Measurement including: measurable attributes and units; techniques tolls and formulas.
Data Analysis and Probability including: formulating questions, collecting, organizing, representing and displaying relevant data; statistical methods; inference and prediction; probability concepts and models.
Geometry including: shape, properties of shapes, relationships; spatial representation, location and movement; transformation and symmetry; visualization, spatial reasoning and modeling to solve problems.
Mathematical Process Dimension
• Phases of problem solving include some or all of:
Modeling and Formulating;
Transforming and Manipulating;
Inferring and Drawing Conclusions;
Checking and Evaluating;
Reporting.
• Processes of problem solving, reasoning and proof, representation, connections and communication, together with the above phases will all be sampled.
Task Type Dimensions
• Task Type will be one of: design; plan; evaluation and recommendation; review and critique; non-routine problem; open investigation; re-presentation of information; practical estimation; definition of concept; technical exercise.
• Non-routineness in: context; mathematical aspects or results; mathematical connections. Theme D – H. Burkhardt & M. Swan
436
• Openness -tasks may be: closed; open middle; open end with open questions.
• Type of Goal is one of: pure mathematics; illustrative application of the mathematics; applied power over a practical situation.
• Reasoning Length is the expected time for the longest section of the task.
Circumstances of Performance Dimensions
• Task Length: in these tests most tasks are in the range 5 to 15 minutes, supplemented with some short routine exercise items.
• Modes of Presentation, Working and Response: these tests will be written.
This idea has been taken further: Daro and Burkhardt (2012) proposed the development of a "population of tasks" that epitomises the curriculum goals, and from which tests will be drawn as balanced samples.
While we do not present these classification schemes as definitive (though they have worked well for specific purposes), we do see task classification as an important part of task design.
4. Principles for the design of tasks and task sequences
We have recently written in some detail
48
on the principles and processes of
task design (Swan and Burkhardt, 2012). Here we have space for a bare list of principles. We argue that curriculum and assessment should be built on tasks that:
1. Reflect the curriculum in a balanced way. Assessment should be based on a balanced set of tasks that, together, provide students with opportunities to show all types of performance that the curriculum goals set out or imply.
2. Have 'face validity'. Assessment tasks should constitute worthwhile learning activities in their own right. The tasks should be recognizable as problems worth solving – because they are intriguing and/or potentially useful.
3. Are fit for purpose. The nature of the tasks and scoring should correspond to the purposes of the assessment. Individual tasks should assess students' ability to integrate as mathematical practices their fluency, knowledge, conceptual understanding, and problem solving strategies. These aspects should not be assessed separately.
4. Are accessible yet challenging. Tasks should be accessible with opportunities to demonstrate both modest and high levels of performance, so the full range of students can show what they can do (as evidenced by high response rates with a wide range of levels of response).
5. Reward reasoning rather than results. Tasks should elicit chains of reasoning, and cover the phases of problem solving (formulation, manipulation, interpretation, evaluation, communication) even though their entry may be scaffolded with short prompts to ensure access.
6. Use authentic or 'pure' contexts. Assessment should contain tasks that are 'outward-looking', making connections within mathematics, with other subjects, and to help one to better understand life and the outside world. As in the real world, they may contain insufficient data (where the student makes assumptions and estimates) or redundant data (where the student makes selections). Students may be asked to respond in a given role: e.g. a designer, planner, commentator, or evaluator. Tasks that use contrived contexts should be avoided.
7. Provide opportunities for students to make decisions. Tasks should be included that encourage students to select and choose their own methods, allowing them to

48
See http://www.educationaldesigner.org/ed/volume2/issue5/article19 Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
437
surprise or delight. Some may be open-ended, permitting a range of possible outcomes.
8. Are transparent in their demands. Students should be clear what kinds of response will be valued in the assessment.
Task sequences in curriculum design
More broadly, we see the concept of task sequence at the heart of curriculum design. Too large a topic for this paper with its systemic focus, it will be the focus of a forthcoming article. Here we will just reinforce the idea with a few examples.
We have already noted that the "incremental learning" approach to curriculum design, characterised by small steps, is strongly reinforced by the nature of assessment. Instead, we have cotinued developing an approach that is very different (see Swan, 2006).
We distinguish whether task sequences are designed primarily to foster conceptual development or problem solving processes. The focus of the first is on discussing different interpretations of mathematical ideas; the second is on the contrasting alternative approaches that may be taken. In both cases we begin by seeking to find out students prior knowledge, by asking them to tackle a carefully chosen task individually, unaided. Their responses are assessed by the teacher, outside the classroom, who must then prepare a series of questions (tasks) designed to prompt students' deeper reflection. We provide a set of questions matched to typical responses and to assist the teacher in this.
In a problem solving lesson, students are then invited respond to these questions and form small groups to produce joint solutions that both combine the best of their individual ideas, and that address the teachers' questions. A sharing of alternative approaches is then undertaken, akin to the Japanese practice of 'neriage'. Often, students do not consider the most powerful problem solving approaches without further prompting. We therefore provide students with some "sample student work", chosen and collected by ourselves. This work is designed to show more sophisticated attempts at the problem. Students' task is now to critique, improve, complete and extend suggested solutions – a challenge to their existing thinking.
The concept-focused lessons are similar in structure to the problem solving lessons, but here we identify the different task genres that promote concept development and select a rich of that kind. Examples are given in the table below:

Task genres Description of tasks
Classifying and
defining
Students devise classifications for mathematical objects, and/or apply classifications devised by others. They discriminate, recognise properties and develop mathematical language and definitions.
Interpreting and
translating between
multiple
representations
Students match cards that show different representations of mathematical objects – words, diagrams, algebraic symbols, tables, graphs. They share interpretations, compare and group the cards in ways that made connections between underlying concepts. The discussion of common 'misconceptions' is encouraged by the inclusion of distracters.
Testing and
evaluating
mathematical
statements and
conjectures
Students are given short mathematical statements or generalisations, are asked to make posters that describe their domain of validity and provide examples, counterexamples and explanations to support their decisions.
Creating and solving
variants of
Students devise new or variants of existing problems, prepare solutions then challenge other students to solve them. They offer support when the solver Theme D – H. Burkhardt & M. Swan
438
mathematical
problems
becomes stuck. This promotes awareness of the structures underlying problems, and focuses attention on the doing and undoing processes in mathematics.
Analysing reasoning
and solutions
Students compare different methods for doing a problem, organise solutions and/ or diagnose the causes of errors in solutions. They begin to recognise that there are alternative pathways through a problem, and develop their own chains of reasoning.
These activities are conducted in a collaborative atmosphere, with the teacher acting as a provoker, using the prepared questions to prompt students to argue and refine their interpretations, with a whole class 'neriage' discussion as wrap-up.
Challenges for research and development
Currently, the tasks presented by high stakes examinations and textbooks, (which in the UK are often written by examiners who focus on repetitive practice of examination-type questions) largely determine the types of task that are used within classrooms. We need to challenge this state of affairs at policy level using such classification schemes as we have described above in curriculum documents to describe learning objectives. A vital component, often missing form such documents, is the vivid exemplification that is necessary to show exactly what such tasks might look like.
At a deeper level, further refinement and illustration of the task-types we have described here is needed; in particular, further classroom evidence of their individual impact on teacher and student practices and performances is required. In addition, research is needed to show how student performances on conceptual and problem solving tasks might be reliably measured and reported. Otherwise examiners and teachers will continue to assess fragments rather than complete performances.
Background and context
While all members of the team contribute to the various aspects of the Shell Centre's work, the authors have played central roles. Malcolm Swan has led the design of tasks and the elicitation of design principles (see e.g Swan and Burkhardt 2012) while Hugh Burkhardt has played a leading role in the development of the analytic frameworks for describing and balancing tasks and the strategic design of tests and their curriculum support (see e.g. Burkhardt 2009). The work has had ongoing national and international support over the past 25 years.

equal contributions.
In this paper we report on two principles of task design arising
from our study of a school-based mathematics teacher professional
development programme in Shanghai, China. The two principles are: a)
developing a 'hypothetical learning structure' for the topic; and b)
developing tasks within a web-like structure of knowledge connections.
This paper provides an example of each and connects the literature
review with the described research design.
Keywords: task design; school-based professional development;
expert teachers; Chinese mathematics pedagogy; collective task design.
Introduction
This paper focuses on the issue of how published tasks (sourced from textbooks) are
appropriated by teachers for instructional purposes and hence how task design
influences mathematics teaching. In particular, we focus on the central aim of the
Working Group Theme D (in the ICMI Study 22 Discussion Document) by reporting
on the design and implementation of tasks by a team drawn from three communities:
academic researchers; the local school district professional developer, who is an
expert teacher with considerable skill in school-based teacher professional
development; and a group of Chinese teachers from Shanghai Soong Ching Ling
School, Shanghai. In doing so, we take the stance highlighted by Kieran, Krainer and
Shaughnessy (2013) that teachers are key stakeholders in research and can play a
significant role in the design of rich tasks for mathematical learning. To add to this,
we argue that the expert teacher/professional developer can also play a significant
role in task design and its 'implementation'.
In China, the 2011 version of National Mathematics Curriculum Standards
(briefly called Standards in this paper) emphasises the shift from the traditional "Two
Basics" (basic knowledge and basic skills) to the current "Four Basics" (adding basic
mathematical thinking, and basic activity experiences). As a result, teachers are Theme D – L. Ding; K. Jones; B. Pepin 442
442
expected to carefully consider and prepare the teaching of particular mathematical
knowledge and skills, in addition to the development of students' individual
understandings and thinking, and to building up students' learning activity
experiences in mathematics (Shi, 2012). The problem now facing educators and
teachers in China is which mathematical tasks, and task sequences, should be
selected/considered (for particular topics), and how to work with such tasks, so as to
implement effectively the range of intentions laid out by the Standards.
Theoretical framework and key pedagogical features
Simon (1995) proposed the notion of Hypothetical Learning Trajectory (HLT) to help
mathematics educators (i.e. teachers, researchers, curriculum developers) to think
about the design and use of mathematical tasks to promote mathematical conceptual
learning. The HLT comprises of three components (ibid p. 136): the learning goal;
the learning activities; and the hypothetical learning process – a prediction of how the
students' thinking and understanding might evolve in the context of the learning
activities. Simon (1995) further points out that teachers need to develop skills to
generate hypotheses about students' understandings (which go beyond soliciting and
attending to students' thinking), to generate HLTs, and to engage in conceptual
analysis related to the mathematics that they teach.
Ma (1999, p. 97) reports that one feature of Chinese teachers' knowledge is
their well-developed "knowledge packages" of the range of ideas needed to teach a
topic like arithmetic. Within such a package, there is a certain "key" piece of
knowledge that is fundamental to enable students to learn other knowledge. Another
kind of key piece of knowledge in the package is the "concept knot" (p. 98), which
links to several different concepts of the learning topic. Ma (1999) considers that
teachers' knowledge packages reveal their understandings of the longitudinal process
of opening-up and developing mathematics of a particular field in students' minds.
Gu, Huang and Marton (2004) identify two types of teaching with variation in
the Chinese mathematics classes. One is conceptual variation (CV), concerned with
understanding concepts from multiple perspectives; the other is the procedural
variation (PV), focused on developing insights into the hierarchical features of
mathematical activity. Gu (2012) further interprets that the PV can be used to
connect, in a dynamic way, different mathematical processes as a whole process. That
is, a teacher can divide the process/es of a mathematical activity into a number of
sub-activities, and then use variation as a means of "pu dian" (i.e. scaffolding) of
knowledge between the sub-activities.
Based on the literature (e.g. Ma 1999; Gu et al. 2004), we identify the
following key features of Chinese mathematics pedagogy: 1) understanding concepts
from multiple perspectives; 2) designing for individual student's actual learning
processes and responses; 3) gradually deepening learning through an orderly-layered
teaching procedure (a teaching/learning method called "Xun Xu Jian Jin" in Chinese).
In our project we utilised a school-based teacher professional development program
(TPDP) (as detailed in the next section) as a means to enable researchers, expert
teacher and school teachers to work together. In the TPDP, we are aware of
Gravemeijer's (2004) notion of a teacher's "local instruction theory" (highlighted in
Choppin, 2011), which is concerned with student thinking about complex tasks and
how this is situated within a broader instructional 'space'. For more on the
mathematical and epistemological basis of our task design study, see Lin (2011). Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
443
The task design study
The main study was arranged in Shanghai Soong Ching Ling School located in
Qingpu district, a western suburb of the city. The school was an international
laboratory school funded by China Welfare Institute with the key mission of
launching innovative and experimental educational classroom studies aimed at
improving the quality of compulsory education for children in the country.
The reasons for this study are twofold. First, the school planned to launch its
own innovative mathematics curriculum to complement the strengths of the Shanghai
(SH) mathematics curriculum. Second, an innovative school-based model of
curriculum was expected to bridge the gap between curriculum developers' intentions
and school teachers' classroom practice.
The methodology of this study is based on a Design-Based Research (DBR)
(e.g. Design-Based Research Collective, 2003) approach to study, document and
advance a model for sustainable teacher professional development. The approach
involved processes such as iteration and feedback loops in such ways that
development and research took place through cycles of design, enactment, analysis,
and redesign (Cobb et al. 2003).
The tasks in the pilot study were sourced from published material from two
countries: the SH official textbooks; and the online professional development
resources from New Zealand (NZ):
http://www.nzmaths.co.nz/professional-development
The participant groups of the pilot study were: (1) three researchers (the three
authors); (2) an expert teacher (called 'Mr Zhang' in this paper); and (3) three
teachers, one of them a teacher-researcher (first author). The three researchers
(authors) designed the study and provided the theoretical background (literature,
research design, etc.). Next, in the school-based TPDP, the first author (a teacherresearcher) designed the first intervention based on ideas from the NZ online
resources. The expert teacher, *Mr* Zhang, commented on it together with other
teachers in the TPDP. Two Grade 4 teachers (one experienced teacher, and one less
experienced teacher) then took Mr Zhang's comments into account in their redesigned lessons of the same topic in two other grade 4 classes. *Mr* Zhang reflected
upon both lessons, together with other teachers. Subsequently, the three researchers
analysed the data, which consisted of data on the context; observations and videos of
the three lessons; discussions/interviews with *Mr* Zhang after each lesson; and
documents, such as curriculum materials and textbooks; also official documents,
guidelines for teaching, syllabi, etc..
In this paper we define a "task" as a learning situation with a specific
teaching goal in a single lesson. The main body of the task design is therefore to
create a sequence of multi-layered learning situations within a broader instructional
plan and to develop a general picture of the students' learning paths. In the pilot study
the teachers were actively engaged in the work of how to select, modify, sequence,
teach, observe and reflect on a single lesson and on a sequence of lessons.
As laid out in the SH Grade 4 mathematics textbook (term II), the chapter on
decimals (30 pages in total) consists of the following sub-topics: decimals in real life;
the meanings of decimals; comparing decimals; the properties of decimals; the
movement of the decimal point; the addition and subtraction of decimals; and the
application of the addition and subtraction of decimals in problem solving. In their
teaching teachers were expected to appreciate the key connections of the
teaching/learning goals embedded in the SH textbook as follows: (for pupils) Theme D – L. Ding; K. Jones; B. Pepin 444
444
1. to learn/understand the relationship between decimals and fractions (to
understand the base-ten place value system of decimals and the meaning of
0.1, 0.01, and 0.001);
2. to learn/understand the units of decimals (e.g., 0.1) (to understand the
meanings of decimals with one, two, three digitals; and to know a whole
number with a decimal);
3. to learn/understand the concept of place value of decimals (to understand the
place value table of decimals).
In what follows, we focus on delineating the two major principles that
emerged from the data analysis of the three teachers' lessons on 'place value of
decimals' (briefly called 'decimal value') and of *Mr* Zhang's comments during the
post-lesson TPDP.
Findings: two principles of the task design study
Principle 1: Developing a 'hypothetical learning structure' for a particular
topic
The first teacher intended to use the NZ online teaching resources to complement the
strengths of the SH mathematics textbook and pedagogy. For the lessons of decimal
value, the teacher's "local instruction theory" (Gravemeijer, 2004) was to enable her
students to accumulate learning experiences with the big idea that the decimal
number system is a base-ten place value system. Thus, she used the NZ online tasks
to enable students to examine two sub-ideas associated with the base-ten place value
system.
1. The places (or columns) in the number system are based around groupings of
ten. For example, 10 ones = 1 ten, 10 hundreds = 1 thousand.
2. The decimal point is a convention that indicates the units place.
The teacher started the lesson by presenting the place value of whole number
(briefly called whole number value) on the blackboard (see the left half in Figure 1).
While students observed it, they recalled previously learnt knowledge such as series,
and a 10-to-1 relationship between the values of any two adjacent places (or
columns). For instance, some students discussed that 10000 equals 1000 of ten.
Others argued that 10000=10×1000. Still others added that the "Wans" (tens of
thousands) are 3 places to the left of "Shi" (tens). This means that there is a
10×10×10 relationship between "Shi" and "Wan".

