking and understanding. In doing so, we infer that these characteristics should not be dependent upon the person's formal mathematical knowledge (FMK); we found in our research support for this inference.
The concept of mathematical insight is closely related to mathematics understanding and comprehension as a result of learning. Our concept of insight is closely associated with learning theories dealing with procedural vs. conceptual knowledge and includes features of both types in accordance with recent studies indicating that they actually should be intertwined in a fruitful process of learning mathematics (see e.g., Schneider & Stern, 2005).
This may be a good point to indicate our personal professional profiles, since they have a direct implication on our tasks and on their further implementations with various populations. One of us has a PhD in mathematics, and the other one has a PhD in mathematics education. Both of us are teacher educators with more than 20-years of experience. One of us has been a primary school teacher; we both are active in inservice educational programs for mathematics teachers, and have written a number of textbooks and learning materials for primary and secondary school, for mathematicsteachers-to-be, and for teachers educators. Theme C – M. Barabash & R. Guberman
294
According to our research (Barabash & Guberman, 2008), the characteristics of mathematical insight (MI) are:
Implementation: the ability to implement, to employ the material being currrently learned in its close "neighborhood", and the measure of closeness of this implementation to the form in which it has been taught in the class ("the farther the better"). This indicates the student's ability to grasp the idea beyond its immediate presentation in a lesson or a handbook.
Skills: the variety of mathematical skills needed or demonstrated by a student in relation to the current issue, and the level of mastering these skills.
Extension / generalization: the ability to extend the acquired knowledge and/or to generalize it, or to incorporate the issue beyond the obvious mathematical context in which it has been originally studied.
Mathematical language: usage of newly acquired terminology; reasoning using relevant mathematical argumentation (appropriate to the formal mathematical (FM) development of the student); usage of formal-mathematical language and ability to appropriately relate it to verbal-non-mathematical expressions and vice versa, etc.
Principal considerations in the basis of our task design
Mathematics learning is known to develop in a spiral-like process, in which each coil is based upon previous ones and unfold out of them. The teaching and learning tasks should support this process in their didactical design and mathematical vision. Tasks can vary not only with respect to mathematics content but also with respect to the cognitive processes involved in working on them (Shimizu, Kaur, Huang, & Clarke, 2010).
In view of these and other similar reference points and in consistency with our own professional and academic experience, we define a task as a series of questions and assignments united by a big mathematical idea. We regard textbooks for primary school as a self-consistent series of such tasks on topics outlined by the curriculum, each task comprising a structured well-planned succession of problems, situations, explanations and exercises aimed at the on-going spiral-like learning of mathematics. By "learning of mathematics", we mean two intertwined processes: the development of students' FM knowledge (i.e., the corpus of notions, facts, techniques, ways of reasoning); and understanding of this corpus, which we characterize as mathematical insight.
Accordingly, we claim that the teaching procedures and materials should be aimed at the current state of the students' insight and designed so that they permanently advance it, regarding each of its characteristics as an ongoing objective. It is in view of this intention that we refer to the 5-year perspective of teaching solids in primary school as it is worked out in our series of textbooks for 2nd through 6th grade (excluding 3rd grade).
In our design of learning tasks, we keep in mind mathematical, epistemological and curriculum-related (MEC), cognitive-developmental (CD), and pedagogical and didactical (PD) objectives of the curriculum issue for which the tasks are being designed, all of them having direct implications on the insight development (Fig.1). We refer here briefly to each of these principles in relation to our textbooks. The abridged notation will serve for further reference. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

Fig.1. Schematic representation of task design principles aimed at the development of students' mathematical insight at any level of FMK
MEC: When we plan a teaching task, for whichever level of FM learning it is aimed, we first consider it from the perspective of its mathematical content and meaning. This is done in view of curriculum indications, on the one hand, and of our mathematical knowledge and of our pedagogical content knowledge (PCK), on the other hand. Obviously, the mathematical and epistemological considerations concerning the primary school geometry textbooks are curriculum-related. They are:
MEC1: Mathematical correctness. We decline any possibility to present a mathematical notion in a way, however seemingly clear, which contradicts the mathematics of the issue, and hence, will render the notion to be sooner or later learned anew in a different way not consistent with the present one. Mathematical correctness is not a synonym to mathematical precision, rigor, and formality. Any mathematical notion, idea or fact intended for the primary school can be learned in a mathematically correct way at an informal, pre-formal or more-or-less formal mathematical level.
MEC2: The mathematical perspective of past and future development of the issue at school and (possibly) in future higher-education studies (longitudinal perspective), in compliance with the "big mathematical idea" being studied.
MEC3: The links of the new topic to other mathematical or outermathematical topics being currently learned (cross-curricular perspective).
MEC4: Intuitive-inductive acquaintance with figures and solids and their properties, with implicit or explicit suggestions for generalization. Where possible and appropriate, we do our best to reveal to the teachers (in the teachers' guide) and/or to the students (in the textbook itself) the motivations for definitions, ways of reasoning, ways of computing, etc. These motivations are conceived so as to pave the future way to more formal mathematical approaches (in compliance with *MEC2*).
CD: An ability to discern various characteristics of mathematical objects, or to find similarities and differences between them is the basis of the classification ability, which is one of the central thinking abilities. Piaget regarded cognitive developmental ability to be one of the most important cognitive abilities. Following Piaget (1962), class inclusion is an understanding of the fact that a set of objects is simultaneously a Theme C – M. Barabash & R. Guberman
296
subset of another, bigger set. The development of this ability starts at the preoperational stage (ages 2-7). At this stage a child may classify objects by one property. At the concrete operational stage (ages 7-11), the child is able to perform classification by a number of properties, and is also able to rank the objects by one of the properties, for example, by size. At this stage, one of the aims may be to develop the Decentration ability (Piaget, 1962), i.e. an ability to shift between the classifications. The classifications may be formal-mathematical or not.
PD: The results and analysis of TIMSS (see e.g., Valverde et al., 2002) indicate that school mathematical textbooks are the main basis for the lesson planning by teachers and have a powerful influence on what is learned and how it is learned (Ball & Cohen, 1996; Yang, Reys, & Wu, 2010). Textbooks more and more tend to form the actual classroom curriculum and guide teaching practices.
According to the National Curriculum, the Israeli students start getting familiar with three-dimensional geometric solids during second grade. The Curriculum specifies the topics to be learned, but suggests no leading principle as to how this is to be done. Hence, textbook authors are more or less free to implement their own didactic principles.
We discern two major possible approaches to teaching solids:
• Allocating a lesson to each solid, e.g. a lesson to the parallelepiped, another lesson to the cube. The comparison between them may be the topic of the concluding lesson.
• Handling together all the solids included in the curriculum, studying their common properties, and the properties special for some of them. This approach leads to classifications by various geometrical properties.
Our decision was to choose the second approach, i.e. non-formal classifications as the basis for our teaching solids. To make things clearer, we outline here the issue of classifications from the mathematical point of view prior to presenting the examples.
Formal classification of mathematical objects is based on rigorous definitions which reflect the hierarchy of mathematical objects by pure inclusion in a settheoretical sense. The primary school handbooks are not based on rigorous definitions; at this stage of learning formal definitions are, generally speaking, implausible.
Unlike formal classifications based on rigorous definitions, informal classifications are based on properties not necessarily defining purely inclusive sets, because they do not necessarily either imply or mutually exclude each other. Though informal classifications may not lead immediately to rigorous mathematical hierarchy, we find them important from the didactical point of view, at least at early stages of mathematics learning (PD), because they enable the concept images to be gradually (*MEC2*, *MEC4*) and mathematically consistently (*MEC1*) constructed starting from the initial stages of geometry learning.
The following examples from our textbooks clarify how the task design principles serve to enhance the geometrical insight of students. We intentionally chose an example from the second grade and an example from the sixth grade in order to demonstrate the self-consistency of our approach throughout primary school geometry teaching (*MEC2*).
Example 1: 2
nd
grade
The kit: This is the students' first encounter in their school studies with six solids included in the curriculum for the 2
nd
Grade: the cone, the cylinder, the ball, the square pyramid, the parallelepiped, the cube. A kit of these solids is attached to every Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
297
student's copy of the textbook. For the sake of the first encounter, all the revolution surfaces are of the same radius; the square bases of the polyhedra are congruent. The heights of all the solids are equal.
The story: A group of intruders (who are actually the six solids) has broken into the math classroom and left it in a great mess. Fortunately, the intruders have left traces: stains on walls and floor, signs of different forms, etc. The famous Mathy the Detective uses these signs to discover who the intruders were. To succeed, he also watches them at night because they keep breaking into the classroom night after night, so he sees their shadows in the night. This "story" is a rich basis for the variety of classifications by a number of features, among which are the following:
The sign left by a solid on a plane. By a sign we mean the result of a momentary contact of a solid with the plane, as if the solid were a stamp. Having experimented with the solid, the students discover that all of them can leave a sign in the form of a point, whereas the segment-like sign may be left by some of them (e.g., a cone) but not by others (e.g., a ball). Actually, the point is the only sign a ball may leave.
–
Fig.2a. "Signs" as a result of a contact Fig.2b. "Stains" as a result of " rolling"
Stains left by a shape on the plain, when one "rolls" the shape on the plane (without sliding). See Fig 2a, b for some examples of signs and stains.
The outline of the solid: which solids have "shadows" of similar form, and which do not? By shadows we actually mean the outline of orthogonal projections. For example, the pyramid and the cone may have the same isosceles triangle-shaped shadow, while the parallelepiped and the cylinder may have congruent rectangular shadows.
These and other similar classifications are used to identify the intruders. At the first step, the students must fill in under each shadow the names of all possible "candidates" among the solids (Figs. 3a, b). Later, they must use all their recently and previously acquired knowledge to recognize the solids. One of the main ways for the students to help the detective is to solve logical problems like: "Who is it who has a rectangular shadow and who has left a circular sign?", or "Can we recognize for sure the intruders whose shadows appear in the following two sets?" (Figs. 3a, b). In order to recognize the intruders by their shadows as they appear in Fig. 3a, the students have to reason more or less as follows: there are three circular shadows, hence in this setting the cylinder, the cone and the circle are certainly involved, though we cannot pinpoint any of them. Hence, the rectangular shadow must belong to the parallelepiped. As to the square shadows, they are of the cube and of the pyramid, but we can't know which is which. Thus, in the first setting one recognizes for certain the shadow of the parallelepiped. To compare, in Fig. 3b there are two triangular shadows; hence, these are of the cone and of the pyramid, but we cannot know which is which. The square shadow then belongs to the cube, and the circular shadows are of the ball and of the cylinder, though again we cannot know which is which. Hence, we have pinpointed the Theme C – M. Barabash & R. Guberman
298
cube. To be sure, the wording of second graders is different, but grosso modo this is the reasoning they must use, including the necessarily correct naming of plane figures and of solids, which by itself may be regarded as a success.
Fig.3a Fig.3b
Fig 3. Using shadows to identify potential solids
Linguistic and thinking skills needed for the solution of these problems are clearly aimed at the students' insight. We will refer later to the generalization possibilities of this task.
Example 2: 6
th
grade
According to the sixth grade curriculum, the solids are to be studied from several points of view: volume and surface computations; closer acquaintance with solids of revolution and with various types of polyhedra; unfolding solids into plane nets. In addition, we also include a number of assignments whose purpose is to form initial understandings related to the three-dimensional version of isoperimetric problems (*MEC2*). For some of these mathematical purposes (volume and surface computations and related issues, including the isoperimetric issues; nets folding and unfolding), it is worth regarding prisms as generalized cylinders, i.e. as surfaces formed by parallel sliding of a straight line along a plane directrix. A circular directrix leads to a circular cylinder, a polygonal directrix leads to a prism; other directrices may lead to

other generalized cylindrical surfaces. Similarly, pyramids are generalized cones: both surfaces are formed by a straight line whose one point is fixed and another is moving along a directrix (circular, polygonal or other) (MEC1). This clarifies the identical methods of the volume and surface computations for cones and pyramids, as well as for prisms and cylinders, and is actually an example of a "big mathematical idea" on which the whole series of textbooks is focused concerning 3-d measurements. Naturally, such grouping differs from the classification of solids of revolution vs. polyhedra which serves different purposes. Nets unfolding, in addition to the previous grouping, suggests yet another approach to classifying the solid surfaces: those who may be unfolded into a net and those who may not.

One of the widely used primary-school approaches to the volume computations of cones (and the one recommended by the Israeli school curriculum) is to fill a conic vessel with water or sand to show that three such vessels fill the cylindrical vessel of the same base and height. The same is to be done with a pyramid and a prism, when the volume of a pyramid is studied. This demonstration may be persuasive enough to show that the volume of the cone or of the pyramid is three times less than that of a cylinder or of a prism, but does not give even a hint as to why it is so. This is not compatible with our concept of insight as a result of meaningful learning. Ignoring the similarity of volume computation formulas for cones and pyramids and for cylinders and prisms seems to be an aggrieving omission of the possibility to teach a mathematically meaningful approach to the volume computations in a way that accounts for the future perspective of this topic. The approach which we undertook in our textbooks is actually based on an intuitive mathematical principle known as Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
299
Cavalieri's principle, which is an example of a big mathematical idea actually going back to Archimedes. It states: Given two solids of equal heights whose bases have equal areas, if the plane sections of these solids at any height have equal areas, then these solids are of equal volumes. We do not propose to explicitly formulate this principle in the class, but this understanding is our mathematical and epistemological source for the overall approach to volume computations in primary school. The grouping of cones with pyramids and cylinders with prisms serves the initial perception of the intuitive 3-d version of the isoperimetric problem, as well as the consistent understanding of how surfaces of similar structure may unfold into plane nets. One has obviously to discern the revolution solids from the polyhedra in order to study intrinsic properties of each type of solid, which renders a completely different grouping.
The following excerpt from the 6
th
grade volume-and-surface-computation
assignment includes also the intuitive minimal-surface-maximal-volume issue. It originates from designing a tent (MEC3). How do we design a tent (Fig. 4a)? We want a tent to be as light as possible (one has to carry it), to provide as much sleeping place as possible on its floor, and to hold as much air as possible (one expects to breathe while sleeping). What do we need to compute in order to fulfill each of these demands? Which tent will we prefer amongst the following three which are of the same height and of equal bases areas (Fig. 4b)?
Fig.4a How do we design a tent? Fig.4b Which tent will we prefer?
The problem thus posed is a situation leading to motivated computation-based decisions: when one needs to compute the basis area, when the surface area is relevant, and when the volume computation is the answer to the question (MEC4). Moreover, it is obvious from the context what the net unfolding is for and why it is essentially the same for all the tents. Here, all the tents are of a conic structure, whatever their base forms are. Alternatively, further in the book the pottery is brought as an example in the context of solids, thus distinguishing solids of revolution from polyhedra.
Since the textbooks have been published and approved by the Ministry of Education, about 2000 school teachers have been using them in their primary school geometry lessons. Interviews with the teachers imply that their students understand that the properties of solids may be presented in different ways through two- and threedimensional notions. The students are able to combine verbal and visual representations, the words they use being similar or identical to mathematical terms.
Here is an excerpt from the feedback of one of the teachers:
"… a student is expected to be familiar with solids already at the primary school. That is, he (or she) must understand them from a number of viewpoints, to be flexible with them.… Flexibility, I would say, means – to feel them, to be able to see them from various directions, to see what they enable us, to see their meanings, when it is convenient to use them… your approach, from all the books I've used, and I've used some textbooks, enables this flexibility for the students, gives them confidence and freedom to "play" with the solids…"
As a result of encouraging reactions of practicing teachers, we included our textbooks as the learning material in our geometry course for students who are being educated as future primary school mathematics teachers or kindergarten teachers.
Analysis of the examples of the tasks from the textbooks Theme C – M. Barabash & R. Guberman
300
We will use now the examples to illustrate how the previously formulated objectives serve to advance the students' insight by each of its parameters.
Implementation. The situation in which a second-grader must follow and apply the classification immediately after its presentation in the class by the teacher or by one of the classmates is an important opportunity to enhance his or her aptitude for implementation. Different behaviors may indicate different levels of insight. For example, examining the stains left by the "rolling" solids, a child may follow closely the "rolling" manner of the teacher, or may decide to roll a solid (e.g., a parallelepiped over its longest side), thus providing a stain in the form of a long and narrow rectangle instead of a shorter and wider one. Performing these activities, the student has to master his knowledge of plane figures acquired previously (during the 1
st
grade) and discern
various signs and stains left by the same solid (MEC2; CD).
Skills. The approach which we propose develops the aptitude of comparing and classifying solids by their properties and adequately using these properties for various purposes, which requires much more than mere recognition. We regard these skills as essentially more meaningful for geometry learning, and for mathematics learning in general (MEC). Examples of such skills are: an ability to discern a special vertex of a pyramid analogous to the vertex of a cone (which is indispensable for the volume computations); discerning specific parts of solids, including those not directly accessible, like the diameter of a sphere; folding and unfolding nets and recognizing the solids by their nets. These skills comprise the integral learning (CD).
Generalization. The approach based on analysis of properties common to a group of objects (such as signs and shadows in 2
nd
grade, common structure for cones
and pyramids vs. structure common to cones and balls in the example of the 6
th
grade)
has direct implication for generalization on this basis. We attempted to demonstrate that this approach is both mathematically (MEC) and didactically (PD) justified.
Language. We regard the mathematical language to be one of the central factors in the development of one's mathematical insight. The linguistic abilities of the student develop when he or she has to explore, formulate hypotheses, explain, motivate, and relate mathematical ideas, as in the activities described previously. These abilities comprise another component in a student's cognitive development (CD). The example of reasoning needed to recognize solids by their shadows speaks for itself, to our opinion, as far as all these aspects are concerned.
Discussion
We hope to have demonstrated that the mathematical and didactical features of our texts, based on the principal considerations formulated above (MEC, CD, PD), serve the on-going purpose of fostering the mathematical insight of young students with that insight as characterized by its four parameters. Moreover, they help to achieve specific objectives which comply with our general line as reflected in these considerations:
Advancing the young students 'half-way' to future formal definitions, ideas, notions and formulas in geometry; in particular, to the general understanding of volume and surface area computations and to intuitive perception of the interrelation between the form of a solid and its minimal-surface-maximal-volume properties (MEC1, MEC2).
Well-motivated outer-mathematical foundations for correct perception of central notions in geometry of solids which sometimes cause a great deal of ambiguity for students, such as surface area vs. volume (MEC1, MEC3, CD). Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
301
Flexibility in the students' perception of solids in ways corresponding to specific mathematical and not-necessarily mathematical contexts (CD), and more.
The Pedagogical-Didactical (PD) objective which is less referenced in the course of the presentation and discussion is obviously central to the series.

How Do Students Learn Mathematical Proof? A Comparison of Geometry Designs in German and Taiwanese Textbooks
Yu-Ping Chang
Technische Universität München
Fou-Lai Lin
National Taiwan Normal University
Kristina Reiss
Technische Universität München
The learning of mathematical proof varies significantly among topics, tasks, curricular materials, and teaching. In this research, we focus on comparing the content of mathematical proof provided by curricular materials, especially school textbooks, between Germany and Taiwan. We first discuss how mathematics textbooks are designed and then report on the differences of geometric content structure between them (focused on grades 7-9) for unveiling a further comparison of the design relative to two common statements, the Pythagorean theorem and the sum of interior angles of a triangle. We compared six different textbook series, three from each country, using three different principles, continuity, accessibility, and contextualization, to inspect the content of these two statements. The results reveal that German textbooks employ a more generic approach to lead pupils to a theoretical position in mathematical proof and offer tasks in divergent contexts whereas Taiwanese textbooks prefer a visual-algorithmic approach to guide pupils to the transition from the pragmatic to the theoretical position by providing physical experiments or algorithmic tasks in the same context.
Keywords: mathematical proof, geometry, design, textbook
Introduction
The design process and usage of curricular materials, e.g., textbooks, are similar in both Germany and Taiwan. However, students' performances on international assessments are discrepant. To study the differences, it might be worthwhile to look deeper into the intended design of mathematics instruction in addition to comparing teaching and learning in classrooms. The importance of textbooks in school cannot be ignored. Although there is an increasing number of comparison studies in mathematics textbooks, most focus on comparing the differences of semantic features or textual presentations; only some discuss the details of the design for specific topics (e.g., Charalambous, Delaney, Hsu, & Mesa, 2010; Stylianides, 2005, 2009; Thompson, Senk, & Johnson, 2012).
Balacheff (2010) indicated the importance of acquiring mathematical knowledge as a process and not only receiving it as a fact. Theme C – Yu-Ping Chang, Fou-Lai Lin & K. Reiss
304
…mathematical ideas do not exist as plain facts but as statements which are accepted only once they have been proved explicitly; before that, they cannot be instrumental either within mathematics or for any application (p. 9).
As Balacheff (2010) said, getting involved in mathematics means for pupils (learners) to change their intellectual position and to become a theoretician. He provided two different types of shift, say from practical geometry (the geometry of drawings and shapes) to theoretical geometry (the deductive or axiomatic geometry) and from symbolic arithmetic (computation of quantities using letters) to algebra.
Mathematical proof is viewed commonly as a core activity in mathematics (Heinze & Reiss, 2007). The basic features of the curriculum, being content, organization, and sequencing, have an impact on pupils' conception of proof (Chazan, 1993; Healy & Hoyles, 2000; Hoyles, 1997; Stylianides, 2007), and the activities of problem solving might provide an easy way for pupils to experience the process of proof (Balacheff, 1988; Pólya, 1981; Schoenfeld, 1992). Tall, Yevdokimov, Koichu, Whiteley,

Kondratieva, and Cheng (2012) collected eight distinct methods of English, German and Taiwanese pupils' proof of the statement that the sum of the interior angles of a triangle is 180°. However, the question remains how the curricular sequences in the three countries differ from each other. Though there are various methods to prove this statement, e.g., empirical argumentation (Lin, 2000), or heuristic worked example (Reiss & Renkl, 2002), it does not mean that all pupils receive the same opportunity to do proof. As we said above, mathematical knowledge (ideas) influences students' learning; once they ascertain the validity of mathematical knowledge (prerequisites) they can apply it to a new statement. In addition, the alignment between designed tasks and how teachers select and use them influences the learners' engagement (Watson & Chick, 2011). Therefore, inspecting the designed tasks is important.
We will argue in the remainder of the paper that the different sequences of acquiring knowledge influence the design of tasks and have an implicit impact on students' opportunities to learn mathematics. We initiate an analysis on comparing the designs of geometry content in different textbooks between Germany and Taiwan and discuss the details of textual presentations as a precursor.
A snapshot of mathematics curricula in Germany and Taiwan
The school system (before collegiate education) in the Federal Republic of Germany differs according to each federal state. However, in general there are three different tracks in secondary school with differently designed curricula: Gymnasium (grades 5-12), Realschule (grades 5-10), and Hauptschule/Mittelschule (grades 5-9). For example, geometry proofs are primarily taught in the Gymnasium track. In contrast to Germany, mathematical proof is supposed to be introduced to all pupils in the unitary school track, junior high school (grades 7-9), in Taiwan.
Role of textbook and design process
Regarding the educational ideas and actual materials used in classrooms, it is necessary to allocate and define the position of related elements of them. In Figure 1, we present three layers with their respective trajectory of involved elements from ideal situation to reality. The dashed lines link the implicit relationships between three layers. The middle layer of three different roles of curriculum is the bridge between ideas and actual materials. Textbooks in German or Taiwanese schools can be viewed as intended curriculum or implemented curriculum depending on how teachers use them in classrooms. They are designed based on national standards and teachers use Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
305
them as a tool to write their own lesson plans or directly include them in their teaching.
The processes of designing mathematics textbooks are similar in Germany and Taiwan. The contents of textbooks are designed by a group which might encompass researchers, mathematicians, mathematics educators, and school teachers, and finally edited by the responsible editor(s). All written textbooks should be designed based on the national standards (and state syllabus in Germany) and approved by the ministry of education, and then can be published. Each individual textbook is designed based on the textbook editors' stated intentions.

Distribution and structures of geometric contents
Geometry content is not in the same sequence in German and Taiwanese textbooks. In Germany, most geometry content is arranged in 7
th
grade, and part in 8
th
and 9
th
grades. In Taiwan, geometry is not taught in 7
th
grade or the second semester of 9
th
grade, but takes a large amount of classroom work in the second semester of 8
th
grade and the first semester of 9
th
grade. A comparison of both countries in different topics is shown in Table 1.

Method
Textbooks are the main materials we used in this study. They are developed and designed with different editors' intents. Therefore, the presentations vary between different textbook series. Nevertheless, they are based on conjoint curricular goals across different settings for instruction. To examine different textbooks from different countries, it is necessary to set principles for comparing them in the same phase, specifically whether they are grounded on the same conceptual knowledge, learning opportunities, and context. Below, we list the materials used in this study and give our exposition of the principles we implemented for the comparison.
Analytical materials
We selected six representative textbook series used in school years 2009-2010, three from the state of Bavaria in Germany and three from Taiwan. In this study, we focus on grades 7, 8, and 9 of the Gymnasium track in Germany and of junior high school in Taiwan. We chose two common statements: the sum of interior angles of a triangle, which is introduced in grade 7 in Germany and the second semester of grade 8 in Taiwan; and the Pythagorean theorem, which is introduced in grade 9 in Germany and in the first semester of grade 8 in Taiwan. The texts from the textbooks can be generally separated into three parts: the corpus texts, which provide various activities and tasks to introduce mathematical knowledge; the summary part, which summarizes the point of one section or one chapter; and the exercises pool, which provides numerous exercises for pupils to practice. We focus only on the corpus texts introducing both statements, and exclude the summary and final exercises pool in order to avoid repetition (summary) and subjective selection without considering the continuity of former mathematical ideas (exercises).
Three principles of content comparison
We set three principles in inspecting the task design to be able to discuss the similarity and dissimilarity of German and Taiwanese tasks on the same scale. Principle one examines the continuity of the mathematical knowledge (ideas) involved, the flow of concepts. This principle contemplates the Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
307
related concepts of a peculiar task from dissimilar societies. Principle two scrutinizes the accessibility, which means the learning opportunities provided by the designed tasks. It addresses whether the presentation allows the students access in a reachable way; in other words, it addresses clarity of the final resultant (goal) and the transparency of figural or textual representations. Principle three reviews the contextualization of tasks. The contextualization refers to the sociocultural perspective, which is regarded as stable physical and discursive elements of a setting in which a learning activity takes place. It refers also to the constructivist perspective, meaning that the personal, cognitive context shaped by the learner's personal interpretations of an activity is taken into account (Nilsson & Ryve, 2010).
Results
Two different approaches to the common statements
The geometric content of German and Taiwanese textbooks varies in topics and content structures as mentioned above. In this part, we show the common statements which relate to different mathematical concepts and are designed in different trajectories in both countries. In general, German textbooks design a new statement validly following the origin/hierarchy of related concepts. We call this a generic approach. In our view, the generic approach can be linked to the idea of Balacheff's (1988) generic example, "involving making explicit the reasons for the truth of an assertion by means of operation or transformation on an object that is not there in its own right, but as a characteristic representative of its class" (p. 219). In Taiwan, the visual-algorithmic approach relies highly on the figures and algorithm and is commonly used for geometry content.
Though some German textbooks simultaneously introduce the same content with a visual-algorithmic approach, it is not the mainstream of knowledge arrangement but an alternative method for teachers/pupils to teach/learn mathematics (and reflects probably the influence of the present international discussion). In this study, we compare only the main approach, the intersection of practice, among textbook series in one country. Below, we present the designs regarding both statements between German and Taiwanese textbooks.
Approaches to the Pythagorean theorem and the design
In both countries, instruction of the Pythagorean theorem should lead to the algebraic formula,

, where , and are three sides of any right-angled triangle, and then the application of this formula in different types of problems. The relationship between the areas of three similar figures, usually squares as Euclid's Elements presents, generated from three sides of a right-angled triangle, is an important method to prove the theorem.
However, the methods of proving the Pythagorean theorem differ in German and Taiwanese textbooks (see Tables 3 and 4). The German curriculum arranges the Pythagorean theorem as part of a series of theorems including hypotenuse-leg theorem (Kathetensatz) and leg-leg theorem (Höhensatz). These are highly connected to the conditions of similarity of triangles, therefore learning the Pythagorean theorem presupposes the topic of similarity. The Taiwanese curriculum arranges this statement after learning the expansion of perfect squares:

and

, with various permutations of geometrical figures. In the Taiwanese design, the visual figures and the algorithm coexist to influence the reasoning. Concerning the conceptual continuity, the routes to this statement are obviously different in both countries.

Approaches to the sum of interior angles of a triangle and the design
The topic connecting angles and geometric shapes is first introduced in 5
th
grade in both German and Taiwanese schools. Textbooks in both countries provide a
physical experiment for students to experience the quantity of angles by measuring
them with a protractor. The difference is that only the Taiwanese curriculum gives the
sum of interior angles of a triangle, 180˚, in the textbook in this school year. Then the
formal reasoning on this topic is set in 7
th
grade in Germany after the statement of
parallel postulates and in second semester of 8
th
grade in Taiwan.
In Tables 5 and 6, we show the related concepts introducing and applying
this statement, and the arrangements of the design. In German textbooks, it is
connected to the formerly learned concept that alternate interior angles of a pair of
parallel lines with a transversal being equal (parallel postulates) and the concept of
straight line (angle). In Taiwanese textbooks, it is not the main work to prove the truth
of this statement (the sum of interior angles of a triangle equals 180˚) but to apply this
"authorized" knowledge in different situations. The introduction of this statement is

One point that needs to be mentioned is that the German design ends with the
generalization

of this statement to the sum of interior angles of other polygons by
the construction of auxiliary line(s). The follow-up of the Taiwanese design continues
to apply the three straight angles and this statement:
180˚ 3 180˚ 360˚, to
introduce the sum of exterior angles of a triangle by calculation, and then to
generalize to all polygons by doing algebraic proof, that is,
180˚ + ,180˚

+ 2- 360˚.
Discussion
There are many factors which influence the design of curricular materials in
different countries, such as design intentions for curriculum, content structures,
educational goals, policy issues, etc. In this study, we restricted ourselves to a single
aspect, the presentation of geometry content in textbooks. It turned out that the
approaches to introducing mathematical proof through geometry content significantly
differed in Germany and Taiwan. This was especially true for the details of the
exemplifications of textbooks above. By examining the designed tasks for the same

The Taiwanese design also presents the similar generalization as the German design does. Theme C – Yu-Ping Chang, Fou-Lai Lin & K. Reiss
310
statements, the Pythagorean theorem and the sum of interior angles of a triangle, we
could identify important differences.
We found that the opportunities to learn mathematical proof differ from
Germany to Taiwan. In Germany, deductive reasoning with hierarchical concepts in
geometry seemed to be pivotal in receiving new mathematical knowledge. In addition,
the German textbooks validated two statements by deductively reasoning with generic
mathematical ideas (theoretical position) and provided various operational tasks, like
construction or physical experiments (pragmatic position). These operational tasks in
German textbooks expected students to experience the concrete knowledge. Yet, this
design of tasks was not always consistent with the central mathematical ideas
(divergent contexts). In Taiwan, authorized knowledge accompanying various
applications dominated the learning... The Taiwanese textbooks used a physical
experiment or reasoning with algorithms accompanied by figures to access both
statements, and then arranged various tasks to apply them by using the algorithm in
different situations. The truth of the statements was only shown with some empirical
examples to "prove" (argue) the conjecture and it seemed the pupils would accept
them. Though the differentiation between a pragmatic position and a theoretical
position in mathematical proof was not clear in either statement, the consistency
between concepts and activities was strong (stable context). Moreover, the application
of algebraic proof, which followed these two statements (authorized knowledge), was
emphasized more in Taiwanese textbooks. In summary, these differences might
correspond to the research which indicates that German students lack strategies in
proving while Taiwanese students lack principles to explain why a property is true
(e.g. Heinze, 2004; Lin et al., 2003; Reiss et al., 2002).
We do not intend to over-generalize our judgement to the quality of tasks.
The usage of tasks might differ with teachers' intentions in using them in class, and
hence differ from teacher to teacher. Moreover, this work should not be seen as a
general cross-cultural comparison, but it provides some evidence for different
teaching styles. We provided an overview of how the same statement can be
introduced in different arrangements and in different cultures; we see this as a first
step for a more profound and more general comparison of textbooks.
This paper is based on part of the first author's doctoral dissertation work
supervised by the other two authors.