1/100
0.01
1/1000
0.001
…
Figure 1. The decimal number system
Next, the teacher drew students' attention to the decimal value (see the right
half in Figure 1). For instance, according to the newly learnt knowledge of decimals,
students were able to discuss in the class that 10 of 1/100 is 1/10. Some represented
such a relationship by decimals (10 of 0.01 is 0.1). The teacher then led students to
pay attention not only to a 1-to-10 relationship between adjacent places to the right
where the places were getting smaller by a factor of ten, but also to the relationship
between any two places in the number system. In observing such relationships as
0.1×10=0.01, 0.1×100=0.001, and 0.1×1000=0.0001, students were also led to think Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
445
about the movement of the decimal point. Moreover, the teacher posed tasks to
enable students to see the connection between the movement of the decimal point and
the units of a number. For instance, 6501.4 (in this case the "ones" is
assumed),650.14 tens (in this case the units are tens),65014 tenths (in this case
the units are tenths),and 6.5014 thousands (in this case the units are thousands).
In the first post-lesson profesional activity (PPA), *Mr* Zhang firstly
commented on the teacher's lesson from three perspectives, namely (1) the HLT of
students; (2) the learning methods; and (3) the degree of learning difficulty.
I found that the (first) teacher dealt with the textbook in her lesson differently
from those in our common lessons. … There is a starter in the HLT. That is, the
anchor of knowledge. For instance, what types of knowledge, experience and
methods of learning the students already have? And to what degree? The starter
of this lesson was at an abstract level, such as the comparison of the place values,
enlarge or reduce a number, the relationship of places, etc. … Some students in
the class may be lost at this abstract level. … Moreover, the learning method is
different. In this lesson, the teacher provided a bit of context of the problems,

students then developed a discussion in the class and then solved some points of problems by themselves. It's considerably random. The logical structure of learning itself is loose. For instance, what is the first step and then the next step of learning? In a whole, what is the general goal of learning? The learning was designed in a macro way.
Next, Mr Zhang drew the teachers' attention to the HLT from a micro perspective of the "concept knots" (the meaning and the places of decimals) (Ma 1999) in the decimal chapter of the SH textbook.
To view the learning from a micro perspective, students are expected to master a number of factors from this topic. For instance, can a number be read on the decimal value (dv) table? Can a decimal be put on the dv table? Can the form of the decimal be explained on the dv table? In the last lesson [according to the SH textbook], it is about the structure of the meaning of decimals. In this lesson, a shift is to be made to the structure of the places of decimals. In the end of this lesson, the two structures should be connected.
From such a micro perspective, Mr Zhang also addressed the importance for teachers to recognize the connection of the "key" piece of knowledge (the whole number value) (Ma 1999) and new knowledge (the decimal value) in the HLT.
When pupils learn the decimal value, their cognitive anchor is on what they have previously learnt of the place value of whole numbers [learned in Grade 4 –Term 1]. Teachers thus should create cognitive conflicts of the new topic for their students, to go beyond their previous knowledge of whole numbers. It is because … to 'fill' a decimal is something new for students. In so doing, their intellect is challenged and they can be engaged in thinking about how to create a decimal value which is the topic of this new lesson.
In our study, we use the term "hypothetical learning structure" (HLS) to distinguish the Chinese expert teacher's concept of HLT from Simon's (1995) HLT, in terms of two considerations: (1) The HLS in our study is not based on the western constructivist theory, but largely on the Chinese expert teacher's expertise in predicting students' learning processes and responses through observing the same topic many years during authentic classroom practice. (2) The use-aim of the HLS is not only to address the teacher's well-developed "knowledge packages" (Ma, 1999) in mathematics, but also to distinguish the learning methods from those of the HLT (Simon, 1995). That is, in Mr Zhang's view, pupil learning could be more 'efficient' (in the sense of 'whole class learning') if students do not randomly use their previous knowledge to respond to the teacher's questions in a set of points, but are engaged in
446
the teacher's well-designed mathematical tasks in a set of 'blocks'. Mr Zhang offered the following 'blocks of tasks' for the decimal value lesson:
1. Write decimals and then write decimals with whole number on the number line;
2. Write units of decimals on the number line (e.g., 0.1, 0.01, and 0.001);
3. Write whole number in the whole number table and then write decimals with whole numbers in the whole number table;
4. Create the decimal table, design the place value in the decimal table and recognize the role of the decimal point;
5. Develop an understanding of the units of decimals in the decimal table;
6. Write the form of decimals in mathematical notation (e.g., 0.23 = ( ) × 0.1 + ( ) × 0.01);
7. Write the form of decimals in word language;
8. Define two types of decimals (decimals and decimals with whole numbers).
Principle 2: Developing tasks within a web-like structure of knowledge connections
Two teachers followed up the conversations with Mr Zhang by carefully planning the second and the third lessons for each of their classes on the same topic of decimal values according to the HLS (outlined above). Their lessons were quite different due to the teachers' different instructional intentions and the different students in each class. The second teacher (with two years teaching experiences in primary mathematics) sought to develop students' understanding of the form of decimals on the concrete geometrical model (the number line), and then their abstract thinking in the decimal table. For instance, in the starter of his lesson, the teacher used a considerable amount of time for students to write decimals on the different sections of the number line (e.g. those between 0 and 1, 0 and 1/10, 0 and 1/100, 0, 1 and 2, and 61, 62 and 63).
The third teacher (with ten years teaching experiences in primary mathematics) did not use the number line, but developed her students' abstract thinking of decimals directly from the form of decimals to the decimal table. For instance, in the starter of her lesson, the teacher posed a number of decimals and a whole number on the blackboard (e.g. 0.23, 0.63, 1.08, 61.52, 88.888, 1045). She then asked students to discuss the form of these numbers. Some of the examples are given below:
0.23 = ( ) × 0.1 + ( ) × 0.01
1.08 = ( ) × 1 + ( ) × 0.1 + ( ) × ( )
61.52 = ( ) × 10 + 1 × ( ) + ( ) × ( ) + ( ) × ( )
In the second PPA, Mr Zhang mainly commented on the two approaches applied by the two teachers, in order to help teachers to develop an insight into selected didactical ideas in mathematics teaching which are advocated in the latest national curriculum reforms. The new curriculum advocates developing students' complex thinking in a web-like knowledge structure, so as to enable students to see the most important feature of how mathematical knowledge is constituted. Mr Zhang said the following:
Different from the second teacher, the third teacher's lesson was from number to table. In fact, there are a considerable number of concepts in the (decimal) table. For instance, 10-to-1 relationship between the values of any two adjacent places,
the place of decimal, the number on the unit of decimal, the unit number of decimals, etc. The (third) teacher's instruction was clearly concerned about the first two concepts, but did not talk about the other concepts in the lesson. The main 'missing point' of the lesson is the lack of concrete diagrams to support students to understand the connection of the abstract concepts, such as the unit of the decimal place and its meaning (as the second teacher did). The advantages of the combination of decimal table and the number line are as follows: firstly, the infinity in dividing a small segment on the number line can be connected to the concept of number place in the table. At the same time, it is an opportunity for students to develop the concept of infinity. In such a way the teacher helps students to see the connection between the representation of the geometrical model and the mental representation of the decimal table. Consequently, the teacher makes the scaffolding for students to understand the abstract concepts and ideas such as infinity, set, 'approaching'. A lesson like this is likely to be a deep learning lesson. … In the latest pedagogy reforms, 'gathering thinking' is highlighted in teaching. That is, thinking is developed as a web, rather than the linear line/progression of knowledge connections. The 'gathering thinking' is based on a rich web of knowledge and a web of experiences. New knowledge is the result of the richer/more connections. The point is to understand what kinds of web new knowledge is based on. Then teachers could see how to help students to develop multiple connections of knowledge and experiences within the web. The connection of a new point of knowledge to the multiple points of knowledge on the web would enable students to enrich knowledge representations, make knowledge transformation and application, and develop complex thinking, namely the 'gathering thinking' in mathematics.
Mr Zhang then drew two web-like structures of knowledge connections of the decimal table. Figure 2 is a macro-level of the knowledge structure of the decimal table. Figure 3 is a micro-level of the knowledge structure of the decimal table.
Figure 2. A macro-level of the knowledge structure of the decimal table
Figure 3. A micro-level of the knowledge structure of the value place of decimal table
The two figures indicate two key theoretical ideas of this expert teacher in helping teachers to develop knowledge and ideas to make the multi-layered task design: first, the conceptual variation (Gu et al., 2004) for understanding concepts from multiple perspectives; second, the "Xun Xu Jian Jin" method to develop the complex mathematical thinking within the whole structure of knowledge connections.

Implications
In this paper, we have delineated two principles which had emerged in our pilot study of the school-based tasks and instruction design project in Shanghai. However, there are challenges for the main study that concern the difficulties of the connection between theoretical frameworks and principles for our task design across communities:
(a) It is challenging to situate knowledge from different design communities into the 'living context' – the classroom in a broader culture (in our study the Chinese culture). In particular, if we wish to introduce innovation in teaching, we need to understand more comprehensively the alternative "local instruction theories" (Gravemeijer, 2004) that different teachers (researchers, professional developer and school teachers in our study) appear to hold.
(b) The HLT (Simon, 1995) features a teacher's design decisions based on her/is best guess of how learning might proceed. In our study the HLS addresses the importance for teachers to develop their "knowledge packages" (Ma, 1999) and to try things out in practice. It would be necessary to understand how the expert teacher's HLS may help teachers to make the connection between the unpredictable nature of individual learning and the pedagogic practice/ mathematical-didactic structures (macro and micro) suggested by the expert. Further, it would be necessary to develop new insights into the different teaching/learning methods underlying Simon's (1995) HLT in the US classroom and the HLS in the Chinese classroom. For instance, the distinction of the western construction (i.e., scaffolding) and the Chinese "Xun Xu Jian Jin" and "pu dian" (i.e., procedural variation, in Gu et al., 2004, p. 340), the theoretical ideas of the 'proper potential distance' (Gu et al., 2004, p. 343), and the micro and macro perspectives of learning viewed by the expert teacher in our study.

Hybrid Tasks: Promoting Statistical Thinking and Critical Thinking through the Same Mathematical Activities
Einav Aizikovitsh-Udi
Beit Berl College, Israel
David Clarke
University of Melbourne, Australia
Sebastian Kuntze
Ludwigsburg University of Education, Germany.
Even though statistical thinking and critical thinking appear to have strong links from a theoretical point of view, empirical research into the intersections and potential interrelatedness of these aspects of competence is scarce. Our research suggests that thinking skills in both areas may be interdependent. Given this interconnection, it should be possible to stimulate both forms of thinking through the one task. An exploratory qualitative study has been undertaken into thinking processes when working on tasks encompassing both these areas. This paper explores the implications of this study for the design of tasks that simultaneously stimulate critical thinking and domain-specific thinking.
Keywords: Statistical and Critical Thinking, Task Design, Hybrid Tasks
Background
Mathematics classroom instruction is generally organized around and delivered through students' activities on mathematical tasks (Doyle, 1988). Notably, in all of the seven countries that participated in the TIMSS 1999 Video Study, eighthgrade mathematics was most commonly taught by spending at least 80% of lesson time in mathematics classrooms working on mathematical tasks (Hiebert et al., 2003). For our purposes, complete description of a mathematical task requires specification of the intentions, actions and interpretations of both teacher and student/s, together with details of the context in which the task was undertaken and by whom (Mesiti & Clarke, 2010). In this paper, "task" mostly refers to the written stimulus, although we also provide the details required to understand the performative realisation of the task

as a mathematical activity. Classroom activities are coherent actions shaped by the instructional context, in general, and, in particular, by what is taught through the use of tasks (Stodolsky, 1988). The tasks that teachers assign can determine how students come to understand what is taught. In other words, tasks serve as a context for students' thinking, during and after instruction. Doyle argues the point that tasks influence learners by directing their attention to particular aspects of content and by specifying ways of processing information (Doyle, 1983, p.161). Theme D – E. Aizikovitsh-Udi, D. Clarke & S. Kuntze
452
To achieve quality mathematics instruction, the role of mathematical tasks to stimulate students' cognitive processes is crucial (Hiebert & Wearne, 1993). Contemporary curricula prioritise more than just procedural knowledge. In the mathematics curricula of countries as culturally and geographically distant as China, Australia and Finland, student thinking is promoted in more sophisticated terms than simply knowledge of facts and procedures. Korea and Singapore, in particular, seek to retain the high level of mathematical competence documented in TIMSS and PISA results, while improving higher order thinking and problem solving expertise. This poses the question as to whether both can be achieved. The possibility is explored in this paper that the same tasks might be employed to realise both goals. The tasks employed came from the research of Kuntze and his colleagues, the actual interviews were conducted by Aizikovitsh-Udi, the analyses of the task responses with respect to Statistical Thinking and Critical Thinking were coordinated by Kuntze and Aizikovitsh-Udi and the task-specific interpretive analysis was done by Clarke.
In summary, the centrality of tasks in mathematics classroom is evident from theoretical perspectives as well as in empirical results from international comparative studies. The role of mathematical tasks provides a key to any attempt to understand teaching and learning in research on classroom practices in mathematics. But can a given task stimulate and promote both discipline-specific thinking and more generic forms of higher-order thinking? To explore this question, we take Statistical Thinking (ST) and Critical Thinking (CT) as our exemplars of the two modes of thought.
Statistical Thinking and Critical Thinking
In a well-known definition of Statistical Literacy by Gal (2004), a "critical stance" is included among the key attitudes for successful statistical thinking (ST) – hence, Gal includes such attitudes in his definition of statistical literacy (cf. also Wallman, 1993; Watson, 1997; Reading, 2002). However, being critical in statistical contexts is not only an attitude. It is possible to describe specific abilities that have to be used in order to critically evaluate statistical data. Two key concepts or overarching ideas in statistical thinking relevant for a critical evaluation of data are manipulation of data by reduction (Krügel, Peschek & Schneider, 2000) and dealing with statistical variation (e.g. Watson & Callingham, 2003). Successfully manipulating data by reduction requires the awareness of such things as that calculating a mean value affords an overview on the original data, but it reduces the initial information. Hence, the resultant statistical value is (only) an indicator corresponding to a specific mathematical model, and we should not forget that it reflects only a part of the information. In order to critically evaluate the data, we might need additional information about the distribution, such as the variance, or information about extreme values.
Critical thinking (CT) skills rely on self-regulation of the thinking processes, construction of meaning, and detection of patterns in supposedly disorganized structures (Ennis, 1989). Critical thinking tends to be complex and often terminates in multiple solutions, each with advantages and disadvantages, rather than a single clear solution. It requires the use of multiple, sometimes mutually contradictory criteria, and frequently concludes with uncertainty. This description of CT already suggests links with ST, such as dealing with uncertainty, contradictions and a critical evaluation of given claims (cf. McPeck, 1981). Dealing critically with information – a crucial aspect for both domains – demands critical/evaluative thinking based on Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
453
rational thinking processes and decisions (Aizikovitsh-Udi, 2012; Aizikovitsh-Udi & Amit, 2008). Can a single task be used to elicit and promote both forms of thinking? In-depth analyses are required into how CT and ST may interdepend. In order to design the type of hybrid tasks proposed here, it is essential that we understand the connection between the two forms of thinking that provide the specific goal for the use of such tasks in mathematics classrooms and how these connect to task characteristics.
Investigating Hybrid Tasks
In attempting to stimulate particular thinking skills, it might be thought best to target either discipline-specific thinking (eg. Twelve numbers have a mean of 10 and a standard deviation of 2, what might the numbers be?) or generic critical thinking skills in discipline-free contexts (eg. Five people are isolated by flood, under what circumstances would it not be appropriate to share the available food equally?). Hybrid tasks seek to promote both. This paper explores the actions such tasks promote, the rationale for their use, and their design characteristics.
In order to explore thinking processes related to tasks in the domains of both Statistical Thinking and Critical Thinking, individual semi-structured interviews were conducted with mathematics teachers. By using mathematics teachers as subjects, basic content competence can be assumed and it becomes possible to examine their content-related higher order thinking skills, both in terms of statistical thinking and critical thinking. The interviews focused on thinking-aloud when solving tasks and each lasted about 40–50 minutes. Beyond solving the tasks, the interviewees were also free to give their personal views on the tasks.
In the following section, the results from one interview with a single teacher are used to exemplify the sort of data generated and the type of task likely to stimulate Statistical Thinking and Critical Thinking. The analysis concentrated on identifying Statistical Thinking (ST) and Critical Thinking (CT) as employed by the interviewees. Our interest is not just in the capacity of a single task to stimulate both ST and CT, but whether the interaction between ST and CT made them mutually supportive or disruptive. A first analysis was done focusing on ST only (Watson, 1997), then a second analysis employed a CT point of view (Ennis & Millman, 1985). We then carried out a combined interpretative analysis in order to examine relationships between CT and ST elements. In this methodological approach, the analyses were done by two coders working in parallel. Figure 1 shows the first task analysed. Theme D – E. Aizikovitsh-Udi, D. Clarke & S. Kuntze
454
Figure 1: Task "population"
(Kuntze, Lindmeier & Reiss, 2008)
Nena was an experienced U.S. secondary Mathematics teacher with 20 years of mathematics teaching experience. She was dedicated to improving her teaching and had been participating in a year-long professional development program for mathematics teachers at the time this interview occurred. In the interview, Nena was asked to solve the problem in Figure 1, while thinking aloud:
Interviewer: What do you think? From which year on has the population been decreasing?
Nena: Well…. the population has been decreasing since 1963 until about 1973, where the population begins to rise a bit….. but it is still down since 1963.….
Interviewer: Are you confident about it?
Nena: Of course… I am sure! You can look at this problem mathematically, anywhere there is a positive slope you could say the population is increasing, where there is a negative slope the population is decreasing. But compared to 1963, it's always been down.
Dealing with assumptions is one of the key elements of Critical Thinking (Ennis & Millham, 1985). Nena initially assumed that the graph of births completely determined the population development. Even when asked to reflect on this assumption, Nena did not generate possible counter-arguments for testing her initial assumption, nor did she appear to question this assumption. She tended to seek confirming evidence rather than evidence that might challenge her initial assumption.
Seen from the perspective of Statistical Thinking (ST), Nena chose an inappropriate statistical model for interpreting the data given in the diagram (cf. description of this task in Kuntze, Lindmeier & Reiss, 2008). She appeared to focus on the data related to the births only, and she deduced her conclusions from a mathematical consideration of slopes. Even when encouraged by the interviewer, she did not check this model against the full data given in the diagram.
Nena's answers show deficits both in Critical and Statistical Thinking.
Looking at the relationships between CT and ST: At the very beginning, Nena shows only a partial perception of the evidence, focusing on the birth data from 1963 on. This selective focus may have been a result of the headline given in the diagram ('The Germans don't have enough children'). This headline may have triggered Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
455
Nena's misinterpretation of the births as determining the population, from the turning point in 1963. It is interesting that Nena emphasised that it was possible to "look at this problem mathematically", which suggests that she saw a discrepancy between looking at the situation from the perspective of a mathematical model and looking at it from the perspective of the context (population and children born in Germany). Possibly the mathematical or statistical model is taken as an authority that is used to justify the appropriateness of the assumption instead of questioning the model chosen initially. It is possible to conclude from this combined analysis that the elements of reasoning in both domains interfere and interact. Given this interconnectedness, help in either domain, either in CT and ST, may have had a positive impact on the thinking process as a whole. Moreover, the CT and ST perspectives offer not only simultaneous and parallel ways of interpreting the reasoning process, but, through a combined analysis, can explain how CT and ST can be mutually beneficial, reinforcing related reasoning approaches. Tasks that stimulate the use of both CT and ST are consequently of practical importance.
However, CT and ST are not always interdependent in an obvious way, as the following example suggests (cf. Figure 2 and the corresponding interview section):
Figure 2: Task
Interviewer: So, what do you think, with which of the following statements do you agree?
Nena: I would agree with the 3rd statement.
Interviewer: Can you explain, please?
Nena: Yes… 400 computers is not a large sample when talking about computers so I would go with the 3rd statement and just listening to the comments of her friends and the consumer's magazine, it is possible that both the computers could be just so.
Interviewer: Are you sure?
Nena: Sure. I like this question!
Seen from the perspective of CT, Nena questions not only the experiences of the friends, but also the results from the study with the 400 laptops. On this basis, she expressed agreement only with the third statement, which highlights questioning evidence as a sub-aspect of CT. However, considering Nena's answers under the lens of ST, she appears not to acknowledge the statistical power of the sample of 400 laptops. Nena remarks that it is not possible to make a prediction on the base of the Theme D – E. Aizikovitsh-Udi, D. Clarke & S. Kuntze
456
data, and she appears to compare the number of the 400 laptops to the number of all laptops. She does not reflect in depth on the statistical power of the magazine study. From a joint perspective, Nena's dominant critical attitude may have blocked her use of elements of ST, e.g. reasoning related to the sample size and representativeness. This example gives insight into how CT and ST may interfere. In this case, CT practice acted to the detriment of ST. Conversely, ST can be dominant over CT, as the following example (associated to the problem in Figure 3) suggests:
Figure 3: Task "crimes"
Interviewer: …and here… Do you agree with the interpretation of the police president? Why or why not?
Nena: I do not see a big difference with the number of crimes for any given year that would warrant extra police force to be hired…
Interviewer: Can you justify it, please?
Nena: It looks like the average is approximately 520 which is close to all the numbers so I do not think anything different is really happening from any given year.
According to Ennis' taxonomy (Ennis, 1989) one crucial element of CT is raising questions, having doubts, and exploring key definitions, like "crime". In this task, the nature of the crimes is a key consideration. For example, if we knew that all the crimes were murders, we might decide differently than if the crimes related to paying taxes or fraud. No question about such a definition was raised by Nena and the focus was purely numerical. In this task, Nena employed a restricted set of CT skills.
From the point of view of ST, Nena used an appropriate model and showed an awareness of statistical variation. By these means, she arrived at the conclusion, that, given the variation of the data of the past years, the rise of the crime number is not significant. Consequently, seen from the ST perspective, Nena showed an appropriate understanding of the statistical situation.
Looking at this part of the interview in the joint CT and ST interpretation mode, the analysis suggests that Nena successfully questioned the statement of the police president by using the data given in the problem and a statistical argument. She appeared to remain in the statistical domain, giving more details related to the model she had chosen (distances to the average value). This focus on ST may have hindered her use of any of the CT skills, such as analysing and questioning the definition of 'crime' as the key notion here, questioning the evidence (i.e. the way the data had been collected), etc.
Questioning data plays a role also in the following example related to the problem in Fig. 4:
Year 2000 2001 2002 2003 2004 2005 2006
Number of crimes 504 528 525 499 529 518 538
The police president shows the following diagram and says: "This diagram shows, Number of crimes that since 2005, the number of crimes in the city center has increased, so that we have to expect that it will further go up in the next years. We need more policemen for patrol in the city center."
In a more extensive press communication, Fred has found the data of the last 7 years:
Do you agree with the interpretation of the police president?
Why or why not? Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
457

Figure 4: Task "tablets" from Kuntze, Lindmeier & Reiss (2008)
Nena: And here… I think tablet one takes too long to get rid of the headache.
Tablet two seems to get rid of the headache a lot quicker for the majority of the
people. You don't really know the age or weight of the people. Many factors play into
the reason why a headache might occur so the statistics are poor. Based on the chart, I
would have to pick tablet number two in hope of a speedy recovery.
From the perspective of CT, Nena not only evaluates the given statements,
but she also shows CT elements when going beyond the data given: She gives
examples of relevant influencing factors, and questions the data provided in the
diagram ("the statistics are poor").
From the point of view of ST, the analysis of Nena's short answer yields that
Nena chose an appropriate model and was aware of the key elements of the problem,
even if she did not explicitly discuss the minority of cases with very slow recovery
for tablet 2. These considerations led to her personal conclusion to pick tablet number
two, as she obviously sees the chance of a "speedy recovery" as more important than
the risk of a very slow recovery.
Looking at both CT and ST, the example appears to highlight how elements
of CT can contribute to ST, e.g. when evaluating data, its presentation and analysis,
planning data collection, etc. In the example, Nena suggests an analysis that takes
into account the age or weight of the persons in the study. Conversely, aspects of ST
like dealing with statistical variation and uncertainty can contribute to CT, especially
when it comes to decisions in non-determinist situations, where full data is
unavailable. These examples are intended to illustrate how both ST and CT skills can
be evoked by the same task. We suggest that this models authentic and useful
thinking practice more effectively than a more closed task that stimulated only
statistical thinking and the application of taught procedures. Our question now, is
"what are the messages for task design?"
Conclusions: The feasibility, utility and design of hybrid tasks
The tasks used in this exploratory study have certain distinctive
characteristics and we would argue that each of these characteristics constitutes a key
principle of task design:
• each uses a "real-world" situation as its "figurative context" (see
Clarke & Helme, 1998); Theme D – E. Aizikovitsh-Udi, D. Clarke & S. Kuntze
458
• each provides succinct statistical information relevant to that
context (Kuntze, Lindmeier & Reiss, 2008);
• the problem is stated very simply;
• some form of evaluation is integral to the problem (Ennis &
Millham, 1985);
• the task affords many reasoning approaches.
The exploratory study demonstrates that connections clearly exist between
Statistical Thinking and Critical Thinking at the level of individual reasoning
practices. In seeking to stimulate both forms of thinking we suggest that an individual
employing Statistical Thinking has access to a structured framework of analytical
principles that guide and support their reasoning. That is, the relationship between
measures of central tendency and variance, for example, structure any consideration
of distribution of data that might be invoked in drawing evidence-based conclusions
or making evidence-based judgements. On the other hand, the components of Critical
Thinking are not related in such a structured fashion and an individual's inclination to
employ one strategy (e.g. Questioning Evidence or Questioning Assumptions) can be
given expression without any obligation to also invoke other components of Critical
Thinking. Some Critical Thinking skills resemble the "heuristics" that were the focus
of the enthusiasm for problem solving in the 1980s and 1990s (Clarke, Goos, &
Morony, 2007). Catalogues of such heuristics were similarly fragmented.
Ennis and others have catalogued critical thinking skills (Ennis, 1989) and
even arranged these categories in a form of hierarchy, but the connection between
specific critical thinking skills is under-theorised in comparison with Statistical
Thinking. Nonetheless, the forms of Critical Thinking identified in such classificatory
schemes are clearly of significance, both as aspects of reasoning and as potential
curriculum content. If it were possible to develop a structure for Critical Thinking in
which the component elements were not only identified, but also their relationship
established, then to invoke one aspect of Critical Thinking would serve to catalyse
the use of other related aspects, because the connections between elements would be
well known and understood. The question of how best to conceptualise these skills,
how to integrate or connect them with other curricular goals, and how best to
promote them and nurture their development in the classroom has been a major
challenge. An earlier study (Aizikovitsh-Udi, 2012), using similar tasks, has
documented efforts to produce CT through a program of instructional immersion in
the related topic of probability. In this paper, we argue that particular tasks can
stimulate the use, promotion and development of both Statistical and Critical
Thinking. We would like to suggest that an instructional program of hybrid tasks
could be devised that provides the opportunity to employ Statistical Thinking, while
simultaneously introducing students to the practices and structure of Critical
Thinking. The design characteristics of such hybrid tasks have been identified.