Problem solving task design is not only the design of a nonroutine problem to be solved by students. We conjecture that, in addition, task design also requires a supporting document that would act as a cognitive scaffold for students in the initial stages of the problem solving process before they can internalize the metacognitive strategies and automate the use of these strategies when faced with a new problem. In this paper we describe the design and use of such a document, which we have called practical worksheet, within our ongoing problem solving research project.
Keywords: problem solving, cognitive scaffold, practical worksheet
A fundamental aspect of doing mathematics is to solve mathematics problems. Mathematical problems are inherent in the structure of the subject itself and are the raw materials for problem solving, which is a highly valued process in mathematics education. There is now a mounting body of literature pointing to the fact that problem solving is still not implemented in mathematics classrooms, or if implemented, then certain routine approaches to heuristics are being adopted (see English, Lesh, & Fennewald, 2008; Lesh & Zawojeski, 2007; Schoenfeld, 2007; Silver, Ghousseini, Gosen, Charalambous, & Strawhun, 2005). Stacey (2005) has suggested that:
To get closer to the goal requires research directed to understanding the problem solving process for mathematics (in all its aspects), developing effective classroom processes, and designing excellent tasks. Moreover, the research needs to be closely intertwined with curriculum development and teacher development projects so that it can make an impact on practice. (p. 341) Theme C – J. Dindyal et al.
314
Our research team has identified several issues in the literature in the international context as well as those in the Singapore local context that need to be addressed to facilitate the implementation of problem solving in schools. Our approach still values the problem solving model of Pólya (1945) and the insights from Schoenfeld (1985). To aid in the implementation of problem solving in schools, we have come to the realization that the design of specific problems or problem solving tasks cannot be the only focus of problem solving; rather, cognitive scaffolds (see Holton & Clarke, 2007) that allow students to solve a wider range of problems should also be an important focus. Accordingly, in this paper, we turn our attention to the design of the practical worksheet that can be used as a cognitive scaffold in problem solving tasks (see Figure 1). We document the development of the practical worksheet based on our design principles and feedback from teachers.
The Problem Solving Task Design Principles
Based on the literature, our research team drafted the following design principles for the problem solving tasks:
1. Each task is challenging, focused around important mathematical concepts, and interesting to the students.
2. Each task would offer the students an opportunity to extend and/or generalize.
3. The task, although fundamental to the design, is only the means to the loftier goal of transfer of problem solving skills to other situations.
4. A task is most meaningful to a student when presented as an assessment task for which the student earns some credit.
5. The process of solving the problem is as important, if not more important, than the final solution of the problem. As such, assessment of problem solving should consider carefully the problem solving process. The students should see that they earn enough credit for specific steps and/or intermediate strategies that they use.
6. Pólya's problem solving model and Schoenfeld's ideas about problem solving guide the development of the problem solving tasks.
Scrutinising the above principles, we came to the conclusion that, no matter how well problems (as tasks for students) themselves are designed, they can at best address the first two design principles. Good selection of problems alone would have little effect in fulfilling Design Principles 3-6, which are about the need for students to attend to the process of problem solving and the motivation for problem solving. As such, in considering task design for problem solving, we need to include elements of design that attend directly to Design Principles 3-6. To address these, we conjectured that the task for students should include a supporting document that would act as a cognitive scaffold for the students in the initial stages of the problem solving process before they could internalize the metacognitive strategies and automatically use these strategies when faced with a new problem. This is in line with the view that any scaffold should be gradually withdrawn as the learner becomes more competent (Rittle-Johnson & Koedinger, 2005; Yelland & Masters, 2007). We have followed Holton and Clarke's (2007) ideas: Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
315
...cognitive scaffolding allows learners to reach places that they would otherwise be unable to reach. With the right word or question or other device a teacher may put in place the scaffolding that will allow new knowledge to be constructed, incomplete or wrong concepts to be challenged or corrected, or forgotten knowledge to be recalled. (p. 129)
Thus, our team's effort was directed towards the development of this important document that we have since called the practical worksheet. The practical worksheet is developed along the same lines as a worksheet that science students would generally use in a science class to help them carry out experiments, record observations, and make inferences. We have also incorporated ideas from Yelland and Masters (2007), who have also used the term cognitive scaffolding in the context of technology use.
We have used the term cognitive scaffolding to denote those activities which pertain to the development of conceptual and procedural understandings which involve either techniques or devices to assist the learner. These include the use of questions, modelling, assisting with making plans, drawing diagrams and encouraging the children to collaborate with their partner. (p. 367)
The way a task is imagined and intended by the teacher may be quite different from the way it is construed and carried out by the students (see Mason & Johnston-Wilder, 2006). The intended learning by students may not happen if the tasks are misconstrued by them. Also, if teachers give too many directions, then the solution process may become too trivial for the students and the solution process may be reduced to a sequence of steps. If the teachers give too few directions, then the students may focus on different things and the implied learning may not happen. As such, the implementation of problem solving in the classroom ultimately hinges on the classroom teacher; in our designing process, we paid careful attention to teacher preparation for problem solving, including the use of the practical worksheet.
Teachers were taught three levels of scaffolding 0 Pólya stages, specific heuristics, and problem specific hints 2 to be used when advising students who are doing problem solving (Toh, Quek, Leong, Dindyal, & Tay, 2011). The levels are hierarchical and the next level of scaffolding should be given only after an earlier level has failed. Consider the Lockers Problem given below.
The Lockers Problem
A new school has exactly 343 lockers numbered 1 to 343, and exactly 343 students. On the first day of school, the students meet outside the building and agree on the following plan. The first student will enter the school and open all the lockers. The second student will then enter the school and close every locker with an even number. The third student will then 'reverse' every third locker; i.e. if the locker is closed, he will open it, and if the locker is open, he will close it. The fourth student will reverse every fourth locker, and so on until all 343 students in turn have entered the building and reversed the relevant lockers. Which lockers will finally remain open?
In the crucial level, which we call Level 0, we emphasise the student learning and reinforcing of the Pólya model (see Table 1). We may ask the student if he or she knows what Pólya stage he is in, and what would one normally do in such a stage. We help by asking these Control questions. In Level 1, we suggest specific heuristics to get the work moving. Level 2 is to be avoided as much as possible and is included only for the important aspect of ensuring that the self-esteem of the student is not Theme C – J. Dindyal et al.
316
seriously damaged by his or her perceived failure and helplessness on the problem. Here, we give problem specific hints, which essentially is a throwback to the 'usual' help afforded by mathematics teachers.

Level	Feature	Examples based on the Lockers Problem
0	Emphasis on Pólya stages and control	What Pólya stage are you in now? Do you understand the problem? What exactly are you doing? Why are you doing that?
1	Specific heuristics	Why don't you try with fewer lockers (use smaller numbers)? Try looking for a pattern.
2	Problem specific hints	Think in terms of the locker rather than the student – which student numbers get to touch the locker?

Table 1. Level of scaffolding
The objective of the practical worksheet is for students to internalize Level 0, and ask for Level 1, and to a much lesser extent Level 2, hints only when pressed for time. Assessment of problem solving is certainly another issue that guides students in problem solving tasks. To this end, an accompanying assessment rubric was developed to focus students on what is valued in the problem solving process. At the same time, the rubric gives them feedback on their strengths and weaknesses.
The Practical Worksheet
Holton and Clarke (2007) have claimed that scaffolding is an act of teaching that supports the immediate construction of knowledge by the learner and as well provides the basis for the future independent learning of the individual. These authors have added that scaffolding does not necessarily require the teacher and the student to be actually physically present together. Furthermore, it is essential for an individual student to be able to scaffold for himself or herself when solving a new problem, termed self-scaffolding by Holton and Clarke (2007). Accordingly, our aim was to find a way of developing the learner's autonomy in taking charge of his or her own learning when faced with an unfamiliar mathematical problem, whether the teacher was present or not. The artifact that we have developed is called the practical worksheet. We relate the evolution of this artifact from 2005 to the present, to scaffold mathematical problem solving behavior within the story of our efforts to teach mathematical problem solving in the schools.
The Development of the Practical Worksheet
In 2005, we developed a problem solving module within the mathematics curriculum of a high ability school in Singapore (see Appendix B). This initial design consisted of a 1.5 hour lecture on problem solving covering Pólya's problem solving model (Pólya, 1945) and Schoenfeld's framework (Schoenfeld, 1985). We had a second attempt in the same school in 2006. In 2009, the research team was invited by another high ability school to develop a module on problem solving. We adopted a design experiment approach (Brown, 1992; Collins, 1999; Gorard, 2004; Wood & Berry, 2003) to produce a workable "design" (an initiative, artefact or intervention, for instance) that could be adapted to other schools. In Gorard's (2004) words, "The emphasis [in design experiments], therefore, is on a general solution that can be 'transported' to any working environment where others might determine the final product within their particular context" (p. 101). We have argued the following theoretical justification for a design experiment for our research on problem solving (Quek, Dindyal, Toh, Leong, &Tay, 2011): Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
317
1. Obstacle - Current instruction on problem solving consists mostly of the teaching of heuristics only.
2. The theoretical basis of Pólya and Schoenfeld remain sound.
3. Mathematical problem solving must include the Looking Back stage of Pólya's model.
4. Mathematics problem solving is valuable enough to be adequately assessed and must be adequately assessed to be valued.
5. Mathematics problem solving is for every student of mathematics.
We then worked on the curriculum package by referencing the classical view of design where the parameters of the product are to be specified a priori (Ullman, 1992). We thus stated the following parameters, underpinned by the earlier theoretical justification, for the design of a package for teaching problem solving:
1. Place in the curriculum: The problem-solving module must be part of the mainstream mathematics curriculum.
2. Model of mathematical problem solving:
i. Pólya's model – all four stages
ii. Schoenfeld's framework – teach Heuristics and emphasise Control
3. Teacher autonomy: Teachers in school will ultimately teach the module themselves. Build teachers' capacity in problem solving and to teach it.
4. Infusion into regular mathematics content: Problem solving skills and habits learnt in the module must be infused into other mathematics modules to prevent

atrophy.
5. Assessment: A valued component in school assessment
The following features were then built into the first prototype of the package
to satisfy the demands of the stated parameters. From our experience with the first
school, we realised that we must first look for a way out of the perennial quandary of
the undervaluation of assessment of problem solving. As before, our package
promoted mathematical problem solving as learning the processes of mathematics akin
to the established science practice as a way to learn science processes. We designed a
mathematics practical worksheet (Figure 1 shows a typical response by a student on a
test which used the practical worksheet) and added a rubric for assessment (further
details are available in the next section). Parameters 1 and 5 were addressed. A series
of lessons to teach students how to use Pólya's model as a scaffold, to teach various
heuristics and choice of heuristics, and to make students aware of the need for control
in problem solving was developed. Parameter 2 was addressed.
To us, it appeared necessary that the teachers make the proposed
instructional approach a routine sufficiently familiar to them so that the approach
becomes classroom practice. To reach this stage, it seemed essential for the teachers
to adapt the researchers' ideas to make them their own, in the sense that their beliefs
of mathematics and of problem solving in mathematics are transformed. Such a
process would pass through a stage where the teachers negotiate and change the
problem solving lesson. Finally, a community of practice would develop among the
teachers to support the change process by providing opportunities to learn to engage
the proposed ways - thinking, talking and reflecting on the new teaching experiences
and ways of doing mathematics (Shulman & Shulman, 2004). The entire process of
transforming an externally proposed instructional approach and curricular change into
classroom and school practice appeared to be cyclical, incremental, and emergent in
nature. This was our approach to Parameter 3.
To address Parameter 4, problems that were from the regular mathematics
curriculum and were rich enough for extended work would be crafted and infused into Theme C – J. Dindyal et al.
318
the regular schedule. The justification was the reference to science practicals going in
tandem with science theory lessons, and the motivation was that these difficult
problems could be used as assessment for learning.
Assessment Using the Scoring Rubric
Traditionally, the assessment of problem solving in the classroom has
focused on assessing the products rather than the processes of problem solving. Our
efforts to meet the challenge of teaching mathematical problem solving to
students call for a curriculum that emphasizes the processes (while not
neglecting the products) of problem solving. The assessment strategy must match
it so as to drive the mode of teaching and learning of mathematics.
It is common knowledge that most students study mainly those curricular
components which are to be assessed. Accordingly, there needs to be a corresponding
assessment strategy that drives the teaching and learning of problem solving as
described in the preceding paragraphs. Effective assessment practice begins with and
enacts a vision of the kinds of learning we most value for students and strives to help
them achieve. To assess the students' problem-solving processes (which we value),
we developed a scoring rubric based on Pólya's model and Schoenfeld's framework.
The scoring rubric focuses on the problem-solving processes highlighted in
the practical worksheet. There are four main components to the rubric, each of which
would draw the students' (and teachers') attention to the crucial aspects of an attempt
to solve a mathematical problem. In establishing the criteria for each of these
components of problem solving, we ask the question: What must students do or show
to suggest that (a) they have used Pólya's approach to solve the given mathematics
problems, (b) they have made use of heuristics, (c) they have exhibited "control" over
the problem-solving process, and (d) they have checked the solution and extended the
problem solved (learnt from it)?
The rubric is outlined below. The complete rubric is in Appendix A.
• Pólya's Stages [0-10 marks]. This criterion looks for evidence of the use of
cycles of Pólya's stages (Understand the Problem, Devise a Plan, Carry out
the Plan), and correct solutions.
• Heuristics [0-4 marks]. This criterion looks for evidence of the application of
heuristics to understand the problem, and to devise/carry out plans.
• Checking and Extending [0-6 marks]. This criterion is further divided into
three sub-criteria:
Evidence of checking of correctness of solution [1 mark];
Providing for alternative solutions [2 marks];
Extending and generalizing the problem [3 marks]. Full marks for this part
is awarded for one who is able to provide (a) two or more problems with
solutions or suggestions to solution, or (b) one significant related problem
with comments on its solvability.
The rubric was designed to encourage students to go through Pólya stages
when they are faced with a problem, and to use heuristics to explore the problem and
devise a plan. They would return to one of the first three stages (see practical
worksheet) upon failure to realize a plan of solution. Students who show control
(Schoenfeld's framework) over the problem-solving process gain marks. For example,
a student who did not manage to obtain a completely correct solution would be able to
score up to eight and three marks each for Pólya's Stages and for Heuristics, making Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
319
a total of eleven, if they show evidence of cycling through the stages, use of
heuristics, and exercise of control.
The rubric allows the students to score as much as 70% of the total 20 marks
for a correct solution. However, this falls short of obtaining the top marks for the
problem. The rest would come from the marks in Checking and Extending. Our
intention is to push students to check and extend the problem (Stage 4 of Pólya's
stages), an area of instruction in problem solving that has not been largely successful
so far (see for example, Silver, Ghousseini, Gosen, Charalambous, & Strawhun,
2005). Theme C – J. Dindyal et al.
320
Figure 1. Student's solution using the practical worksheet Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
321
Conclusion
The practical worksheet holds promise for teachers who want to elevate
problem solving to a prominent position in the mathematics classroom. They can
now not only encourage problem solving in their classes, but they can also make
transparent to students the criteria for assessment and the processes that are valued.
Taken altogether, our task design, which includes the practical worksheet, assessment
rubric, a set of problem solving lessons, and teacher scaffolding, has shown great
potential in developing student self-scaffolding in problem solving.

RUBRIC FOR ASSESSING PROBLEM SOLVING
Name: _____
Pólya's Stages
Descriptors/Criteria (evidence suggested/indicated on practical
sheet or observed by teacher)
Marks Awarded
Correct Solution
Level 3 Evidence of complete use of Pólya's stages – UP + DP + CP;
and when necessary, appropriate loops. [10 marks]
Level 2 Evidence of trying to understand the problem and having a clear
plan – UP + DP + CP. [9 marks]
Level 1 No evidence of attempt to use Pólya's stages. [8 marks]
Partially Correct Solution (solve significant part of the problem or lacking rigour)
Level 3 Evidence of complete use of Pólya's stages – UP + DP + CP;
and when necessary, appropriate loops. [8 marks]
Level 2 Evidence of trying to understand the problem and having a clear
plan – UP + DP + CP. [7 marks]
Level 1 No evidence of attempt to use Pólya's stages. [6 marks]
Incorrect Solution
Level 3 Evidence of complete use of Pólya's stages – UP + DP + CP;
and when necessary, appropriate loops. [6 marks]
Level 2 Evidence of trying to understand the problem and having a clear
plan – UP + DP + CP. [5 marks]
Level 1 No evidence of attempt to use Pólya's stages. [0 marks]
Heuristics
Descriptors/Criteria (evidence suggested/indicated on practical
sheet or observed by teacher)
Marks Awarded
Correct Solution
Level 2 Evidence of appropriate use of heuristics. [4 marks]
Level 1 No evidence of heuristics used. [3 marks]
Partially Correct Solution (solve significant part of the problem or lacking rigour)
Level 2 Evidence of appropriate use of heuristics. [3 marks]
Level 1 No evidence of heuristics used. [2 marks]
Incorrect Solution
Level 2 Evidence of appropriate use of heuristics. [2 marks]
Level 1 No evidence of heuristics used. [0 marks]

Table 1: Development of the Practical Worksheet
Year Research Emphasis Objective Notes/Issues
2005 Development of a problem solving module in school XX (a 1.5-hour lecture followed by eight 1-hour lessons) To help students to: understand a problem before rushing in to solve it; devise a plan to attack the problem; use heuristics to understand the problem and as a plan of attack; check a solution attempt; pose new problems with reference to a successful solution of the original problem Moderate success. Students were reluctant to apply the stages of the Pólya's model. Even higher achieving students did not check and extend the problem
2006 Second attempt in same school. An approach to treat the mathematics lesson as a 'mathematics practical' lesson. Development of a worksheet (first version of the practical worksheet) Accommodate the different problem solving strategies of students. Not to force all students to go through each of the four Pólya's stages Some issues still persisted. Some students were unfamiliar with the problem solving heuristics. Some students could not quite differentiate among some of the Pólya's stages.
2007 Teachers in the same school were left on their own to implement the problem solving module. Teachers to develop autonomy and work independently of the researchers. Develop such a problem solving module sustainable in a mainstream school. Some students were still not filling the worksheet as desired. The lead teacher decided to put tick boxes for the students to tick rather than write out certain parts.
2009 In another school for more able students Adopt a design experiment approach in the research and produce a workable design not only of the problem solving module but as well of the practical worksheet. Have a greater focus on teacher development for use of the worksheet in their lessons. There was better success in this school. A scoring rubric focusing on the processes of problem solving had to be developed to be used in tandem with the worksheet.
2010–2012 Dissemination of the problem solving module to more schools Adapt the problem solving module using the practical worksheet for implementation in a wider range of schools. Positive feedback so far on the use of the practical worksheet Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

Textbooks' Design and Digital Resources
Ghislaine Gueudet
CREAD, IUFM, University of Brest
Birgit Pepin
Høgskolen i Sør-Trøndelag, Norway
Luc Trouche
Institut Français de l'Education, ENS de Lyon
In this paper we report on the comparison of the design and conceptualization of two very different French lower secondary mathematics textbooks: one which was developed, as it is 'traditionally' done, by 'experts' (teacher educators and researchers); and one which was developed, innovatively, by teachers using a digital platform. These different designs and conceptualizations had repercussions on the content, structure, potential and intended use of the books, which we investigated using specially designed questionnaires given to the two groups of textbook authors. Our results point to re-conceptualisations of the notions of 'quality' and 'coherence' of resources, such as textbooks, taking into consideration teachers' documentation work, in particular their often collective work with digital resources.
Keywords: digital teaching resources, mathematics teaching resources, quality process, textbooks authors' intentions; teacher communities; textbooks' design; teachers' documentation work; textbook use
Introduction: digital means and evolutions of the textbooks' design
As stated in the ICMI study 22 discussion document, "most teachers use textbooks and/or online packages of materials as their total or main source of tasks." Moreover, the textbook content and structure influence teachers' choices (Haggarty & Pepin, 2002; Pepin, 2009), for example, in terms of their choice of tasks or sequencing of the topic area; both content and structure depend on the textbook's design. We investigate textbook design and its developments brought about by digital means. Textbooks are now often complemented by digital materials: files to be projected during the lesson by the teacher; animated figures and exercises using different software and providing feedback to students, available on a CD or on a website. We focus on the following question:
"How can or should new digital formats influence textbook design: e.g. use of podcasts, twitter, and other social media; implications for design and coherence of materials (either original digital design or transfer from print) if teachers are able to select tasks in varied orders?" (ICMI study 22, discussion document, p.19).
We consider that this question is a complex one. It encompasses indeed several aspects of the evolutions resulting from digital means, in particular the Theme C – G. Gueudet, B. Pepin & L. Trouche
326
following: digital means provide new opportunities for the structuring of textbooks for their use by teachers. They also open up new possibilities for design and further evolution. In previous works, we provided evidence that digital means foster collective teacher work (Gueudet & Trouche, 2012): teachers discuss by e-mail; or online teacher associations create resources to be shared by all, not only members. Like many other kinds of teaching resources, now the textbook can also be designed by groups of teachers: "bottom-up" designs (in contrast to a traditional "top-down" design) are now developing, in particular in countries where national policies allow it. This constitutes a major evolution, which we retain as a central focus of our study.
Considering these developments, what does the concept of "coherence of a textbook" mean? The discussion document mentions (p. 17), "conceptual coherence." This can be understood as the correctness of the mathematical content; an alignment or 'consistency' with the official curriculum; a sequencing of the notions and properties introduced to avoid gaps in the mathematical progression; a correct articulation between the text of the course and the associated exercises and problems, or an emphasis of 'abstraction' as an 'umbrella concept' for the coherence of the textbook. In the case of a collective design, coherence can also mean that the individual mathematical intentions of the individual authors, their epistemological stances, are well coordinated; and that the whole textbook corresponds to the same "mode of address" (defined as the positioning of the user induced by the material (Remillard, 2012)). Moreover, in terms of implications for learning, the most important issue linked to coherence is certainly the 'coherence' of what the teacher produces when drawing on the textbook. Similar to Shield and Dole (to appear), we consider that analysing textbooks can only inform about their potential to assist in teaching and learning, because teachers interact with textbooks in various ways. Investigating the potential of a resource leads to an exploration of the concept of quality. We consider that the intrinsic quality of a resource has to be distinguished from its adequacy with respect to institutional and users' expectations (Trouche, Drijvers, Gueudet, & Sacristan, 2013). The intrinsic quality encompasses mathematical, didactical, and ergonomic (ease of use) aspects. It also depends on the mathematical topic considered. For example, Trgalová, Soury-Lavergne, & Jahn (2011) assessed the quality of dynamic geometry resources, and they differentiated between nine dimensions of quality: mathematical content; technical aspects; instrumental aspects; added-value of dynamic geometry; didactical implementations; pedagogical implementations; the potential of the resource integration into a teaching process/sequence; ergonomic aspects (e.g., presentation and adaptability); and metadata (e.g., accuracy facilitating searchability).
Traditional textbook analysis (e.g., in TIMSS (Valverde et al., 2002)) proposes three aspects: content (e.g., number, measurement, geometry); performance expectation (knowing, using routine procedures, problem solving, mathematical reasoning, and communicating); and perspective (attitudes, careers, participation, interest, and habits of mind). Most textbook analyses focus on tasks (e.g., exercises and working tasks), and many studies have analysed problem-types (Zhu & Fan, 2006), problem solving procedures (Fan & Zhu, 2007), procedural complexity (Vincent & Stacey, 2008), cognitive demand (Jones & Tarr, 2007) or concept treatment (Cai, Lo, & Watanabe, 2002).
However, how textbooks deal with depth of understanding, for example in terms of mathematical abstraction, is largely left untouched. Without going into deep philosophical discussions, textbooks are without doubt didactical materials, and as such can be seen as providing 'tools and products of abstraction' (e.g., in their tasks, Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
327
representations, contexts). Textbooks use different registers of representation (Duval, 2006), e.g. usual language symbols; figures; representations of technological tools. This variety, and the need for conversion between different representations, can be associated with 'depth of understanding'. Another way of analysing depth of understanding might be by conceptualising 'understanding mathematics' in terms of 'making connections' (Pepin, 2008): e.g., connections to what the pupils already know; to authentic situations; across mathematical topics; across other subjects. This is in line with the literature on 'learning mathematics with understanding' (e.g., Hiebert et al., 1997). They contend that students build mathematical understanding by 'reflecting and communicating', and tasks should allow and encourage these processes. This means that such tasks should have the following features:
"First, the tasks must allow the students to treat the situations as problematic, as something they need to think about rather than as a prescription they need to follow. Second, what is problematic about the task should be the mathematics rather than other aspects of the situation. Finally, in order for students to work seriously on the task, it must offer students the chance to use skills and knowledge they already possess. Tasks that fit these criteria are tasks that can leave behind something of mathematical value for students." (p.18)
In summary, and considering the above, the notion of 'quality' is complex: it involves the notion of coherence and depth of understanding in textbook analysis, and this in the light of the evolutions brought on by digital means. We discuss this further in what follows, drawing on the comparison of two differently designed textbooks.
The main research questions are: What are the differences between a textbook

designed by a team of experts (researchers, teacher trainers, etc.); and a textbook designed by a group of teachers using a digital platform? What are the 'consequences' of these different designs, in particular in terms of coherence and quality of the textbooks produced?
In the next section, we present the study and subsequently the findings and results. The findings are presented under three headings: (1) the two contrasting teams of authors and their different conceptualisations of their respective textbooks; (2) authors' choices concerning content and structure; and (3) authors' intentions concerning the use of their textbooks.
The study
Our study took place in France, where no institutional control of textbooks exists. France has a National Curriculum, which is presented as a text detailing mathematical objectives and accompanied by detailed comments for teachers, in addition to a booklet giving a structured list of pupil competences. For our study we selected two very different textbooks on the basis of contrasting cases. Both textbooks were grade 6 books (first year of lower secondary school, collège, in France). Because no official statistical figures were available on the most commonly bought mathematics textbooks for this grade, we cannot claim that these textbooks were the most used by teachers. However, they were the most commonly used by the teachers we worked with, and most mathematics teachers in the region knew of them.
The differences between the two books not only concerned their content or the material they offered; the differences were also linked to the authors' teams and the design processes. Therefore, we designed a questionnaire for each of the authors' teams. The questionnaires were designed by drawing on our knowledge of previous studies on textbook analysis (e.g., Pepin & Haggarty, 2001) and on our knowledge of the books, including what teachers told us about their use. The questionnaires Theme C – G. Gueudet, B. Pepin & L. Trouche
328
included questions on the textbook's design mode; the authors' perspectives on mathematics and their teaching; and on the design choices, on a general level and on specific aspects of the textbook studied. The results we present here draw on a cursory analysis of the textbooks, but more importantly on the analysis of the responses to the questionnaires. The analysis involved the identification of similarities and differences, category generation and saturation based on constant comparison using a procedure similar to that described by Woods (1996). In particular, we have chosen to focus on the differences in this paper.
Different authors, different conceptualizations
In terms of textbook design, Hélice 6
e
(Chesné, Le Yaouanq, Coulange, & Grapin, 2009) has been developed by a team of four "experts": three teacher educators, two of them with a masters' degree in mathematics education; and a researcher in mathematics education. A grade 6 teacher (not considered an author) 'tested' some of the tasks in his class. Asked about the way they evaluated the relevance of the content, the authors declared that they trusted "research results, or [their] training experience" – we call it 'expert evaluation'. These experts were clearly aware of their expert position.
Sesamath 6
e
(Sesamath, 2009) has been developed by a large group of authors: approximately 57 lower secondary school mathematics teachers (being involved in producing both the paper version and the digital complements), their work being coordinated by members of the Sesamath association
21
: teachers who are involved in the design of online resources. The Sesamath association (Gueudet & Trouche, 2012, Sabar & Trouche, 2013) designed many other resources: online exercises; adigital geometry software; and a complete virtual environment, LaboMep
22
. LaboMep allows the co-ordination of various kinds of resources, from Sesamath or from other sources on the web, and their preparation for student use. The "Sesamath 6
e
" textbook was published under a free license; it can be downloaded from a website
23
, or used online (Figure 1). A paper textbook exists, corresponding to the text files (which are available in .pdf and .odt). Other complementary files (e.g., dynamic geometry files, spreadsheets, slides, online exercises) can only be accessed using the website.
In terms of evaluation of the content relevance, the teacher authors and other members of the association used the developed textbook in their classrooms and observed and evaluated it, in particular in terms of their students' involvement with particular features of the book. Referring to a distinction introduced in the field of computer supported collaborative learning (Dillenbourg, Baker, Blaye, &O'Malley, 1996), we consider that the collective work of the authors in the case of Hélice was collaborative (the authors sharing each part and step of the work). In the case of Sesamath, we consider the authors' collective work as co-operative: different tasks had been assigned to different authors.
Another important difference which we develop in the discussion was that the content of the digital textbook continuously evolved, according to the experiments

21
The name of the association itself, Sesamath, is interesting and linked to « Open sesame », the famous phrase from the Arabian Nights. The motto of the association is "mathematics for everybody".