Effects of variations in task design using different
representations of mathematical objects on learning: A case of a
sorting task
Boris Koichu
Technion – Israel Institute of Technology
Orit Zaslavsky
Technion – Israel Institute of Technology and New York University
Lea Dolev
Technion – Israel Institute of Technology and ORT Israel
The goal of our study was to examine how variations in task
design using tools may affect the process and object of learning. The
study focuses on sorting tasks, i.e., learning tasks that require grouping a
given set of mathematical items, in as many ways as possible, according
to different criteria suggested by the learners. We present an example of a
sorting task for which the items to be grouped are related to basic
concepts of analytical geometry that are connected to the notion of loci of
points. Based on an experimental study
49
with three groups of in-service
secondary school mathematics teachers, we report on intended and
enacted objects of learning inherited in three versions of the task.
Empirically-based suggestions are drawn about design principles of
sorting tasks that potentially to evoke desirable enacted learning.
Keywords: Analytical geometry; classifications; sorting task; variation
theory
Introduction
The study aims at examining how variations in task design may affect the process and
object of learning. We focus on sorting tasks, i.e., learning tasks that require grouping
a given set of mathematical items (e.g., graphical, symbolic or word representations
of mathematical concepts), in as many ways as possible, according to different criteria
suggested by the learners (Zaslavsky, 2008a; Zaslavsky, Chapman & Leikin, 2003).
In particular, we analyse a sorting task based on a set of items related to basic
concepts of analytical geometry that are connected to the notion of Loci of Points (we
refer to this task as the LP sorting task).
The study can be seen as an application of variation theory to design of a
task aimed at enhancing learners' awareness of mathematics as a connected field of
study. Briefly, in variation theory terms (Marton & Booth, 1997; Runesson, 2005),

49
This study was conducted as part of a Ph.D. dissertation by the third-named author under
the supervision of the first- and second- named authors (Dolev, 2012). Theme D – B. Koichu, O. Zaslavsky & L. Dolev
462
awareness of mathematics as a connected field of study was an intended object of
learning, a particular sorting task was a medium of learning, the number and content
of mathematical items included in the task were subjects of didactical manipulations,
and the learners' ways of handling the task, which was offered in three different
versions, constituted a variation space or an enacted object of learning. The latter is
the focus of our study.
The study was guided by the following research question: What is the nature
of learning that may occur in small groups of mathematics teachers while working on
the different versions of a sorting task? Based on the empirical answer to this
question, we address at the end of the paper the more general one: What are the
characteristics of a set of mathematical objects for sorting that can enhance
opportunities for the learners to achieve the intended object of learning and what
design principles underlie the construction of such a set?
Theoretical Background
Sorting tasks
Sorting or classification tasks are recognized as a useful teaching/learning tool either
in a mathematics classroom or in a teacher professional development workshop. For
instance, Sawada (1997) found that students who were not motivated to take part in
traditional mathematics lessons were responsive when given a sorting task in the
context of geometry and could classify the given items in the variety of ways.
Zaslavsky, Chapman and Leikin (2003) discuss the learning potential of
sorting tasks in the context of symbolic and graphical representations of functions.
They pointed out the open nature of the task and its potential to evoke different
mathematical solutions. Zaslavsky (2008a) analyzed a sorting task based on a set of
graphical representations of functions and argued that engaging in the task can draw
students' attention to subtle similarities and differences between the items.
Zaslavsky and Leikin (2004) described how a group of mathematics teachers
coped with a sorting task based on a set of algebraic equations and inequalities. They
found that the participants first suggested ways of sorting based on surface features
(i.e., features that can be observed without solving the statements), and only after a
while turned to more structural features (i. e., those that may be identified only by
solving the statements). A compatible result was found by English and Sharry (1996)
for high school students working on a similar sorting task. In their study, the
participants tended to classify equations by arithmetic manipulations involved in
solving them, but, as a rule, not by deep-level mathematical structure of the equations.
In spite of an increasing attention to the potential of sorting tasks, none of the
studies on this type of tasks examined iterative aspects of task design; rather they look
at a final version of a task. As a rule, the processes of designing sets of objects for
sorting remain salient, though the design processes of some other kinds of open
learning tasks have been usefully unpacked (Zaslavsky, 2008b; Liljedahl, Chernoff &
Zazkis, 2007). Our study focuses on the task design iterations as well as the

differences in the learning experiences inherited in the different versions of the task.
Variation theory of learning
A central premise of a variation theory of learning is that "there is no
learning without something being learned" (Runesson, 2005, p. 70), or, in other
words, "learning always has an object" (ibid). The theory encompasses three types of Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
463
objects of learning (Marton & Booth, 1997; Runesson, 2005). A lived object of
learning denotes what is actually learned from the point of view of a learner. It is
difficult to reveal. An intended object of learning denotes the capabilities the teacher
wants the learners to develop. An enacted object of learning is constituted in the
interaction between learners and the teacher or between the learners and themselves,
and denotes what is possible to learn in a particular situation. Intended and enacted
objects of learning may or may not coincide.
Analyzing the enacted object of learning requires identifying the affordances
and possibilities for developing a certain capability as inherited in the learning
situation. In connection to task design, revealing the enacted object of learning means
that the design team should critically evaluate, based on empirical evidence, which
experiences the task affords and to which extent those are beneficial for coconstructing the intended object of learning.
An additional premise of the variation theory is that objects can be perceived,
understood or experienced by a learner or a group of learners in different ways,
depending on which aspects of the object one's awareness is directed to and how.
Consider an example in the context of sorting tasks. When deciding whether or not
two mathematical items belong to the same group, a group of learners can direct their
attention to the appearance of the common words or symbols in the items'
formulations. Alternatively, they can direct their attention to small differences in the
items' formulations and eventually find out that similarly looking formulations
describe different mathematical objects. Such possibilities constitute a space of
variations inherited in the learning situation or task. In variation theory, variations in
ways by which a certain object may be perceived or experienced by an individual or a
group are considered fundamental for learning. Accordingly, our analysis focuses on
the diversity of the teachers' ways of experiencing the different versions of the task as
well as on their final responses.
The study
The settings
An LP sorting task was developed by the third-named author for the use in 90-minute
workshop for in-service secondary school mathematics teachers as learners and
potential users of the task in their classrooms. The LP task design was driven by the
following learning objective: to facilitate learners' awareness of mathematics as a
connected field of study by directing their attention to structural similarities and
differences among the basic concepts of analytical geometry and loci of points.
Each workshop had the following structure: a brief presentation of different
representations of conic sections – 10 minutes; instructions for working on a sorting
task – 5 minutes; small group work on the LP task – 40 minutes; reflective discussion
in a whole group – 15 minutes; discussion of those cards that were perceived by the
teachers as the most difficult ones – 10 minutes. The instructor refrained from
intervening in the main part of the workshop.
Data sources and analysis
Overall, 53 secondary school mathematics teachers participated, as learners, in the
study. Each of them took part in one of three 90-minute workshop. Each workshop
used a different version of the LP task. Nineteen learners divided into 6 groups took Theme D – B. Koichu, O. Zaslavsky & L. Dolev
464
part in the first workshop; 18 learners divided into 5 groups – in the second one and
16 learners divided into 5 groups – in the third one.
The data consisted of transcribed videotape-recorded small-group and whole
group discussions, in addition to their sorting actions. For each small group, the
completed sorting sheets were collected and analyzed.
The between-group variations in the sorting criteria and the order, in which
they appeared in the course of the learners' actions were deduced from the data and
considered to be the variation spaces for each version of the task. Patterns of the
learners' experiences while working on the task were identified by juxtaposition of the
participants' discourse, sorting actions and corresponding sorting sheets. The main
two patterns were: (i) making sorting decisions by recognizing the objects as familiar
from past study of analytic geometry, and (ii) making sorting decisions by 'solving'
the item, i.e., by applying algebraic manipulations in order to obtain a familiar
symbolic or pictorial representation of the loci of points. The variation spaces of each
version of the task were compared to determine to which extent they are compatible
with the intended object of learning: to facilitate awareness of structural similarities
and differences among the basic mathematical concepts of analytical geometry rather
than similarities and differences based on surface features of the items.
Three task iterations
Intended and enacted objects of learning: The first version
Generally speaking, the initial process of the set construction for the LP task was
compatible with that described by Watson and Mason (2006) for designing teaching
sequences of exercises based on the students' (presumed) perceptions. Specifically, it
started from the analysis of how the chosen concepts are represented in textbooks and
included decisions about which controlled variations should be considered so that the
learners "might observe regularities and differences, develop expectations, make
comparisons, have surprises, test, adapt and confirm their conjectures within the
exercise" (Watson & Mason, 2006, p.109).
The first version of the LP task consisted of 24 items (see Table 1 in the
Supplementary Material (SM) file
50
). It was created so that three types of controlled
variations would be maximized. The first type of variation was related to the
mathematical objects described in the cards for sorting: a straight line, circles,
parabolas, ellipses, hyperbolas and the empty set. Two items disguising the empty set
and one item disguising a straight line were included in order to increase the
participants' awareness of the internal mathematical features of the mathematical
objects under consideration; we refer to these items as "pathological" ones. The
second type of variation was related to the type of representation: symbolic, graphical
and verbal. Furthermore, the verbal items varied with respect to two factors: the main
operation involved in the loci generation and the generating elements given in the
descriptions (see Table 2 in SM). The main desirable way of classification was by the
names of loci of points. This is because this way of classification required from the
learners to unravel structural similarities and differences among the items.
The third type of variation was related to the types of experience needed to
handle the task, in relation to the (presumed) mathematical knowledge of the

50

465
participants. It was hoped that the participants could identify most of the loci of points
based on their prior knowledge and on the information given in the introductory
presentation, and thus, would have enough time to look for structural similarities and
differences. The reality turned to be more complicated than our plans.
First, though all the groups considered several ways of sorting as requested,
only two groups wrote more than one way in their sorting sheets and one group did
not write in the sheet at all. This finding suggests that the offered format of the task
was not comfortable for most of the participants, in spite of (or may be due to) its
openness. Second, all the groups started from the most apparent way of sorting, by the
types of representations, but only one group wrote it in the sorting sheet. This
suggests that most of the participants did not perceive this way as worthwhile sharing.
Third, the desirable way of classification, by names of the loci of points, was
considered by all the groups only in advanced stages of the work on the task and was
documented by 5 out of 6 groups. Forth, the need to "solve" the verbal items
manifested itself stronger than we expected. There were 69 attempts to classify 18
verbal items, and in 44 cases (59%) the sorting decisions were made based on
algebraic manipulations. Only 21 sorting decisions (36%) were made based on the
prior knowledge. This means that the task was much more "technical" for the
participants than we expected and that an essential part of the enacted learning was
not related to sorting, but to the ways of "solving" the verbal items by means of
algebraic manipulations. Finally, it became clear that the overall number of the items
was overwhelming. The characteristic assertions on this issue included: "There are too
many cards. It is impossible to consider them all!" and "It is a lot of work… we still
have 5 cards to sort, but I don't want to do it any more…"
In conclusion, the first version of the LP task, which was designed in
accordance with the principle of maximizing the chosen types of variations, resulted
in partial success: the desirable way of classification was considered, but a lot of time
was devoted to the technical work and to classifying the items by surface features.
Intended and enacted objects of learning: The second version
The second version consisted of 18 items (see Table 1 in SM). The items, which have
been approached in all the groups only algebraically, were excluded. (The intended
characteristics of the second set of cards are presented in Table 3 in SM).
We found that in spite of a smaller intended variation space, in comparison
with the first version of the task, the enacted variation space became richer. The main
sorting criteria were: "by the type of representation – symbolic, graphical or word" –
9 appearances; the (desirable) criterion "by the name of locus of points – parabola,
hyperbola etc." – 5 appearances; the criterion "by key words in the items descriptions
– 'sum of distances', 'ratio' etc." – 7 appearances, and the criterion "by the ability of
the group to identify the loci without 'solving the item'" – 3 appearances.
This time all the groups completed the sorting sheets, and 2 out of 5 groups
documented in the sheets more than one way of sorting. The desirable way of sorting,
by names of the loci of points, was considered by all the groups earlier than in the
first workshop and was documented by 4 out of 5 groups. This finding suggests that
the teachers were more engaged in looking for structural similarities and differences
than in the first version of the task.
The analysis of the teachers' actual experiences with the task supports this
suggestion. Fifty-five attempts to classify 11 verbal items were made, and in 29 cases
(53%) the sorting decisions were made based on the prior knowledge. In 7 cases Theme D – B. Koichu, O. Zaslavsky & L. Dolev
466
(13%) the decisions were made based on algebraic manipulations (5 decisions were
correct), and in 12 cases (22%) algebraic manipulations were used to verify the
decision based on prior knowledge (for instance: "I've solved no. 12. It is a straight
line. It was for nothing – I could see [from the formulation] that it is about a
midline…").
With respect to the teachers' experiences, it is interesting to point out that in
7 cases (13%) the teachers fixed, by means of algebraic manipulation, their earlier
wrong decisions based on their prior knowledge. For instance, the "pathological"
items were treated in this way and summoned attention and interest of the
participants. Overall, it can be concluded that in the second version of the task the use
of algebraic manipulations supported the teachers' classification actions, but was not
the main experience they gained from the task.
Still, 4 out of 5 groups started from considering the apparent, but not
especially instructive criterion "by the type of representation." Moreover, it was
evident that the presence of the well-familiar pictorial and symbolic representations in
the task postponed and probably hindered the learning experiences related to making
sense of the verbal items. For this reason, we decided to leave in the third version of
the task only 11 verbal items (see Table 1 in SM).
Intended and enacted objects of learning: The third version
As mentioned, in the third version of the LP task our intention was to supress the
appearance of sorting criteria by surface features, in favour of criteria related to
identification of structural similarities and differences. The prospective
characterization of the set of items can be found in the "verbal representations" part of
Table 3 in SM. The findings show that this goal was achieved.
As in the second workshop, all the groups completed the sorting sheets, and 2
out of 5 groups wrote in the sheets more than one way of sorting. As in the second
workshop, all 5 groups considered the desirable way of sorting, and 4 out of 5 groups
wrote it in the sorting sheets. The overall number of the considered sorting criteria
(26) was also compatible with that from the second workshop (30), though the
number of items to be classified was considerably smaller, 11 instead of 18.
One essential difference between the second and third versions appeared to
be related to the types of experience utilized for making sorting decisions. Out of 55
sorting decisions, 41 (75%) were based on the use of prior knowledge, and only 8
decisions (15%) – on algebraic manipulations. Another difference was related to the
use of the "by key words" criterion (15 out of 26 appearances). In the first and the
second versions this criterion reflected the learners' attention to certain words in the
formulations, but usually without particular attention to their mathematical role in
generating the loci. In the third version, the criterion was used more meaningfully
and, as a rule, on the way to the desirable criterion "by names of the loci of points."
In closing, the two main enacted subcategories of the "by key words"
criterion in the third version of the task – "by the main operation for generating the
locus" and "by the main generating elements" – were remarkably close to one of the
intended types of variation of the LP task.
Discussion: Articulation of the principles underlying design of the LP
task
In each successive version of the LP task, the enacted variation space was closer to
the intended variation space than in the previous one. In this section, we attempt to Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
467
pinpoint this phenomenon by extracting from the findings the characteristics of the
sets of items for sorting and, in a more general mode, by formulating seven design
principles underlying their construction, in addition to the principles formulated in
past research.
From only partial success of the implementation of the first version of the LP
task, two design principles can be deduced:
1. An amount of work needed to handle the task should be feasible for learners
under the given time constraints and their incentives to be engaged in doing
the task meaningfully, and not only formally.
2. In order to preserve the central role of the main intended activity (in our case –
classifying), the task should not be overloaded with mathematically
challenging items that may require "solving" by means of complementary
mathematical techniques (in our case – by algebraic manipulations).