329
and contributions of the teacher users. In fact, Sesamath proposed a website, 'Sesaprof', which was open for teachers and comprised of a 'discussion forum' section (discussing the textbook). These online discussions led to modifications of the textbook's content: for example, when a large number of users asked for the solutions of the textbook's exercises, these were added in the digital textbook.
Beyond these differences, both teams claimed that they were constrained by commercial publishing and user expectations. For example, the Hélice team explained that they had wanted to write more guiding comments for the teacher, but had been asked by the publisher to limit these comments. For the Sesamath team, the grade 6 book was the last in a series; they had started with and accomplished textbooks for grades 7, 8 and 9 (in this order) due to curriculum changes. Thus, the structure of these earlier textbooks gradually became a model familiar to users, and the authors were obliged to keep a similar structure for the grade 6 textbook.
Figure 1. Sesamath online textbook for grade 6. The text on the screen background corresponds to the content of the .pdf, or paper version. The "complements" window opens when the mouse is placed on a selected activity.
Authors' choices concerning content and structure
The analysis of the textbooks and the authors' answers to the questionnaire showed many differences concerning the textbook content. We illustrate these statements with examples from the mathematical topic of 'area'.
Organisation of the content
Concerning the textbook's global structure and the organisation of the mathematical content, Sesamath provided a "classical" organisation: chapters were organised according to the headings of the official National Curriculum. As an example, the topic of 'area' was in the section entitled "Area and Perimeter", which was the second section of the chapter entitled "Quantities and Measures".
Hélice had a very special, spiral organisation, hence the title "Hélice" (meaning "Helix"). The book was not structured in chapters, but in "units", working with different 'thematical' lessons, and a 'unit' finished with problems and exercises linking the different notions learnt. The authors of Hélice presented this (spiral Theme C – G. Gueudet, B. Pepin & L. Trouche
330
organisation) as their central and original structure. Indeed, in France Hélice was the only textbook retaining this composition. The authors specified that the intention had been that the learner revisited and deepened the same notion at different stages – a spiral curriculum. At every stage the notions were associated with different representations; links between different chapters were frequently made; and differentiation in terms of pupil learning (e.g., pace) was taken into account. The topic 'area' appeared twice in the table of contents: in the unit entitled "Distance and areas" (Unit 4; lesson called "Area: comparison and sharing") and in the unit entitled "Division and computation of area" (Unit 5; lesson called "Areas: measure and computation"). Moreover, the area of a circle was in fact presented in Unit 7, as an activity demonstrating that the area of a circle and the square of its radius are proportional.
We claim that this difference in terms of structure was influenced by the different design modes and author teams. Following a complex and coherent structure, such as the one retained by Hélice, was only possible for a 'steady' author team, and likely to be very difficult for a large and 'variable' author group, such as the Sesamath group. A large 'collective' process, like Sesamath, required splitting the content into different parts, which then were designed by different authors who did not necessarily communicate. This splitting of tasks, we argue, has also influenced the coherence of the textbook. Bringing together the work of more than fifty authors and achieving a coherent didactical structure would require an enormous coordination effort, more than the one organised by the Sesamath team.
Different methods, or a single expert method
Hélice authors stated that it was important for them to propose different representations and a rich vocabulary in their book. They also favoured exercises with different possible solutions.
In Sesamath, our analysis showed that some additional research activities suggested and fostered the search for several solutions. However, we contend that most of the exercises led to a single and final solution. In particular, the worked examples were all one-solution exercises, the authors called them 'expert solution' in the questionnaire (Figure 2).
Figure 2. Extract of Sesamath 6
e
. Method 2: evaluating an area.
Example 1. Determine the area of this figure by choosing the yellow triangle as the unit, then calculating the area of this rhombus. To find the area of the figure, you have to count the number of area units of the figure. The purple figure is made of 9 triangles. Its area is thus the area of 9 yellow triangles. The rhombus is made of two yellow triangles. The area of the purple figure, in number of rhombi, is thus twice as smaller. Hence the area of the figure equals 4.5 rhombi. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
331
Primary-secondary link
Another important aspect, given that the textbooks were for grade 6, was whether the primary-secondary link was explicitly addressed. Some of the Hélice authors were teacher educators, both for secondary and primary school level. Thus, they had considerable knowledge about the content taught at primary and secondary school. They identified several crucial cognitive and didactical changes in terms of the transition from primary to secondary school mathematics. Concerning 'area', one important choice, according to them, was to start with activities on the comparison of areas of two figures, without using any kind of measures. The activity in Figure 3 illustrates this choice.
Figure 3. Extract of Hélice 6
e
. Lesson 12. Areas: comparing and sharing.
Activity 2: Cutting and arranging. The objective of the activity is to demonstrate that all these figures have the same area as the square, by cutting and adjusting to obtain a superposition with the square.
The official curriculum mentioned "geometrical comparison of areas" as a teaching objective. This aspect was particularly developed in Hélice; and this was a deliberate choice of the authors, in order to provide a better link to primary school notions where comparing areas without using measure was a common task. Sesamath authors declared that they had only limited knowledge of primary school mathematics curricular aspects when they started writing the grade 6 book. Concerning 'area', the textbook focused on area computations, whereas the official curriculum also stipulated "geometric comparison of areas". This geometric comparison, without measures, was not evident in the Sesamath textbook. With a better knowledge of primary school, where such tasks were frequent, the authors may have inserted it. However, the Sesamath authors paid attention to one 'classical' difficulty: the potential problem to distinguish between area and perimeter of a figure. This difficulty was known to be important for primary school, and also for grade 6 students, and as teachers of grade 6 students the textbook's authors knew about it. Writing the book raised the authors' awareness of transition questions (e.g., the importance of mental arithmetic for grade 6.). The paper version of Sesamath did not reflect this, but in the associated online resources, in particular online exercises, the authors attended to this aspect of primary-secondary transition. Whilst the paper book has remained the same since 2009, the authors claimed that they had attended to particular 'shortcomings' and that the online complements had considerably developed since that time (e.g., in LaboMep many online exercises of mental arithmetic for grade 6 had been added). Theme C – G. Gueudet, B. Pepin & L. Trouche
332
Authors' intentions concerning the use of their textbooks
In the questionnaire, the Hélice designers adopted a general stance about teachers' adaptations of the book to their specific contexts. They said that "it [was] impossible to anticipate all possible adaptations" (in terms of contexts) and that they did not regard it as their "responsibility" to attend to these. This view was reflected in several statements throughout the questionnaire, e.g. the following: "the gap between what is planned and what happens in class is large - the gap between the authors' intentions and the teachers' use is even larger". They also declared that they would anticipate that teachers would combine Hélice with the use of other textbooks. However, the spiral progression made such a practice difficult and the complex spiral structure was clearly an obstacle for the adaptation, or combination of several textbooks.

For Sesamath, the possibility of adapting the content was an important issue.
The authors conceptualised the book, from its inception, as a digital textbook, each
chapter file in .odt format. This offered opportunities for teachers to modify the texts
of the exercises, and of the lessons. The book also offered a large amount of exercises,
with the intention of leaving their choice to teachers. According to the Sesamath
authors, the digital textbook was a "collection of bricks". Moreover, they stated that it
should be thought of as belonging to a more general set of different kinds of resources
available in the virtual environment LaboMep. Sesamath authors considered that it
was the teachers' responsibility to 'build coherent lessons' and a 'coherent
progression'. In their view this was made possible by providing a large range of
resources to choose from, the textbook being only one of these. In addition, they
wanted to provide 'efficient tools', such as LaboMep, for teachers to build their own
teaching from these 'initial bricks'.
Discussion
Going back to our initial questions ("What are the differences between a textbook
designed by a team of experts (researchers, teacher trainers, etc.) and a textbook
designed by a group of teachers using a digital platform? What are the 'consequences'
of these different designs, in particular in terms of coherence and quality of the
textbooks produced?), we answer these by comparing the two contrasting textbook
cases (Helice and Sesamath).
The investigation of the two textbooks showed that there are differences
concerning essentially six levels (at least):

• the modes of design: more collaborative in the first case, more co-operative in
the second;
• the nature of the structure: the first book is a single whole, with an organised
structure (organised by the team of experts); the second is an atomistic system
that can be arranged differently by different users;
• the organisation of the content: more didactically original, linked to the
didactical choices of a 'homogeneous' team in the first case; more aligned
with the institutional instructions in the second;
• the content: more open to a variety of ways for solving a given problem in the
first case; more driven by an expert solution in the second;
• the integration into the whole grades 1-9 mathematics curriculum; links with
primary school more taken into account in the first case than in the second;
and Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
333
• the links to the users; the textbook provided as a final product given to the
teachers in the first case; and as a proposal to be enriched by teachers'
contributions in the second.
For Helice, the coherence is insured by the authors' didactical expertise, i.e.
the mastering of the concepts at stake and of the potential difficulties and
misconceptions for learning. It could be said that it is a transcending coherence. For
Sesamath, the coherence is insured by the link with the curriculum and the
institutional prescriptions; by teacher evaluation in class; and by the discussions
among authors faced with the different contributions. Sabra and Trouche (2011)
describe, for example, the discussion in another Sesamath author team (for a grade 10
book) in terms of reaching a coherence and consistency between the introduction of
equations (in one chapter), and the introduction of function (in another chapter). We
argue that this is a collective and institutional coherence.
Helice was, we claim, of high didactical quality. It offered many rich tasks,
organized according to a carefully considered and complex structure. It took into
account central aspects of the primary-secondary transition. The Sesamath textbook
appeared to be, in its initial version, of a lower intrinsic quality: it offered fewer
problems and fewer rich tasks. In terms of structure it simply followed the structure of
the official National Curriculum.
However, the "digital additions" and possibilities of Sesamath prompted us to
re-consider the notions of 'quality' and 'coherence'. Helice remained the same, in
both its paper and pdf versions, we call this static quality. In contrast, the online
version of Sesamath had already been modified several times, to take account of 'user
comments', i.e. users' experiences and needs. The digital means offered possibilities
for modifications, and these were integrated by Sesamath in the process of re-design.
The association perceived this as a necessity for meeting users'/teachers' needs in
order to insure the quality of the textbook, we call this dynamic quality. Both Helice
and Sesamath authors recognized that teachers would select and adapt elements of the
textbook for their teaching. However, only Sesamath supported these adaptations and
drew on user contributions.
We argue that this was a major development linked to digital means: the
involvement of a large group of teachers in the design of resources, which in turn
continuously evolved. This also deepens our knowledge of already established
phenomena: even teachers who were not involved in the design of textbooks could be
considered as 'designers' of their own teaching materials, as teachers selected
resources, combined them, and set them up in class – a process that Gueudet &
Trouche (2009) called teacher documentation work. This leads us to consider that the
question raised in the discussion document, "[Which] implications for design and
coherence of materials […] if teachers are able to select tasks in varied orders?",
does not sufficiently recognize the complex link between 'design' and 'coherence'
and the evolving role of teachers. Exploiting the potential of digital means for the
design of teaching resources, including textbooks, requires the acknowledgement of
this new role.
Drawing on the results presented here, we argue that textbooks can be
considered as lived resource (Gueudet, Pepin, & Trouche, 2012), or even living
resources, as they get continuously enriched and renewed by teachers' experience.
This new conceptualization of the textbook is likely to be associated with new forms
of design, for example, in terms of reflection on meta-design (Fischer & Ostwald,
2005), resources which support the design by teachers. It can also lead to favour Theme C – G. Gueudet, B. Pepin & L. Trouche
334
teams of textbooks designers who combine and involve different 'experts' and
expertise (e.g., teachers and other 'experts' such as researchers). From the literature
(e.g., Kieran, Tanguay, & Solares, 2012), it is clear that teacher documentation work
and professional knowledge are intrinsically intertwined, one leading to the evolution
of the other (e.g., Gueudet & Trouche, 2012; Pepin, 2012). This has implications, also
in terms of policy, for teacher professional development (of 'users' and of
'designers'); mathematical task design and digital means/possibilities; and the reconceptualization of the quality of resources in mathematics education.

Pedagogical Content Analysis of Mathematics as a
Framework for Task Design
Eric W. Hart
American University in Dubai
This paper describes a pedagogical content analysis framework
for task design in mathematics. This framework has been developed and
applied through the author's ongoing work to develop textbooks,
classroom materials, professional development materials and programs,
and standards, particularly in the area of discrete mathematics.
Keywords: mathematics, discrete mathematics, tasks, teaching,
learning, textbooks, curriculum
Introduction
Mathematics instructional tasks are at the heart of teaching and learning mathematics.
Effective tasks are the core of good textbooks, classroom lessons, and professional
development programs. Designing worthwhile tasks is challenging, but doing so has
immense educational payoff. Student learning is developed, deepened, and extended
through engagement in rich mathematical tasks; teacher skill and knowledge are
strengthened through teaching with and designing tasks; textbooks become teachingand-learning books rather than just reference books and sources for homework
problems when they are developed around worthwhile instructional tasks.
It is difficult to design mathematics tasks that are effective for teaching and
learning. This paper describes a useful design framework developed and applied by
the author to design sequences of tasks in a variety of settings: for textbooks, through
the Core-Plus Mathematics Project and the Transition to College Mathematics
Project; through individual tasks for classroom lessons and teacher professional
development; through projects for the U.S. state of Iowa (Every Student Counts and
Iowa Core Mathematics); through projects for the National Council of Teachers of
Mathematics (Illuminations website project); and through a state-funded lesson study
project (Important Mathematics and Powerful Pedagogy). Most of the tasks are in the
area of discrete mathematics, designed to be used at the high school level.
There are many types and sizes of mathematical tasks. In this paper, the
discussion ranges from sequences of tasks to individual tasks, including tasks that
generate or clarify a definition and those that develop major concepts or procedural
skills. Task in this paper means textbook material or classroom lesson material that a
teacher uses to help students gain a deeper understanding of mathematics. Several of
the examples are what can be called "problem-based instructional tasks," as defined in
Iowa Core Mathematics (2010, p. 3):

Problem-Based Instructional Tasks:
• Help students develop a deep understanding of important mathematicsTheme C – E. W. Hart
338
• Emphasize connections, including to the real world
• Are accessible yet challenging to all
• Can be solved in several ways
• Encourage student engagement and communication
• Encourage the use of connected multiple representations
• Encourage appropriate use of intellectual, physical, and technological tools.
Effective mathematical instructional tasks must take into account the nature of mathematics and knowledge, as well as issues of teaching and learning. A key idea in all these domains is connections. Mathematics is a connected and coherent subject, it should be taught that way so students can learn it that way. As Schoenfeld (2009) states, "I truly believe that (a) mathematics is special because of the way it coheres-it really does make sense!-and (b) mathematics can be taught so that students come to see it so" (p. 168). Similarly, "mathematics is an integrated field of study.... When students can connect mathematical ideas, their understanding is deeper and more lasting" (National Council of Teachers of Mathematics, 2000, p. 64).
Understanding is of course our goal. A key perspective on understanding is the construction of knowledge. "Understanding involves the construction of knowledge by individuals through their own activity, so that they develop a personal investment in building knowledge" (Carpenter & Lehrer, 1999, p.23). As stated by Gardner, "When you've encountered an idea in your own way and brought your own thinking to bear, the idea becomes more a part of you ... it's a part of your own experience" (1993, p. 6). Teaching for understanding is not just a platitude, there is a large body of research that helps identify what it means, why it is effective, and how one does it (for example, see Hart, 2010). Teaching for understanding can be operationally defined as in the Every Student Counts Project (ESC, 2008, p. 3):
Teaching for Understanding means
• Developing deep conceptual and procedural knowledge of mathematics
• Posing problem-based instructional tasks
• Engaging students in the tasks and providing guidance and support as they develop their own representations and solution strategies
• Promoting discourse among students to share their solution strategies and justify their reasoning
• Summarizing the mathematics and highlighting effective representations and strategies
• Extending students' thinking by challenging them to apply their knowledge in new situations, including in real world situations
• Listening to students and basing instructional decisions on their understanding.
The design framework described in this paper takes the above perspectives into account. The resulting tasks are used in textbooks (Fey et al., 2010; Hirsch et al., in press), in teacher resource books and journals (e.g., Hart, Kenney, DeBellis, & Rosenstein, 2008), in classroom lessons (e.g., Resources for the Iowa Additions of Iowa Core Mathematics, 2012), and as objects of reflection for professional development (e.g., in the Every Student Counts and Important Mathematics and Powerful Pedagogy projects). They are used by teachers to teach, students to learn, educators to provide professional development and teacher training, and scholars to study (e.g., Ziebarth et al., 2009). The framework will now be described, with examples. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
339
Pedagogical content analysis framework for task design
This framework is based on analyzing the target mathematics (i.e., the specific mathematics to be learned in the task or sequence of tasks) from the perspective of mathematics, learning, teaching, curriculum, tools, models, and applications.
Outline of the framework
The framework can be outlined as follows. First, for the targeted mathematical content, analyze the mathematics by answering these questions:
• What is it? [deeply, simply, in essence]
• How do you do it? [compute it, compute with it, find it, operate on it, operate with it]
• What is it connected to? [interconnected web of mathematical ideas, concepts, methods, representations]
• What is it good for? [applications, contexts, models]
Next, analyze the mathematics pedagogically. That is, understand, identify, and develop strategies for addressing:
• Common misconceptions
• Common student content difficulties
• Sequencing
• Questioning
• Scaffolding
• Tools
• Pedagogical mathematical language.
These analyses are carried out with more or less formality. If time permits, a lesson study approach is very effective. It can be helpful to engage in an explicit process of unpacking and then repacking. The analysis may also take place informally in real time during teaching. In all cases, ultimately the perspective and process become a habit of mind and habit of practice.
Example: multiplicative inverses in modular arithmetic (Zn)
In this example, we see instances of analyzing the mathematics, and addressing the issues of misconceptions, common difficulties, sequencing, scaffolding, questioning, and tools. A sequence of tasks is designed through a process of systematic analysis, development, and revision based on results from classroom tryouts. The tasks are designed for use with high school students in a fourth-year (final year) math course that is an alternative to a pre-calculus course, but with similar prerequisites.
As background to this sequence of tasks, previous analysis and design includes establishing an engaging context (cryptography, in particular the RSA public-key cryptosystem), and developing a prior sequence of tasks for the ideas of equivalence mod n, reducing mod n, addition and multiplication mod n, and the integers mod n with the notation Zn. Also, although the target is multiplicative inverses, because this is what is needed for RSA, additive inverses are also developed to provide an accessible lead-in to multiplicative inverses and to more fully develop the key mathematics.
To begin, a mathematical analysis includes considering the four questions outlined above: What is a multiplicative inverse in Zn? How do you find a multiplicative inverse? What are connections to other and previous ideas in mathematics? What are multiplicative inverses in Zn good for? Of course, a huge Theme C – E. W. Hart
340
amount of mathematics emerges from the answers to these questions. This can be thought of as "unpacking." Then we must "repack" to identify the target mathematics for this particular sequence of tasks as it is situated in a particular curriculum and classroom. In this case, the target mathematical ideas are analyzed to be (a) multiplicative inverses in Zn are similar to and different from multiplicative inverses for real numbers with "regular" multiplication, (b) not every number in Zn, for all n, has a multiplicative inverse, and (c) there are important properties of numbers that determine if a multiplicative inverse exists.
The most fundamental and universal design decision is that all tasks are structured sequences of questions. Key decisions pertain to the issues of which questions to ask, in what sequence, and with how much structure.
The first design decision is easy – additive inverses are easier and will help lead into the more difficult idea of multiplicative inverses. Even here, careful decisions are made. For example, how much mathematical formality should be developed, in particular, where and how should the idea of additive identity fit in? How much scaffolding should be provided? Scaffolding refers to guidance in terms of open-endedness of questions and size of steps in the step-by-step sequence of questions.
The task is initially designed with no explicit mention of additive identity, just use of 0, and little scaffolding. The initial attempt is based on trying out the hypothesis that students will find additive inverses in Zn to be straightforward analogs of additive inverses with real numbers. Thus, after a question about informally finding additive inverses with real numbers, students are asked to find additive inverses in Zn, for a few different values of n:
a. What is the additive inverse of 6 in Z10?
b. What is the additive inverse of 3 in Z8?
Classroom testing showed that students struggled mightily, they could not make the jump from their previous work with real numbers to inverses in Zn. So the questions were redesigned to provide more scaffolding initially, and then gradually relax the guidance:
2a. Find a number in Z10 that you can add to 6 to get 0 mod 10. Such a number is the additive inverse of 6 in Z10.
2b. Find a number in Z10 that you can add to 2 to get 0 mod 10. Such a number is the additive inverse of 2 in Z10.
2c. What is the additive inverse of 3 in Z10? Explain.
2d. What is the additive inverse of 3 in Z8? Explain why this answer is different than the answer you got for the additive inverse of 3 in Part c.
Students seemed to have no difficulty with the idea of an additive identity (probably because it is 0 for real numbers and Zn). For the target high school students, formal understanding of mathematical structures, such as rings and fields, is not deemed appropriate. Nevertheless, for the integrity of the mathematics, additive identities are also more formally defined in the first question about real numbers:
1. Think about additive inverses. The additive inverse of a number is the number that you add to it to get 0. For example, with real numbers, the additive inverse of 3 is -3, since 3 + -3 = 0. The number 0 is called the additive identity. Find the additive inverse of each of these real numbers:
5.

.
, and -1.5. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
341
After the previous two tasks, students are getting comfortable with inverses in modular systems. They see some differences compared to additive inverses with real numbers, but it is still true that every number has an additive inverse.
Now to the harder idea of multiplicative inverses. Through an iterative process of pedagogical content analysis and classroom testing, the following design issues and decisions emerged.
Start with a task similar to the first additive inverse task (#1 above), to anchor the investigation in students' past experience with real numbers. For Zn, begin by investigating Z7, a prime modulus, in which all non-zero numbers have a multiplicative inverse, so that students get introduced to the idea in the simplest setting. They only have to deal with one new idea – a modular system, without yet needing to face the issue that some non-zero numbers in some systems do not have a multiplicative inverse. This task ends with a question to find the multiplicative inverse of 6 in Z7. Because 6 is its own inverse, students are confronted with their next carefully-planned disequilibration, because no real number (other than 1 and -1) is its own multiplicative inverse.
Which modular system would be best to investigate next? The first try is Z6. This choice was quite confusing for students. Why might this be so? Part of the reason might be because there are too few numbers with inverses, only 1 and 5, and both are their own inverse. This is a bad pedagogical step because the example is too special; it only illustrates numbers that are their own inverses, and thus raises the danger of students' over-generalizing this pattern.
The next try is Z8. This choice is better because more numbers have inverses. However, the numbers without inverses are all the even numbers, which could again lead to over-generalizing a pattern. Once again, every number with an inverse is its own inverse. Also, the modulus is a power of 2, that is, the only prime factor is 2, which will not be helpful when looking for properties of numbers that do and do not have inverses. Thus Z8 also is pedagogically problematic because it has too many special characteristics.
The analysis thus far points to the need for a modular system in which the modulus has more than one prime factor, not all numbers with inverses are their own inverse, not all numbers without inverses are even, and the modulus is not too large so that computing is not a barrier. This leads to the decision to use Z10 next.
Now the next big step is to find a pattern for which numbers have an inverse and which do not. Consider Z10. The following design decisions are made:
• For the first time thus far, give students an empty multiplication table, ask them to complete it, and see which numbers have a multiplicative inverse and which do not. It is an important decision when to give support, such as this multiplication table. In previous problems, the intent is for students to think it through on their own in their own way. They may decide to use a multiplication table or not. Such decisions are important for students to consider before the decision is made for them.
• Ask first about patterns for numbers that do not have multiplicative inverses. [2, 4, 5, 6, 8]
• Then, after students work for a while, if they need more guidance, ask progressively more focused probing questions:
How do such numbers relate to 10?
Do you see any factors of 10? Are they all factors of 10?
Do you see any connections between the factors of 10 and the factors of these numbers? Theme C – E. W. Hart
342
• Ask for patterns for numbers that do have a multiplicative inverse.
At this point, referring back to the three target mathematical ideas identified at the beginning of this discussion, students are expected to have made substantial progress learning that (a) multiplicative inverses in Zn are similar to and different from multiplicative inverses for real numbers (in ways that students can describe), (b) not every number in Zn, for all n, has a multiplicative inverse, and (c) there are important properties of numbers that determine if a multiplicative inverse exists. Teachers may decide that complete attainment of (c) is not necessary, or that it is not attainable in a timely manner, for their students. To help provide differing support for this goal, for some or all students, the design decision is to first ask for a pattern in Zn in an open-ended question. Then provide guidance to help get the general result, as follows:

You discovered in previous problems that not all numbers in a given
modular system have a multiplicative inverse. Think about when multiplicative
inverses exist in Zn.
a. Make some conjectures about which numbers have multiplicative inverses
in Zn, either for a general n or for particular values of n. For each
conjecture, try to prove it or disprove it. (You can disprove it by finding a
counterexample.)
After trying some of your own conjectures, complete and prove the
following three statements.
b. When n is _____, then every nonzero integer in Zn has a
multiplicative inverse.
c. If n and m have a particular relationship to each other, then m does not have
a multiplicative inverse in Zn. What is that relationship?
d. m has a multiplicative inverse in Zn if and only if _____.
This concludes this example of designing a sequence of tasks using the
framework of pedagogical content analysis. We have seen an application of the
mathematical analysis outlined in the description of the framework, along with
consideration of many of the issues in the pedagogical analysis. These issues and
examples from this sequence of tasks include common misconceptions (overgeneralizing, for example, that all numbers have a multiplicative inverse), common
student content difficulties (making the jump from inverses for real numbers to
inverses in Zn), sequencing (doing additive inverses before multiplicative inverses, or
asking about patterns for numbers that do not have inverses before patterns for those
that do), scaffolding (numerous examples of strategically providing more or less
guidance), tools (when to introduce a multiplication table), and questioning (examples
of trying to find the right question, at the right time, with the right open-endedness).
Brief examples illustrating aspects of the pedagogical content analysis
framework
The one issue not yet addressed in this task design framework is so-called
mathematical pedagogical language. This refers to the use of language that is
mathematically accurate, though not conventional, and it is pedagogically powerful.
This is language that helps students understand a mathematical idea through the name
of the idea or the notation used for the idea.
For example, consider graph theory. The word graph is used in many ways,
and for students it usually means a graph in the coordinate plane, or perhaps a data
plot. But these are not at all what is meant by graph in graph theory, where a graph is Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
343
a collection of vertices and edges. So why not modify the language, maintaining
accuracy, to make the name more sensibly reflect the object. Thus, the term vertexedge graph is used when designing tasks for high school students in graph theory.
Another example is recursion. This idea, before it is mathematically
formalized, is intuitive for most students. They find it quite natural, for example, to
think of the next counting number in terms of one more than the number you have
now. So why not make use of the language of “next” and “now.” Consider the
following incomplete function table:
x y
0 3
1 7
2 11
3 15
4 19
Based on many classroom trials, when students are asked to find patterns in
this table, they are likely to say things like “it goes up by 4” or “add 4 each time.”
That is, they are seeing the recursive pattern in the y-values. When asked to write an
equation that describes that pattern using the words NOW and NEXT, students have
little trouble writing NEXT = NOW + 4. In contrast, students have great difficulty
with the conventional subscript notation for recursion. Of course, students should also
be able to find the x-y pattern: y = 4x + 3. To see one strength of the NEXT–NOW
language, notice how concretely and meaningfully the slope is shown in the recursive
equation, as opposed to the more abstract representation of slope in the y = 4x + 3
equation.
This example illustrates some of the characteristics of pedagogical
mathematical language, and why it is an important feature of task design. The
language must be mathematically accurate and also pedagogically powerful. In the
case of NOW/NEXT, this language captures the essence of recursion, as used to
describe sequential change. The language helps make an otherwise notoriously
difficult idea accessible to all students. It also has substantial payoff in terms of
deepening understanding of linear and exponential functions, constant rate per unit
interval versus constant percent rate per unit interval, and making concrete the
connection to arithmetic and geometric sequences. It promotes “semantic learning” as
opposed to only “syntactic learning” (the latter is a danger when moving too fast to
subscript notation). It is a “bridging language” in that the formal notation will be used
at an appropriate later time. Students will definitely need understanding and facility
with subscript notation to utilize the full modelling power of recursion. Finally, note
that such pedagogical mathematical language may have limitations that must be
carefully monitored. In the case of NOW/NEXT, this notation is not so useful for
modelling change related to quadratic functions, and one must be careful to consider
the incremental change in the x-values as well when looking for a NOW/NEXT
relationship in the y-values.
For one last brief example, consider a lesson on the slopes of perpendicular
lines developed as part of a lesson study project. The first iteration of the lesson used
transparencies to rotate several lines 90˚, gather and record the data on slopes of pairs
of perpendicular lines, look for a pattern, and conclude that the slopes are negative
reciprocals. After classroom tryouts, several features in the pedagogical content
analysis design framework became particularly evident.
First, the use of the transparencies (an instance of the tool issue) proved to be
confusing to students and needed to be refined. For example, if no axes are drawn on Theme C – E. W. Hart
344
the transparency, which is on top of the paper with a line drawn, then when the paper
is rotated students get confused about how to interpret the new position of the axes. If
the transparency is rotated, then students are confused because it seems to them like it
is the “same” line so it must have the same slope. The best solution proved to be
putting axes on the transparency, and then rotate the paper underneath. This way, two
lines appeared on the transparency with the axes fixed. Such small adjustments can
often make a big difference in a lesson. Second, it turns out there had been a lack of
mathematical analysis, specifically with regards to the first question outlined in the
description of the framework, namely, with respect to the target mathematics, What is
it? In this case, the answer to the question, “What is the slope of a perpendicular
line?,” is not that it is a pattern in the data. Rather, the slope is a consequence of the
definition of slope and the nature of a 90˚ rotation, which is exhibited as a pattern in
the data. This was an important learning episode for both teachers and students – that
finding patterns in data is important, but you must try to understand those patterns in
terms of the underlying mathematical concepts and relationships that caused the
pattern.
Conclusion
This paper presents a framework for task design in mathematics that has been
gradually developed and applied over the last two decades by the author in work on
several research and development projects for textbooks, classroom lesson
development, and teacher professional development programs. The framework is
called a pedagogical content analysis to highlight that it involves both analyzing the
mathematics and analyzing the mathematics pedagogically. Through iterations of task
design and classroom tryouts, specific features that operationally define this
framework have been identified, refined, and applied.

Task Modification and Knowledge Utilization by Korean
Prospective Mathematics Teachers
Kyeong-Hwa Lee
Seoul National University, Korea
Eun-Jung Lee
Seoul National University, Korea
Min-Sun Park
Seoul National University, Korea
It has been asserted that mathematical tasks play a critical role in
the teaching and learning of mathematics. Modification of tasks included
in intended curriculum materials, such as textbooks, can be an effective
activity for prospective teachers to understand the role of mathematical
tasks in the teaching and learning of mathematics; designing of new tasks
requires more knowledge and experience. This study aims to identify the
patterns that Korean prospective mathematics teachers seem to follow
when they modify the mathematical tasks in textbooks. Knowledge
utilized by prospective teachers while they modify textbook tasks is
identified and characterized to understand the possible factors that have
impact on Korean prospective mathematics teachers' modification of
tasks.
Keywords: task modification, prospective teachers, teacher knowledge
Introduction
It has been asserted that mathematical tasks play a critical role in the teaching and
learning of mathematics (Crespo, 2003; Henningsen & Stein, 1997; Stein, Grover, &
Henningsen, 1996; Watson & Mason, 2007). Henningsen & Stein (1997), for
example, pointed out that the nature of tasks may provide different opportunities to
develop students' mathematical thinking and reasoning skills. Furthermore, they
argued that teachers' goals, mathematical knowledge, and knowledge of students can
influence how the teachers set up the tasks included in intended curriculum materials,
such as textbooks. This indicates that students' mathematics learning can be positively
influenced by tasks that teachers modify or develop through their content and
pedagogical knowledge. Therefore, the issue of teachers' competency to modify and
pose meaningful tasks needs to be addressed more actively in teacher education.
However, according to Watson & Mason (2007), who reviewed the submitted
proposals for the special issue of the Journal of Mathematics Teacher Education, only
a few papers dealt with issues in teachers' critical analyses such as task analysis, task
evaluation, or posing tasks. This tendency is in line with the comment by Prestage and
Perks (2007), which is that the issue of how teachers pose and organize tasks to
educate students in classrooms has been ignored. Theme C – K.-H. Lee, E.-J. Le & M.-S. Park
348
Teachers' ability to analyze and modify tasks to be used in the classroom or
pose worthwhile tasks may be a critical factor affecting students' mathematics
learning. However, such skills cannot be developed in just a short time, so teachers
need continuing and systematic support to develop the skills (Crespo, 2003; Prestage
& Perks, 2007).
In the case of Korea, especially, most teachers, in fact about 90% of secondary
mathematics teachers, tend to use textbooks as a major resource in classrooms
(Mullis, Martin, Gonzalez, & Chrostowski, 2004). Therefore, it seems very important
for prospective teachers to have opportunities for performing critical analyses of tasks
and the modification of them. The purpose of this study is to identify the patterns that

Korean prospective mathematics teachers seem to follow when they modify the mathematical tasks in textbooks. Knowledge utilized by prospective teachers while they modify textbook tasks is identified and characterized to understand the possible factors that have impact on Korean prospective mathematics teachers' modification of tasks.

Theoretical Background

Tasks can be designed in different forms according to the objective and orientation, and every single task form provides a different learning opportunity for students. Prestage & Perks (2007) suggested that transforming only the conditions of closed problems in school textbooks by adding or deleting conditions can foster students' mathematical thinking. When conditions are deleted, students can decide for themselves. When conditions are added, students can extend the knowledge from the national curriculum. Thompson (2012) attempted the transformation of textbook exercises according to the following strategies to reflect the new curriculum's point of view, which emphasizes both reasoning and communication: a) reframe a basic problem by including one or more conditions; b) use relationships to find patterns or predict other results; c) generate conjectures for students to investigate; d) encourage students to solve a problem in multiple ways; e) evaluate student solutions; f) write a question appropriate for a given answer; and g) connect procedural and conceptual knowledge. The different learning opportunities from each task can be identified when tasks in textbooks are modified to require high cognitive demand (Kaur & Yeap, 2009) or to develop critical thinking and creativity (Krulik & Rudnick, 1999). Competency in task design has been taken into consideration in mathematics teacher education. Zaslavsky (2008) showed changes in the teaching and learning of mathematics after task modification. Analyzing different versions of tasks promotes teachers' development of adaptability; fosters their awareness of similarities and differences; helps them learn how to cope with conflicts, dilemmas and problem situations; encourages them to learn from the study of practice; teaches them to select and use (appropriate) tools and resources for teaching; helps them to identify and overcome barriers to students' learning; and allows them to share and reveal self, peer, and student dispositions. Teachers can foster their professionalism after analyzing the tasks. Voica & Pelezer (2009) investigated the difference between prospective teachers' and inservice teachers' task design of problem posing. Inservice teachers considered the students, reflected the curriculum, and applied their pedagogical knowledge and mathematical knowledge, whereas prospective teachers mostly focused on the context without considering the students or the level of difficulty. Differences between inservice and prospective teachers are typically caused by differences in teacher knowledge. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

349

Ball and her colleagues suggested Mathematical Knowledge for Teaching (MKT) based on Shulman's categories of teacher knowledge (Ball, Thames, & Phelps, 2008; Hill, Ball, & Schilling, 2008). According to them, MKT is categorized into two main domains: Subject Matter Knowledge (SMK) and Pedagogical Content Knowledge (PCK). SMK is subdivided into three categories: Common Content Knowledge (CCK), Specialized Content Knowledge (SCK), and Horizon Content Knowledge (HCK). PCK is also subdivided into three categories: Knowledge of Content and Students (KCS), Knowledge of Content and Teaching (KCT), and Knowledge of Content and Curriculum (KCC). Each type of teacher knowledge constituting MKT is explained briefly as follows (see Ball et al., (2008) and Hill et al., (2008) for more details). CCK, which is included in SMK, is defined as mathematical knowledge regardless of teaching, whereas SCK is mathematical knowledge and skill for teaching. To distinguish mathematical knowledge for teaching as a mathematics teacher from mathematical knowledge, SMK was conceptualized by Ball and her colleagues, who emphasized the importance of SMK. KCS, which is included in PCK, is the combination of knowledge about students and knowledge about mathematics; for example, teachers with KCS can identify and predict the common errors that students are more likely to commit as well as their misconceptions. Finally, KCT is defined as the combination of knowledge about teaching and knowledge about mathematics. Teachers who possess KCT can identify appropriate examples they should first use to help students understand mathematical concepts or appropriate teaching sequences and methods for the design of instruction.