The second and the third versions of the task also taught us that:
3. Inclusion of a small number of mathematically challenging items constructed
so they can create a feeling of surprise for the learners (in our case,
"pathological" items fulfilled this role) is beneficial for learning.
The next design principle, which arises from comparison of all three versions of the
task, is in the spirit of the proverb "sometimes less is more:"
4. Well-informed reduction of the intended variation space of a task does not
necessarily lead to reduction of the enacted variation space, and, in some
cases, may even increase it.
In addition, we observed that:
5. Having items based on different types of representations of the same concepts
does not necessarily enhance an experience of looking for structural
connections between the chosen concepts.
This principle may seem counterintuitive in light of the professional literature, which
calls for engaging the students into experiences that require connecting different
representations of the same mathematical concepts (e.g., NCTM, 2000). One possible
explanation is as follows. Well-familiar symbolic and pictorial representations in the
first and the second versions of the task served as reference points for looking for
ways of how to sort the verbal items by names of the loci of points. By reference
points we mean pieces of knowledge the learners hold as true and use as an anchor for
planning or monitoring (cf. Harel, Koichu & Manaster, 2006, for the compatible use
of a 'reference point' notion in the context of a problem-posing task). Coming back to
the LP task, it seems that from the learners' perspective, the verbal items in the first
and the second versions should have been "solved" in order to reveal their symbolic
or pictorial representations to be then compared with the items presented in symbolic
or pictorial forms from the beginning. Symbolic and pictorial representations were
unavailable as reference points in the third version, but an idea to sort the items by
names of the loci of points was still apparent, given the participants' prior knowledge.
Consequently, the participants were forced to look for the subtler reference points in
the items' formulations. The main operations for generating the loci and the main
generating elements were considered as such.
The next two principles stem from the observed regularities in the order, in
which the teachers considered different sorting criteria.
6. Task design should take into account that learners tend to start from easy-tomake decisions on their way to making more effortful (and meaningful)
decisions. Theme D – B. Koichu, O. Zaslavsky & L. Dolev
468
7. The easy-to-make decisions can either hinder or support the intended object of
learning, thus, the effort should be made to anticipate and organize them so
they would serve as reference points on the way to more meaningful decisions.
Simply put, these two principles are in the spirit of the well-known saying "a
journey of a thousand miles begins with a single step." A more sophisticated
argument is presented below. To recall, we found that in the first and the second
versions of the task most of the groups started from sorting the items by the most
apparent criterion, "by the types of representation – symbolic, pictorial or verbal". We
first observed that in many cases this criterion had been surface-level only for the
learners and as such it might hinder the desirable deep-level reasoning around the
verbal items. However, when the possibility to consider the types of representations
as a sorting criterion was suppressed in the third version, the learners began to
consider instead the next most apparent criterion, "by key words". A closer look at the
data reveals that this criterion was not always only a surface-feature one for the
participants. As we have argued above, in many cases it could be seen as an indicator
that the participants looked for the reference points to start with on their way to more
mathematically meaningful criteria. Having this idea, we started to reconsider the role
of the "by the types of representations" criterion in the first and the second versions.
We now are inclined to think that the criterion that appeared at first was not only due
to some weakness of the early versions of the task, but also due to some fundamental
mechanisms embedded in cognitive activity of classifying or, more generally, in
human thinking (cf. Zaslavsky, 2008a, for an elaborated argument).
Back to the LP task, we assume that in virtually any version of the task we
can think of, the participants would probably always start from considering some
easy-to-see criteria. To recall, English and Sharry's (1996) and Zaslavsky and Leikin's
(2004) results indirectly support this assumption. And only after critical evaluation
whether the first criterion is interesting enough to be written, the participants might
start digging dipper. The pedagogical implication of this simple idea is formulated
above as Principle 7. To put it in other words, instead of trying to supress the
immediate (as a rule, not especially deep) ideas of the learners coping with an open
learning task, the task designers should worry about whether the task provides
opportunities for developing these initial ideas into more sophisticated, desirable,
ones. The presented case suggests that this goal is feasible, though it is not easy to
achieve.

Principles of task design to foster proofs and refutations in
mathematical learning: Proof problem with diagram

Kotaro Komatsu
Faculty of Education, Shinshu University, Japan
Yosuke Tsujiyama
Faculty of Human Sciences, University of Tsukuba, Japan

Proving is an essence of mathematical activities, and therefore
educational studies should seek effective tasks that foster students'
proving activities. Among various aspects of proof and proving in
mathematics education, this study aims to develop a set of tasks by which
students can experience an authentic process of proofs and refutations. In
particular, this paper focuses on proof problems with diagrams, and
elaborates task design principles for such problems from a theoretical
perspective based on a notion of deductive guessing which Lakatos
formulated as one of the heuristic rules. In later cycles of this study, the
authors and teachers will jointly scrutinize the design principles from
practical perspectives.

Keywords: proof and proving, refutation, Lakatos, deductive guessing,
proof problem with diagram

Introduction

Mathematical tasks are one of the most essential tools for promoting students'
learning. In particular, what kinds of problems should be posed to students and how
teachers should deal with the problems in their classrooms are vital for quality
mathematical learning (Henningsen & Stein, 1997; Hiebert & Wearne, 1993). It is
also necessary to make clear which mathematical activities are targeted at, because
effects of a task depend on the nature of mathematical activities (e.g. conceptual
understanding, procedural fluency, mathematical modelling or inquiry, and so on).
This study chooses proof and proving as a main target of mathematical
activities, because proving is an essence of mathematics, and therefore it should be a
core of students' experiences at all grades (NCTM, 2000). Several mathematics
educators have already conducted important researches about tasks related to proof
and proving (e.g. Bieda, 2010; Buchbinder & Zaslavsky, 2011; Lin et al., 2012;
Stylianides, 2009). For example, Stylianides and Stylianides (2009) develop an
instructional sequence which consists of a series of tasks and associated instructor
actions so that students can recognize a limitation of empirical arguments and a need
for deductive proofs. They deal with one of the most prevailing difficulties that
students do not feel a need to learn deductive proofs.
Among various aspects of proof and proving, this study focuses on processes
of proofs and refutations that task design researches do not seem to have examined so Theme D – Kotaro Komatsu & Yosuke Tsujiyama
472
far. In particular, we intend to develop task design principles for an authentic learning
which mirrors mathematical processes that Lakatos (1976, 1978) described. He
insisted that "informal, quasi-empirical, mathematics ... grow(s) through ... the
incessant improvement of guesses by speculation and criticism, by the logic of proofs
and refutations" (Lakatos, 1976, p. 5). He described processes of mathematical
development through rational reconstruction of actual histories about Descartes-Euler
conjecture on polyhedra and about uniform convergence. Thus, relying on Lakatos's
research could lead to design tasks by which students can experience developmental
mathematical activities, which gradually progress through conjectures, proofs and
refutations.
As a task which can allow us to realize such authentic learning in regular
classrooms in junior or senior high school, this study focuses on "proof problems with
diagrams" (the definition and illustration will be provided in the following sections).
We first refer to the context of this study briefly, that is, mathematics education in
Japan. Japanese students start to learn geometric proofs from the eighth grade (13-14
years old), and eighth and ninth graders learn to prove geometric statements about
various properties of triangles, quadrilaterals and circles, using conditions for
congruent or similar triangles. In Japan, proof problems with diagrams are standard
for students and teachers in the sense that most of the proof problems in school
geometry include diagrams that indicate meanings of problem sentences (such
problems seem to be common in other countries as well; for example, see Herbst &
Brach, 2006). This study attempts to reflect on whether and how an authentic
mathematical learning based on proofs and refutations can be realized through such
standard problems.
This paper is the first report of a larger study that aims to develop, through
collaboration between researchers and teachers, a set of proof problems with diagrams
and associated teachers' guidance which prompts students to engage in processes of
proofs and refutations. Toward this overall goal, this paper focuses on the first aim of
the Working Group on Theme D, that is, to delineate task design principles within a
singular community of researchers. Current roles of the authors are to elaborate task
design principles for proof problems with diagrams from theoretical perspectives and
to develop several tentative tasks, and we address these aspects in this paper. Later on,
the authors and teachers will jointly re-examine the principles and tasks from practical
perspectives, enact the tasks in classrooms, and refine these principles and tasks from
results of the enactment.
Before taking up the main subject, it is better to clarify the definition of
"task" in this study. We regard task as a problem such that at once students try to
solve it and teachers plant an educational aim of getting students to experience certain
mathematical processes during solving it (e.g. Fig. 1 and 3); problems are usually set
by teachers or textbooks, but in some cases students may formulate problems by
themselves. In task design, it is essential to select or develop problems that have high
possibilities to achieve the intended educational aims. In addition, teachers'
interaction with students plays a vital role for quality mathematical learning because it
is unrealistic to expect that only posing the problems can facilitate students' activities.
Therefore, task design in this study involves not only selection or development of
problems but also teachers' instructional guidance related to the problems. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

Deductive guessing in Proofs and Refutations

In elaborating task design principles, this study takes into account a mathematical
perspective primarily, in particular a mathematical process which Lakatos (1976)
described in Proofs and Refutations. Among various methods shown in the literature,
this study focuses on "increasing content by deductive guessing" (hereafter, deductive
guessing) that has not been sufficiently deliberated in mathematics education
literature so far. Deductive guessing indicates that after one proves conjectures and
then faces their counterexamples or non-examples, one invents deductively more
general conjectures which hold true even for these examples (Lakatos, 1976, p. 76).
Lakatos formulated it as one of five heuristic rules which summarized several
methods for coping with counterexamples. The word "heuristic" seemed to have a
normative meaning in his philosophy of mathematics, because he was largely
influenced by Polya's mathematical heuristic (Davis & Hersh, 1981; Lakatos, 1976),
and Polya (1957) stated that "(m)odern heuristic endeavors to understand the process
of solving problems, especially the mental operations typically useful in this process"

(pp. 129-130, emphasis is original). Thus, Lakatos appreciated deductive guessing as a useful and productive action for advances of mathematical activities.
Since deductive guessing is a mathematical notion, some examination from pedagogical perspectives is also necessary to regard deductive guessing as a central component for task design principles. For a pedagogical rationale of the principles, this study adopts "the intellectual-honesty principle" that Stylianides (2007) indicates. On the principle, he argues that when conceptualizing the notion of proof in school mathematics, it is essential to take into consideration "both the normative aspects of proof in mathematics … and what is known or conceptually accessible to the learners under teacher guidance or collaboration with peers" (Stylianides, 2007, p. 3). Further, he implies that the intellectual-honesty principle should be applied to not only the notion of proof in school mathematics but also other notions or activities.
It is already mentioned in the above that Lakatos regarded deductive guessing as a normative action in mathematical research. In addition, there is some evidence that shows the accessibility of deductive guessing to primary or junior high school students (Komatsu, 2010, 2011). For instance, Komatsu (2011) carried out an experiment in which, after a pair of ninth graders proved their conjecture and then confronted with counterexamples of the conjecture, they could invent a more general statement that held true for the counterexamples. Thus, selecting deductive guessing as a central component for task design principles would enable mathematics teachers and educators to attain an authentic mathematical learning which at once mirrors processes of proofs and refutations and is accessible to students.
Principles of task design for proofs and refutations: Proof problem with diagram
Proof problem with diagram
In order to develop certain kinds of tasks which lead to mathematical processes advocated by Lakatos, this study focuses on "proof problems with diagrams" in geometry. A proof problem with diagrams is a problem in which a statement is described with reference to particular diagrams with symbols (one diagram in most cases) and solvers are required to prove the statement (Fig. 1). In the following, we briefly summarize the nature of such problems and then illustrate that specific kinds
of such problems could give students opportunities to find and deal with counterexamples and non-examples.
Not only in Japan but also in many other countries, students encounter proofs within geometry at junior or senior high school, and proofs in school geometry have their origin in Euclidean geometry. In Euclid's Elements, propositions are stated in general and abstract words without any symbol or diagram. To prove such proposition, one needs to draw particular diagrams, attach symbols to points, construct deductive arguments according to these diagrams and symbols, and finally examine whether the arguments can demonstrate truth of the given general proposition. In the final phase, it is necessary to see each diagram as "a representative special case" (Polya, 1954) of the general proposition (on this dual nature of diagrams, see Tsujiyama, 2010).
In contrast, in many cases in school geometry, students are given proof problems to which diagrams and symbols are already attached. Mathematics educators in Japan have discussed the educational values of such problems. They argue that the attached diagrams bring some diversity in interpretations of such problems and that the diversity can give students an opportunity to engage in productive inquiry. In particular, Shimizu (1981) discusses that, after students solve such problems, it is important for the students to further inquire "of what (mathematical) relations the given diagram is a representative special case" (Shimizu, 1981, p.36) by utilizing already-obtained proof. He illustrates such inquiry by using a specific kind of proof problems with diagrams as below.
Fig. 1 shows an example of proof problems with diagrams. We consider a case in which one completes the proof of the statement by showing ΔBPA ≡ ΔAQC, BP = AQ and AP = CQ. One might have a doubt on meaning of "in the diagram" or "a straight line l through point A" in the statement, and this doubt will bring an occasion to inquire what may happen if one changes the position of the straight line l. This inquiry leads to encounter non-examples and counterexamples such as the diagrams shown in Fig. 2; line BP does not exist in Fig. 2-a (but, BP + CQ = PQ in a sense), and BP + CQ K PQ in Fig. 2-b and c. These examples disclose an implicit assumption in the statement in that "in the diagram" means a case where the straight line l and triangle ABC share only point A. On the other hand, if one observes Fig. 2-b and c with the already-obtained proof, one will find that |BP CQ| = PQ holds in the diagrams because ΔBPA ≡ ΔAQC, BP = AQ and AP = CQ are still true. Furthermore, it is possible to organize the relations among segments PQ, BP and CQ in the overall cases in terms of "sum" and "difference" (Shimizu, 1981, pp. 33-36).
In the diagram, angle A is a right angle and AB = AC. To a straight line l through point A, we draw perpendicular lines BP and CQ from points B and C respectively. Then prove that BP + CQ = PQ
Fig. 1: Proof problem with diagram (Shimizu, 1981, p. 30) Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

Fig. 2: A non-example and counterexamples of the problem (ibid., pp. 34-35)
This illustration shows the nature of proof problems with diagrams that the attached diagrams sometimes make obscure the domains of the statements because the diagrams may include some implicit assumptions. This feature enables us to practice processes of proofs and refutations which Lakatos advocated, for example, to find counterexamples and non-examples through changing the attached diagrams, to restrict the domains of the statements by articulating the hidden assumptions, and to investigate new conjectures which hold for the counterexamples and non-examples. But, students will need some support from teachers in order to practice these activities successfully, and in next section we elaborate task design principles which would facilitate students' activities.
Principles of task design for proofs and refutations: Proof problem with diagram
According to both deductive guessing in Lakatos's research and the nature of proof problems with diagrams, this study derives three principles of task design which aim to achieve an authentic mathematical learning based on proofs and refutations:
1) Educators and teachers should select or develop a certain kind of proof problems with diagrams where students can find counterexamples or non-examples and engage in deductive guessing through changing the attached diagrams.
2) Teachers should promote their students to change the attached diagrams with keeping the conditions of the statements so that the students can find counterexamples or non-examples of the statements.
3) After students face the counterexamples or non-examples, teachers should plan their instructional guidance with which students can utilize their proofs of initial problems to invent more general statements that hold true for these examples.
The first principle is about selection or development of problems, and it seems to be quite an obvious principle from the intention of this study. Nevertheless, all of proof problems with diagrams do not allow us to find counterexamples or nonexamples and engage in deductive guessing by changing the diagrams. Thus, it is necessary for mathematics educators and teachers to select or develop a certain kind of proof problems with diagrams that enables students to practice such activities.
The second is about teachers' instructional guidance for discovery of nonexamples and counterexamples. Before deductive guessing, students need to confront with counterexamples or non-examples of the statements, and as shown in Fig. 2, changing diagrams attached to proof problems with keeping conditions of statements leads to finding such examples. However, it would be difficult to expect that students change the attached diagrams spontaneously, because it seems that the diagrams are typically given by teachers or textbooks in ordinary classrooms, and that there are few opportunities where students vary the shapes or places of the diagrams (Herbst &
Brach, 2006). Hence, teachers need to

Concluding remarks
This paper elaborated three task design principles for proof problems with diagrams
by which students could experience an authentic mathematical process of proofs and
refutations, and illustrated these principles with a familiar problem on parallelogram.
Here, we refer to implications of this paper on teachers' community, keeping in mind
the context of our study. In Japan, as stated earlier, proof problems with diagrams are
standard for students and teachers, and learning activities where students inquire into
domains of statements by changing the attached diagrams has been already discussed
(e.g. Shimizu, 1981) and also may have been practiced in some classrooms. This
paper can provide teachers with theoretical supports that show the mathematical
authenticity of their practices according to a Lakatosian perspective. In addition,
teachers can utilize the principles of this study as a guideline for their task design
including necessary instructional guidance when they use proof problems with
diagrams to attain mathematical learning based on processes of proofs and refutations.
This paper still remains only a theoretical consideration by a single
community of researchers. In order to develop a set of appropriate tasks for regular
classrooms, the team of the authors and teachers will later scrutinize the theoretical
consideration from practical perspectives. For example, this study plans to re-examine
the design principles and tasks shown in this paper from teachers' abundant
experiences about teaching and learning of proofs. It is also necessary to enact the
tasks in classrooms, and to refine these principles and tasks from results of the
enactment.

The "Language and argumentation" project: researchers and
teachers collaborating in task design
Francesca Morselli
Department of Philosophy and Educational Science, University of Turin (Italy)
This contribution illustrates the "Language and argumentation"
project, carried out since 2008 by the Mathematics Department of the
University of Genoa. The project is aimed at designing, experimenting
and refining task sequences for a smooth and meaningful approach to
proof in lower secondary school. Two examples illustrate the way of
working of the team (the cycles of experimentation and refinement) and
some special tasks explicitly aimed at promoting students' reflection on
processes and products.
Keywords: language, argumentation, proof, low-secondary school,
sequence of tasks, students' processes, cycles of experimentation
Introduction
This contribution presents the "Language and argumentation" Project (lower
secondary school strand), carried out by the Mathematics Department of the

University of Genoa since 2008. The aim of the paper is to describe the structure of the Project team, the theoretical assumptions underlying the task design activity carried out by the team, the special tasks that were created and the way they were progressively refined throughout cycles of experimentation.
The contribution aims at addressing the following questions, as presented in the ICMI Study 22 Discussion Document (Theme D): If you identify yourself as a member of a design group that cuts across communities, which ones are they? How did this cross-community come to be formed? When you or your group engages in designing tasks, what are you trying to achieve? What are your primary considerations? Which theoretical, mathematical, pedagogical, technological, cultural, and/or practical aspects are taken into account when designing a task or a task sequence? Are the designed tasks subject to revision in later cycles of the work? If so, what is it that specifically leads to the redesign? On what basis and according to which principles is the redesign carried out?
In reference to the Discussion Document, we take tasks as the mediating tool between teaching and learning, and we illustrate the way in which, in our project, tasks are used in order to achieve specific educational goals (fostering the approach to argumentation and proof).
Background: proof and task design
Scholars agree on the fact that teachers should set up proper actions so as to arouse students' need for proof and proving (Zaslavsky et al., 2012), and also point out that Theme D – F. Morselli
482
teachers need preparation and support in doing that. Indeed, teachers face many challenges when dealing with proof in the classroom (Lin et al., 2012b): they must establish suitable socio-mathematical norms, choose and manage the good tasks, or even create their own tasks, guide the students towards deductive thinking without turning proving into a "ritual" activity. Also teachers' beliefs about proof and its role in the teaching and learning of mathematics play a key role in influencing the effectiveness of the teaching of proof (Furinghetti & Morselli, 2011). For instance, many teachers seem to believe that geometry is the most suitable domain to teach proof and that proof is an advanced mathematics issue, to be taught only in secondary school.
In the literature we can found many examples of task sequences that were created with the explicit aim of improving the teaching and learning of mathematical proof (Stylianides, 2007). Lin et al. (2012a) list a series of principles for task design for conjecturing, proving and the transition between conjecture and proof. Concerning conjecturing, we mention the importance of providing an opportunity to engage in observation, construction, and reflection. Concerning proving, the authors point out the importance of promoting the expression of arguments in different modes of argument representation (verbal arguments, symbolic notations etc.), asking the students to create and share their own proofs and to evaluate proofs produced by the teacher (thus "changing the roles"). Finally, concerning the transition from conjecture to proof, the authors suggest that the teacher should establish "social norms that guide the acceptance or rejection of participants' mathematical arguments" (p. 317).
This contribution will illustrate the way the team of the "Language and argumentation" project designed and experimented task sequences aimed at arousing students' "need for proof" in lower secondary school.
The "Language and argumentation" project
In 2004 the Italian Ministry for Instruction, University and Research (MIUR) founded the national Project "Lauree Scientifiche" ("Scientific degrees") (PLS in the following), whose aim was fostering the enrolment in university courses with scientific orientation, stimulating young people's interest in studying sciences and providing a better education in the base sciences. The project had several strands, going from special interventions for "high-achieving students" to pre-university orientation programs. Among them, the so-called PLS Laboratories, that is to say special lessons, performed in the school environment through a collaborative work between university researchers and school teachers.
Within this framework, in 2008 the Mathematics Department of the University of Genoa started the "Language and argumentation " project, a special case of "PLS Laboratory" aimed at designing and experimenting task sequences with a special focus on argumentation and proof.
Three main features characterize the "Language and argumentation" project:
1) task design is a central part of the collaboration between university and school; 2) argumentation and mathematical proof are the core of the task sequences; 3) teachers of different school levels (and not only higher secondary school) are involved, since the project members share the belief that argumentative competence should be developed in a long-term perspective, starting from the very first years of school and throughout all the school levels.
For each school level a team (university + school) was created. The different
teams met regularly in order to share theoretical references on argumentation and take Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
483
advantage of the exchanges and discussions. This contribution specifically refers to the work of the lower secondary school team. The next section illustrates the organization of the teamwork and the theoretical tools that were shared within the team and that helped to perform the didactical and methodological choices.
Task design: the team
Structure of the lower-secondary school team
The lower-secondary school team is currently made up of 7 members: the author FM, a researcher in mathematics education, three teachers with at least 10 years of teaching experience (two of them, MT and EZ, have a university degree in mathematics, one, EQ, has a university degree in chemistry), two teachers with less than 10 years of teaching experience (one, EP, has a degree in mathematics, the other one, GA, has a degree in biology), one retired teacher, AS, with a long experience in collaborative research in mathematics education. The teachers entered the project voluntarily and their participation was strongly supported by the school head. All the teachers (except for AS, retired, and GA, who changed the school after the first year but kept the work in the team) work in the same school.
The team was born in 2008-09: this means that the team just finished its fourth year of work. The first two years were dedicated to the development of a common frame (both in terms of theoretical references and of didactical methodologies). Starting from the third year, task design became a crucial activity for the team. This contribution will especially deal with this part of the project. We also point out that the teachers could design and experiment more than one task sequence for the same group of students
51
, throughout the school years from 2008-09 to 2011-
12. This means that a sort of mini-curriculum with a focus on argumentation and proof was created, and that students could experience more than one task sequence.
The way of working of the team
The author organized all the team meetings (one scheduled meeting per month, starting from November and until June) and acted as an observer during the class sessions. She also made video recordings of the sessions and collected all the students' written productions. Besides the team meetings, she had individual meetings with each teacher, before and after the class experimentation.
The way of working may be synthesized as it follows: during a preliminary meeting, the researcher proposes the theme of the task sequence and sketches a first draft of the core task. The core task is discussed and the teachers, together with the researcher, set up the sequence of tasks, with a special care in the sequencing of tasks. Afterwards, a first experimentation is carried out. Teacher and researcher perform the analysis of the experimentation immediately after the experimentation; the whole team performs an additional analysis during regular meetings. The analysis may lead to the refinement of the task sequence and, thus, to a new experimentation. Two modalities of experimentation were tested: parallel experimentations of the same sequence, and sequential experimentations. In the first modality, two teachers realized

51
In Italy, lower secondary school is made up of three years. Usually the
teacher teaches the same group of students throughout all the three years. Theme D – F. Morselli
484
the task sequence in their classes, almost in the same period. Regular meetings during and after the experimentation allowed a continuous exchange between the two experiences. In particular, students' processes were compared and the actual development of the task sequence in the two classes was analysed and discussed by the whole team. In the second modality, a first experimentation was carried out in one class, afterwards the whole team discussed the way the experimentation was carried out. Possible modifications to the task sequence were discussed, thus leading to a modified sequence to be experimented. In this way, a cycle of planningexperimenting-analyzing-modifying-testing the modified sequence was realized.
In both types of experimentation, the degree of variability left to each teacher is quite high, provided that his/her choices are discussed a priori or analysed a posteriori by the whole team.
In Italy teachers are often involved into research in mathematics education, under the Italian paradigm of the "Research for innovation" (Arzarello & Bartolini Bussi, 1998). Within this paradigm, teachers (who are called "teachers-researchers") collaborate with the researchers in the planning and analysis of the teaching experiments, and theoretical reflections and teaching experiments are performed dialectically, so that the analysis of the teaching experiments may lead to the evolution of the theoretical framework itself. In our case, the teachers were at their first experience of collaboration with researchers. We may say that the "Language and argumentation" project had also the final aim of fostering the professional growth of a new generation of teachers-researchers. Indeed, during the project the teachers did not only receive and implement in their classes the innovative task sequences, rather they were involved in theoretical reflection and a posteriori analysis.
Task design: principles and didactical choices
As regards the level of low secondary school, two educational goals are to be attained: from one side, fostering the development of argumentative and linguistic competences (thus, seeing argumentation as strictly linked to proof, see Durand-Guerrier et al., 2012), from the other side, promoting the first encounter with mathematical proof. Stylianides (2007) proposes the following definition of proof that can be applied in the context of a classroom community at a given time:
"Proof is a mathematical argument, a connected sequence of assertions for or against a mathematical claim, with the following characteristics: it uses statements accepted by the classroom community (set of accepted statements) that are true and available without further justification; it employs forms of reasoning (modes of argumentation) that are valid and known to, or within the conceptual reach of, the classroom community; an it is communicated with forms of expression (modes of argument representation) that are appropriate and known to, or within the conceptual reach of, the classroom community". (Stylianides, 2007, p. 291).
Accordingly, the team believes that a smooth and meaningful approach to proof requires the students' progressive acquisition of basic content knowledge, but also the ability to manage (from a logical and linguistic point of view) the reasoning steps and their enchaining (modes of argumentation) and the ability to communicate the arguments in an understandable way. It is important to develop a sort of "argumentative attitude", that is to say being aware of the fact that each choice, opinion, affirmation should be justified by means of a discourse that must be understood and accepted by peers. This is also in line with the idea that learning proof is approaching a form of rationality, as expressed by Morselli & Boero (2009), who Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
485
proposed an adaptation of Habermas' construct of rationality to the special case of proving, showing that the discursive practice of proving may be seen as made up of three interrelated components:
"- an epistemic aspect, consisting in the conscious validation of statements according to shared premises and legitimate ways of reasoning […];
- a teleological aspect, inherent in the problem solving character of proving, and the conscious choices to be made in order to obtain the aimed product;
- a communicative aspect: the conscious adhering to rules that ensure both the possibility of communicating steps of reasoning, and the conformity of the products (proofs) to standards in a given mathematical culture". (Morselli & Boero, 2009, p. 100)
Starting from the theoretical assumptions that were previously sketched, a list of methodological principles were derived and specific task design principles followed. It is important to underline that argumentation is a major educational goal, but also a means to achieve other educational goals, i.e. a better understanding of specific contents: argumentation is the goal and also the means. Hence, the task sequences are conceived with argumentation as a pervasive activity. We may distinguish between a core task, setting the problem to be worked on (a property to be discovered and justified), and the further tasks. Core tasks are usually proposed as open-ended questions (What can you tell about…?) where, according to the sociomathematical norms of the class, each answer must be justified. The further tasks are conceived so as to foster students' awareness of the epistemic (this is true because…), teleological (I have this goal…) and communicative (how could I communicate it in a proper way?) requirements inherent in the conjecturing and proving process. More specifically, tasks encompass: formulation of conjectures; comparison between different conjectures; justification of conjectures; comparison between individual processes and between individual final products. Didactical methodologies such as group work and mathematical discussions (Bartolini Bussi, 1996) are widely used.
The team also explored the importance of having students analyse students' written individual solutions, as it is advocated within the theoretical framework of the fields of experience didactics (Boero & Douek, 2008). We point out that the methodological choices are also in line with the principles listed by Lin et al. (2012a).
In this way, two types of argumentation are fostered: argumentation at content level, as a part of the proving process, and argumentation at meta-level, as a means for fostering reflection on the practices of mathematical proof related to the three components of rationality. Within the task design process, a crucial goal was to create occasions for meta-level argumentations aimed at promoting students' awareness of the epistemic, teleological and communicative requirements of proving. To this aim, specific tasks were created. Some examples are illustrated in the subsequent section.
Some examples
Example 1 – Isoperimetric rectangles
The task sequence "Isoperimetric rectangles" was conceived for grade 7 (age of the students: 13-14) and encompassed about 20 hours. The core activity is the conjecture and explanation of the fact that, among all the rectangles with fixed perimeter, the

square has the maximum area. That is the task sequence that underwent the most
evident changes and refinements throughout the years of experimentation. The first
version of the task sequence started with an explorative task in paper and pencil ("Draw four rectangles with a perimeter of 20 cm. What can you tell about the areas
of the rectangles?"), followed by a more direct question
area. The students conjectured that the square is the rectangle with maximum area and
in some cases they even tried to provide some numeric justifications. Afterwards, the
conjecture was proved by m