Method

Participants were 38 prospective secondary mathematics teachers who enrolled in the course, "A Study of Teaching Materials and Teaching Methods," taught by the first author of this paper. In the course, participants learnt about the Korean mathematics curriculum and teaching materials. At the end of this course, they were asked to analyze the tasks presented in the introduction of each unit of the secondary textbooks and modify them. The selection of tasks and the direction of modification were left up to the prospective teachers. Hence, they chose tasks from different units, such as function, geometry, algebra, or numbers; in particular, the function and geometry units were most frequently selected.

Most of the prospective teachers analyzed and modified more than 2 tasks, so all of the tasks that were done by each participant were analyzed in this study. In addition, the prospective teachers tended to use different types of teacher knowledge simultaneously in the processes of task analysis and modification, so all of those types of teacher knowledge were counted in the data analysis.

In this study, the task modification of prospective teachers was classified into three types: context modification, condition modification, and question modification. Context modification refers to modification by changing the context of tasks, making them student-friendly or diverse. Condition modification refers to modification by adding, deleting, or transforming the conditions in tasks (Prestage & Perks, 2007). It can be related to 'what-if-not' strategies of Brown & Walter (1990), who mentioned the manipulation of the conditions of a problem when posing a new problem. Question modification refers to modification by changing what students are required to answer. We can find an example of question modification in Crespo (2003), who suggested changing the task into a more open-form or one that requires a process of investigation. Theme C – K.-H. Lee, E.-J. Le &, M.-S. Park

350

The authors of this study classified the modified tasks presented by the prospective teachers into types, and the classifications not agreed on by all of the authors were discussed until we finally reached an agreement. In addition, this study analyzed the types of teacher knowledge that the prospective teachers used for the task analysis and modification, according to the classification of teacher knowledge suggested by Ball et al. (2008). The types of teacher knowledge used by the prospective teachers were also analyzed in the same way that the classification of the modified tasks was analyzed.

Findings

Types of task modification

As aforementioned, the modified tasks presented by the prospective teachers were analyzed by the following criteria: context modification, condition modification, and question modification. Figure 1 shows the number of each modification type. As can be seen in the figure, the conditions of the tasks were the most often modified by the prospective teachers.

Figure 1 The number of each task modification type made by the prospective teachers

In addition, some prospective teachers changed only one among the three: context, condition, and question; others simultaneously changed more than two for their modification. Therefore, to analyze the results from the prospective teachers' modification types in detail, both cases are described in the following section.

The case of focusing on only one among context, condition, and question

The number of tasks in which only the conditions were modified was 26 out of 64; most of the prospective teachers modified the conditions to correct misconceptions that students might have or to adjust the difficulty level of the tasks. Most prospective teachers who modified the conditions of the tasks to adjust the difficulty level tended to add graphs or pictures to help students' understanding of the tasks. The other prospective teachers noted that students might have misconceptions about mathematical ideas from the tasks in textbooks, so they modified the conditions of the tasks to prevent the misconceptions. For example, Hee (hereafter, all names presented in this study are pseudonyms) mentioned that the task in the introduction of the function unit (Figure 2) might cause some misconceptions. Hee was concerned that students may misunderstand that function as discrete, because the given domain of the task was not continuous as it asked for each moving distance after 1 second, 2 seconds, 3 seconds, and 4 seconds, respectively. Thus, Hee modified the task by changing the condition to 'Show the graph of the moving distance for 4 seconds after Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

351

P-waves started moving'. This modification focused only on preventing a misconception that students might have, that might have made it difficult for students to perform a task given in the introduction of the unit.

Figure 2 A textbook task to introduce concept of function

The number of tasks in which only the context was modified was 10 out of 64, and in most of the cases, the context was changed to attract students' interests. The prospective teachers who performed context modification claimed that the contexts used in the tasks in the textbooks could not draw students' interest. Thus, they suggested that materials in which students were interested or contexts related to students' real life experiences should be used in tasks. For instance, Nam analyzed an existing task (Figure 3); the context of the task was related to real life but could not engage students' interest. Thus, Nam changed the context by using electronic devices such as MP3 players that students often used. This finding from the context modification indicates that the Korean prospective teachers who participated in the study believed that contexts in mathematical tasks should be related to real life and students' direct experiences, and they tended to use context in a very limited view.

Figure 3 A textbook task to introduce a real life application of function

The case of focusing on more than two among context, condition, and question

There were some prospective teachers who modified the task by focusing on more than two among context, condition, and question. Because condition was the most frequent aspect of change as mentioned above, in this section, we show the responses of prospective teachers for the cases of modifying condition and context, condition and question, or context, condition, and question.

The number of cases in which the prospective teachers modified condition and context at the same time was 2 out of 64. Sol modified the task from the Introduction Theme C – K.-H. Lee, E.-J. Le &, M.-S. Park

352

of the function unit (Figure 2). She considered that the task did not show arbitrariness and univalence, so it would lead to the misconception of the function. She thus modified the context by selecting material which shows the function concept properly and provides appropriate difficulty and interest to students, and added a condition by presenting one more new relation. By considering the condition and context at the same time, this prospective teacher presented a much richer and more meaningful task than people who considered only the condition or context. Her modified task is given in Figure 4.

Figure 4 Sol's modified task of the original task in Figure 2

The number of cases in which the prospective teachers modified both the condition and question at the same time was 15 out of 64. Jong modified the task from the introduction of an isosceles triangle in geometry (Figure 5, left). He raised the question of the problem in the textbook being focused only on the shape of the triangle rather than on the properties of the figure. Thus, he changed the condition to focus on the same properties without mentioning the side or the angle by modifying the question so it was an open-ended question asking in general about figures with the same properties (Figure 5, right). In that sense, Jong provides an opportunity for discovering propositions and allowing students to explore the figure, requiring more deep mathematical thinking through changing the question altogether.

Figure 5 A textbook task to introduce properties of a triangle (left) and Jong's modified task (right)

The number of cases in which the prospective teachers modified context, condition, and question at the same time was 6 out of 64. Young attempted to modify the condition to complement the weak point of the problem (Figure 2), and in that procedure, she also tried to modify to arrive at a proper context and question (Figure 6). Because she pointed out that the problem in the textbook only treated the direct Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

353

proportion restrictively, she added a condition to extend to the reciprocal proportion. She presented a distribution situation which shows the reciprocal proportion and is familiar to students. In addition, by asking them to share their thinking about the relation of x and y, she tried to make students more explorative.

Figure 6 Young's modified task of the original task in Figure 2

Teacher knowledge

As aforementioned, teacher knowledge can influence how teachers actually set up tasks in textbooks used in classrooms (Henningsen & Stein, 1997). Similarly, when the prospective teachers modified tasks, teacher knowledge of content and pedagogy might affect the direction and process of modification.

According to what prospective teachers considered when they modified tasks, we classified teacher knowledge. When prospective teachers considered the difficulty of the task or misconceptions and interest of students, they demonstrated KCS. When they focused on what example should be given or the way of teaching, they demonstrated KCT. KCC includes consideration of curriculum or the order of the mathematical content, and SCK includes the good usage of mathematical terms, mathematical ideas, mathematical history, and appropriate examples. CCK is related to general mathematical knowledge, and HCK is related to the relevance of the whole curriculum.

Figure 7 shows types of teacher knowledge used by the prospective teachers in the modification process. As can be seen in Figure 7, the prospective teachers used PCK more frequently than SMK; among PCK, KCS and KCT were more often used than the others. SCK among SMK was more frequently used than CCK and HCK. The SCK used by the prospective teachers was knowledge about mathematical ideas, its historical backgrounds, and various representations.

The fact that the prospective teachers used SCK more frequently than CCK indicates that they considered content knowledge as more important for teaching than using only mathematical content knowledge for their modifications. SCK related to mathematical ideas seemed to have an impact on the identification of misconceptions that students might have, and the prospective teachers tried to modify tasks by suggesting teaching methods or procedures to prevent those misconceptions; in other words, SCK might affect KCS and KCT. The prospective teachers, furthermore, tried to modify tasks by applying the historic-genetic principle or asking students to present different representations on the basis of SCK related to historical backgrounds and

various representations. From these findings, it can be clearly seen that content
knowledge is closely related to pedagogical content knowledge. Theme C – K.-H. Lee, E.-J. Le &, M.-S. Park
354
As mentioned earlier, the prospective teachers participating in this study
modified the conditions of tasks more frequently than the context or question. The
types of teacher knowledge that the prospective teachers used to change the
conditions were KCS related to the identification of misconceptions and consideration
of difficulty level, KCT related to teaching methods, and SCK related to mathematical
knowledge for teaching. As can be seen in Figure 1 and Figure 7, therefore, most of
the prospective teachers changed the conditions of existing tasks, and teacher
knowledge types such as KCS, KCT, and SCK played an important role in the task
modifications.
Considering teacher knowledge utilized in the task modifications in this study,
it is noteworthy that the prospective teachers tended to use several types of teacher
knowledge simultaneously to modify one task, rather than using only one type of
teacher knowledge. It is presumed that Korean teachers' high level of mathematics
content knowledge (Park, 2004) might help them activate teacher knowledge, such as
KCS relevant to the difficulty of task and misconception, and SCK relevant to various
representations, good usage of mathematical terms and mathematical ideas.
Consequently, their awareness of this kind of knowledge led them to consider
appropriate teaching methods or strategies. Therefore, it can be said that different
types of teacher knowledge are closely interconnected and influence each other to
activate knowledge. This suggests that an activity, such as task modification, may be
a good way to develop teacher knowledge by encouraging teachers to consider
different types of knowledge at the same time.
Figure 7 The number of teacher knowledge by types that the prospective teachers used
Conclusion
In this study, we examined the types of task modification conducted by the
prospective teachers and the types of teacher knowledge that were activated during
the modification process. By classifying the types of modification into context
modification, condition modification, and question modification, we found that
condition modification was performed at the highest rate. In addition, we found that
when prospective teachers focused on more than two among context, condition, and
question rather than focusing on only one, they modified the tasks in a more
appropriate, richer, and meaningful manner. KCT and KCS were the types of
knowledge that prospective teachers used most frequently during modification, and
they also used SCK at a high rate. However, other types of teacher knowledge were
hardly displayed.
Prospective teachers modified the conditions mostly when they considered
students' misconceptions and difficulty level, and intended to provide students with an Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
355
opportunity to make a discovery. This result is consistent with the highest rate of the
usage of the KCT and KCS teacher knowledge types when prospective teachers
modified the tasks. Also, because cognitive ability is necessary when modifying the
conditions, it can be related to the high rate of usage of SCK.
Prospective teachers who used KCS as their type of teacher knowledge,
especially those who considered students' interest, modified the context. So, when
they focused only on the context, they usually modified the context on a superficial
level by presenting students with a familiar situation. When prospective teachers
focused also on the condition or question along with context, they attempted to
modify by using their KCS, especially the knowledge of misconceptions, and KCT. In
this sense, prospective teachers who focused on more than two aspects at the same
time were able to generate a more meaningful task because they activated various
factors of teacher knowledge.
The number of prospective teachers who modified the context, conditions, and
question all at the same time was not that high, surprisingly. To modify tasks in a
meaningful way by considering all three factors, prospective teachers not only need
KCT, KCS, and SCK but also need knowledge of the curriculum or attempts to relate
to other mathematical concepts. Therefore, the reason that many prospective teachers
did not consider all the aspects at the same time is that they possess narrow
knowledge rather than balanced teacher knowledge.

The Lemon Squash Task
Anna L. V. Lundberg
Upper secondary school mathematics teacher and PhD student at Gothenburg
University
Cecilia Kilhamn
Teacher educator and mathematics education researcher at Gothenburg University
The Lemon Squash Task affords many learning opportunities in
connection with algebra and proportionality. In this paper, we show that
although opportunities are embedded in the task, they do not necessarily
surface when the task is treated in a classroom setting. Depending on the
context in which a task is placed and the knowledge and intentions of the
teacher, the task may contribute to very different kinds of learning.
Modeling real world situations often has its limitations and can, as in this
case, make the problem unsolvable unless it is accepted as a 'textbook
task' disguised as real but adjusted to the norms of school mathematics.
Keywords: textbooks, tasks, mathematics, proportionality, algebra
Introduction
When a mathematics textbook task is designed for school use, it is generally intended
to offer an opportunity to support the learning of some particular mathematical idea.
One branch of research about textbook tasks concerns the tasks themselves in relation
to, for example, creativity (Lithner, 2008) or cognitive demand (Brändström, 2005),
or how tasks appear in the context of assessment such as the TIMSS framework
(Mullis, 2005). Quite often, the way tasks are treated in classrooms is absent in this
research. Additionally, classroom studies often take textbooks for granted and do not
analyse textbook tasks in detail. According to the didactic tradition in the Nordic
countries, most studies assume curricula and teaching materials as the basis for their
analysis and there is a need for content related classroom studies (Klette, 2007). We
argue that few Nordic studies analyse how specific textbook tasks are interpreted in
the classroom and we relate this to the affordances and constraints of the tasks per se.
What happens with the intended learning opportunities of a textbook task when
transposed by the teacher in a classroom setting?
In this paper, we use the term task to mean tasks found in mathematics
textbooks in line with Chevallards' (2006) definition. Tasks are also seen as cultural
artefacts, influenced by the mathematics culture at large as well as by the time and
place in which they are created and used. Tasks are a valuable instrument in
mathematics education, particularly in a textbook intense teaching culture as the one
in Sweden (Johansson, 2006). We seek in the following sections to analyse one
particularly interesting task related to algebra and proportionality found in a Swedish
grade 6 mathematics textbook and try to answer the following questions: Theme C – A. L. V. Lundberg, C. Kilhamn
358
• What are the affordances and constraints of the chosen task?
• How do these come into play when the task appears in the classroom?
We will also discuss how the results of our analysis could be of use for textbook
authors.
Being a teacher and a teacher educator, we take special interest in what types
of tasks appear in the classroom and how teachers use the tasks. We are particularly
interested in proportionality tasks because proportionality has been a new concept in
the Swedish national curriculum for grade 6 since fall 2011 (Lgr11, 2011).
Proportionality and proportional reasoning
Proportionality can be defined in several ways and we chose to define it as a linear
relation such that
- where y and x are magnitudes and a is the proportional
constant. Miyakawa & Winsløw (2009) call this dynamic proportionality, as opposed
to static proportionality expressed as a multitude of equal ratios
%
&

0
1

2
3
.
Proportionality can be expressed as internal or external depending on whether it is a
relation within or between measure spaces, according to Freudenthal (1983).
Proportional reasoning is used to denote reasoning in a system of variables between
which there exists a linear functional relationship (Karplus, Pulos, & Stage, 1983).
The Lemon Squash Task studied in this paper involves a mixture of juice,
sugar, and water. Tasks involving mixing substances in different proportions have
been studied by several researchers (e.g., Mellar, 1991; Noelting, 1980; Nunes, Desli,
& Bell, 2003). These are often called mixture problems by Tourniaire and Pulos
(1985) and differ from rate problems in that the elements in a mixture create a new
object and different quantities are often expressed in the same unit. Tourniaire and
Pulos (1985) also describe three context variables that affect the difficulty of a
mixture task; firstly the mixture as such, being an object where the different parts are
not distinct and therefore more difficult to handle; secondly, it is more easy to
visualize discrete quantities than continuous quantities; and finally, if the context is
familiar the task is often found to be easier.
The Anthropological Theory of Didactics
The Anthropological Theory of Didactics (ATD) postulates an institutional
conception of mathematical activity (Chevallard, 2006). It starts from the assumption
that mathematics, like any other human activity, is produced, taught, learned and
diffused in social institutions, and designed in terms of mathematical organisations
(MO). Knowledge content and form in these activities is a consequence of the
didactic transposition process, i.e. a change or adaptation of a selected existing
knowledge to 'teachable' knowledge. Mathematics treated in school can be analysed
as several types of knowledge (Bosch & Gascón, 2006):
1. Scholarly knowledge;
2. Knowledge to be taught, described in curricular documents;
3. Knowledge actually taught which can be gleaned from the teachers' classroom
discourse and the tasks he or she prepares for the students;
4. Knowledge actually learned.
The MO is constituted on two levels, the 'know-how' and the 'know-why'
related to a given task, and has a praxeology comprised of four components: type of
tasks, techniques, technologies, and theories. The praxis 'know-how' contains types
of tasks to be carried out and techniques to do so, technique being considered here in Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
359
a general sense of 'ways of doing'. The logos or 'know-why' includes technology and
theory (Bosch & Gascón, 2006). In this paper, we focus on the 'know-how' of the
Lemon Squash Task and the transposition between steps 2 and 3.
Contextualised tasks
In a contextualised task, the realistic touch of the question is supposed to increase the
meaning of the task, but it also increases the cultural burden on the student in the
solving process, in light of the task being a cultural artefact (Wyndhamn & Säljö,
1997). Everyday contexts will trigger the use of out-of-school knowledge, everyday
concepts and common sense, but these may not always be applicable. The Lemon
Squash Task is interesting because it entails a switch between everyday concepts and

scientific concepts (Vygotskij & Kozulin, 1986). A contextualised textbook problem
intended to be a 'realistic' problem is, argues Jablonka & Gellert (2007), neither
mathematics nor a real world problem. With reference to the work of Dowling, they
discuss the "myth of reference":
"It is conveyed through problem settings that are constructed mathematically and
only retain a trace of non-mathematical significations. It does not remain possible
for the learner to evaluate the solution of the problems from a practical point of
view."(ibid, p. 2)
The interpretation of a task is also constrained by certain norms of school
mathematics, regulated by the so called didactical contract (Brousseau, 1997).
Method and setting
Data for our analysis in this paper is taken from a larger set of video data collected
within the project VIDEOMAT (Kilhamn & Röj-Lindberg, 2012), a comparative
video study including students from Sweden, Finland, Norway and California about
the introduction of algebra in grades 6 and 7. In each country, 4-5 classes were video
recorded for 4 consecutive lessons. There was no intervention because the aim was to
record authentic instruction and classroom activity concerning introduction of
variables. When looking through the Swedish data, the Lemon Squash Task caught
our interest because teacher-student interaction around the task appeared seven times
in the recordings of one of the grade 6 classrooms. These episodes were selected to
form a case study. In addition to the video recorded lessons, a post lesson interview
was conducted with each teacher; six months later, a focus group discussion was held
with all the teachers where this particular task was discussed.
The choice of analysing the Lemon Squash Task was naturally influenced by
our background as teacher and teacher educator (Goodwin, 1994), and our method of
analysis can be described as "a whole-to-part inductive approach" (Erickson, 2006).
After viewing the seven episodes, they were carefully transcribed, reviewed many
times, and also viewed in groups to establish agreement about the phenomenon.
The Lemon Squash Task in our data was found in the algebra unit in a
commonly used grade 6 textbook (Carlsson, Liljegren, & Picetti, 2004). With the aim
of investigating the transposition of "knowledge to be taught" into "knowledge
actually taught", content analysis of the task as it appears in the textbook was first
made, focusing on embedded aspects of proportionality and algebra, since it appears
in the algebra unit and concerns proportional relationships. The algebra unit in the
textbook spans over 26 pages, including 127 tasks of various kinds. It has a strong
emphasis on the learning of algebraic symbolic language and the meaning of the
terms equation, expression, and variable. There are 6 pages in the teacher's guide on
the algebra unit and an additional 8 worksheets. Tutorial notes are given in general
terms and no guidance is given in relation to any particular task. The text in the guide
concerning the page where the Lemon Squash Task appears is as follows:
"An expression consists of one or more variables written with letters and
sometimes one or more numbers. An expression does not have a fixed value until
the value of each variable is known. That is a big difference compared to an
equation. The letters in an equation have a fixed value and it is that value you find
out by solving the equation. Therefore the letters in an equation are not variables."
(Carlsson et al., 2004, p. 64).
The local curriculum, where the core content is explained in more detail,
states as learning goals for the unit that students should be able to: interpret and write
expressions with variables, work with equalities, and solve simple equations. The
teacher in this particular class is a generalist teacher for grades 4-6. She has been
teaching the class since grade 4 and said in the post lesson interview that she feels
insecure teaching algebra. When she last taught grade 6 three years ago, the national
curriculum did not emphasise algebra until grade 7; so she had actually never taught
algebra as explicitly as she now does, in spite of her 10 years of teaching experience.
The notion of proportionality is part of the national curriculum but not treated as an
explicit topic in the textbook. In this classroom, mathematics lessons consist of a short
whole class introduction followed by individual deskwork where the teacher walks
around helping students when they get stuck. Students work through the textbook unit
at their own pace, which means they are seldom working on the same task at the same
time, a common practice in Sweden (Carlgren, Klette, Myrdal, Schnack & Simola,
2006).
The Lemon Squash Task
The Lemon Squash Task
24
appears in the textbook under the heading "Expressions".
There are two pages where students are asked to write expressions translating from
verbal to algebraic representation, followed by one page with tasks where a number is
to be inserted in the place of a letter in an expression. The last task is the Lemon
Squash Task. A contextualised task like this is a cultural artefact. We believe that the
authors of the textbook chose this context because mixing and drinking this type of
drink, usually called saft, is a common point of reference for Swedish children
25
.
Figure 1: The Lemon Squash Task in the textbook (Carlsson et al., 2004, p. 103), our
translation.

24
We have chosen to use the name "Lemon Squash" although the Swedish name for the task is
"Törstsläckare" which literally means "Thirst reliever".
25
Saft is a Swedish sweet drink, which is close to the British cordial. Traditionally it is made
from juice of berries mixed with sugar and water.
47 You want to mix "Lemon Squash". You have 5 dl
lemon juice, x = 5 dl. How much do you need of
a) water? b) sugar?
48* How much lemon juice is there in 7dl
mixed "Lemon Squash"?

Results
The results will be presented in two parts. First a content analysis of the Lemon
Squash Task is made, highlighting its affordances and constraints. The next section
presents how this task was treated in a grade 6 classroom in a Swedish school.
Content analysis
The Lemon Squash Task presented here includes tree subtasks. The first two subtasks
(47a, b) are both closed questions with a unique solution. Proportions of the three
ingredients are given in symbolic representation in the 'recipe', and the student is
asked to interpret the algebraic expressions x lemon juice, 2x water and x/2 sugar.
There are two ways of solving these tasks. The interpretation of 2x water and x/2
sugar leads to proportional reasoning through a translation into "twice as much water
and half as much sugar as the amount of lemon juice." Translating from a symbolic to
verbal representation gives x a meaning and makes use of proportional reasoning
within the recipe, i.e. how the parts relate to each other. Another solution technique is
to stay within the algebraic representation, exchange x for 5 in each expression and
interpret water as 2 · 5 = 10 and sugar as 5/2 = 2.5. In the second case, it is not certain
that x has any meaning outside the fact that is it to be replaced by a number, and no
proportional reasoning is necessary. The two tasks could be used as an opportunity to
develop proportional reasoning and meaningful interpretations of algebraic
expressions, or to practice the procedure of replacing x in an expression to calculate
the value. Task 48, however, is much more complex involving the total volume of a
mixture of fluids and solid matter. Here we find the first and most striking constraint
of the task, namely the fact that mixing these ingredients in reality and the intended
mathematics content are not aligned. We will deal more with this constraint in the
classroom analysis and the discussion, and for now analyse what we interpret as the
intended mathematical content.
Lemon Squash is made of three ingredients: lemon juice, water, and sugar.
Task 48 gives the proportions of these ingredients as algebraic expressions and the
total amount as a set quantity asking for the amount of water. It can be seen as a
proportionality task by considering how the total number of parts (one batch) is
related to the total quantity. To find out the number of parts in a batch, the algebraic
expressions in the recipe need to be translated into a verbal representation giving x the
meaning of one part. One part of lemon juice, two parts of water, and half a part of
sugar adds to 3½ parts. We then want to find out how much one part is when 3½ parts
are 7 dl. This can be described as an external proportionality where 7 dl:3½ parts = x
dl:1 part, or as an internal proportionality where 1 part· 3½ parts = x dl:7 dl. It can be
solved using different techniques, for example by using number facts (7 is 2 · 3½) or a
cross multiplication algorithm (7·1 = 3½· x). Proportional reasoning in combination
with a trial and error approach is also possible, i.e. if each part is 1 dl the total would
be 3½ dl, but 7 is twice as much as 3½ so each part must therefore be twice as much
as 1. In this case the proportionality is static.
When Task 48 is interpreted as a linear relation, the total quantity
can be
expressed as
· . If a is a scalar operator (Vergnaud, 1988) then
4
· 4
1. We know that 4
1 3½ and we want to find 4
7; we see
that 7 · 3½. In this case the meaning of x is the number of times we need to take
the whole mixture (all the parts) to get 7. However, if a is a function operator, then
4
3½ · and the meaning of x is what quantity I need to take 3½ times to get 7.
In this case, the proportionality is dynamic. Whichever way the linear relation is
interpreted, a graphic representation could be a useful solution technique.
A more primitive example of proportional reasoning is to consider only the
internal proportions among the ingredients and use a trial and error solution
technique. If we have 1 dl of lemon juice, we would need 2 dl of water and ½ dl of
sugar, which adds to 3½ which is less than 7; so we try with 2 dl of lemon juice.
Despite the way proportional reasoning is used, the translation from algebraic
to verbal representation of the expressions presented in the recipe becomes an
essential part of the solution technique. The task can be said to afford different types
of proportional reasoning and different solution techniques, making use of translation
between symbolic and verbal representations.
A different approach to the task is to stay within the algebraic representation
and model an equation by adding the expressions: 2 2 7 ⁄ . Again the
solution technique can either be one of trial and error, or of formally solving the
equation for x to get 2. In this case the task affords the opportunity for modeling
and solving of an equation with one variable. Because the expressions are already
given, the modeling part is limited. No switch of representation is needed, although it
is possible to translate the algebraic equation into a visual or concrete representation
instead of using a formal equation solving procedure.
The Lemon Squash Task involves all the three context variables that often
appear in mixture problems according to Tournlare and Pulos (1985). It is a mixture
where parts are not distinctly visible, it deals with continuous quantities, and students
are familiar with making such mixtures.
Classroom Analysis
The classroom analysis is grounded on the first two episodes where the teacher
explains the Lemon Squash Task to individual students (in total she does it 7 times).
In the first episode, the teacher first misinterprets the task. She points to the recipe in
reasoning proportionally about the amount of water, lemon juice and sugar, and starts
discussing doubling and halving 7. The textbook section is about expressions, not
equations; suddenly the Lemon Squash Task appears, challenging students to make a
mathematical model using an equation. Task 48 seems difficult because there are no
clues in the preceding pages on how to model an equation. Our interpretation is that
the teacher therefore uses the same technique as in the preceding task. She exclaims
"Ah!" when she realises that 7 dl is the total amount, not a part (see excerpt 1).
Excerpt 1:
T: So, then you can first calculate how much, (.)
Ah! it also says seven decilitre of mixed, yes.
[…]
T: and water gives twice as much (.) and it will be (.) mmm in itself. I wonder
if sugar also gives some amount there? (.) I have to think, does it really it's
no amount of sugar it just ends up in the liquid. Eh, this will be seven
together.
S1: mhm
T: something plus something plus something will be seven.
When the teacher has realised her mistake, she considers the modeling of the
task. Knowing that sugar dissolves in water, she contemplates whether it contributes
to the total volume. She wants to use the given algebraic expressions in the recipe but
her experience tells her that sugar dissolves in water and does not increase the
volume. Initially she discards the sugar and considers only the lemon juice and the
water, which means, she needs to divide 7 dl into 3 parts. When she realises that 7/3
will be a long decimal number
be treated as if it did contribute to the total volume in the same way as the fluids
excerpt 2). In fact, the sugar does contribute, but not as m
avoiding the continuous variable, expecting the task to include only discrete numbers.
Excerpt 2:
T: That was a difficult calculation!
S1: mm
T: Wasn't it? It would have been easier if it were six (.
Maybe they count yes eh I think they eh mean that they consider the sugar
to give some amount. Because then I can work it out!
After this the teacher solves the task by translating from an algebraic into a
visual representation, drawing four lines represen

In the discussion, one teacher assumed a simple proportionality of 1 part
sugar, 2 parts lemon juice, and 4 parts water making 7 parts, but without realising that
interpreting the x/2 as one part is not a trivial matter for students. One of the other
teachers said she skipped the task during the algebra unit, using it in a class discussion
about recipes later on.
Discussion
When the teacher starts to explain the task, she uses the recipe in the margin because
she expects the solution technique to be found in the textbook (Lithner, 2008). The
didactical contract says that the task is solvable. The teacher considers the amount of
sugar and how it will disappear in the total volume, but she continues to use the recipe
even if she realises that it is unsolvable. She constructs a model of the recipe using
lines with different lengths and successfully solves the task, subsequently repeating
this solution technique each time. However, the constraints of her model are never
made explicit. The Lemon Squash Task affords many opportunities of learning
proportionality, internal and external, dynamic as well as static, but they stay hidden.
The Lemon Squash Task differs from other mixture problems reported in
previous research literature (Tournlaire & Pulos, 1985), which are often comparison
problems. When making lemon squash, there are three quantities involved (sugar,
water and lemon juice), and these ingredients are in a proportional relation to each
other. If you add more sugar, the sweetness of the lemon squash will increase
proportionally; if you increase lemon juice, the taste will again be less sweet by
proportion. The amount of lemon juice is inversely proportional to the taste of
sweetness because the juice of a lemon is sour. When the mix is blended with water,
again the taste will be weaker. So in order to mix lemon squash, there are both direct
and indirect relations between quantities. In this case the within quantity is taste and
the between quantity is the amount of sugar, water, and lemon juice. As the task is
presented, the sweetness is irrelevant and only the between quantities are focused.
Different mixtures are not compared, but the whole idea of mixing water, juice and
sugar is an implicit aspect of familiarity relevant as a context variable (Tournlaire &
Pulos, 1985) that clearly affects the solution procedure, at least for the teacher.
In this paper we have studied a teacher in the process of transposing the
knowledge embedded in a textbook task into knowledge taught. We argue that the
teachers' interpretation of the Lemon Squash Task is constrained by the context in
which the task is placed and by an existing didactic contract. The task appears in the
algebra unit focusing on the use of symbolic notation. Proportional relations, such as
static or dynamic proportionality, embedded in the task become a background feature
and do not stand out as affordances to the teacher. A relevant solution technique is
expected to be found earlier in the unit and difficult calculations are not expected to
appear in the algebra unit. These features of the didactical contract lead her to discard
her everyday experiences (the sugar does not contribute to the volume) as well as the
scientific concept of volume when she says, "I think they mean that they consider the
sugar to give some amount". She interprets the task as a mathematics task, not a
realistic problem, a common feature in so called 'realistic mathematics' where "The
focus is on the mathematics, not the 'realistic' situations from which the
mathematisation is hoped to be derived" (Jablonka & Gellert, 2007, p. 4). Although
the task appeared in the algebra unit, the teachers found that setting up an equation
was too difficult for the students, so they resigned to working it out using trial-and-Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
365
error. Getting the correct answer became the main goal. Solving it as if it were an
everyday situation became the goal instead of some specific mathematics learning.
We have shown that a textbook task can be seen as a cultural artefact greatly
dependent on the context in which it is placed. Consequently, a task cannot be judged
as good or bad in itself, and the learning opportunities a task designer sees in the task
may not stand out as affordances to the teacher. We conclude that textbook authors
need to elaborate more on tasks in the teachers' guide, making affordances of a task
explicit and include tutorial notes about learning, especially concerning modeling
tasks. The Lemon Squash Task becomes exceptionally difficult because the intended
mathematical relations are in conflict with both the scientific and the everyday
concept of volume when mixing fluids and solid matter. We see it as an unfortunate
choice of realistic context and suggest task designers pay a good deal of attention to
both everyday experiences and scientific validity of the chosen context.