"), followed by a more direct question concerning the maximum
area. The students conjectured that the square is the rectangle with maximum area and
in some cases they even tried to provide some numeric justifications. Afterwards, the
conjecture was proved by means of algebra, under the guidance of the teacher. The
starting point of the proof was drawing a generic rectangle and a square (with t
same perimeter) and superposing them (see figure 1). Once observed that the
rectangle HGDA is part of both the rectangle and the square, the areas of th
figures GFDE and BCGH were expressed algebraically in order to show that the area
of the square is greater than that of the rectangle.
Isoperimetric rectangles: the starting point for algebraic proof
During the first experimentation, one student, looking at the two superposed figures
(see figure 1), raised her hand and proposed to "cut" the rectangle GFDE and place it
over the rectangle BCGH, so as to "see" that one surface is bigger than the other one.
the teachers of the team that giving students some cardboard to
manipulate (and even "cut") could be another step before algebraic proof. A crucial
point was the place (and role) of the "cardboard" part with respect to the conjecture
about the maximum area: was it to be proposed after the drawing phase (within the
conjecturing phase), or after the conjecture of the property of the square (so as to
promote the idea of superposing figures and pave the way to the algebraic proof)?
es of experimentation allowed for exploring the issue, shedding light on
the different roles that the "cardboard phase" may have within the sequence. During
the third experimentation, there was also a very rich discussion on the way of drawing
rectangles with a given perimeter (how much are they; how it is possible to create
another rectangle from a given one; is it always possible to draw "couples" of
rectangles, that differ only from a rotation of 90 degrees). This suggested
the same experimentation, after the ingoing analysis of the session) another task of
individual reflection, so as to foster the connection between geometrical facts and
numerical properties. . The students were asked to write down their reflections about
Why is it that adding and subtracting one unit (to the sides) the
perimeter doesn't change? Is it the same if we add and subtract two units? Why is it
that changing the basis with the height the perimeter doesn't change?".
At the end of the sequence, there was a "balance" task, conceived in order to
foster students' reflection on the value (and limit) of different approaches: drawing on
paper, cutting cardboards, using algebra. A key point is that each approach offers a
different perspective on the problem, helps to grasp some aspects and contributes to
the whole comprehension. The students were asked to answer individually

What may you say of the different approaches?
Did the different approaches allow you to understand the same things?
Were they equally easy to understand?
The "balance" task was aimed at promoting the argumentation at a meta-level on the
potentialities and limits of each approach (for instance, drawing may only help the
conjecturing phase, but it is not a real "proof"), and on the power of algebra as a
proving tool. It encouraged the reflection not only on the correctness (epistemic
rationality), but also on the comprehensibility (communicative rationality) and
usefulness in relation to the final goal of proving (teleological rationality).
Furthermore, the task gave the teachers data for an a posteriori evaluation of the task
sequence.
Example 2: sum of consecutive numbers
The task sequence "Sum of consecutive numbers", conceived for grade 7,
encompassed exploration, conjecturing and proving in elementary number theory. The
whole sequence lasted about 10 hours. The students were proposed a first task ("What
can you tell about the sum of three consecutive numbers?"). They worked in small
groups and shared and compared the group solutions within a mathematical
discussion. Afterwards, the students were given three connected tasks to be solved
individually: "What can you tell about the sum of two consecutive numbers? What can
you tell about the sum of four consecutive numbers? What can you tell about the sum
of five consecutive numbers?". As usual for the norms of the class, each answer was
accompanied by a justification. The teacher and the researcher analysed all the
individual productions and for each task (sum of 2, 4 and 5 numbers respectively)
selected three productions to be compared and commented by the students
themselves, according to the following task:
Read the following answers provided by some of your classmates. Compare them
and write your reflections. What about the properties they found? What about the
explanations they provided?
A mathematical discussion followed. This task fostered a reflection on two connected
issues: the truth and comprehensibility of the conjectures, and the validity and
comprehensibility of the related explanations (epistemic and communicative
components). Students could reflect on the value of numeric examples (for discovery
of the conjecture and communication of the property: teleological and communicative
component), but also on their limits for justification (epistemic and teleological
component). They could also compare justifications in natural language with
justifications in algebraic language. In this ways, an argumentation at a meta-level
was promoted.
In our opinion this task is an application of the principles listed by Lin et al.
(2012) concerning having students produce their own justifications and evaluate
justifications presented by others. Furthermore, this task paves the way to the concept
of proof as presented by Stylianides (2007) and brings to the fore the importance of
three dimensions of rationality, communicative included. We also point out that
creating new tasks of reflection starting from students' own productions makes the
task sequence very "dynamic", since each implementation must take into account new
students' productions. Theme D – F. Morselli
488
Discussion and conclusions
The short examples that were described in the previous session show how the
model of rationality guided the team in the task design process. The core tasks, aimed
at introducing the mathematical content (a property to be discovered and justified),
are accompanied by further tasks, aimed at fostering the reflection on the proving
process as a rational activity. For instance, the "balance" task (example 1) was aimed
at bringing to the fore the role of different methods at epistemic, teleological and
communicative level. The "comparison" task (example 2) was aimed at making
students reflect on the fact that the same conjecture and proof may be presented in
different ways (communicative component) and that different justifications are
possible (epistemic and teleological component).
Example 1 also illustrates the cycles of design, experimentation, analysis and
refinement that characterize the teamwork. One key feature is that the task sequences
are always under refinement. The team analysis may lead to a change in the task
formulation or in the sequencing of the tasks.
Furthermore, as evidenced in example 1, additional tasks, especially tasks
fostering reflection, may be inserted. Each teacher may suggest modifications to the
task sequence.
Finally, it is worth noting that some tasks are "open" and must be set up
during the experimentation. Any task sequence cannot be completely set up a priori,
because it depends on the students' processes and products. The teacher, with the
cooperation of the team, must be able to evaluate "on the spot" the emergence of
issues to be deepened (as in example 1), and to analyse students' products and
promote students' own reflection on productions (as in example 2).

Designing and using exploratory tasks

João Pedro da Ponte
Instituto de Educação da Universidade de Lisboa

This paper addresses the role of exploratory tasks in mathematics learning. We present the rationale and the main characteristics of these tasks and provide three examples to show how they may support students' reasoning at different school levels. We argue that these tasks, requiring students to model situations and to design their own strategies, drawing on previous mathematical and nonmathematical knowledge, have an important potential for mathematics learning.

Keywords: Exploratory tasks, Generalization, Justification

Introduction

In Portugal, the new mathematics curriculum for basic education (Ponte, Serrazina, Guimarães, Breda, Guimarães, Martins, Menezes, Oliveira, & Sousa, 2007) indicates that teachers must use a variety of tasks in the classroom, stressing in a particular way the value of exploratory tasks. This promoted an important movement of study around such tasks and how to use them in the classroom. At the Institute of Education of the University of Lisbon several teaching experiments have been conducted to suggest ways of teaching specific topics of this new curriculum using exploratory tasks as well as to investigate the possibilities of such tasks for other school levels, with a special attention in the development of students' mathematical reasoning (e.g., Azevedo, 2009; Branco, 2008; Henriques, 2011; Quaresma, 2010). In addition, several collections of tasks, most of which are exploratory, together with teachers' supporting materials, have been designed and made available in the internet (e.g., Ponte, Matos, & Branco, 2009; Ponte, Oliveira, & Candeias, 2009; Ponte, Silvestre, Garcia, & Costa, 2010).

Worthwhile mathematics tasks are central in mathematics teaching (NCTM, 1991). However, tasks appropriate for some teaching purpose may not be for another. In addition, tasks need to be suitable for the students to whom they are proposed. Thus, the teacher needs to decide the purposes regarding students' learning and, taking into account the working conditions of the school, choose suitable tasks for his/her students, regarding mathematical challenge (Potari & Jaworski, 2002), underlying context (Skovsmose, 2001), task structure, classroom organization and Theme D – J. P. da Ponte et al.
492

time required (Ponte, 2005). Classrooms in which the students do some extended work on tasks, in an autonomous way, solving problems, modelling situations and devising strategies to solve the questions proposed are becoming more common in our country. In some cases, the questions require considerable interpretation and even some reframing to be tackled in a mathematical way. After this initial work, often done in pairs or in small groups, during which students record their representations and solutions, they are asked to present their strategies and solutions to the whole class, to justify them, and to discuss the work of other students. This view of the mathematics classroom fits with what some documents refer to as "reform mathematics teaching" (e.g., NCTM, 2000).

The teaching experiments that we carry out are framed as design research (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003), with specific hypothesis relating exploratory tasks, use of different representations, and a mode of classroom work that provides opportunities for students' autonomous work and whole class discussions. Data is collected by observing classrooms (usually with video recording), gathering students' written productions, and doing clinical interviews with individual students (see further information on these experiments in the on-line appendix: http://www.ie.ul.pt/portal/page?_pageid=406,1590938&_dad=portal&_schema=PORTAL).

The present paper illustrates this work. Our aim, as a team that cut across diverse communities, is to discuss the characteristics of exploratory tasks, to indicate how they may be used in the classroom, their potential to promote students' learning, their feasibility for regular classroom use, and the critical features that make them suitable for mathematics learning. We begin by presenting the institutional context, definitions and research and design principles of our work and base our argument with snapshot of three examples at different school levels.

Context, definitions and principles

Role of authors, institutional, systemic, and resourcing context of the work

Three of the authors of this paper are classroom teachers involved in research who conducted the implementation of teaching units (Quaresma, grades 5-6, Mata-Pereira, grades 7-9, Henriques, 2
nd
year university). The first author (Ponte) has mostly a research profile with the role of supervision of the design process. All the four authors participate in the design of tasks and of its classroom use. Usually, the first idea for a task is provided by the classroom teacher and the subsequent refinement is done in interaction with the first author and with other researchers at the Institute who also occasionally discuss particular tasks and transversal issues. This developmental work has been conducted at Institute of Education of the University of Lisbon, within teaching experiments carried out as part of academic degrees. It is based in the close collaboration of two different kinds of expertise – mathematics education research expertise and classroom teaching expertise – that is shared in different levels by all authors. The resourcing (printing copies, audio-visual material for recording classes, etc.) is provided by the Institute, sometimes with external grants or contracts, and also by the schools of the teachers involved in the experimentation.

Mathematical and epistemological perspectives

We regard mathematics as an activity in which students solve problems and produce and justify mathematics statements. In this activity students may use mathematical representations, draw on mathematical concepts, known facts, properties and Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
493

procedures to design strategies, implement them, and arrive to conclusions. Such strategies include moments of problem posing, conjecturing, making generalizations, testing conjectures (analysing cases, doing computations, experimenting with technological tools, etc.), making connections and establishing relationships. An important part of the mathematical activity is also explaining and justifying solutions and statements. Our epistemological perspective is that mathematics knowledge develops by the process of carrying out mathematical activity and reflecting on such mathematical activity (i.e., carrying out meta-mathematical activity) which includes problem solving and systematization of ideas that is achieved by individual work and social interaction (with colleagues and with the teacher).

Tasks and teaching units

Following Christiansen and Walther (1986), we take a task as a statement of a situation to be solved by the students. It is presented to students both in written and oral form, together with indications about the time available to work on the task, the kind of students' production expected, and the mode of organization of the work suggested. A task may correspond to a single question or to a structured sequence of related questions (and possibly subquestions). In our work we strive to develop exploratory tasks, that is, tasks that may lead students to exploratory activity, from which they do substantial work and learn new mathematics. In exploratory activity students have to interpret situations in mathematical terms, formulate mathematics questions, and reason in an inductive way, making conjectures and generalizations. This is the basis for symbolizing and formalizing ideas and providing justifications to statements based on known facts and properties, assumed assumptions and definitions.

The key role of such tasks in mathematics teaching has been recognized by mathematics educators such as Sullivan, Bourke and Scott (1997), Boaler (1998), and Skovsmose (2001). We are aware that the kind of classroom work that we have in mind is quite demanding on the teacher. The selection of tasks involves a high level of understanding of the mathematics involved as well as in-depth knowledge about students' abilities and interests. Teachers must know how to introduce such tasks, negotiating the meanings that are critical for the work to carry out, but without providing too many clues that will solve the task for the students. Furthermore, the teachers are called to support the students' autonomous work, while maintaining the cognitive demand of the activity (Stein & Smith, 1998), and to be able to conduct productive discussions during which mathematics ideas are presented, confronted and clarified. In these discussions teachers must provide opportunities for all students to intervene, stimulating moments of controversy and argumentation as well as moments of systematization and formalization of mathematical ideas. In order to allow for a smooth integration in professional practices, we often produce tasks with parts or elements that are not so different from usual tasks, combining them with questions that points towards exploratory activity.

Design principles

Some tasks are intended to provide for the development of new forms of representation, new concepts, and new problem solving strategies. Others are intended to lead students to mobilize and clarify mathematical notions that they already learnt and/or to make connections among different ideas. The structure of a task may vary from seemly simple statements that require considerable interpretation and Theme D – J. P. da Ponte et al.
494

specification of cases by students to complex statements that include a breakdown of questions in a structured way. However, in this case, often there is a combination of different kinds of questions, beginning with quite straightforward and computational questions to end up with open questions that require significant thinking from the students. The tasks will be ultimately organized in a sequence to be undertaken in several classes in order to promote students' understanding of an important mathematical idea or topic.

Tasks need to be engaging for most (if possible, all) students, not very difficult to get involved in, and lead to the formulation of important mathematical notions (representations, concepts, properties, procedures). In order for the tasks to be engaging for a student they must have an element of challenge, without being too difficult. The tasks involve different kinds of context. Some of them just have a purely mathematical context (usually numbers or geometric figures) whereas others are close to the daily experience of students. However, contexts must not be artificial, must not pose problems for students' understanding, and, of course, must not promote prejudices or stereotypes. It is assumed that, after tasks are introduced, students will spend an extended time working on them, in an autonomous way, and afterwards there is another extended period of whole-class discussion.

In our work, we start with an overall planning of the teaching unit, which includes the formulation of the learning objectives, assumed previous knowledge of students (often based on diagnostic assessment), time available and organization of the schedule (as there are variations among schools). Tasks are later selected to fit the overall planning of the teaching unit, and then there is a dialectic movement of adjustment between the macro level of the unit and the specific level of the task. Next, we present three tasks constructed according to these design principles (See a summary in Table 1).