Designing Interdisciplinary Tasks in an International Design Community

Katja Maass
University of Education of Freiburg
Fco. Javier García García
University of Jaen
Nicholas Mousoulides
University of Cyprus
Geoff Wake
University of Nottingham

A major difference between the world of school and the real world is that, in the former, knowledge application to solve problems is clearly connected to a single 'academic' discipline whilst, in the latter, solving problems requires interdisciplinary knowledge application. The gap between these "worlds" provides a challenge, particularly from a materials design perspective. In this paper, a theoretically based design process of a package of ten interdisciplinary tasks and associated interactive resources is discussed. First, the theoretical foundations behind the design process are introduced. Second, our concept of iterative cycles of improvement, with a structured approach to formative assessment, is presented. Finally, results and outcomes from the analysis and implementation of the package are discussed.

Keywords: interdisciplinary teaching and learning, inquiry-based learning, iterative cycles of improvement.

Background: Interdisciplinary teaching in day-to-day teaching

Mathematics and the sciences in school are often taught as isolated subjects. This, however, does not meet the needs of the world of work, which demands integrated, interdisciplinary solutions to complex problems often requiring the use of technology. In consequence, students should not only be prepared for application of knowledge and skills in single 'academic' domains but learn to solve complex real world problems.

Although in many countries school curricula contain some aspects of interdisciplinary learning, particularly across the sciences
26
, in general lessons remain

26
See e.g., the so-called Fächerverbund (Connection of subjects) in Baden-Württemberg, Germany; the new integrated science subject (Advanced Science, Mathematics and Technology) in the Netherlands since 2007; methodological guidelines in the regional curriculum of Andalusia; and new mathematics and science curricula in Cyprus. Theme C - K. Maas et. al
368

mono-disciplinary. In the reality of day-to-day curriculum implementation in schools, there are many obstacles to interdisciplinary approaches to teaching and learning. These include, amongst others, the high degree of organisational work required of teachers (in organising interdisciplinary teaching with their colleagues), training in single disciplinary areas for most teachers, interdisciplinary problems viewed as too complex and time consuming by teachers for their students, and few materials that support mathematics and science from an interdisciplinary perspective. In this paper we present the design work carried out within the EU-project COMPASS
27
, which addressed the issues raised above by aiming to provide teachers with a set of challenging interdisciplinary tasks relevant and usable within day-to-day teaching. Fundamental to the project was the development of new approaches to teaching that aim to motivate learning both within and across the disciplines. Pragmatically, given that there is little official demand for such curriculum in most countries, this required careful understanding of how such an innovation might be motivated in ways that ensure current curriculum demands are met.

Our design community and its aims

The COMPASS design community aimed to develop teaching materials connecting the sciences and mathematics with each other and most crucially with the lives of individual students and their communities. We wanted to foster in young people a desire to learn mathematics and science throughout their lives by coming to realize that such learning is essential if they are to be empowered as active citizens with critical scientific inquiry and problem solving skills. In achieving the above aims, the project focused its activities mainly on designing and developing materials to support teachers with their day-to-day teaching.

The design community was comprised of 15 mathematics and science educators from six countries, geographically spread across Europe (the Netherlands, Spain, England, Cyprus, Slovakia, Germany), ensuring a range of complementary expertise. The consortium included design experts in the fields of interdisciplinary tasks, real-life-based tasks, modeling tasks, and ICT mediated tasks, together with partners having considerable experience in the design and implementation of continuing professional development courses. Further, the expertise of the participants was enriched with stakeholders from school authorities and teachers from schools who contributed to the further refinement of the materials during iterative cycles of improvement.

A theory-based design approach

In this section, the theoretical foundation adopted in the design of the COMPASS tasks is summarized.

Interdisciplinary work

In general terms, "interdisciplinary work" – in relation to science and mathematics – refers to some connection between these 'academic' disciplines. However, there is much debate in the literature about what might be considered interdisciplinary teaching. Many authors base their classification systems on the tightness or looseness of the connection between disciplines in an integrated curriculum. These connections range from no connection at all between disciplines, to some coordination, or to total integration into a new subject (Nikitina, 2006). Geraedts, Boersma and Eijkelhof (2006) mainly consider the context in which interdisciplinary work is established and distinguish between interdisciplinary work implemented at the macro, meso, or micro levels ranging from interdisciplinary work being demanded by curriculum specification to ad-hoc implementation by teachers in their day-to-day teaching). A totally different way of looking at interdisciplinary approaches is proposed by Nikitina (2006) who does not look at the bonding between disciplines but rather at the concrete focus of the interdisciplinary tasks/teaching units. Here, three different ways of doing interdisciplinary work are identified:

- Contextualising, when the material is embedded in a cultural, personal, philosophical or historical context in order to gain a better understanding of the social and cultural development of knowledge.
- Conceptualizing, when core content that is central to two or more disciplines (e.g., change, linearity) are considered, with the intention of going, beyond facts, to the underlying concepts. The goal is to understand essential laws of the world and establish a connection among them.
- Problem-centering, when an ill-structured real-world problem is used as an axis of connection among disciplines. The aim is to generate possible solutions for this problem, bringing together different disciplines.

From this perspective the COMPASS tasks were developed taking a problem centred approach (first major design principle), starting with a problem that is initially ill-structured but situated in a real-world context and of immediate relevance and importance to European citizens. Contexts such as saving energy, environmental pollution, and biodiversity have been used in developing the COMPASS tasks. Our choice of problem-centering as a design principle had a major impact on task design; we envisage that the tasks would have looked quite different if we had chosen to work within conceptualizing or contextualising perspectives. Conceptualising approaches are often taken when developing interdisciplinarity in mathematics and science. For example, proportionality and linearity may be explored from mathematical and scientific viewpoints emphasising scientific principles and applications such as Ohm's, Newton's and Hooke's Laws. Alternatively a contextualising approach would have emphasised connections between mathematics and science and the social and historical situation and not necessarily to strong links between mathematics and science. An example Theme C – K. Maas et. al
370

might involve exploration using mathematics and science of the impact of the recent catastrophe in Fukushima on the policy for atomic power plants.

Inquiry-based learning

Our second major design principle focused on inquiry-based learning pedagogies that we sought to underpin classroom implementation. Inquiry-Based Education (IBE) refers to a student-centered paradigm of teaching mathematics and science, in which students are invited to work in ways similar to how mathematicians and scientists work. Students are guided to observe phenomena, ask questions, seek mathematical and scientific ways of answering related questions (for example, carrying out experiments, systematically controlling variables, drawing diagrams, looking for patterns and relationships, making conjectures and generalizations), interpret and evaluate their solutions, and communicate and discuss these effectively (Dorier & Maaß, 2012).

Added value through the optional inclusion of digital-technological tools

Our work builds on the previous wave of research into use of information and communication technologies (ICT) in science and mathematics teaching, which has focused on the design of pedagogical principles for applications such as simulations, dynamic geometry environments, and spreadsheets (Andersen, 2006; Hoyles & Lagrange, 2009; Linn, Davis, & Bell, 2004). These principles are summarized in the following possible activity triads: Predict, test, explain; Tell, explore, check; Construct, validate, prove; Observe, find a pattern, generalize; Explore, validate, document.

Underlying all these principles (which have also been advocated by software developers and implemented in their systems) is the notion that direct manipulation of abstract representations of concrete objects and phenomena can assist students in exploring and testing out their ideas about the natural world in comparison with the theoretical world of science and mathematics (Hoyles & Lagrange, 2009).

Based on these reflections the third major design principle was that all COMPASS tasks are designed to include ICT that supports inquiry-based learning. A library consisting of nine applets has, therefore, been provided as complementary to the COMPASS materials. The applets have been designed as interactive microworlds, offering idealized, dynamic and visual representations of physical phenomena and experiments.

An example of a task (at the end of several cycles of improvement)

During the project, ten interdisciplinary tasks were developed for students age 14 – 16, each comprising six to eight lessons. Each task is introduced by one overarching question placed in a meaningful, problem-centred context. Tasks could be used following a project-based-learning approach, or a more guided series of lessons in both mathematics and science. Each task is divided into sub-tasks, which are all introduced by guiding questions themselves and allocated to the different subjects (mathematics and the sciences) involved. As an example, the following table gives an overview for one of the tasks Desertec
28
:

28
All tasks are available at http://www.compass-project.eu/ Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
371

Desertec task

Overarching question: To what extent do solar power plants potentially contribute to European energy needs?

Task 1: Science

How efficiently is solar energy converted into
electricity?
Concepts: Solar vs. gas power station, energy
production, energy conversion
Task 2: Mathematics
Solar power plants consist of mirrors with
curved surfaces. These mirrors are constructed
with the help of computer technology.
Imagine you are a constructor: Find a function
that describes the form of the mirrors to be
used for computer-based construction.
Concepts: Parabolas and their construction,
circles, focus point, quadratic functions
Task 3: Science
What are the advantages and disadvantages of
cylindrical/spherical mirrors as compared to
parabolic mirrors?
Concepts: Spherical mirrors, parabolic
mirrors, reflection of light rays
Task 4 – Mathematics
Can a power plant like Desertec really provide
15% of the energy needed in Europe by 2050?
What surface area of mirrors would be
needed?
Concepts: Area, proportional reasoning
Task 5 – Science
How can the energy be transported?
Concepts: Alternating current, continuous
current
Returning to the overarching question: Can solar power stations in the desert – such as the
Desertec project – make a meaningful contribution to the energy needs of Europe?
All materials include pedagogical guidelines and explanations for teachers, in
addition to worksheets for students. Moreover, for most of the tasks, interactive
software in the form of applets have been designed so that students can inquire about
important aspects of the task with a focus on developing important conceptual
understanding. For instance, the applet in the Desertec task offers a simulation where
students can inquiry about how mirrors of different shapes reflect parallel sunlight or
beams from focused light sources (see Figure 1).
Fig. 1. Desertec task: interactive applet Theme C – K. Maas et. al
372
Our concept of iterative cycles of improvement with a structured
approach to formative assessment
The design of sustainable and robust materials for use in day-to-day practice was core
to the project objectives. A design that works in the laboratory, or can be used by
experts, may not work in the average classroom (Walker, 2006). For this reason we
studied the resource requirements thoroughly and involved stakeholders in judging the
quality of the design (Walker, 2006) during iterative cycles of design and
improvement. Our process followed Nieveen's (2009) six steps of formative
assessment and improvement to result in the final version of the materials:
a. Analysis of the context: To meet the requirements of the users we carried out an
analysis of the context following a systematic approach based on the
Anthropological Theory of Didactics (Chevallard, 2006). This analysis ensured
careful understanding of the conditions and constraints that might favour or hinder
the use of interdisciplinary approaches to the learning of mathematics and science
across the different nations of the consortium.
b. Screening: Each national design team identified problem contexts relevant, both
at a local community level, and also at a more general European level, that might
allow the development of the core concepts of mathematics and science. Each
team developed a first draft of its chosen tasks working within constraints agreed
by the consortium as a whole, relating to the important characteristics of the tasks
and their structure. Following these characteristics, one national team checked the
tasks of another team and provided feedback.
c. Expert appraisal: During this first cycle of improvement, the first version was
presented to stakeholders from school authorities and schools. They were invited
to comment on the tasks and problems posed during a focus group.
d. Micro-evaluation: In each country a small number of teachers (between 3-10)
read the materials, piloted them and commented on them raising a number of
questions, which lead to a third version of the tasks.
e. Try-out: In each country, about 20 teachers piloted this version in their
classrooms and gave feedback comprising both qualitative and quantitative data to
inform the development of the final version of the tasks.
f. Evaluation of the dissemination: Following Kelly (2009) that design research
should continue to explore models for diffusion of innovation, we implemented
several dissemination activities, including teacher conferences, professional
development courses, newsletters, and other information materials, such as posters
and flyers. The impact of our dissemination activities was also evaluated, in an
attempt to contribute to the design of the materials.
Impact of the steps on the design principles
The design process itself and the feedback that was generated informed a further
iteration in the development of design principles which we outline below.
The analysis of the context showed that competency-oriented curricula have
been introduced in most countries of the COMPASS consortium. Most of these also
include a clear orientation towards interdisciplinarity, suggesting integrated and/or
project oriented approaches. Thus curricula specifications provide favourable
conditions for interdisciplinary teaching and learning, although this is still
underdeveloped in many countries. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
373
Despite this, there are also several constraints that pertain across the
consortium. A major constraining factor is the lack of interdisciplinary tasks in
national tests. This testing is particularly important in England and Germany, where
these tests have a strong systemic influence, but also in the other countries of the
consortium. Testing has a particularly negative effect on the introduction of
interdisciplinary tasks within the teaching of mathematics, particularly because
assessment is often seen as particularly high-stakes in the curriculum.
In addition, day-to-day school systems and practices, such as the distribution
of subjects, the existence of different teachers for mathematics and science, their
initial training or the limited collaboration between them, act as barriers for the
implementation of interdisciplinary oriented methodologies. Further, data from
different studies and reports show that highly structured teaching practices are
dominant, to the detriment of student-oriented practices (OECD, 2009). These act as
difficult obstacles to the introduction of interdisciplinary oriented tasks that follow an
inquiry-based learning approach.
In our analysis, a tension (sometimes even a contradiction) between
curricular intentions and societal demands, on the one hand, and current school
organization and teaching practices, on the other hand, were identified. Teachers can
play a crucial role in the reduction of such tensions.
These insights led to the following design principles:
• The materials are designed so as to signal to teachers a clear vision of
interdisciplinarity throughout the tasks.
• The materials are well-engineered, carefully planned, realistic in terms of
their requirement of time and students' and teachers' efforts, and
optimally adapted to each national context, including supporting an
adequate use of ICT resources.
The screening and the expert appraisal lead to the following more refined
principles:
• A clear reference to the official curriculum specification at the beginning
of the task should be provided, so as to support teachers in deciding
whether or not to use the materials.
• The tasks should offer the opportunity for true interdisciplinary work, but
teachers should also be supported to understand how the whole task,
which would need several lessons, can be subdivided into interlocking
sub-tasks that can be used in separate subjects.
• An overview about the sequence of the required lessons should be
provided.
• The tasks should be written in a way that teachers can use them directly in
their lessons.
• Interesting and motivating guiding questions for students should be
provided for each sub-task.
• The individual tasks should contribute to the solution of the whole
overarching question and the links should be made clear.
• A national adaptation to the specific cultural context of the tasks might be
needed and this should be signalled to teachers.
The micro-evaluation (via formative questionnaires, interviews in workshops
and written reviews) resulted in further revision and again more detailed design
principles, namely:
• A short, yet concrete, theoretical part needs to be included in each
activity. Theme C – K. Maas et. al
374
• The materials need to have clear descriptions of the tasks for students,
including possible solutions, along with pedagogical guidelines for
teachers.
• The materials need to provide a list of mathematical and scientific
competencies addressed in the activities (as to align them with the
curricula which are competence based).
• The materials need to provide suggestions and guidelines for
differentiation.
• Students' worksheets need to be provided separately. The layout of the
materials needs to facilitate their use; it must be ensured that teachers can
differentiate at first glance between student tasks, background
information, solutions, etc.
• The materials need to provide pedagogical alternatives, e.g. for both
teachers who want to follow a very open approach (by giving only the
overarching questions) and those who want to follow a more structured
approach.
Summing up, the initial overarching 'visionary' major design principles
guided early drafts of materials; feedback, following trials of these, led to more and
more detailed design principles to inform the eventual development of final versions
of the materials. A final try-out (step e) suggested that no further improvement
seemed necessary, with the design being considered as complete and the final phase
of dissemination and exploitation process of the materials (step f) being started.
Results of the try-out and evaluation of the dissemination
For the evaluation of the trial of our materials, we used a mixed method-design, using
both qualitative formative questionnaires and quantitative questionnaires in a pre-post
design.
The teachers and the students who participated in COMPASS highly valued
the developed materials. Further, the majority of teachers reported positive attitudes in
using the materials after the end of the project. In the teachers' view, the materials
contained motivating and interesting practical activities and dealt with relevant
problems for society and realistic questions of sustainability. Furthermore, after
testing the COMPASS units, COMPASS teachers showed interest in further materials
for interdisciplinary teaching. However, the degree of satisfaction in relation to the
practicality of use in day-to-day teaching as well as teachers' opinions about how well
the tasks were described was only mediocre. These reactions show what a big step it
is for teachers to include interdisciplinary problems in their daily teaching, bringing to
the foreground, once again, the systemic conditions that hinder the use of these kinds
of activities (mainly through the general organization of schools that supports well
established school subjects). Both student and teacher questionnaires revealed that
teaching had changed towards a more student-centred and application-orientated way
of teaching.
It is difficult to determine the effectiveness of the dissemination and
exploitation of the materials. However, we can claim that the dissemination activities
carried out have been quite successful, although counting participants at an event,
subscribers to a newsletter, the number of distributed flyers, and so on, is not a clear
indicator of the success. The question remains whether that really gives a reliable
insight into the success of the dissemination. For example, more than 250 teachers
from across the consortium nations, but mainly from the host nation Germany. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
375
attended the final project conference. The project may have an impact on these
individual teachers; further 'reach' can be secured by engaging the interest of just one
individual, such as the representative of the Baden-Württemberg school authority,
responsible for the education of all teacher trainers in the region, who attended the
conference and has adopted use of the materials with this group. Altogether,
COMPASS ideas and designed tasks and software have reached more than 9500
teachers through dissemination activities, such as conferences, professional
development courses, video conferences, etc. Website visits, tasks' and applets'
downloads, and positive teacher reactions in workshops and conferences provide us
with confidence that COMPASS interdisciplinary tasks have been well adopted and
are used in various classrooms in a number of European countries.

Enabling Education for Values with Mathematics Teaching

Nitsa Movshovitz-Hadar
Technion – Israel Institute of technology
Yael Edri
Technion – Israel Institute of technology

In the fall of 2007, we conducted a workshop for high school
teachers that served as a spring board for a 3 year multi-faceted study
focusing on the integration of values education in the ordinary teaching of
mathematics in high schools in Israel. This paper is focused on the
guidelines and principles underlying the development of text-based tasks
for the study. Each of them has the potential for contributing slightly to
values education, in addition to the learning of some mathematical topic
of the mandatory curriculum. The paper also includes a few relevant
results of the main part of the study, which included action-research
carried out by 12 mathematics teachers at 8
th
grade who worked with us
for a year interweaving in their regular math teaching various tasks of that
sort.

Keywords: values and math education, personal values, social values,
text-based tasks, action research, thought experiment

Introduction

As in many other countries, the educational system in the state of Israel is
based upon the law of mandatory education (1949) and the law of national education
(1953, am. 2000, 2003). These laws state that education for values is in the forefront
of the national goals of upbringing youth towards becoming literate citizens: some of
them are social values like equity, tolerance, social justice; others are personal values,
such as being rational, achieving, and exhausting one's intellectual potential. In
practice, the study of subject-matter usually takes over, and values education subsides
to a negligible corner, in high school even more so than in primary education. The
majority of the professional teachers, and particularly high school mathematics
teachers, devote their classtime to instruction of their disciplines, and see themselves
exempt from values education. Some math teachers may even argue that this
combination is in contradiction to the "objective" nature of mathematics.
The mandatory curriculum for high school in Israel is centralized, and
includes details about the various subjects to be taught in each grade-school. In the
introduction, there is a statement about the general goals for teaching mathematics.
These goals set the stage for teaching a large variety of mathematics content,
emphasizing that teaching this content should (i) improve students' mathematical
thinking, (ii) provide skills and competency in problem solving, (iii) take into
consideration differences among students' learning styles and capabilities, avoiding as
much as possible students' frustration and failure, and (iv) make students like
mathematics and appreciate its beauty (Israel Ministry of Education, 2012). This
introduction to the syllabus leaves room for interpretation about the place of values
education in mathematics education.
Analysis of formal documents of the ministry of education, the mandatory
mathematics curriculum, and introductions to mathematics textbooks shows that there
is a gap between the legislators' intentions and the availability of means for their
realization. Indeed, it is well known that knowledge impartation, particularly
preparation for the matriculation exams, take precedence, in most cases over
education for values.
We challenged the possibility for combining values education with
mathematics teaching in a multi-faceted research study (Edri, 2010)
29
. This is a
further step along the line of research initiated by A. Bishop (1988, 2008), who
offered a theoretical model of values in mathematics education, and by Harmin,
Kirschenbaum & Simon (1973) and Shechtman (1980) who offered a model of three
levels of teaching for Clarifying Values Through Subject Matter. The basic drive for
this study stemmed from the a-priori assumption that if a possibility for combining
values education with mathematics teaching exists, it is necessary to exhaust it.
The Basic Idea
Basically there are three settings in which each secondary school teacher
treats values education:
1. As a role model (not necessarily in class, but also in the courtyard, during a
fieldtrip, in a preplanned personal meeting, or a meeting by chance). Teacher's
personal norms are the basis for the education s/he gives at such settings.
2. As a classroom manager, regardless of the discipline the teacher is supposed to
teach. A mixture of different methods of classroom management and personal
norms of the teacher, which usually come from personal background, gives rise to
values education at this level, for example, teacher's tolerance to differences in
level of achievements among students, teacher's culture of listening to others,
teacher's respect to time, etc.
3. As a subject matter teacher, utilizing the curriculum as a lever to education for
values. Surely, teacher's personal norms are reflected here, but along with that the
discipline itself, in our case mathematics, has a crucial effect on the selection and
exploitation of the opportunities that the discipline allows for values education.
The first two settings are common to teachers of all school subjects. The
third is dependent on the specific discipline and the opportunities embedded in it for
values education. In this paper, we focus on the third setting, addressing opportunities
for values education from within mathematics. Needless to say, in practice it is
inconceivable to separate the three settings, as they naturally complement each other.
Hence, it is a matter of emphasis and priority that we put on the third one.
The study

29
Partial support was granted by the Israel Science Foundation (Grant No. 1180/08), the Levi Eshkol
Foundation of the Ministry of Science, the Ministry of Education, and Technion Research Fund.

A preliminary enquiry through interviews with mathematicians and
mathematics educators, and through written questionnaires administered to
mathematics teachers, and the top percentile graduates of the educational system,
revealed various ways these populations perceive the relevance of values education to
mathematics and its learning/teaching. The common thread among these groups,
representing an accessible sample of the literate society in Israel, was skepticism
about the feasibility of connecting the two. It is noteworthy that many of the high
school mathematics teachers considered it important to combine values education
with the teaching of any subject. However, they found it difficult to connect it to their
own subject-matter and cumbersome to intentionally do it in mathematics teaching,
beyond the role-model each of them obviously plays as an adult human being who
manages a mathematics classroom. This enquiry also revealed that personal values,
such as critical thinking, accuracy, and persistence, are mostly perceived as inherent
to mathematics instruction, whereas the social ones, such as tolerance, social justice,
and empathy, are perceived as not inherent to it.
In the professional literature, we were able to find some less sceptical views:
Because mathematics is a discipline that nurtures common sense, it has the potential
for education for values (Bishop, 2008; Ernest, 2004; Vinner, 2009) including to
social ones (D'Ambrosio, 1990; Gutstein & Peterson, 2006; Osler, 2007; Taplin,
2009; Voss, 2012). Despite the risk, our study originated from the hypothesis that
embedded in the mathematics curriculum is a potential not only for personal values,
but also for social values education. If this is indeed the case, ways must be found to
exhaust this potential. We found some support to this hypothesis in a number of
examples given by Mistrik &Thul (1997), Gutstein & Peterson (2006), and later on by
Taplin (2009) and by Voss (2012).
The first stage
To start, we conducted a thought experiment, in which an analysis of the syllabus was
carried out to identify places in the curriculum suitable for linking to various values.
This search yielded "The values-annotated math curriculum". This work was based
upon the following guidelines established in a workshop that took place prior to the
thought-experiment:
• Replacing the context of 'word problems' (keeping the underlying mathematical
model) so that they can yield, beyond the mathematical solution a discussion that
has bearing on values, such as environmental conservation and protection,
preventing drugs, smoking and drinking, and more.
• Linking mathematical concepts and terms to values (e.g., equality, inequality,
true vs. false statement, identity, negative and positive numbers, rational and
irrational numbers).
• Assigning higher level tasks and training students to persist in solving harder
problems, to join their effort, to collaborate in solving difficult problems, to not
give up easily, to seek and experience the fulfilling intellectual satisfaction
attained by a solution reached following an investment of effort.
• Providing education for life in a democratic society through mathematics:
- Axiomatic systems can be compared with The Constitution. Acceptance and
follow-up, rather than argue and quarrel.
- Laws /rules/mathematical theorems can be employed as a springboard for a
discussion of values in a more general way - distinguish between lawful and
unlawful actions, observing mathematical laws prevents mistakes, and Theme C – N. Movshovitz-Hadar & Y. Edri
380
observing civil laws prevents other trouble. A law in a democratic society is
accepted by the majority and can be changed by the majority; in
mathematics, there is no democratic vote, there is a proof.
- Connecting mathematical actions to parallel ones outside of mathematics For
example, in court there is a demand for a proof for any claim; in court, a
proof is only beyond a reasonable doubt. In mathematics, a proof stands on
logical basis; once proven, a theorem ("verdict") cannot be reopened for
consideration (although there is always room for purification of the proof
itself).
- Conflicts and conflict resolution among friends, siblings, rivals or political
parties can be brought up following tasks focused around mathematical
paradoxes. Emotions, such as frustration, can be reflected. Accepting
differences in opinion as a basis of friendship without forcing a consensus, as
opposed to the necessity to resolve cognitive conflict and mathematical
paradoxes resulted by some hidden errors.
- Encouraging debate in mathematics through tasks involving paradoxes is a
challenge in itself. What is right and wrong in mathematics is not determined
by a majority vote.
- Freedom of thought with tools and limitations linked to such tasks. There can
be distinction between random actions and arbitrary choices, action based on
intuition or on rational explanation.
- The ability to reason logically and the power of being rational, rather than
emotional or impulsive, in explaining your stance and in drawing
conclusions.
- Accountability is another important issue that can be integrated.
• Using a clear and accurate language orally and in writing can be linked to
learning mathematics. More precisely, the ability to define clearly a concept, and
to sequence logically a chain of arguments which follow one another, can be
enhanced through mathematics. This includes:
- Alternative (equivalent) definitions
- Finding "holes" in arguments presented by others (in a civilized manner),
- Responsibility for accurate wording, and liability
- Elaborating on idioms in the language borrowed from mathematics. For
example, "Squaring the circle" (for an impossible mission), "They have a
common denominator" (for comparing two issues), Two things are
"orthogonal" to each other (meaning cannot go hand in hand) or parallel (go
hand in hand but never meet), "This is an axiom" (meaning - one should
accept it as true)
• Bringing up human values, such as equity, freedom, determination, and modesty,
through interweaving stories about the lives of mathematicians and the history of
mathematics that have to do with values. For example:
- The life story of some female mathematicians, for example, Sophie Germain
(1776-1831) who used the pseudonym of a man, Anthony La- Blank, to find
her way among the mathematicians of the time and win their respect. Such
stories can lead to a short discussion about gender these days, and about
"masculine" vs. "feminine" professions.
- Cartesian coordinate system leads naturally to Rene Descartes. He was a
sickly child and his parents let him get up late in the morning and stay home
a lot. He used it to think and create mathematics. He is quoted as saying: "I
prefer truth over beauty." He dealt with the difficulties and even managed to Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
381
create despite the difficulties. He was known as a humble man who lived a
Spartan life but never criticized others for having a different life style.
• Addressing matters inherent to teaching, particularly to the teaching of
mathematics, that teachers need to be aware of, to emphasize during the teaching
process, and to leverage explicitly or implicitly to values education, such as:

- Self-confidence and lack of it, the freedom to make mistakes and learning
from a mistake, acknowledgement of potential ability, patience and
tolerance, consistency, persistency, self-control, delayed gratification,
intellectual courage.
- Express feelings of anxiety and fear of failure in mathematics and compare
them to similar feelings in students' lives. Hope and despair, frustration and
joy of achievement, a sense of power and confidence versus inferiority - how
do you deal with them?
- Exceptions, such as the prohibition of division by zero, can be linked to
treating exceptional cases in society.
- Quantification of the size of an error (in learning statistics) can be linked to
the courage to speculate, to guess, to take the risk of mistake. (The freedom
to err is the freedom to learn.)
- Unexpected solutions to a mathematics problem or some other mathematical
surprises can be used to talk about situations in life where a problem was
solved unexpectedly, the joy of discovery.
The next stages
The second stage was a development of 23 exemplary text-based tasks that teachers
would be able to assign to their students while teaching mathematics in the 8
th
grade.
In the main part of the study, 72 experimental lessons were taught in 7 high schools
by twelve 8
th
grade teachers who applied some of the exemplary tasks in their classes
and created more tasks inspired by the exemplary tasks and following the guidelines.
The rest of this paper is devoted to 3 of the 23 exemplary tasks. An intentional effort
was made to keep the part of values education limited to a small part of the
mathematics lesson, so that progress in teaching and learning the mandatory
mathematics curriculum would not be harmed as a result of assigning these tasks to
the students.
Sample Task 1
This task is basically a word problem. At the mathematical level, it is a
practice task in basic calculations of percentage rate adapted from a common
textbook, by changing the context and adding two parts -- no. 1 and 4, which add the
values education aspect (see below). At the values education level, the goal is to
educate for social equity by raising students' awareness to an affirmative action taken
by the government of Israel to promote appropriate representation of minorities in the
civil service. Theme C – N. Movshovitz-Hadar & Y. Edri
382
The Task
30
In 2007, minorities (Arabs, Druze, and Circassians) were one fifth of the
population in Israel. Despite this, only 6.2% of all civil service employees in this year
were minorities. Over the years, the Israel government has made decisions (in 2004,
2006, and 2007) to promote suitable representation of minorities in the civil service,
setting 10% as a target for the percentage of employment of minorities in the civil
service.
1. What do you think about the goal that was set by the government?
2. The Ministry of Housing and Construction had 741 employees in 2007. Had the
target set by the government been achieved, how many members of minorities
would have worked in the Ministry of Housing and Construction?
3. Twelve employees in the Ministry of Housing and Construction were minorities in
2007. What percentage of all employees in the ministry were minorities?
4. What do you have to say about the two results you obtained?
Integrating Education for Social Justice in the Lesson
The answers to Part 1 varied. Some students explained that because minorities were
one fifth of all citizens, their proportion in the civil service should be 20% which
represented a fifth of the citizens. Other students claimed that people are selected for a
job according to their capabilities, and it may be difficult to find suitable people
among the minorities for some jobs. They maintained that there is no reason to hire a
person who is not qualified only because he belongs to a minority group.
The mathematical solutions of parts 2 and 3 of the task
31
were handled in the
common way, starting by independent student-work, followed by a dialogue between
the teacher and the students to elucidate the particulars.
Responses to Part 4, which was intended to make students aware of the huge
gap between the situation in 2007 and the goal set by the government, indeed gave
start to the social-values-oriented discussion that followed.
In the course of the class discussion, the teacher provoked questions about
the issue of affirmative action for minorities in Israel. For example, the teacher asked:
"Why at all was the government promoting employment of minorities in the civil
service?" There were various answers:
• One student said that the principle of equality among people should lead to
equality in representation of minorities in all areas.
• Another said that the principle of equity among people should be interpreted
as equality in the criterions for hiring for a job.
• Another student said that Arab parliament-members were exerting pressure on
the government to take action in this area to improve the economic and social
status of the Arabs in Israel.

30
The figures in this problem were taken from a report by a parliamentary investigative committee on
the subject of accepting Arab employees in the public service, headed by MP Ahmed Tibi (2008).
31
The mathematical solution to Part 2: 10% of all the employees in the Ministry of Housing should
have been members of minorities, i.e. 74 employees.
The mathematical solution to Part 3: 12 employees constitute 1.6% of all the employees
in the Ministry of Housing. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
383
• Some others claimed that improving the economic and social status of Arabs
in Israel is in our interest, if we wish to live in peace.
• Two girls had a dispute between them: one claimed that promoting equality of
Arabs was liable to harm the interests of Jews in Israel which was established
as a homeland for the Jewish people. The other girl said that when Jews were
a minority in the Diaspora they suffered from injustice; now in Israel, we
ought to give equal rights to the minorities in understanding their suffering.
A few clarification issues were also addressed: What is civil service work?
What reasons could cause difficulties in implementing the government decision to
promote employment of minorities in the civil service?
The task drew students' attention to the question of representation of
minorities in The Ministry of Housing and Construction, and in the government in
general. Nevertheless, in the course of the discussion about these questions, several
related issues came up. One was the kind of work minorities do in Israel. The
discussion diverted to other workplaces: schools, hospitals, post offices, the Israel
Broadcasting Authority, and more. For example, one student mentioned that in this
school an Arab woman worked as an Arabic teacher, and 12 more Arab women
worked as cleaners. Another student said that a few Arab doctors can be seen in the
hospitals, but many Arabs working there are cleaning staff.
The teacher summarized, acknowledging the importance of the discussion
and leaving some of the issues open for further discussion in the future and outside
the mathematics classroom. Then the teacher moved to another activity related to
percentage rate.
Sample Task 2
At the beginning of the chapter on solving linear equations, students were assigned
for homework a Google search or any dictionary/encyclopaedia search of words
related to "equation," summarizing the definition of the words they found.
Students came back to class reporting about the definitions of equator,
equality, equilibrium, equalizer, and more.
The teacher indicated that upon completion of the study of solving
mathematical equations, students would be asked to compare their understanding of
the processes involved in equation solving with their understanding of the related
non-mathematical terms they found.
This final task, which apparently consumes a minimal part of in-class time,
was a trigger for summarizing the mathematical aspects of solving linear equations
from a new perspective and quite naturally opened the door to the discussion of
inequality - gender inequality, racial inequality and even inequality in family
relationships. This discussion also served as a nice transition to the next mathematical
topic – solving linear inequalities.
Sample Task 3
This task is adapted from One Equals Zero (Movshovitz-Hadar and Webb
1998). It is appropriate for presentation either before or after the study of area of a
parallelogram, or earlier when the notion of area is introduced.
1. In Figure 1, four strips of width d are marked 1, 2, 3, 4. They connect
the two parallel lines PP' and QQ'. Which strip has the largest area?
Which one has the smallest area? Theme C – N. Movshovitz-Hadar & Y. Edri
384
2. Copy the parallelogram (2) so that its left side coincides with the left
side of the rectangle (1). Express the area of the parallelogram as a
difference between two areas, and reconsider your response. Would
you now change your mind?
3. Read the following explanation:
Were you convinced? Did reading this explanation change your mind?
4. Share with your peers the feelings this task gave you. Did you feel
that it was unfair to present the task the way it was presented?
5. Would you agree that the freedom to err in mathematics is actually
the freedom to learn?
The teacher can stop the individual activity after part 1 and have a vote or
even rank order the strips by students' votes.
Many students tend to choose Strip 1 as the smallest in area and Strip 3 as the
largest. It would take "Poker-Face Pedagogy" on the teacher's part to let students
continue working on the next two parts. (See more about "Poker-Face Pedagogy" as
related to tasks, in Movshovitz-Hadar, 2011.) This work might put at stake the
students' knowledge about area and hopefully yield a deeper understanding of it. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
385
Nevertheless, some students may feel cheated. Some of them may suspect the teacher
is intentionally misleading them, while actually the teacher is intentionally
challenging the fragility of their knowledge. (See more about "Knowledge Fragility"
as related to tasks, in Movshovitz-Hadar, 1993.) Of course, pedagogically speaking,
there is nothing wrong or unethical in presenting this task or others like it. However, it
is up to the teacher to handle such tasks with care, so as to prevent possible frustration
from creeping in, and exploit the potential opportunity for values education by
moving to parts 4 and 5 of the task.
In part 4, students are asked to express their feelings about the task. Have
their senses ever tricked them? - Hearing some noise that seemed frightening but
proved to be nothing more than a cat; entering a swimming pool and feeling that the
water is much colder than it feels after a few minutes; eating a sweet candy after salty
French fries. Through tasks of this kind, students can become aware of the power of
being rational rather than emotional or impulsive in drawing conclusions. They would
gather that they should be careful about their intuition and about taking what they see
as a basis for decision making too quickly. The value of trusting one's sense of reason
is enhanced as more fundamental than trusting one's intuitive eye-sight.
Emotions such as surprise and frustration can be reflected. This has an
embedded potential for connecting to values education as follows. Students can be
encts ncaged to talk about other incidents of frustration following conflicts which they
encountered or heard about, such as conflicts among friends, siblings, rivals or
political parties. The role of conflict resolution can be discussed and the relief it
brings when it is achieved. Some students may even point at a difference between the
necessity to resolve a cognitive conflict resulting from some hidden mathematical
error or misconception and the unnecessary enforcement of consensus among friends
who respect and tolerate each other despite different political views they hold.
Encouraging debate in mathematics paradoxes is a challenge in itself. This
task brings up the point that right and wrong in mathematics is not determined by a
majority vote. Mathematics has its own tools. Unlike spoken language in which
misunderstandings occur because interpretation often depends on the context, and
may sometimes lead to conflicts and unfortunate incidents, in mathematics there is
very little (if any) room for dispute.
The moral of this task is that the freedom to err yields an opportunity to
learn.
Effect of the Experimental Work on the Teachers
The findings of the study (Edri, ibid) indicated that the teachers' involvement in the
experimentation contributed to their personal and professional development. Here are
a few statements from the reflections of participating mathematics teachers
32
:
…At first, I was very dubious about integrating values education in my
mathematics teaching. Values such as accuracy or intellectual courage, are values
that I could see fit in with mathematics, but social values?!? When I heard about
the study, I thought that if social values were to be integrated, it would be
artificial… Up until now, I never considered integrating values education in the
framework of mathematics lessons at all. I didn't think this could really be done.
It surprised me that it was possible to integrate values such as "social justice" in
mathematics lessons… I thought it could be done only at the margins and only

32
The study was conducted in Hebrew and the quotes were translated to English by the
authors. Theme C – N. Movshovitz-Hadar & Y. Edri
386
indirectly… When I gave the lessons in statistics concerning violence among
students, it opened the way to a lively discussion on the subject… Without my
expecting it, students spoke about personal experiences related to violence…
During our in-service preparation meetings the examples presented to us started to

inspire me… however, when I started employing them in my class, integration of values in teaching mathematics subjects became gradually a second nature to me … the students dared saying to me that my teaching changed, became much more interesting, and relevant to life, and I also enjoyed it a lot… They say that you don't really absorb material until you teach it, and that's exactly what happened to me. Until I experienced activities that combined values education with mathematics in class, I didn't understand how much I could affect the students, and what values discussion could develop around mathematical activity… Today, I make sure to include some task that has to do with values education in almost every lesson I prepare…
Note that all 12 teachers who took part in the study succeeded in integrating personal as well as social values education in their teaching without harming the results of teaching mathematics according to the mandatory curriculum. They attested that their involvement in the experimental teaching contributed to their professional growth and to their personal development as educators.
Summary and relevance to ICMI22 Theme C
In this paper, we focused on a description of sample tasks aimed at integrating values education in teaching subjects from the mandatory mathematics curriculum. The integration is achieved by following the guidelines mentioned at the beginning of the paper into text-based tasks for students, which teachers can adapt to their own classes and teaching style. This was quite a challenge.
Examining the tasks and employing "reverse engineering" analysis
33
, the
following are suggested as the design principles underlying our work on the development of text-based tasks:
1. The tasks are mathematics-curriculum based assignments, which can be completed within the framework of one class period or one homework session.
2. They include a clearly phrased introduction followed by two kinds of short questions: (i) Mathematical problem solving, preferably of exploratory nature or thought provoking nature; (ii) Dialogue promoting questions intended as a vehicle for values clarification through bridging between the contents and student's feelings, views, and behavior (Harmin, Kirchenvaum & Simon, 1973; Raths, Harmin & Simon, 1978).
These questions are sometimes provocative, however "neutral" in nature, so as to allow the surfacing of various personal attitudes about human values and avoid any implicit hints as to "the desired" response. These questions may serve as triggers for a short whole-class debate connected to the mathematical work, but not necessarily in a strict way.
3. The text is carefully expressed so as to avoid in as much as possible obstacles in the form of editorial faults (see more in Movshovitz-Hadar, Inbar, & Zaslavsky, 1987).
4. Tasks can be assigned as individual work, or as group work, for class time or for homework, depending upon the teacher's preference. The teacher's manual

33
Reverse engineering as a tool for validating a goal-oriented task development was introduced in Amit and Movshovitz-Hadar (2011)Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
387
includes recommendations for facilitating and handling values-related discussions, which usually are not an ordinary part of mathematics teachers' background.
The amazing fact that values education can be integrated even in mathematics, a leading rational field, was confirmed by the team of teachers who participated in the experimentation of the idea. Beyond the feasibility of the integration itself, it was also proven that it is possible to do so without lagging behind the mandatory curriculum on the one hand, and on the other hand without harming students' achievements, even improving them in many cases.
As we discussed in an earlier occasion (Edri & Movshovitz, 2009), turning the integration that has been proved possible into a tool regularly used by mathematics teachers is essential, but it will obviously require (i) preparation of suitable tasks for the various age levels and many subjects appearing in the curriculum, and their introduction into textbooks, and (ii) preparing inservice teachers as well as future teachers to use them and possibly invent more of the kind.
The constant search for opportunities to integrate values education in mathematics teaching adds a missionary aspect to the mathematics teacher's work, and justifies the great investment, from which the resulting satisfaction enriches not only the students, but also the teacher.

Designing Interdisciplinary Curriculum for College Algebra
Susan Staats
University of Minnesota, U.S.A.
Jason Johnson
University of Minnesota, U.S.A.
Interdisciplinary curriculum, long viewed as a "best practice" for early undergraduates, is usually delivered through team teaching or learning communities. However, the complexity and expense of these approaches preclude wide implementation. This manuscript proposes an approach to designing supplemental, interdisciplinary curriculum for college algebra textbooks that a single mathematics instructor can deliver. Key elements of the model include an essay and disciplinary introduction co-developed by a mathematics instructor, a disciplinary specialist, and a creative writer; explicit learning goals to limit the responsibilities that a teacher feels for expertise in another discipline; and interdisciplinary homework questions. We discuss a sample module that was designed to engage students pursuing social sciences and human services majors.
Keywords: interdisciplinarity, algebra, modeling, undergraduate education
Introduction
This paper proposes an approach to designing interdisciplinary curriculum to supplement college algebra textbooks. Higher educational leaders in the United States have called for increased interdisciplinary undergraduate education for decades, but its implementation has been relatively uncommon (Ellis, 2009; Leskes & Miller, 2006). We outline an approach to designing curriculum for first-year algebra courses that is authentically interdisciplinary, that is, the curriculum supports learning goals that are significant within the partner discipline as well as in algebra.
Our work takes place in college algebra classes that serve students pursuing studies in education and other human services disciplines, such as social work, family social science, sport management, and human resource development. For most of these students, college algebra is their final mathematics class. Teaching students at the end of their formal educational journey in mathematics poses significant dilemmas of responsibility. Within the framework imposed by the institution, how can a teacher help students strengthen their skills and their sense of purpose sufficiently so that mathematics may remain relevant in their academic work and in their lives?
In addressing this dilemma, we focus our curriculum experiment on connections between algebra and the social sciences and the humanities rather than the sciences (Usiskin, 2003). The curriculum module described below takes the unusual step of linking the algebra of finance with a classic theory in psychology, one Theme C – S. Staats & J. Johnson
390
that students often encounter in an introductory psychology course. Erik Erikson's theory of life stage development holds that people experience identity crises throughout their lives; productive engagement of these crises results in the person's positive psychosocial development. As an uncommon curriculum partner for algebra, psychology provides a useful case for probing the problems and limits of creating interdisciplinary curriculum, more so perhaps, than partnering algebra with a scientific discipline in which the applications are well-understood.
This module is intended to be used as a homework supplement to a college algebra textbook, and so it occupies the curriculum level that Usiskin calls a "lesson" (2003). In this paper, however, we focus primarily on principles of organizing modules so that they support interdisciplinary teaching by a single mathematics instructor. We consider this curriculum as a type of task that is designed according to specific principles and that creates a non-traditional learning environment (Becker & Shimada, 1997).
Staats is an associate mathematics professor in the College of Education and Human Development (CEHD), University of Minnesota, USA, where she teaches college algebra and interdisciplinary seminars, primarily to undergraduates enrolled in education and human services fields of study. One of her research strands involves designing interdisciplinary algebra curriculum and analyzing student reactions to it (Staats, 2005, 2007; Staats & Robertson, 2009). Staats' doctoral degree is in cultural anthropology; her experiences teaching with anthropology curriculum influenced her thinking about interdisciplinary algebra curriculum. Jason Johnson is a graduate student studying educational public policy. Johnson taught mathematics at Henry Sibley High School in Minneapolis, Minnesota for nine years, where he became interested in interdisciplinary curriculum development through founding and coaching the school's debate team.
The theoretical background for this experiment in task design is the pedagogy of mathematical modeling and studies of mathematical discourse. Mathematical modeling involves cycles of simplification, solving, interpretation, validation and generalization, or critical reflection leading to improved solutions and methods (Lesh, et al, 2003; Maaß, 2006). The module discussed below is assigned within a college algebra class that is dedicated to modeling. Interdisciplinary writing assignments are presented as a particular style of interpreting and validating mathematical work.
Studies of mathematical discourse also inform this work. Gerofsky (1996, 2004) and Morgan (1998) have detailed ways in which mathematical writing and speaking rely on stylistic and grammatical patterns or genres that may influence the responses that students consider appropriate to offer. The genres of mathematical

writing thus problematize the goals of interdisciplinary learning. In the curriculum
design model discussed here, a creative writer constructs the core essay for the
module, helping to establish expectations that are less centered in one discipline.
Interdisciplinary Math in Higher Education
The Curriculum Foundations study by the Mathematical Association of
America (1999-2001) identified interdisciplinary, team-written curriculum for early
undergraduate mathematics curriculum as a high priority (Ganter & Barker, 2004).
However, typical means of organizing interdisciplinary education are complex,
expensive, and require an enormous commitment from institutions and instructors
(Boix Mansilla, Miller & Gardner, 2000; Burrill & Hernández-Gantes, 2003; Klein, Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
391
1990; Lattuca, Voigt. & Fath, 2004; Usiskin, 2003; Wentworth & Davis, 2002). In a
team-teaching model, two or more faculty members provide instruction on an
interdisciplinary theme to a single class of students. In the learning community model,
all the students who enrol in one class also enrol in a class in a different discipline.
Although both models ensure that students receive instruction from disciplinary
experts, the complexity of scheduling classes, registering students, and achieving an
adequate balance between faculty compensation and generated tuition means that the
best practices for interdisciplinary education are beyond the means of many higher
education institutions.
Strong disciplinary boundaries also make interdisciplinary work challenging.
Instructors often feel uncomfortable leading explorations outside their area of
expertise, particularly in mathematics. Mathematics curriculum may be defined more
rigidly than in other fields (Grossman & Stodolsky, 1995). Mathematics faculties
often have limited professional interactions with faculty in other disciplines (Ewing,
1999). At times, even the philosophical basis of mathematics is held in contrast to the
integrative goals of interdisciplinary education (McGivney-Burelle, McGivney &
Wilburne, 2008; Siskin, 2000). This sense of disciplinary authority and curricular
boundedness can impede the adoption of deeply interdisciplinary curricula in
mathematics classes (Staats, 2007). When the ideal delivery models for
interdisciplinary education are not feasible, carefully-designed, supplemental texts
may empower a single mathematics teacher in a standard college algebra class to
deliver short, restricted units of interdisciplinary content.
Design Principles
Drake (2010) found that teachers often introduce supplemental materials
when their textbooks lack varied activities and when they wish to engage students
with far-ranging needs and interests, needs that interdisciplinary curriculum can help
fulfill. First, an interdisciplinary curriculum clearly must enable students to
demonstrate competency on topics drawn from each discipline. Correspondences
between the goals of interdisciplinary education and several contextual approaches to
mathematics education can further guide development (Staats, 2007). The modeling
approach emphasizes the creative process, critical reflection, and refinement. Realistic
mathematics education seeks scenarios that are authentic and relevant to students.
Social justice approaches seek to create greater awareness of social issues. Each of
these themes -- relevance, awareness of social complexity and taking a critical
perspective on one's own solution -- are key goals of interdisciplinary learning as
well. A supplemental interdisciplinary curriculum for college algebra should also be a
useable module that a single mathematics teacher can deliver. The following design
features help to fulfill these goals:
1. A module is co-authored by a mathematics teacher, disciplinary specialist,
and creative writer.
2. The module core is an "essay," written in any genre, which poses questions or
presents scenarios that require consideration of algebra and another discipline.
The role of the creative writer is to present the interdisciplinary scenario in a
lively and engaging way, and to ensure that the module avoids framing
questions within the ideology of a single discipline.
3. An introduction can convey disciplinary content in more direct fashion than
the core essay. This allows for more expressive latitude for the essay. Theme C – S. Staats & J. Johnson
392
4. The essay is followed by a list of explicit learning goals for both algebra and
the partner discipline. The learning goals help limit the content from the
partner discipline that the mathematics teacher will discuss in class.
5. Homework includes scaffolding questions on algebra and on the partner
discipline, and interdisciplinary activities.
6. The final component is a short bibliography to support further reading by
either instructor or student.
This structure for curriculum writing is modeled in part after a style of
undergraduate curriculum writing that is prevalent in the social sciences. In a typical
introductory anthropology class, for example, students use a textbook which conveys
the course content directly and a reader with case studies in the subfields of cultural,
biological and linguistic anthropology and archaeology. A reading has an introduction
and a case study, either one written as curriculum, or an excerpt from a published
work. This style of curriculum writing allows instructors to present material that
diverges widely from their own specialty. Scientifically-oriented biological
anthropologists, for example, regularly teach about linguistics or symbolic analysis,
perhaps having taken only a single class in this subfield. The case of anthropology
curriculum development and delivery suggests that it is possible for a single instructor
to teach across wide epistemological differences.
In the proposed algebra curriculum project, enlisting a creative writer to
develop the focal essay helps to ensure interdisciplinary integrity. The creative writer
chooses a genre -- fiction, life history, poetry, academic prose, nonfictional
exposition -- that conveys the perspectives, philosophies, and curricular needs of the
two disciplines in a lively way. The essays must invite students to demonstrate
analytical skills in two disciplines, but they should not privilege one perspective over
another. Creating this dynamic tension between different viewpoints and different
ways of organizing ideas is at the heart of the writer's craft and, perhaps, of
interdisciplinary thinking as well.
Mathematics teachers are not expected to be experts in the linked discipline. It
is, however, reasonable to expect mathematics teachers to be able to learn a limited
amount of first-year university-level material and to lead a critical, not authoritative,
classroom conversation based on this reading. Some mathematics teachers do this
when they use newspaper clippings as a basis for mathematics lessons. Some
universities assign instructors from across the disciplines to lead discussions on a
book that all entering students read. These teaching activities are relatively
commonplace situations in which mathematics teachers lead students in discussion of
material outside their area of scholarly specialization. They position mathematics
instructors as lifelong learners who have developed basic intellectual and civic
competencies through the liberal education process that their first-year students are
about to commence.
The sample module that connects financial mathematics to Erikson's theory of
psychosocial development can be viewed at z.umn.edu/icmi22. The core of the
module is a short story titled Indebted, in which a young man wrestles with the
question of how to pay for his college education. The young man visits his
grandfather, who suffers from Alzheimer's disease and lives in a nursing home. The
grandfather hoped to contribute to his grandson's education, but instead, he was
obligated to use his life's savings for his own health care. The young man considers
mathematical scenarios associated with indebtedness, such as rapidly rising college
tuition and the per capita value of the national debt. Finally, he uses an elegant writing
pen, a gift from his grandfather, to sign his college loan papers. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
393
Relevance in K – 12 Settings
In primary grades, interdisciplinary learning is often experiential, sometimes
drawing from the foundation of community knowledge. For example, an elementary
school in Arizona explored a wide range of mathematical, environmental and literacy
topics by creating a class garden (Kahn & Civil, 2001). These active lessons are
sometimes called predisciplinary curriculum (Applebee, Adler, & Flihan, 2007, p.
1005). The interdisciplinary activities in this design model could certainly suggest
experiential or ethnographic activities. Students could educate peers on financial
literacy through social media, record a financial life history of an elder in the family,
or interview adults about their methods of reconciling monthly wages and payments.
Still, the project described here focuses on principles of organizing written
texts for use by individual students. For this reason, it seems to be most applicable in
an upper secondary setting as a bridge experience into university life. The modules
could introduce students to a wider range of disciplines than they would encounter in
secondary school. They would help students reflect on the theoretical foundation of
disciplines, a goal of a recent curriculum reform in Danish schools which calls for the
development of multi-disciplinary learning activities (in contrast to integrated,
interdisciplinary ones) (Andresen & Lindenskov, 2009). Interdisciplinary activities
can also support opportunities to write from a variety of perspectives, including
research-based, persuasive, fictional, or experiential. Overall, this curriculum
approach seems more appropriate for students making the transition to the writingbased academic experiences that are typical of university learning.
In some settings, secondary schools are working towards interdisciplinary
learning in ways that could be enhanced by this curriculum. A case study of 11
interdisciplinary teaching teams serving over 500 students in middle and high schools
found a variety of levels of curriculum integration, from simply juxtaposing subjects
to fully reconstructing the curriculum (Applebee, Adler, & Flihan, 2007). The team
that included a mathematics teacher represented relatively little integration. A team of
9
th
grade teachers developed substantial integration across English, social studies, and
art through the theme of teaching respect and understanding for varied cultures and
peoples. Team members reported a sense of being co-learners as their own
interdisciplinary understanding emerged. They developed interdisciplinary exam
questions together, but many student activities were developed "individually out of
each teacher's sense of the issues shared by the team as a whole" (Applebee, Adler, &
Flihan, 2007, p. 1027).
Portions of the proposed design model would capture some of this intensely
interpersonal work so that it could be shared in new settings or with new team
members. Artifacts of the team's work that would prove useful to others include
learning goals for each discipline, student activities, and disciplinary materials
(corresponding to items 4 – 6 in the previous section). The teaching team's reflections
on the disciplinary ideas that informed student activity could form the introduction of
the module. The focal essay, however, would not develop from the work of the
teaching team in a natural way. A creative writer would have to construct a scenario
that affords consideration of all the subjects.
The structure of the design model might make interdisciplinary learning more
acceptable within the institutionalized curriculum frameworks which are prevalent in
K-12 settings. Teaching across disciplines is at times controversial and politicized. In
Boyle & Bragg's 2008 study of combining curriculum in the U.K., mathematics and
history were taught as single subjects more often than other subjects, even during time Theme C – S. Staats & J. Johnson
394
periods of increasing cross-curricular teaching. The organization of the proposed
curriculum, in particular, listing explicit learning goals for each discipline, may help
empower teachers to justify connections to required curriculum.
The Indebted Module: Research in Practice
Staats has used this module in her college algebra classes over the last three
years, revising components of it at the end of each semester based on the quality of
students' work. This section briefly outlines some of the design choices made during
this research-in-practice (Schoenfeld, 2009). Revisions were governed by four
questions:
1. What format would make this module a usable homework supplement to a
college algebra textbook for an instructor who does not work in an
interdisciplinary program?
2. What types of interdisciplinary questions encourage students to synthesize
ideas from algebra and psychology?
3. What kinds of interdisciplinary questions stimulate students to pose and
answer algebra scenarios that are more complicated than textbook word
problems?
4. What kinds of interdisciplinary questions do students seem to enjoy?
The financial mathematics section of the class textbook (Harshbarger &
Yocco, 2010) was both engaging and frustrating for students. Many students find this
topic relevant and interesting, particularly when problems allow them to understand
the high accumulated interest costs of major purchases, such as houses and cars.
However, many students also find it difficult to decide which equation -- compound
interest, present or future value of annuities, amortization -- to use for different
scenarios. Occasionally a student made a wry comment about homework problems
that presented overly positive scenarios of parental savings for children's higher
education. In the spring of 2009, Staats asked her colleague, Gary Peter, if he would
write a short story that would help students develop a critical perspective on the
financial mathematics section of the textbook. Gary Peter is a literature and sociology
of law instructor who also writes fiction.
The first version of the module, then, was the short story itself. The story
begins:
"For all the important documents in your life," my grandfather said. "Your
marriage license, your first mortgage…you know. A young man about to go out
into the world should have a really nice pen for those things."
As the story progresses, the young man comes to understand his
grandfather's deeply held polarity between hard work and personal debt. He learns of
his own father's financial troubles. Trying to grasp the relative sizes of debts, the
young man calculates his own share of the U.S. national debt. Near the end of the
story, he receives an application for a student loan:
Neither a borrower nor a lender be. Sorry, Grandpa. We all should have listened
to you. But it was too late now.
I picked up the pen, the pen that my grandfather gave me, and signed my name.
During the first semesters of the module's use, several students decided to
model tuition increases at the University of Minnesota. In accordance with revision Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
395
principle 4, we added a small bit of text to the story in response to this student
interest:
Maybe I should just work for a while before college. Save up my own nest egg,
pay for tuition straight up. Less debt. But then I remembered the newspaper
article last month: University tuition increases 3%. Would it be worse if I waited?

This revision to the story was intended to encourage students to consider
modeling debt issues in matters related to their lives.
A mathematical dilemma that has always been present in implementations of
this module is that the underlying mathematics of the formulas for this section of the
class requires consistent payment and interest values. The algebra of geometric series
limits the variety of scenarios that students can mathematize algebraically.
Consequently, students most commonly pose a series of financial problems for
various life stages. At the end of each life stage, the student reconciles the account
and uses the output as the input for another problem. This can assist students'
mathematical understanding because it deepens their understanding of how to choose
a formula that applies in a particular situation, one of the typical difficulties.
However, students typically do not extend the algebraic formula, for example, by
deriving a new equation. In the following semester, we plan to use a spreadsheet
exercise to encourage students in creating more flexible numerical models to
accompany their short stories (revision principle 3).
In the original version of this module, its interdisciplinary character was not
clear. Was it economics, sociology of aging, or literature? Establishing the
disciplinary partner for this story explicitly was a necessary stage in making the
module usable by other teachers (revision principle 1). In the spring of 2010, Staats
asked a retired psychology professor (her mother, Sara Staats of Ohio State
University!) to read the story and comment on any themes that are addressed in an
introductory psychology course. Erik Erikson's model of lifelong identity struggles
seemed to provide an academic means of analyzing the positions of the young man
and of his grandfather. Staats and Staats developed the introduction to the module so
that it became more formally an experiment in linking the disciplines of algebra and
psychology. In this module, because the story was written first, all disciplinary
content had to be placed in the introduction, but in the future, maintaining these as
two separate components will likely prove useful, as well. The introduction provides a
space for explaining framing ideas, and this allows the essay to present focused case
studies and lively exposition. At this point, the learning goals and the scaffolding
questions in algebra and in psychology were also added to the unit. Both the learning
goals and the introduction are written to communicate to the instructor as much as to
the student, to highlight direct disciplinary content as well as the "intentions and
purposes" of the module to aid instructor implementation (Mason & Johnston-Wilder,
2006, p. 28).
Once the introduction and learning goals were added to the module, students
could be held accountable for content in psychology. The introductory material made
it easier to ask students to think about the emotional stories that lie unspoken behind
the assumptions of an equation. Interdisciplinary homework questions were revised to
create thinking around life stage dilemmas, personal relationships, financial
behaviors, and modeling the results of these behaviors. The interdisciplinary
assignments have changed or been refined with almost every semester as Staats
learned more about the scholarship of interdisciplinary teaching and learning. For
example, one of the original questions was: Theme C – S. Staats & J. Johnson
396
When David's grandfather entered the nursing home, the family didn't have time
to develop a different savings plan. What if the grandfather's illness happened
earlier and the family did have time to change their savings plan?
Make up an example in which a family uses two different savings plans to save
for college. Try to estimate how much they will be able to save. You can make
whatever assumptions about income and interest rate that you want, as long as
you state them clearly.
This question prompt was no longer adequate because it did not ask students
to engage a psychological perspective. Each semester, there were always quite a few
students who seemed to enjoy writing fictional stories, and so new interdisciplinary
questions (revision principle 2) asked students to write stories that portray life stage
dilemmas:
Create a character representing a person moving through several of Erikson's life
stages: adolescence, young adulthood, middle adulthood, and senior. Discuss the
identity conflicts that this person experiences in each stage, and describe the
character's financial behaviors, with a sample calculation, for each stage. Can you
create a scenario using a single equation that produces a similar financial outcome
for this character?
The last question in this prompt, "Can you create a scenario using a single
equation that produces a similar financial outcome for this character?" proved to be
problematic. The question asks students to reflect on their story and calculations and
then to create a single equation that would create the same financial outcome as their
series of posed equations. It was inspired by the scholarship of interdisciplinary
teaching and learning that suggests that students should take a reflective stance
towards their solutions, to recognize that alternative solutions are possible. The
question also responded to revision principle 3, as an attempt to create a deeper
modeling orientation in students' mathematical work. In practice, though, most
students ignored this part of the question, a sign that they didn't understand it or that it
was uninteresting to them. They wrote stories that illustrated lifelong identity
questions supported by sample calculations, but only a few students produced a final
"life equation." This question might be more successful if it were separated from the
first one. It could be a follow up question for students to answer after they completed
their stories.
Interdisciplinary question prompts also created a dilemma for students who
wished to write creatively while at the same time demonstrating objective knowledge
of Erikson's theory. Some students resolved this problem by incorporating phrases
from Erikson's model, as when a student wrote in her story, "She was restless, and
had a very difficult time connecting with people, struggling with intimacy versus
isolation." Here, the student draws phrases directly from the essay introduction. Other
students portrayed conflict or life choices less directly, through descriptions of the
characters' relationships.
That same lady is on a bus many years later…at the time she was not aware she
was pregnant with her first child…people were waiting for her, her parents,
brothers and sisters, friends and her best friend…who she knew she loved (but
didn't always know it). Sitting in the sun she realized that she was happy to go
home and meet up with everyone who was missing her.
The woman saved money for her child once a year.
Regular payment =1000, Interest rate = 6%, length of time = 18 years

Characterizing an adequate interdisciplinary synthesis of both algebra and
psychology is an open research question. In this selection, the student poses the
character's dilemma subtly, and leaves it to the reader to acknowledge that this
represents a resolution of Erikson's young adulthood conflict of balancing intimacy
with isolation. The student initially wrote a problem representing monthly deposits of
$1000, and then changed the problem to coordinate with the annual payment schedule
that she posed. She avoided a typical difficulty of understanding the relationships
among variables in the formulas. While the student has arguably demonstrated
disciplinary understanding in both algebra and psychology, the question of whether
the response is an interdisciplinary synthesis is no doubt debatable. To some, the
narrative itself, in which mathematical examples represent the outcome of a life stage
crisis, are evidence of synthesis. Other readers may desire a tighter synthesis. For
example, if the student had explained how the character's choice of annual payment
was connected to her resolution of her relationship with her partner, it might have
achieved a greater synthetic quality.
Conclusion
Textbook word problems on annuities and amortization use geometric series
which assume consistent investment patterns — implied behaviours that are
unrealistic for many people. Setting financial mathematics problems within a
psychological theory of lifelong identity challenges allows students to pose and
answer more realistic and humanistic mathematical questions, and it allows them to
incorporate mathematics into a more personal vision of a human life-span.
Currently, we are developing additional interdisciplinary modules that align
with standard college algebra textbooks, seeking reviewers from disciplines of
psychology and mathematics for this module, and seeking grant funding to allow
classroom testing of these modules. The long-term goal of this project is to establish a
peer-reviewed, open-access website for interdisciplinary algebra curriculum that
would help provide professional recognition for university level teacher-designers
(Wiitman, 1985). Such a website would also allow algebra teachers to incorporate
low-cost interdisciplinary teaching into their classes.
The general, liberal education experiences of an undergraduate degree
program set students on the pathway of becoming lifelong learners who can evaluate
complex social and political questions. Students' instructors, having already
completed this training, can be expected to model this perspective. The project is
based on the assumption that a mathematics instructor can engage many of the topics
of the first-year undergraduate curriculum, not as a disciplinary expert but as a welleducated, thoughtful adult. By asking this of instructors, we can better engage nonSTEM majors, the largest university mathematical audience, and make their last
formal mathematical training more deeply relevant.

Barbara Zorin
MATHBones Pro
Many classroom teachers use the assessment tasks that
accompany their adopted curriculum materials, assuming that these
assessments align with the curriculum. In this paper, we share results
suggesting that these assessment tasks may limit students' opportunities to
demonstrate mathematical understanding and we share a framework that
curriculum designers, researchers, and teachers could use to inform future
development and use of such resources.
Keywords: ancillary resources, mathematical assessment, conceptual
understanding
Introduction
Curriculum materials, specifically textbooks, are an integral part of the mathematics
classroom throughout the world. The nature of textbooks, including the types of
lessons (e.g., inquiry vs. direct instruction) and emphasis of problem sets for student
practice (e.g., focus on procedural skills or conceptual understanding), influences the
opportunities students have to learn mathematics. In addition, the assessment tasks
that accompany those materials potentially provide a variety of insights to teachers
about their students' understanding of mathematics (e.g., ability to complete skills or
engage with mathematical processes). According to the National Council of Teachers
of Mathematics (NCTM) in the United States, assessment that is aligned with the
current vision of school mathematics should provide students "with opportunities to
formulate problems, reason mathematically, make connections among mathematical
ideas, and communicate about mathematics" (1995, p. 11). In particular, assessment
should be "an integral part of instruction that encourages and supports further
learning" (NCTM, 1995, p. 13).
As noted by Valverde et al. (2002), textbooks translate the intended
curriculum of national standards into the potentially implemented curriculum of the
classroom. Thus, textbooks provide evidence for teachers of the recommended focus
of instruction. In the United States, adopted curriculum materials are typically
accompanied by a suite of ancillary materials, including at the minimum a teacher's
edition with suggestions on instruction and assignments, supplementary practice Theme C – D. R. Thompson, P. D. Hunsader & B. Zorin
402
activities, and assessment resources (i.e., unit tests). These ancillary materials are
often used extensively by classroom teachers. In fact, some researchers (e.g.,
Delandshere & Jones, 1999; Hunsader, Thompson, & Zorin, 2012b; Senk, Beckmann,
& Thompson, 1997) have documented that many classroom teachers use the unit tests
accompanying their curricula, often with only minimal adjustments and
modifications.
Assessments that occur as summative measures at the end of a unit of
learning "should promote valid inferences about [students'] mathematics learning."
Given that "an inference about learning is a conclusion about a student's cognitive
processes that cannot be observed directly" (NCTM, 1995, p. 19), those assessments
need to provide opportunities for students to demonstrate the depth of their
mathematical understanding and knowledge. So, an issue for focus in this study
conference is whether curricular assessments have been designed in ways that support
the instructional goals of the curriculum, and by extension national/state standards.
That is, if it is important during instruction for students to engage with mathematical
processes (e.g., reasoning and proof, communication, connections, representation),
then assessments need to provide opportunities for students to demonstrate
performance with those processes. Because tests are often developed at the end of the
design cycle, they are not necessarily given the same attention by curriculum
designers or researchers as other aspects of the curriculum. Consequently, the nature
of such tests may undermine the instructional goals of the curriculum as teachers use
them for gauging students' mathematical achievement, and possibly make incomplete
inferences about the nature of their students' understanding of the mathematics being
studied.
Our perspective on tasks
In this paper, we use the term "task" to refer to the entirety of a unit test designed to
assess students' mastery of the concepts, processes, and procedures of the
mathematics under study. Clearly, an individual item provides insight into a particular
concept, yet no one item can or should be expected to assess knowledge across all
aspects of a concept. By focusing on the set of items comprising a unit test, we are
able to consider what might be lacking from that set of items, an analysis that would
not be appropriate at the level of an individual item. Reviewing comparable analyses
across a set of unit tests for a particular curriculum then provides insight into the
extent to which the assessment tasks for that curriculum focus on important aspects of
mathematical understanding, including both content and mathematical processes.
We have not designed the tasks (that is, the unit tests) that are the focus of
this paper. Rather, we have developed a means to analyze the tasks that accompany
published curricula and have thought about how that analysis can potentially be used
with teachers, researchers, and curriculum designers to improve them. Our views and
the subsequent issues we discuss are based on our detailed analysis of tests
accompanying the elementary grades 3, 4, and 5 (ages 8-10) curriculum from three
different publishers in the United States.
Integrating processes into curriculum and instruction
Skemp (1971) provided a means of classifying instructional tasks as focused on
instrumental learning (i.e., procedural learning) or relational learning (i.e., conceptual
understanding). With the release of the Curriculum and Evaluation Standards for
School Mathematics (National Council of Teachers of Mathematics, 1989) in the Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
403
United States, curriculum materials began to be designed so that both of these types of
learning were explicitly addressed. In addition, the Standards identified not only
content foci (e.g., number and operations, algebraic thinking), but mathematical
processes that needed to be part of both curriculum and instruction, specifically
representation, connections, communication, reasoning and proof, and problem
solving. These processes are essential to students' demonstration of their conceptual
understanding of mathematics. As students explain their thinking, teachers are able to
gain greater insight into their level of mathematical understanding than is possible
solely from the manipulation of procedural skills.
It is relatively straightforward to determine if specific content
recommendations are implemented into the textbooks or ancillary materials, such as
tests. Designers, researchers, and teachers can do a simple checklist to indicate
whether the content is present because evidence of content is explicit. However,
identifying whether the mathematical processes are part of the textbook or the tests is
more difficult because, by their nature, evidence of the mathematical processes tends
to be implicit. Yet, it is through the mathematical processes that students are able to
demonstrate their relational understanding. Without opportunities on assessment tasks
to demonstrate understanding through the mathematical processes, it is often difficult
for teachers to see beyond a surface level what students know about mathematics.
Just because the curriculum and the instruction based on it provide
opportunities for students to engage with the processes, one cannot assume that the
task used to assess mastery of that curriculum (i.e., the unit test) also includes
opportunities to engage with the processes. Indeed, in the United States the
development of ancillary materials is often outsourced to development firms. So,
consumers of the materials, the teachers, may assume that the task provides the same
opportunities for engagement with the processes as is true with the materials
themselves, but this is not necessarily the case. Teachers may also assume that the
task will provide them with adequate evidence about their students' conceptual
understanding of the content to inform future instruction.
In a survey of 43 teachers, mathematics coaches, and mathematics
supervisors in our own state, 81% used the assessments that accompanied their
curriculum and 68% of these reported using them because they ensured alignment
with the curriculum (Hunsader et al., 2012). Furthermore, when asked to indicate the
extent, on a scale of 1 (low) to 5 (high), to which they perceived the tests engaged
students with the mathematical processes, only problem solving (mean = 3.4) and
representation (mean = 3.2) had a rating over 3. But both the ratings and the rationale
for using the assessment tasks accompanying the curriculum are based on perceptions.
What evidence can or should exist that these perceptions are on target? What evidence
would inform curriculum designers or researchers about future design or research
about these tasks? What evidence could be used to persuade teachers to take a critical
and objective look at their assessments rather than assuming that these tasks give
them the needed insight into students' understanding to guide future instruction?
These are the questions we explore in the remainder of this paper.
A framework to guide the analysis and design of mathematical processes
on assessment tasks
As a means to analyze assessment tasks in an objective manner, we developed the
Mathematical Processes Assessment Coding Framework (MPAC Framework) in
Figure 1 to determine the extent to which the mathematical processes were embodied Theme C – D. R. Thompson, P. D. Hunsader & B. Zorin
404
in assessment tasks accompanying published curricula (Hunsader, Thompson, &
Zorin, in preparation).
Reasoning and Proof
N The item does not direct students to provide or show a
justification or argument for why they gave that response.
Y The item directs students to provide or show a justification or
argument for why they gave that response ('Check your work'
by itself is not justification).
Opportunity for Mathematical Communication
N The item does not direct students to communicate what they are
thinking through symbols (beyond a numeral answer),
graphics/pictures, or words.
Y The item directs students to communicate what they are thinking
through symbols, graphics/pictures, or words.
V The item only directs students to record a vocabulary term or
interpret/create a representation of vocabulary.
Connections
N The item is not set in a real-world context and does not explicitly
interconnect two or more mathematical concepts (e.g.,
multiplication and repeated addition, perimeter and area).
R The item is set in a real-world context outside of mathematics.
I The item is not set in a real-world context, but explicitly
interconnects two or more mathematical concepts (e.g.,
multiplication and repeated addition, perimeter and area).
Representation: Role of Graphics
N No graphic (graph, picture, or table) is given or needed.
S A graphic is given but no interpretation is needed for the
response, and the graphic does not explicitly illustrate the
mathematics inherent in the problem. (superfluous)
R A graphic is given and no interpretation is needed for the
response, but the graphic explicitly illustrates the mathematics
inherent in the problem.
I A graphic is given and must be interpreted to answer the
question.
M The item directs students to make a graphic or add to an existing
graphic.
Representation: Translation of Representational Forms
N Students are not expected to record a translation between
different representational forms of the problem.
SW Students are expected to record a translation from a verbal
representation to a symbolic representation of the problem or
vice versa.
GS Students are expected to record a translation from a symbolic
representation to a graphical (graphs, tables, or pictures)
representation of the problem or vice versa.
WG Students are expected to record a translation from a verbal
representation to a graphical representation of the problem or
vice versa.
TG Students are expected to record a translation from one graphical

representation of the problem to another graphical
representation.
A Students are expected to record two or more translations among
symbolic, verbal, and graphical representations of the problem. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
405
Figure 1. Mathematical Processes Assessment Coding Framework.
Source: Hunsader, Thompson & Zorin (in preparation).
The framework focuses on four of the five processes from the Principles and
Standards for School Mathematics (NCTM, 2000); for representation, we generated
two criteria to reflect different aspects of this process standard – the role of graphics
and translation between and among representational forms. We were interested in
analyzing the assessed curriculum as reflected in written tests, without the need to
analyze the intended written curriculum of the textbook or the enacted curriculum of
classroom instruction. Hence, the framework does not address the problem-solving
standard because whether an item on an assessment requires problem solving or is a
routine exercise depends on prior experiences students have had, which would require
analyzing the textbook and instruction.
We have applied the framework to analyze over 100 complete unit tests and
over 2000 individual items across those tests. Table 1 summarizes the extent to which
these assessment tasks (i.e., tests) provide opportunities for students to engage with
the mathematical processes.
Process Standard Minimum % Maximum % Median %
Reasoning & Proof 0 23 0
Communication (yes) 0 85 13
Communication (vocabulary) 0 73 0
Connections (R or I) 0 100 44
Representation (role of graphics: M or I) 0 100 22
Representation (translation of forms) 0 67 9
Table 1. Range and Median Percent of Items Per Assessment Task Addressing the
Mathematical Processes.
Note: The unit of analysis is an entire test.
With the advent of the Standards movement in the United States, most
curriculum materials purport to integrate those standards, both content and process.
However, the results in Table 1 suggest that there is a wide range in the extent to
which the process standards are integrated into the assessment tasks.
How might designers and researchers use this coding framework and
related analysis?
The potential value of this framework is that it provides an objective look at
assessment tasks – either to confirm perceptions or suggest where changes are needed.
Consider the item in Figure 2 cloned from an item on one grade 3 assessment task.
Five friends have 20 pieces of candy to
share equally. How many pieces of
candy will each friend get?
Figure 2. Clone of an Item from a Grade 3 Assessment.
We would classify this item as providing no opportunity for reasoning or
communication because students are simply asked to provide a numerical answer but
not to explain what they were thinking or why their answer is correct. For the role of
graphic, we would classify the item as S because no interpretation of the graphic is
needed to answer the item and the graphic does not explicitly illustrate the
mathematics inherent in the problem. Note that the student does not need to consider Theme C – D. R. Thompson, P. D. Hunsader & B. Zorin
406
the graphic to solve the problem nor could the student make sense of the problem
simply by interpreting the graphic.
A closer analysis of the item raises some interesting issues. Although the
graphic is not needed to answer the item, it does not appear to be random. The
designers did not use a single candy, or 5 or 10 candies. They used the exact number
needed in the problem, and yet, they never explicitly asked students to use the
graphic. Is the graphic there to support struggling students or those who are English
language learners? Is the graphic there because the curriculum encourages students to
use graphics to help solve problems? Is it there simply to liven up the page? Is the
graphic possibly distracting to students who do not need it?
The issues raised by this one item provide potential research opportunities.
One might ask designers why they chose to include this particular graphic but not to
ask students to use it in any way. Researchers or teachers might observe students as
they answer the item to determine how many use the graphic without leaving any
written record of its use as well as how many actually show their solution on the
graphic. Researchers might ask teachers how they perceive their students will attend
to the graphic. Another question might be whether such related, but not needed,
graphics are a regular part of the curriculum and whether this type of use encourages
students to ignore graphics in their mathematics textbook. What might be the
unintended consequences later in students' mathematical careers if they become
accustomed to ignoring the graphics in their curriculum?
Figure 3 adapts the item from Figure 2 in three different ways. How do these
adaptations engage students with the process standards and what further insights into
students' thinking do they provide teachers?
Adaptation 1. Five friends have 20 pieces of candy
to share equally. How many pieces of candy will
each friend get? Write a number sentence to show
how many pieces of candy each friend will get.
Adaptation 2. Five friends have 20 pieces of candy
to share equally. How many pieces of candy will
each friend get? Write a number sentence to show
how many pieces of candy each friend will get. Use
the picture to explain your thinking about the
problem.
Adaptation 3. Five friends have 20 pieces of candy
to share equally. Draw a picture to show how many
pieces of candy each friend will get. Write a number
sentence to represent your picture.
Figure 3. Adaptations of the Item from Figure 2.
Note: Adaptation 3 from Hunsader, Thompson, & Zorin (2012b).
Adaptation 1 does not resolve the issues about the use of the graphic raised in
the discussion of Figure 2. But having students write a number sentence does provide
insight into what they were thinking. So, when students write a number sentence to
translate the problem from words to symbols as part of the solution, they
communicate what they were thinking and give teachers more insight about their
understanding than simply providing the answer 4.
Adaptation 2 explicitly asks students to use the graphic to explain their
answer, thus requiring them to interpret a graphic in the sense that the student must
illustrate a solution on the graphic. Hence, this adaptation engages students in both Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
407
communication and reasoning by having them show what they were thinking (e.g., the
number sentence) and why they gave that response (e.g., the solution on the graphic).
Adaptation 3 also engages students in both communication and reasoning,
while also requiring them to make a graphic to illustrate a solution. Thus, Adaptation
3 extends the requirements of Adaptation 2 so students independently demonstrate
their ability to connect verbal, symbolic, and visual representations of a problem.
All three adaptations have the potential to provide teachers insight into
students' conceptual understanding as well as the procedural understanding expected
from the original item. To some extent, there is also a sequence to these items so that
researchers could investigate whether achievement varies for different versions of the
item and different explicit references to use of the graphic.
If the original item (Figure 2) were the only such item in a set of items
comprising an assessment task, one might overlook the apparent haphazard use of
graphics or the lack of explicit engagement with the process standards. After all, no
one expects every item on an assessment task to integrate one or more of the process
standards. However, if such items are the norm on a given assessment or are the norm
across assessments, as suggested by the results in Table 1, then consumers of those
tasks might rightly question whether the task is providing the insight into students'
mathematical thinking and understanding that is expected from an assessment. Thus,
the framework and analysis can help curriculum designers ensure that assessments
maintain the same focus on processes as they design into their curriculum.
Researchers can use the framework and analysis to understand how variations of
items might enhance student achievement.
How might teachers and teacher educators use this coding framework
and related analysis?
Classroom teachers might be encouraged to use such a framework and the
analysis it provides to better understand the nature of the assessment tasks they use
with students. As indicated previously, teachers often use the assessment tasks that
accompany their curriculum because they assume such assessments are well aligned
to the textbook. Thus, having them reflect on the nature of these assessments can be a
powerful influence on their future practice.
For instance, after we have worked with practicing or prospective teachers to
help them recognize the need for more mathematical discourse in the classroom and
for use of the mathematical processes, we have had them analyze several items or
tests associated with their curriculum. The results typically lead to a stark reality –
there is often little or no integration of the process standards. Although the
assessments clearly relate to the content of the related unit, opportunities for
reasoning, communication, representation, or connections may be limited. Teachers
then consider how they might adapt some of the items comprising the overall task so
that opportunities to engage with the processes are more evident. The potential impact
of such work with assessment tasks is reflected in the following comments from
teachers:
"The [MPAC] framework reminded me to consider areas of the problem that I
sometimes overlook."
"…actually doing the test item analyses really made me think outside of the
box in how I would teach students about math and assess them."
"[The experience] will greatly impact my formulation of chapter tests in
mathematics when I am a teacher." Theme C – D. R. Thompson, P. D. Hunsader & B. Zorin
408
Conclusion and relation to the study conference
Obviously, the design of assessment tasks to accompany a curriculum can
only occur after the curriculum has been designed. At that point, there may be fewer
financial resources available for development, or assessments may not have been the
intention of the designers but are required for commercial publication. Our analysis of
assessment tasks from three different elementary publishers found some variation
across publishers, content domains, and grade levels, but the overall pattern was
consistent – connections (i.e., real-world problems) were moderately integrated into
assessment tasks, but other process standards were less so. Subsequent analysis of
tests associated with U. S. middle grades curricula has found a similar pattern.
The issues raised in this paper suggest that more attention needs to be paid to
the assessments associated with curriculum, particularly if those assessments are used
to judge the effectiveness and quality of a curriculum and to make inferences about
the student learning that such a curriculum facilitates. If the curriculum and the
assessments are not aligned in terms of the process standards, then accurate
information about learning is not obtained. Consequently, teachers may have an
incomplete picture of their students' mathematical knowledge as they design future
instructional tasks. They may assume students have a depth of knowledge about
mathematical concepts that is not supported by the type of performance elicited on the
assessment tasks, and thus fail to develop appropriate instruction to extend or enhance
mathematical knowledge.
One issue for the study conference to address is how research such as that
described here can or should inform future curriculum designers and the next round of
curriculum revision. A second issue is how to ensure that all aspects of the curriculum
cycle – textbook or material development, instructional implementation, and
assessment tasks – are aligned and receive equal attention in the design process.

Different features of task design associated with goals and
pedagogies in Chinese and Portuguese textbooks: The case of
addition and subtraction
Sun Xuhua
University of Macau, China
Teresa B. Neto
University of Aveiro, Portugal
Loudes E. Ordóñez
University of Jaén, Spain
This paper presents different features of task design for addition

and subtraction in Chinese and Portuguese textbooks and their different goals and pedagogies. Through comparison, we address the question, "what is the effect of different cultural backgrounds on tasks and task design for addition and subtraction", and propose some conjectures that arise from answers to this question.
Keywords: variation theory, example and exemplification, addition and subtraction, Chinese mathematics education, textbook design, Portuguese mathematics education

Introduction

China has a clear textbook-centred tradition. Textbooks play multiple functions in the Chinese mathematical education system, such as tools for teachers` professional development by studying textbooks (e.g. Ma, 1999), self-learning instruments for out-of-school learners, and the main medium for teaching and learning in the classroom. In these ways, textbooks play a central role in shaping students' learning and teachers' teaching through their central role in the interactions of local groups of teachers and academic organizations. Although Chinese textbooks play a critical role in schooling, it is worth noting that Chinese textbooks are designed by local experts based on their experience and local curriculum standards. Principles of task design are generally not explicitly articulated. However, Marton (2008) has identified a specific implicit underlying principle of task design in Chinese culture as expressed in the following words:

There is a very powerful pedagogical tradition in the Chinese culture. The careful molding of 'the space of learning', the blending of necessary different components of learning and of different ways of supporting it, might occasionally run counter to the ever shifting pedagogical fashion. But what is proven to work well in practice and what is theoretically not only defensible, but even positively implied, should not be replaced, but developed further. ...Chinese students do very well when compared to students from other cultures. Teachers spend much more time on planning and reflecting than teachers in other countries, and they develop their professional capabilities by the teaching, in which patterns of Theme C – S. Xuhua, T. B. Neto & L. E. Ordóñez
410

variation and invariance, necessary for learning (discerning) certain things, usually brought about by juxtaposing problems and examples, illustrations that have certain things in common, while resembling each other in other respects. By such careful composition, the learner's attention is drawn to certain critical features and each problem and example make a unique contribution to the things that the learner will hopefully pay attention to in the future, instead of just going through problems that are supposed to be examples of the same method of solution. (p. 1)

These principles were expressed and illustrated by Liu (2004). More recently, Sun (2007, 2011) indicated that two kinds of problem variation (变式题) could describe these features of example design in China: OPMS (One Problem Multiple Solution methods) and OPMC (One Problem Multiple Changes), both of which are local routine teaching terms,. Liu's examples were concerned with absolute value, and Sun's with division of fractions. In the present paper, we compare textbooks from two countries using the question "what varies?", and ask whether this is helpful to identify differences in the space of learning.

According to variation theory (Marton & Booth, 1997), which emphasizes "simultaneity," the "one-thing-at-a-time" design might miss the chance to discern critical aspects among two or more topics. More importantly, the contemporaneous variation approach, to a greater extent, emphasizes "general relationships" more than others. Thus, problem variations aim to discern, compare the invariant feature of the relationship among concepts and solution methods, and provide opportunities for making connections; comparison is considered the pre-condition to perceive the structures, dependencies, and relationships that may lead to mathematical abstraction. The emphasis on "general relationships" reflects the soul of variation theory, emanating from the work of Marton, who argues that "learning will take place through discernment of variation in simultaneous events"; "variation is a necessary condition for effective discernment" (Bowden & Marton, 1998, p. 35).

As mentioned before, Chinese teachers are required to study textbooks intensively (研究教材) and this is regarded as an important method for professional development. Textbooks, together with their teachers' guidebooks and a professional research group (Yang, 2009), are the predominant force in a teacher`s professional life. This professional development environment is rarely known outside of the Chinese community, so to study the detail of design in textbooks is a strong proxy for studying the way content is shaped through professional development. In this study, we explore how example design, and the associated curriculum standards and reference books, might influence teachers' teaching, and hence, the space of learning... For comparison, a Portuguese textbook and teaching guide are used as a "mirror". The research questions of this study are:

What are the different features of task design in the topics of addition and subtraction within Chinese / Portuguese textbooks?

How might features of task design in textbooks influence the space of learning in Chinese / Portuguese classrooms?

We focus on a Chinese textbook (Mathematics Textbook Developer Group for Elementary School, 2005) that has been used for over 30 years by the majority of Chinese students from diverse backgrounds. It represents the Chinese national curriculum and is seen, with its teaching guide, as an authoritative guide on what to Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
411

teach/learn. However, all national examination problems are required to be "from textbooks, but above textbooks"; hence, the material is supposed to extend knowledge beyond the procedures that might be carried out in the textbook. The Portuguese textbook (Gregório, Valente, & Calafate, 2010), with supporting teacher guide (similar to the Chinese teacher guide in that it informs teachers about appropriate goals and pedagogies), reflects typical practices of teaching and learning these topics at this level in Portugal.

Different features of task design for addition and subtraction within Chinese /Portuguese textbooks

The content structure of Chinese textbooks is fixed. The organization is consistent without repetition:

• knowing numbers 1-5 as a foundation, then knowing addition and subtraction from 1-5;
• knowing numbers 6-10, then addition and subtraction from 6-10;
• knowing numbers 11-20, then addition and subtraction from 11-20;
• knowing numbers within 100 (1000,10000), then addition and subtraction algorithms within 100(1000,10000), step by step.

Invariant concept vs. variant concepts embedded in Chinese / Portuguese textbook examples

Addition and subtraction are almost always elicited together in examples of OPMC in the Chinese textbook
34

, rather than separated in different chapters as they are in the Portuguese textbook. The two concepts of addition and subtraction are always connected by problems with variation. Here are two typical "prototype" examples of OPMC in the Chinese textbook.

34

In Chinese, OPMC references "changes"; in English, variation theory would likely use the word "transformations" to mean the same thing. Theme C – S. Xuhua, T. B. Neto & L. E. Ordóñez
412

Fig.1 from Mathematics Textbook Developer Group for Elementary School, 2005, 68

Fig.2 from Mathematics Textbook Developer Group for Elementary School, 2005, 57

It is interesting to note that the Chinese textbook authors did not separate the subtraction concept from the addition concept, even in the first lesson (Sun, 2011). Figure 1 shows a paradigmatic example of problem variation: 10+3=13, 13-3=10, 3+10=13; 13-10=3.The problem set intends to help learners recapitulate the relationship between addition and subtraction, and the meaning of "equal". The textbook design offers visual models enabling learners to understand the underlying additive relationship.

Every example in the Portuguese textbook introduced the concept of addition and subtraction without any connection, and without a visual model to situate the problem. The pages below are from two separate chapters. Addition and subtraction concepts are introduced as counting in the following examples. While the number line model provides a method of calculating the answers, it is unclear whether it enables learners to use the underlying meaning to connect addition and subtraction.

Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
413

Fig. 3 The example introducing addition concept by counting in one of the Portuguese textbooks (Segredos dos Números 1, Matemática 1º ano o Ensino Básico, 2010, p. 75)

Fig. 4 The example introducing subtraction concept identifying inverse operation in one of the Portuguese textbooks (Segredos dos Números 1, Matemática 1º ano o Ensino Básico, 2010, p. 76)

Although the Chinese textbook authors appear to use multiple concepts in every example, the underlying invariant concept is of part-part-whole relations and the tool being used is knowledge of numbers. –In contrast, the addition examples in the Portuguese textbook use multiple underlying physical concepts, such as "counting" (as in Figures 3 and 4), "combining", and "adding". The subtraction examples in also use multiple concepts such as, "taking away", "comparing", and "identifying the inverse operation of addition" but they do not relate these to the addition concepts in any direct way. In the Chinese textbooks, the meaning of the additive relation is invariant, but the way it is represented and enacted varies. In contrast, in the Portuguese textbook the meanings of the addition and subtraction concept appear to vary, and they are not connected except by the notion of 'inverse'. Thus, the space of learning (i.e., what is available to be learnt) is different in the two countries.

Single solution vs. multiple solution methods embedded in every Chinese / Portuguese textbook example

In the Chinese textbook, multiple solution methods are almost always elicited together, illustrating the OPMS principle, rather than a single solution method as in the Portuguese textbook. Theme C

Fig. 5. Three solution methods for variations of 4+1=5 (Mathematics Textbook Developers Group for Elementary School, 2005,1(

Figure 5 is a typical example in the problem variation, of addition. Within the problem set in the example, there are three solution given. The first one is that of addition by counting from the addend that of counting from the addend with 4 and 1. Figure 6 shows solution method is that of addition by regrouping with regrouping with 9 and 1, decimal system. Compared with example in the Portuguese solution method without necessarily connecting that method to other approach the book. For example, as shown in Figure 7 through a specific single concept on each of these two pages does not vary; however, a learner might not connect this method to other models of addition, nor to subtraction, nor be able to choose when to use these methods without juxtaposing the examples, as Marton suggests (2008), with some that are not solvable using 'doubles' or 'doubles plus 1'. The patterns of variation and invariance from which the learner might discern the underlying conceptual relations are unclear.

Fig. 7 The example elicits addition by the solution method of in one of the Portuguese textbooks (Segredos dos Números 1, Matemática 1º ano o Ensino Básico, Theme C – S. Xuhua, T. B. Neto & L. E. Ordóñez
414

hree solution methods for variations of 4+1=5 (Mathematics Textbook Developers Group for Elementary School, 2005,1(16))

Fig. 6. Three solution methods for variations of 9+5=14 (Mathematics Textbook Developers Group for Elementary School, 2005, 1(30))

typical "prototype" example of OPMS in the Chinese textbook

In the problem variation, 4+1=5 is designed to introduce naturally a solution system of addition. Within the problem set in the example, there are three solution . The first one is that of addition by counting from 1 to 5; the second solution is counting from the addend 4 to 5; the third is that of addition by regrouping shows the problem variation of OPMS, 9+5 solution method is that of addition by regrouping with 5 and 5; the second one is , both of which highlight the "make-10 method"

ompared with the Chinese multiple-solution method approach uese textbook is intended to be carried out using without necessarily connecting that method to other approach the book. For example, as shown in Figure 7 a typical design to introduc single solution method of "doubles" or "doubles plus 1 concept on each of these two pages does not vary; however, a learner might not connect this method to other models of addition, nor to subtraction, nor be able to choose when to use these methods without juxtaposing the examples, as Marton

008), with some that are not solvable using 'doubles' or 'doubles plus 1'.
The patterns of variation and invariance from which the learner might discern the
underlying conceptual relations are unclear.

415
Invariant solution method vs. variant solution methods embedded in Chinese
/ Portuguese textbook examples
Although Chinese textbook authors use multiple solution methods in every
example, the particular methods in the Portuguese textbook, which depend on
counting and doubling, are rarely introduced. Only one specific solution method,
"make-10"," is addressed explicitly among all the addition /subtraction examples
within the first 6 chapters. In contrast, the addition examples in the Portuguese
textbook suggest multiple solution methods, such as "doubles", "doubles plus 1",
"compensation" (6+8=7+7=14), and "reference number" (6+7=5+1+5+2=10+3=13).
The subtraction examples use multiple solution methods, such as "counting back",
"the use of tables for the addition to subtraction", and "identifying the inverse
operation of subtraction as addition".
Different goals and pedagogies in teaching reference books
Different cultural traditions have different educational goals and traditional
pedagogies. The Chinese curriculum goal is "two basics", i.e. knowledge and skills;
these are the central aspect of the unified teaching outline of the Ministry of
Education (1963, 1991, 2001).The basics include important mathematical facts and
experiences, mathematical thinking, and skills for further development. In this case,
the basic knowledge is the "part-part-whole" or additive relation as a foundation for
algebra, and the "make-10" foundation for place value and the decimal system. The
textbook emphasises these as basic knowledge and skills and the examples illustrate
how this is done.
In general, to realise the "two basics", the Chinese develop specific
pedagogies, starting from analyzing the focal points of the curriculum content (重点),
then identifying the difficulties that students might encounter (难点) and the critical
points for learning (关键点) (as derived from students' difficulties in learning), and
finally building in relevant variations in the teaching that focus on these three points.
Because this theory is at too general a level for teachers to enact in every lesson, the
concrete goals and pedagogies for every lesson are clearly presented in the teachers'
guide. For example, Figure 8 shows the focal points for knowing numbers 6-10
(EMD, 2005, p. 67). Theme C – S. Xuhua, T. B. Neto & L. E. Ordóñez
416
Fig. 8 The concept struture of knowing numbers 6-10 (EMD, 2005, p. 34)
The Chinese example design principle
Based on the Chinese examples and analysis above and knowledge of the
teacher guide, we could infer the underlying design principle of 'two basics' by
noticing: the foundation of knowing numbers; the connection between addition and
subtraction; and the invariant concept/ solution: part-part-whole /make-10 solution.
Portuguese curriculum goals and pedagogies
The Portuguese textbook and supportive guide does not reflect such a
coherent knowledge structure (Gregório, Valente, & Calafate, 2010). The initial work
about addition and subtraction =focuses =on addition understanding it as combining,
and performing it using counting, doubling, compensation, or using and adapting
known facts, with subtraction also having several meanings. The underlying design
principle is not made explicit; we could infer that it is more fragmented, more focused
on learning one method at a time, and less dependent on foundational principles for
future work.
Summary
The task design discussed in this paper shows a pedagogical phenomenon in
organizing a curriculum with an emphasis on discerning relationships through the
variation approach. Many readers may argue that the variation approach may be
confusing and that a sequential organization with time gaps ("one-thing-at the-time")
should be preferred. In fact, the variation approach might come from different kinds
of pedagogical traditions and philosophies developed for centuries. The issue of
variations in problem sets directly reflects the old Chinese proverb, "no clarification,
no comparison" (没有比较就没有鉴别), rather than "to consolidate one topic, or
skill, before moving on to another," a notion broadly used in most textbook
development (Rowland, 2008) in Europe and throughout the world. In contrast, the
"one-thing-at-a-time" design would clearly provide fewer opportunities for making
connections compared to those of contemporaneous variation approaches. The "onething-at-a-time" design might possibly reflect the hidden belief that learners would Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
417
naturally make the relevant connections. In this context, the role of the curriculum in
presenting connections might be taken for granted and remain implicit.

Theme D
Principles and Frameworks for task design within and across
communities
Carolyn Kieran
Université du Québec à Montréal, Canada
Michiel Doorman
Utrecht University, Netherlands
Minoru Ohtani
Kanazawa University, Japan
Considerations and principles for designing and sequencing tasks depend
highly upon the context of the design activities. Various design communities, such as
those consisting of researchers, teachers, professional developers and teacher trainers,
or textbook writers, have different aims and agendas for task design. Thus, principles
for task design vary across the context in which the communal practice is situated. In
addition, principles for task design can vary as to whether they are applied to the
initial creation of tasks or to the shaping and modification of existing tasks
(Remillard, 2005), as well as to whether they are applied to the design of a single task
versus a sequence of tasks. Moreover, tasks can be designed not only by members of a
singular community but also by groups whose members cut across two or more design
communities (see, e.g., the international examples of such efforts (Kieran, Krainer, &
Shaughnessay, 2013). For example, recent projects where teachers are regarded as
key stakeholders in research (i.e., as (co)producers of professional and/or scientific
knowledge) and where they have a significant role to play in the design of tasks have
been shown to yield not only rich task designs for mathematical learning, but also
make the link between research and practice more fruitful for both sides. In this
working group, we address the diversity and the interactions between design
principles and communities that are involved in task design and attempt to make
explicit those principles of task design within and across design communities that
have up to now been largely tacit.
This Working Group has a twofold aim:
• To solicit papers that delineate principles and frameworks for task
design within singular design communities so as to illuminate
differences and commonalities across the specific contexts of the
various communities.
• To solicit papers that delineate principles and frameworks for task
design by teams that cut across the various diverse communities so as
to illuminate the nature of, and thereby aid in encouraging the further
emergence of, such interactive, cross-community approaches to task
design. Theme D – Introduction
420
Papers being submitted to this working group should specify which of the
two above aims is the main focus of the paper. Papers being proposed for this group
should also address and develop some subset of the following questions, in addition to
whatever other issues might be considered relevant to the given theme:
• If you identify yourself as a member of a singular design community,
which one is it? Or if you identify yourself as a member of a design
group that cuts across communities, which ones are they? If the latter,
how did this cross-community come to be formed?
• When you or your group engages in designing tasks, what are you
trying to achieve? What are your primary considerations?
• Do the principles applied to task design depend on the nature of the
mathematical activity inherent in the tasks (i.e., tasks for exploration,
concept development, practicing, generalizing and reflection)? If so,
in which ways?
• In which ways do the principles for task design interact with the issue
of the time factor, that is, whether a task sequence is to occur across
several lessons or within one given lesson?
• Which theoretical, mathematical, pedagogical, technological, cultural,
and/or practical aspects are taken into account when designing a task
or a task sequence? Which aspects are considered primary?
• Is there a particular framework or theory of learning that is drawn
upon in designing a task or task sequence, and how is this framework
reflected in the task design?
• What is the extent to which individual/communal value systems and
beliefs about how mathematics is to be learned enter into the
designing of tasks?
• What is the extent to which the inclusion of digital-technology tools
within a task or task sequence is reflected in the principles employed
in designing the task or task sequence?
• Are the designed tasks subject to revision in later cycles of the work?
If so, what is it that specifically leads to the redesign? On what basis
and according to which principles is the redesign carried out?
• What constitutes the main differences and commonalities between

design principles for different design communities?
• What constitutes the main differences and commonalities between
design principles for different age groups and school levels?

Task design within the Anthropological Theory of the
Didactics: Study and Research Paths for pre-school.
Fco. Javier García García
University of Jaén
Luisa Ruiz-Higueras
University of Jaén
Abstract. Task design has become a central issue within the
Anthropological Theory of Didactics, connected to the necessity of a
renewed paradigm in the teaching and learning of Mathematics. It is the
aim of this paper to situate "task design" within the Anthropological
Theory of Didactics, to introduce how the term "task" is conceptualized
(study and research paths and activities), to outline key design principles
and, finally, to exemplify the design process in the case of a task for preschool.
Keywords. Anthropological Theory of Didactics, Study and Research
Path, Study and research Activities, Pre-school.
Introduction
The Anthropological Theory of the Didactic (ATD, from now on) has been developed
over the last 30 years, giving rise to a rich and complex theoretical model. In its
evolution, initial constructs have been developed and enriched. The emergence of new
problems and the enlargement of initial questioning have led to new developments of
the theory, in a continuing process that is still going on.
The origins of the ATD can be found in the reconceptualization of
mathematics as a human activity (Chevallard, 1999). This fundamental hypothesis
gave rise to the notion of praxeology, which captured the essential components of any
(mathematical) activity: tasks, techniques, technologies and theories. "Tasks" and
"techniques" considered as the "know-how", whilst "technologies" and "theories"
interpreted as the "knowledge" that explains and justifies the techniques used to deal
with kind of tasks.
(…) no human action can exist without being, at least partially, "explained", made
"intelligible", "justified", "accounted for", in whatever style of "reasoning" such
an explanation or justification may be cast. Praxis thus entails logos which in turn
backs up praxis (Chevallard, 2006, p. 23)
Therefore, from the very beginning the notion of "task" has been central
within the ATD. In this initial approach, the word "task" has to be considered in a
very general sense and institutionally situated.
Thanks to the notion of praxeology, and the subsequent development of the
theory, researches within the ATD have been able to analyse the teaching and
learning of mathematics, to identify didactic phenomena, to formulate didactic Theme D - J. G. García & L. Ruiz-Higueras
422
problems, to find tentative answers and, of course, to create new didactic
infrastructures. Looking backwards, an important part of this research has to do with
the design of tasks (for instance, in the doctoral dissertation of García (2005),
Barquero (2009), or Ruiz-Munzón (2010)).
It is the aim of this paper to summarize the notion of "task" used in our
research within the ATD, linked to a deep understanding of the "didactic system" and
to an explicit epistemological and didactic paradigm of school mathematics, to reveal
the design principles behind, and, finally, to exemplify them in the case of a study
process designed and experimented in preschool.
Towards a new paradigm of mathematics at school
The notion of "task" we will introduce in the next section is strongly connected to a
particular paradigm
35
about the teaching and learning of mathematics. This "new
paradigm" is the rationale for this kind of "tasks" and, reversely, the design and
implementation of this kind of "tasks" shows to what extent this "renewed paradigm"
could be possible.
Let consider mathematics as a human activity, institutionally situated, and
modelled in terms of mathematical works or praxeologies, being the mission of
school to make possible the encounter and appropriation of some of them by new
generations. Then, analysing how school and mathematics are organized in order to
make this encounter and appropriation possible, and also developing new ways of
making this process more effective, could be considered as one of the main aims of
the research in the didactics of mathematics.
The traditional paradigm of organizing this encounter and appropriation, still
dominant in many places, is what Chevallard (2012) called the paradigm of visiting
works. According to it, mathematics is split in several little works, which students
visit at school (like monuments), being the teacher the guide. Considered as cultural
and historical works, students are expected to admire and enjoy this visit. Some side
effects of this paradigm are students' difficulties to give sense to the works they are
visiting (lack of their raison d'être), the atomization of mathematics in little works
that can be linearly programmed in a school syllabus, or the disconnection and
deficient articulation between some of this pieces.
In contrast, Chevallard (2012) pled for a (counter)paradigm of questioning
the world. If we model the didactic system as a triplet (X, Y, O), being X the set of
students, Y the set of teachers (normally restricted to a single person) and O the
didactic stake (learning outcome), the main change of this paradigm is that students'
access to O has to be through meaningful and generating questions Q. It is through the
study of Q, and the subsequent questions that might arise from it, that students will
find O, or at least some elements of O, in order to get to possible answers to Q. This
study process might need considering, studying, and even evaluating, already existing
works Oj as well as already existing answers H
◊
, created and diffused by other
institutions (which form the didactic milieu M). At the end, the aim is to get to an
answer
♥
, which will depend on the path followed by the community of study and

35
The word paradigm is considered here in the sense of "a set of rules prescribing, however
implicitly, what is to be studied—what the didactic stakes O can be—and what the forms of studying
them are" (Chevallard, 2012, p. 2)Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
423
on the works and answers found in the journey. This study process can be synthesized
in what Chevallard calls the Herbartian schema:
In this paradigm, works are not desirable by themselves, but insofar they
contribute in the process of getting to a better answer
♥
. They do not arise as
meaningless objects but, on the contrary, they get their meaning from the questions
they are contributing to get to an answer. The division and isolation of school
mathematics is reduced, as meaningful generating questions give rise to a connected
activation of several praxeologies, even extramathematical ones. Also because the
analysis and evaluation of existing answers, as well as the development and
justification of new ones, situates the activity beyond the routine application of
techniques, giving place to the technological dimension of the mathematical activity
which, in turns, originates that students' work is placed, at least, at the level of local
praxeologies
36
.
The paradigm of questioning the world offers some clear connections with
what it is named as inquiry-based learning. Like this one, is still rather marginal in
many educational systems. It is beyond the aim of this paper to analyse this issue.
However, it is clear that the adoption of this paradigm needs a completely renewed
understanding of the "tasks" used at school. And, reversely, only through the design
of a totally different kind of tasks will there be a chance for this paradigm to exist.
Study and Research paths and activities
Very briefly, in this section we will introduce the main features of the kind of tasks in
accordance with the paradigm of questioning the world. Therefore, we make our
definition of "task" explicit.
Within the ATD, the term study and research path and activity has been
coined to refer to tasks in which:
1. The starting point is a crucial and "alive" question Q0. Therefore, the
community of study (X, Y) considers that the study of Q0 is worth it, and
not just an excuse to introduce some pieces of mathematics.
2. Q0 is a generating question. The study of this question will lead to new
questions Qi. That might make the study process open and even
undermined in advance.
3. There is a collaborative and shared study process, looking for good
answers as well as for good questions. In this process, the classical
distribution of responsibilities between X (students) and Y (teachers) will
be continuously renegotiated. Specifically, Y avoids been the questionposer, the unique source of information (media) and the ultimate source of
validity (milieu).
4. The study of the questions Qi will need to consider intermediate answers.
Some if these answers might be already available within the community of
study, others might be "imported" from other institutions, and, even others

36
Within the ATD, punctual praxeologies are those characterised by a single technique to
solve an isolated task (like solving linear equations in grade 9 by the technique of transposing terms
from one side to the other). Local praxeologies are characterized by a technology that articulates and
connects several punctual praxeologies (like solving polynomial equations with one variable). Beyond
these, regional praxeologies are characterized by a unifying theory for a set of different local
praxeologies (like the theory of algebraic equations). Theme D - J. G. García & L. Ruiz-Higueras
424
might have to be constructed ad hoc. In particular, extra-mathematical
works might have to be considered.
5. The access to intermediate answers will be mediated by the media
37
accessible to the community of study. As far as these answers might have
been developed elsewhere, the study and adoption of some elements of
theses answers should include their possible validation and justification
against the didactic milieu available to the community of study (dialectic
process between media and milieu, Chevallard, 2006).
6. The study process will culminate with the development of a possible,
sometimes tentative, answer. This answer might include both
mathematical and non-mathematical contents, which are the didactic stake
(Chevallard, 2012). It will be meaningful as it offers an answer to the
initial question Q0, as well as to the subsequent questions Qi
. Therefore,
students in X will learn in order to think about and interact with the world
they live in, and not just about a world already thought by others.
The whole process can be visualized under the light of a modelling process.
Questions do not live isolated, but embodied in systems (biological, economical,
social…). The study of Q0 involves the study of at least one system and some of its
relationships. Answers (already built, or created throughout the study process) entail
considering or creating models (not just mathematical ones). Intermediate questions
might arise from the original system but also from the progressive models considered.
Particularly, the process would lead to the development of praxeologies of increasing
complexity (García, 2005). The final answer will depend on how the initial system
has been modelled: which relations have been considered and which ones ignored
(structuring and simplification), which kind of model has been used (setting up a
model), the kind of information produced by the model (working inside the model)
and how this information has been interpreted and validated against the starting
system.
Within this context, a distinction between study and research activities
(SRA) and paths (SRP) has to be made. In a SRA, the didactic stake (learning
outcome) has been set in advance. That means that, starting from a generating
question, the study process has been designed to ensure that students meet some
praxeologies already decided. On the contrary, SRP are undetermined by definition.
Starting from a generating question Q0, it will be the responsibility of the community
to decide which path they will follow, which will determine the praxeologies they
meet with. Particularly, an SRP might include one or several intermediate SRA in
order to build some needed praxeologies to make the study process advance.
Designing study and research paths and activities: principles and
process
In accordance with the paradigm of questioning the world, the identification of
generating and crucial questions is a critical issue. It is not just finding nice and
motivating questions. At least, three conditions must be considered: mathematical,
functional and social legitimacy (García, 2005).
The mathematical legitimacy implies that studying and looking for answers
to the initial question should give rise to the mathematical praxeologies the study
process is aiming at, in the case of SRA, or at least to a set of possible mathematical

37
In the sense of "mass media", like books, press, TV, or Internet. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
425
praxeologies identified in advance (the didactic stake). In that way, mathematical
praxeologies will emerge as motivated objects, as far as they are tools to deal with the
initial question, as well as with the questions derived from this.
Identifying questions with generating power for some mathematical

praxeologies need to carry out a deep work of mathematical engineering. The design process needs to consider and explicitly question all the steps in the didactic transposition process
38
. That is, instead of accepting the dominant and culturally unquestioned transpositions of scholarly knowledge as the unique ones, researchers need get out of school (considered as an institution) and question the meaning of the mathematical objects they are working with, their origin and evolution, their relation with other parts of mathematics, their integration in one or another praxeology. The result will be an explicit epistemological model used as the reference for the design of the SRP/A. Specifically, this mathematical engineering process is crucial to identify the meaning (one or several) of the mathematical praxeologies that will be integrated within the SRP/A
39
. It is this meaning which will inform the kind of generating questions that might be considered.
The social legitimacy implies that questions should overcome the limits of mathematics and school, and be connected with society and its problems (questioning the world). Many of the questions currently studied at school have a pretended social legitimacy that rapidly vanishes. Extra-mathematical context are used mainly for motivational purposes, and disappear quickly to give rise to a decontextualized intramathematical activity. The functional legitimacy means that the questions should be selected so that its study does not lead to a dead end. On the contrary, crucial and generating questions should allow the study community to explore new territories, interesting both from a mathematical and social perspective. From the mathematical side, the epistemological analysis and the construction of the epistemological reference model will be again crucial to determine the functional legitimacy of a question. From the extra-mathematical side, the functional legitimacy is connected with the social one.
The initial design of SRP/A mainly involves researchers in the field of didactics, especially to carry out the mathematical engineering process. But the collaboration of teachers has been quite productive in our research. In particular, to identify and consider restrictions emerging from school that might provoke that the final product does not fit in school. However, the ecology of the SRP/A is a main issue that we cannot discuss here.
In line with the didactic engineering methodology (Brousseau, 1997), the apriori design just explained has to be complemented with the piloting of the SRP/A and its a-posteriori optimization. Researchers and teachers normally carry out this step jointly, and it is structured in advance. During the piloting, it is tested both students' mathematical activity (mathematical praxeologies) and teacher's teaching

38
Scholarly Knowledge Knowledge to be taught Taught Knowledge Learned,
available knowledge
39
For instance, in the SRA designed in García (2005), the epistemological analysis questioned the isolation of proportionality in the Spain curriculum. Proportionality is culturally modelled arithmetically and considered more as a static relation between magnitudes than a functional one. The epistemological reference model we built integrated proportionality in the world of functional relationships, as a possible (and not unique) relation in a variation system. As a consequence, in the SRA designed, students had to work in a variation system (savings plan) in which different variations hypotheses were possible. So, proportionality emerged as a kind of functional relation, not as a privileged one. (García, Gascón, Ruiz-Higueras and Bosch, 2006). Theme D – J. G. García & L. Ruiz-Higueras
426
activity (didactic praxeology). In the students' dimension, it is analysed: how the different elements of the intended praxeologies emerge; the creation of techniques to deal with problems; the identification and formulation of new questions; the exploration of mathematical techniques, including determining its validity and limits; how the mathematical activity is described and justified (technological moment); how the mathematical objects are evaluated by the community of study; the institutionalization of the intermediate and final answers. From the teacher's dimension, it is analysed: the "place" of the teacher and students during the study process (topogenesis); the management of the didactic time and its consequences in the evolution of the mathematical activity (chronogenesis); the management of the learning environment (mesogenesis)
40
. Further, piloting also offers evidence about the ecology and the economy of the designed task.
Study and research path for pre-school: taking care of our silkworms
In this section we will introduce, very briefly, a study and research activity for preschool (4-6 years old students). Researchers and pre-school teachers have designed it jointly and it has been implemented several times
41
.
From the mathematical perspective, the didactic stake is learning about elementary arithmetic. In this level, students are supposed to develop quantification skills and the cardinal sense of numbers, languages and forms of expression to communicate about quantities, as well as start building the sense of some arithmetic operations (addition and subtraction mainly). Following Ruiz-Higueras (2005), which relies on the work of Brousseau and his colleagues in the 80s and 90s, an epistemological reference model was developed. Briefly, the cardinal sense of numbers will emerge in measuring situation with discrete magnitudes. Numbers emerge as models to express the measure of a set, to verify its conservation, to manage it, to remember the quantity, to reproduce or produce a set of a known quantity and to compare two or more sets. Numbers (as mathematical objects) and codes to express them (numerals) will emerge naturally in communicative situations where the aim is not just to measure a discrete set, but to communicate about it so that another person can produce a set similar to the initial one without having access to it (neither visually nor manipulatively)
42
.
Having in mind this reference model, many a-didactical situations have been designed elsewhere. However, they are normally isolated and, sometimes, the context is quite fictitious. So, we wanted to embed numbers in the study of a system that would be real and meaningful for pre-school students, and also rich enough to allow a generating activity that might give rise to the emergence of new questions and different mathematical and extra-mathematical praxeologies. This context came up from the collaboration with a pre-school teacher. She suggested using collections of silkworms, considering that it was springtime and students were bringing some of them into the classroom.
The initial question faced by students was: if we've got N silkworms, how many leaves do we need to feed them? Firstly, they could go to the playground and

40
For the SRC described in the next section, a detailed description of the analysis of the mathematical and didactic dimension can be found in Ruiz-Higueras and García (2011).
41
In fact, some elements of this work have given rise to the publication by the teacher of a textbook for pre-school (Aguilar, 2010).

427
collect the leaves from a mulberry tree. But after a few days, they had to ask the gardener to collect the leaves for them, using a written message. That provoked the need of using codes to express quantities
43
.
In this stage, the mathematical activity is meaningful and significant for pupils, but restricted to elements of a single praxeology. The turning point is when the biological system starts to evolve: silkworms turn into cocoons, then moths arise and, finally, they die. Pupils have to control a heterogeneous collection made of silkworms, cocoons and moths, ruled by a conservative law
44
. This is challenging for pupils:
• Firstly, because they need techniques to record the evolution of the system.
In the experimentation, the teacher prepared a table to record and control the evolution of the system (Fig. 1). She introduced a new artefact into the didactic milieu so that students could take the control of the evolution of the system under their own responsibility.
Fig.1: Table to record control system's evolution
• Secondly, because addition, in the sense of "combining", appears and new techniques are also needed. Due to the conservative law of the system, pupils need to control that the total initial amount remains constant.
Additionally, an expected issue emerged from the study of the system. The magnitude "time" was not expected a-priori (undetermined character of an SRP). However, pupils raised the question of how long will it take to a moth to rise since the cocoon was formed. This task involved the need of developing techniques to record and control the time. In the experimentations carried out, pupils used a calendar and their counting skills as a technique to measure time. Starting from an a-priori hypothesis from the media (answers H
◊
, given by their parents
45
), they had the opportunity to evaluate this "already existing answer" against their learning milieu, getting to their "own" answer
♥
. Finally they found that a silkworm inside a cocoon needed 12 days to become a moth (later, they discovered a little variation in this time).
Tables like the one in Fig 1. had to be adapted as the system was changing. Moths had to be included and, finally, alive moths and dead moths as well.
At the end, when all the moths died, the system disappeared. However, pupils had lots of information about its evolution. And a final task was proposed: reconstructing the system. From a modelling perspective, the process is inverted. Now, interpreting models make it possible to recover information about the life of system that will never be back again.

43
In this early age, many pupils identify written numerals but do not give them a meaning in terms of quantities. Indeed, most of them use self-invented codes (drawings) to communicate about quantities. Gradually, through activities like this one, they start giving some sense to the Arabic numerals and leave their primitive codes.
44
Each state of the system can be described with the vector (t, n(t), c(t), m(t)) where t is time, n is the number of silkworms, c is the number of cocoons and m is the number of moths. A conservative law rules the system: for every t, n(t)+c(t)+m(t)=N, being N the original number of silkworms.

Fig. 3. Reconstructing the system from the model
Conclusions
Task design within the ATD is a complex process. On the one hand, tasks are intrinsically linked to an epistemological conception of mathematics as a human activity, modelled in terms of praxeologies. On the other hand, it is connected with an explicit paradigm about mathematics in school, the so-called paradigm of questioning the world, in contrast with the paradigm of visiting works, still dominant in many school systems.
Study and research activities and paths within the ATD constitute a promising field of research and design. Among others, affordances of this approach are that it is aiming at a renewed school epistemology sensible to the world and its problems, opened to a more democratic flow of knowledge between school and society (Chevallard, 2012). Also, it contributes to a better articulation and integration of topics that are normally separated in school mathematics (García et. al., 2006), and even topics from different disciplines.
Also, it contributes to a better articulation and integration of topics that are normally separated in school mathematics (García et. al., 2006), and even topics from different disciplines.
On the contrary, limitations of the approach are connected with the cognitive dimension. As far as cognition is considered institutionally within the ATD, what remains unexplored is the issue of the cognitive demand of a designed SRP. Further research in this direction would probably clarify and strengthen the scope of this design approach.

Task design for systemic improvement: principles and frameworks
Hugh Burkhardt
Shell Centre Team, Centre for Research in Mathematics Education, University of Nottingham and UC Berkeley.
Malcolm Swan
Shell Centre Team, Centre for Research in Mathematics Education, University of Nottingham and UC Berkeley.
Tasks play many roles in mathematics education, some of them unintentional. They come in many forms, spanning many dimensions, including those of mathematical content, processes and practices, length, and modes of working. In this paper we point out the crucial role that tasks play in forwarding or preventing the process of improvement of teaching and learning - and thus of an education system. We argue that multi-dimensional schemes of task classification have a powerful role to play in the design of tasks and task sequences.
Keywords : classification, dimensions, balance, curriculum, assessment, sequences
Tasks in this paper will mean "activities that students are asked to do, in which mathematics has an important role". Students meet tasks in the course of classroom learning, in informal tests or examinations, in the course of their everyday lives, and in other school subjects. Task design for all these roles has been a central concern of the work of Shell Centre team over the last 30 years, which the authors have led (Swan and Burkhardt, 2012). Our mathematical and epistemological perspectives are eclectic, reflecting the priority in the team's research given to direct impact on systemic improvement.
In discussing tasks and their design, exemplification is absolutely essential to clarify the meaning of descriptions. As so often with print, the limitations of length in this paper mean that we cannot give examples here; we shall accept the opportunity to extend the range on-line, with links in the text to examples of various kinds.
1. Tasks and their various roles
The major focus of this Study will be on the nature and use of tasks in teaching and learning in classrooms. From the systemic viewpoint of this paper, however, it is appropriate to describe and discuss their roles starting with the system, and moving through assessment in its various forms to the classroom. Theme D - H. Burkhardt & M. Swan

In specifying a curriculum Currriculum
46
specifications are normally in the form of descriptions of principles, amplified by an analytic model of the domain. The latter in particular, vary greatly in length, from a few pages on competencies in the Denmark to long and detailed lists of mathematical content in British or US documents. The one common feature is that they are largely expressed through language. Such descriptions do not, in fact, specify learning or performance goals - for example, lists of mathematical content could be taught and assessed entirely through short tasks on separate elements, or through substantial projects in which the student chooses and uses appropriate elements of content and process for the investigation in hand - or, more sensibly, for a balanced variety of types of performance. Task exemplars can play a crucial role in reducing this ambiguity. We have argued (Burkhardt, 1990) that a curriculum specification needs three different elements: an analytic model of the domain: an exemplar task set, with each task linked to the model; a list of the range of classroom learning activities that should be involved (for a brief example, see Cockcroft Report, 1982, paragraph 243).
In high-stakes examinations In countries that have tests where the results have life consequences, the range and balance of types of task in the tests have a strong influence on the range and balance of classroom learning activities (see e.g. OFSTED 2012). Indeed they often seem to define the de facto "implemented curriculum" in most classrooms, whatever the intended curriculum of the last paragraph may say. So high-stakes assessment, and the tasks the tests contain, plays three roles:
• A: to 'measure' performance - ie "to enable students to show what they know, understand and can do" but also, with high-stakes assessment that impacts students' and teachers' lives, inevitably
• B: to exemplify the performance goals - assessment tasks communicate vividly to teachers, students and their parents what is valued by society, and thus
• C: to drive classroom learning activities (What You Test Is What You Get)
These roles carry responsibilities for test designers and those who commission tests - responsibilities that are widely ignored. Psychometricians, too, focus on measurement and statistical error, ignoring the systematic error that comes from assessing only a part of what you want students to learn. Ignoring roles B and C, and the systemic responsibility for test design that they imply, is a major source of the mismatch between intentions and outcomes in school systems.
In classroom assessment In some countries including ours, classroom assessment has traditionally reflected the formal tests, with similar task sets. This is a natural way for teachers to check progress towards an important goal. Some teachers, aware of the limitations of the tests, have always used a broader range of task types in the classroom. In the last decade there has been growing awareness of the power of formative assessment, when well done, in forwarding student learning (see Black and Wiliam 1998, 2001). This approach integrates assessment and teaching in a form where the design of task sequences plays a crucial role. This is challenging for teachers so there has been work on the design of support, initially through live

46
By curriculum, we mean the whole set of learning activities that a student experiences in school. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
433
professional development and, more recently, through classroom materials (Swan et al., 2011)
In teaching and learning We expect the roles of tasks in teaching and learning to be the focus of most of the papers in this study - so here we shall be brief. That their range and variety should cover all the learning and performance goals of the intended curriculum is clear. What makes this area rich are the issues of, and principles for, designing task sequences that will lead students along the road to the understanding and performance goals. One may view task sequences as the spine around which all teaching is built, whether they be the succession of closely related exercises of "incremental learning" and its behaviourist relatives or, at the other extreme, the mathematical microworlds of "open investigation", where creating a task sequence by posing questions is part of the student's responsibility. We shall say something more in this in Section 3.
2. Task difficulty
The issue of task difficulty is often ignored but is important in all aspects of task classification and design. It is known from research that the difficulty of a task depends on various factors, notably its:
• complexity - the number of variables, the variety and amount of data, and the number of modes in which information is presented, are some of the aspects of task complexity that affect the difficulty it presents.
• unfamiliarity - non-routine tasks (those which arent just like the tasks one has practiced solving) are more difficult than routine exercises.
• technical demand - tasks that require more sophisticated mathematics for their solution are more difficult than those that can be solved with more elementary mathematics.
• student autonomy - guidance from an expert (usually the teacher), or from the task itself (e.g., by structuring or "scaffolding" it into successive parts) makes a task easier than if it is presented without such guidance.
Assessments of student performance need to take these factors into account. For example, these factors imply that, in order to design a task for a given level of difficulty, a relatively complex non-routine task that students are expected to solve without guidance needs to be technically easier than a short exercise that employs a routine skill. Focusing on technical aspects alone can lead to rich tasks as being dismissed as "below grade".
The difficulty of a task is determined by trialling the task with a random sample of students drawn from the target population. All assessment tasks, whether for use in the classroom or in summative tests, should be developed in this way, establishing their level of difficulty without undermining their validity as good mathematics.
3. Task variety and task classification
Given the range of roles that tasks play, outlined above, it is clear that appropriate forms of task classification may be useful for various purposes. In this section we set out some schemes and ways they have proved useful in supporting various task roles. There is a constructive duality between holistic and analytic dimensions of classification. Theme D - H. Burkhardt & M. Swan
434
Novice, Apprentice and Expert tasks
This simple holistic dimension of classification (Swan et al 2011) has proved useful in drawing attention to the mismatch between widely accepted goals of mathematics education and current practice in both assessment and curriculum
47
.
Mathematical skills and practices can be taught and/or assessed partly in isolation, partly under scaffolded conditions, and partly when students face substantial problems without scaffolded support. We call tasks that assess these three different types of performance novice, apprentice, and expert tasks respectively. More specifically:
• Expert Tasks. Experts solve problems as they arise. Expert tasks are rich tasks, each presented in a form in which it might naturally arise in mathematics, science or daily life. They require the effective use of problem solving strategies, as well as concepts and skills. Performance on these tasks indicates how well a person will be able to do and to use mathematics beyond the mathematics classroom. Expertise is the end goal of mathematics education.
• Novice Tasks. Novices are learning the tools of the trade. Novice tasks are short items, each focused on a specific concept or skill. Reflecting the highstakes assessment, mathematics teaching and learning in Britain and the US is mainly focused on novice tasks.
• Apprentice Tasks. Apprentices solve problems, but usually carefully structured problems with guidance from an expert. Apprentice tasks are substantial, often involving several aspect of mathematics, and structured so as to ensure that all students have access to the problem. Students are guided through a "ramp" of increasing challenge to enable them to show the levels of performance they have achieved. Because the structure guides the students, the strategic demands and the range of mathematical practices involved are at a comparatively modest level. Apprentice tasks have a role in developing expertise.
A Framework for Balance
Clearly, classification needs to go well beyond this. The NSF-funded project Balanced Assessment for the Mathematics Curriculum aimed to design assessment that reflected the goals set out in the NCTM Standards (NCTM, 1989, 2001). We set out two supervening design principles: Curriculum balance: a test should be such that a teacher who "teaches to the test" is led to deliver a curriculum balanced in accord with the Standards. Curriculum value: doing the assessment tasks should be a worthwhile learning experience. To articulate what this means we developed the Framework for Balance, summarised in the table below.
The headings are self-explanatory except, perhaps, for reasoning length.
This is the time envisaged for the student to work on the longest prompted section of the task - so a 10-minute task that is structured into many equal parts may have a short reasoning length. (Driven by the naïve criterion-referencing behind the National Curriculum, this is common in the UK, where tasks often consist of a sequence of

47
The reader can find examples of each at http://map.mathshell.org.uk/materials/tasks.php Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
435
short items, set in a common context.). The most important features of the Framework for Balance are:
• the classification is multidimensional, addressing the major aspects of performance
• the dimensions are both analytic (content, process, etc.) and holistic (task type, openness, goals, etc.)
• it provides a method of choosing a set of tasks for a tests to meet conditions, particularly balance, for this
• the analytic dimensions are handled semi-quantitative, with the elements of content or process in a task given rough proportions
• an associated "balancing matrix" can be used to ensure that, while every combination of properties cannot be assessed, the main dimensions are samples with appropriate weight.
This approach was first used for balancing collections of classroom materials (Balanced Assessment 1997-99). It also produced a way around a design dilemma: the more constraints you impose on a task designer (such as a cell in a content matrix to assess), the poorer the holistic quality of the tasks that result. The alternative approach is to free designers to design good mathematical tasks, classifying them later and choosing a balanced set for each test.
Framework for Balance
Mathematical Content Dimension
• Mathematical content in each task will include some of:

Number and Operations including: number concepts, representations relationships and number systems; operations; computation and estimation.
Algebra including: patterns and generalization, relations and functions; functional relationships (including ratio and proportion); verbal, graphical tabular representation; symbolic representation; modeling and change.