Design principles	Folding and folding again	Multiplication of integers	Working with intervals
1. The objectives support the development of new representations, concepts, and strategies, lead students to mobilize and clarify mathematical notions, and/or to make connections.	i. To understand and use rational numbers in different meanings. ii. To recognize that they may have different representations, and understand the associated language.	i. To develop new knowledge regarding integers (definition of multiplication). ii. To develop the ability to generalize.	

i. To learn concepts
and procedures of
interval arithmetic
(definitions of
operations and image
of a function).
ii. To develop the
ability to generalize
and to justify.
2. The structure varies
from simple to complex
statements with different
questions (straightforward,
computational, open…).
Some questions are quite
simple and others require
interpreting complex
commands ("represent",
"compare").
Some questions are
simple and others
lead to connections
and reasoning
(generalization and
justification).
Open questions,
requiring reasoning
processes
(formulation, testing,
generalization and
justification).
3. Engaging with an
element of challenge.
Challenge in interpreting
"represent" and
"compare".
Challenge in
question 4,
especially 4c).
Challenge in both
questions.
4. Different kinds of
context (purely
mathematical and close to
the students' experience).
Use of manipulative
materials (paper strips).
Mathematical
context.
Mathematical context.
Table 1 – Application of design principles to the production of tasks Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
495
Example 1: "Folding and folding again"
This exploratory task is included in the supporting materials of the mathematics
curriculum (Menezes, Robinson, Tavares & Gomes, 2008). It was proposed in the
first class devoted to the study of rational numbers in a teaching experiment at grade 5
focused on comparing and ordering rational numbers and equivalent fractions
(Quaresma, 2010). The class, with 22 students, enjoys working in new problems and
maintains a productive pace of work. All students show commitment regarding the
mathematics work, most of them have good achievement but a smaller group has
difficulties in this subject. The task, with two questions, intends to lead students to (i)
understand and use rational numbers in the part-whole and measurement meanings,
(ii) recognize that simple non-negative rational numbers may represented in the form
of fractions, decimals and percent, and (iii) recognize and use the language associated
with rational numbers in different representations and meanings. An important aspect
of the task is the use of manipulative materials (paper strips) and of written
representations, creating many opportunities for oral interactions among the students
and the teacher. Question 1 is quite explicit as it asks to do several folds, but then it
makes a request to represent them that most students have difficulty in interpreting as
an indication to use the decimal representation, favouring an exploratory activity.
Question 2 asks students to compare different parts of the strips and to "draw
conclusions", which is a quite open indication, that may lead to various solutions.
Task. 1. Find three pieces of paper geometrically equal. Fold them into equal
parts: a) the first in two parts; b) the second in four; and c) the third in eight parts.
After folding each strip represent the parts that you got indifferent forms.
2. Compare the three parts of the strips that you got. Record your conclusions.
We present some episodes from collective discussions after the students did
some extended work on the task. The students work in 6 groups (3 or 4 elements) in
an autonomous way, with discreet support of the teacher for about 20 minutes on each
question, after which begins the whole class discussion. To support this discussion
each group posts their work on the blackboard. Presenting the work of the first group,
Diana says: "In [item] b) we wrote: fourth-part, 1 of 4 [1/4]; 1 divided by 4, 25% and
0.4." The other students do not realize the mistake and the teacher decides to return to
question later and continues by asking the group of Tiago to present their work:
Tiago: So we have: fourth-part, one of four ,

.
], one divided by four, 25 and
0.25%.
Teacher: (…) Do you agree Diana?
Diana: Yes…?
Class: No! That is wrong…
Teacher: What is wrong?
Rui: It's 0.25…
Teacher: Why?
Rui: Because it is the fourth part.
Daniel: It is 0.25 because it is a half of the first. The first was 50, if we make half
is 25.
André: Oh teacher! I think it is 0.25 because it is the fourth part of 100. Because
25 times 4 gives 100.
The direct questioning of the teacher to Diana suggests that there is
something that needs attention. This student becomes confused and her colleagues
strive to clarify the situation. After the teacher question "why?", several students
provide successively more refined explanations to indicate that the part shall not be
represented by 0.4 but by 0.25. The style of questioning the teacher is punctuated by
inquiry questions ("What is wrong?", "Why?" …). The culture of the classroom Theme D – J. P. da Ponte et al.
496
includes the notion that students can contribute to different responses to disagree and
argue with each other.
Working on this task led the students to understand the meaning of
representing parts of the strips using different representations of rational numbers,
developed their language associated to rational numbers and to compare various parts
of the strips. The fact that the first part of question 1 ("folding") is quite explicit and
uses manipulative materials, engaged students in the task, while the second part, more
open ("representing") prompted students to carry out exploratory activity and to
understand the meaning of "to represent". In question 2 (see examples in the
appendix) students further established different multiplicative and fractional
relationships among quantities.
Example 2: "Multiplication of integers"
This example is taken from a teaching experiment about integer numbers carried out
in a grade 7 class with 20 students. This is an exploratory task aiming students to
develop new knowledge about properties and concepts regarding integers, namely the
definition of multiplication, based on previous knowledge of properties of natural
numbers and inciting generalization. The task has four questions with a purely
mathematic context. Some of these questions require simple procedures, while others
lead students to establish connections and reasoning processes such as generalization
and justification. The last question seeks to identify properties of the multiplication of
integers, particularly regarding the sign of the product of two integers, based on the
connection between multiplication and successive addition of integers:
Task. 1. Find the result of the expressions 3+3+3+3+3+3+3+3+3+3 and
7+7+7+7. Explain how you found your answer.
2. Try to formulate a rule that indicates the same result without using addition.
3. Represent the expressions (-3)+(-3)+(-3) and (-4)+(-4)+(-4)+(-4)+(-4)+(-4) using
multiplication. Find the result of these expressions.
4. Try to formulate a rule that indicates the sign of the product of two integers if
they are: a) Both positive; b) One negative and one positive; c) Both negative.
The task was included in a set proposed to students on paper in a 90-minute
class and discussed in the first 20 minutes of the next class. The students, who sat in
pairs or groups of three, were asked to read all questions before starting to solve it.
There was a small whole class discussion, widely participated in by students,
supporting their interpretation of the task. As students were working, the teacher
moved around the classroom, asking them questions to clarify or probe their answers.
In the final whole class discussion, in order to construct common meanings, the
students were responsible for presenting and justifying their responses and
formulating questions regarding the responses of their colleagues.
The students solved questions 1, 2 and 3 with no difficulty. For the last
question, most students obtained the intended rules, particularly as regards the sign of
the product. Pedro, a student in this class, uses natural language in his written solution
to present his generalizations and uses symbolic language (without variables) to
present an example for each item. When questioned to justify his answers to items
4.a) and 4.b), he states:
Pedro: The first one was easy, because we had already done it long ago, both
positive. I wrote an example, four times four, sixteen. Therefore, if we multiply a
positive with a positive would be positive.
Teacher: And one positive and one negative? Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
497
Pedro: Negative. I made an example, but then I also thought in the sum. A
negative with a positive would be negative. Therefore, minus three minus three
would be minus six.
In this question the students justify their answers based on prior knowledge
and mathematical properties used in the previous questions. This exploratory task led
them to establish generalizations, developing knowledge about the properties of
multiplication for integer numbers, based on known properties of natural numbers. As
the students still do not know the algebraic language, they justify their responses
exemplifying with particular cases. Some of the initial questions required some
interpretation but the students easily engaged in the task since it essentially involved
known properties or properties used in previous questions, as the relation between
multiplication and successive addition of equal addends. Therefore, the structure of
the task provided students with the possibility to begin with simple questions and end
up dealing with highly demanding questions as question 4. (Other situations in
appendix.)
Example 3: "Working with intervals"
This example is taken from another teaching experiment (Henriques, 2011),
supported by exploratory tasks conducted during one semester in a numerical analysis
course, in order to promote students' experience of doing mathematics and the
learning of concepts and procedures. The participants were 36 second year university
students. The task has two open questions in a pure mathematical context. Question 1
intends to lead students to deduce and justify the rules of interval arithmetic, which
were unknown to them. Students were challenged to formulate, test and justify
conjectures involving the exploration of particular cases of known elementary
operations (addition, subtraction, multiplication and division) using intervals of real
numbers. The second question has similar features and aims to extend the interval
arithmetic to functions, requiring the use of prior knowledge on functions and their
properties as well different representations to get a solution.
Task. 1. Look at the following situations
[1, 2] + [5, 7] = [6, 9] [0, 1] + [-5, 2] = [-5, 3] [-3, -1] + [1, 3] = [-2, 2]
a) Find a rule for adding real number intervals? Do all real number intervals
follow that rule? Investigate.
b) Investigate what are the rules for subtraction (X-Y), multiplication (X×Y) and
division (X/Y).
2. Consider a function f: D⊂ IR→ IR, given by f (X) = X + X and X = [x1, x2] ⊂
D, a real number interval of its domain.
a) What's the image of X = [2, 7]? Explain clearly how do you find your answer.
b) What's the image of a real number interval if now the function f is given by
f(X) = X
2
or f(X) = e
X
?
During the exploration of this task, which lasted about 100 minutes, the
students worked in small groups of 3 or 4. Afterwards, they presented their work
orally to the class, explaining their ideas and strategies, and, prompted by their
colleagues and the teacher's questioning, sought for justifications. Outside the
classroom, they also wrote a report (WR) aiming their reflection, since it requires
students to articulate ideas, at explaining procedures and reviewing the processes used
and the results obtained. The work of a student (Gonçalo) is chosen to illustrate a
variety of aspects of students' mathematical activity and learning.
Gonçalo begins exploring the task by observing the examples. That
observation raises in him some questions as he tries to find a pattern and to understand
what was really happening. He is led to a first conjecture about the rule for adding real Theme D – J. P. da Ponte et al.
498
number intervals: "We concluded that by adding the lower bounds and the upper

bounds of the intervals, based on examples" (WR). Later, in an interview, he explains
the constructed meaning for the interval obtained from adding two other intervals:
Before the beginning of this task, I had never seen an addition of intervals and I
was really unaware of what it was. But then I realized that considering [a1, a2] +
[b1, b2] = [c1, c2], any value between a1 and a2, added with any other value
between b1 and b2, will be into the interval c. (E)
Gonçalo continues the exploration of the task formulating and testing
conjectures about the rules for other elementary operations (subtraction,
multiplication and division), leading him to further generalizations. In question 2, the
student feels the need to use graphical representations to extend the interval arithmetic
to functions (We show these aspects of the student reasoning in the appendix.).
In summary, the students were challenged to carry out exploratory tasks very
different from the usual ones done at university level. This kind of task, in connection
with the classroom work organization, led students to experience mathematics
processes such as looking for regularities, posing questions, formulating and testing
conjectures, generalizing and justifying them. Authentic mathematics activity was
stimulated by exploratory tasks. This work also provided students opportunities to
develop their understanding of the concept of interval, the rules of interval arithmetic
and to make connections with other mathematical topics, in particular with previous
knowledge about properties of numbers and functions. Thus, the results highlight the
potential of exploratory tasks to learn numerical analysis concepts and procedures,
suggesting that they may be used in university mathematics courses.
Conclusions
The three exploratory tasks reported in this paper demand considerable
interpretation by the students and their involvement in mathematical work. The three
tasks require students to formulate generalizations and justifications, in one way or
another, involving them in mathematical activity. They also were effective in
supporting students to achieve a variety of learning objectives related to rational
numbers, integer numbers and interval arithmetic. The critical features of these tasks
include a combination of structured elements with explicit indications with open
questions that require interpretation and the design of strategies. Another critical
aspect is the settings that enabled interaction among students and with the teacher in
the role of a facilitator. However, the tasks proved to be feasible for a qualified
teacher, requiring no special effort. The particular combination of authors in this work
– given their complementary roles and their use of a common research framework –
seems to be fruitful for the production and experimentation of this kind of tasks and
their trial in the classroom. In addition, the experience in Portugal shows that
commercial publishers draw on tasks produced in this kind of setting and introduce
them in textbooks. Of course, being demanding of teachers' expertise such tasks
require a combined effort of task design, classroom implementation studies,
curriculum development, and teacher education as we had in Portugal in the last five
years.

Developing Theory for Design of Mathematical Task
Sequences: Conceptual Learning as Abstraction
Martin Simon
New York University
This paper describes an emerging approach to the design of task
sequences and the theory that undergirds it. The approach aims at
promoting particular mathematical understandings. Central to this
approach is the identification of available student activities from which
students can abstract the intended ideas. The approach differs from
approaches in which learning to solve the problem posed is the intended
learning. The paper illustrates the approach through data from a teaching
experiment on division of fractions.
Keywords: mathematical tasks, reflective abstraction, learning theory,
didactical engineering
Introduction
The "Task Design in Mathematics Education Discussion Document" stated, "We
would like to encourage an interest in tasks that have more limited but valid
intentions, such as tasks that have a change in conceptual understanding as an aim."
That is the specific aim of this paper and the research program from which it derives.
The research and theoretical work build on several core ideas advanced by
Piaget and therefore could be considered constructivist in orientation. As such the
paper could be categorized, according to the Discussion Document, as delineating
principles and frameworks for task design within a singular design community
researchers working from a constructivist perspective). However, our view is that
multiple theoretical perspectives are needed to do the work of design of mathematical
tasks. Consistent with this view, we see our work as complementary to the work of
many other research programs that work from a different core set of theoretical
constructs. Further, in our work we use principles from Cobb and his colleagues'
(Cobb & Yackel, 1996) emergent perspective and Davydov and his colleagues'
Russian activity theory (Davydov, 1990). However, it is beyond the scope of this
short paper to discuss our use of these different theories.
The emerging task design theory that I present here is narrowly focused on
the learning of mathematical concepts and as such offers an approach to addressing
difficult to learn concepts and to working with students who are struggling to learn
specific concepts. This task design approach does not address other important areas of
learning mathematics, particularly the important area of mathematical problem
solving. Therefore, the approach is meant to complement existing approaches, not
replace them. The emerging task design theory is a product of a research program
aimed at understanding conceptual learning, particularly the development of Theme D – M. Simon
502
abstractions from one's own mathematical activity (activity that occurs in the context
of designed sequences of mathematical tasks). Thus our research program involves a
spiral approach in which we design task sequences to study learning through student
activity, and we use what we come to understand about learning to improve our
understanding of task design, and so forth.
We work with a broad definition of task, consistent with the one embraced
by the Study Group, as either a question that a student is asked or an objective that
they are given to accomplish (e.g., Why is a triangle the only rigid polygon? Measure
the length of line segment BC.).
Theoretical basis
The theoretical basis of our research program derives from Piaget's (2001) work on reflective
abstraction. DiSessa & Cobb (2004) pointed out,
Piaget's theory is powerful and continues to be an important source of insight.
However, it was not developed with the intention of informing design and is
inadequate, by itself, to do so deeply and effectively. (p. 81)
Our research program is aimed at building theory that can inform
instructional design.
Two Piagetian-based constructs that are foundational to our work are goaldirected activity and reflection. Goal-directed activity includes both physical and
mental activity. The notion of goal-directed is important, because the learners' goals
partially determine both what knowledge they call upon and what learners pay
attention to and can notice. Reflection, following von Glasersfeld (1995), refers to an
innate tendency (often not conscious) to distinguish (associate) commonalities in
one's experience.
In our research and theoretical work, consistent with Piaget and others, (c.f.,
Hershkowitz, Schwarz, & Dreyfus, 2001; Mitchelmore & White, 2008), we consider
mathematics conceptual learning as the process of developing new and more powerful
abstractions, in particular reflective abstractions. Again following Piaget, we
understand abstractions to be learned anticipations and reflective abstractions to be
those abstractions that result from reflection on one's activity and result in knowledge
of logical necessity. (See Simon, 2006) for a discussion of the distinction between
reflective abstraction and empirical learning processes.)
Our task design approach builds on this theoretical base and involves
specifying hypothetical learning trajectories (Simon, 1995) at multiple levels. In this
paper, I focus on the level of design of particular understandings, not the planning of
trajectories for larger mathematical topics. A hypothetical learning trajectory consists
of three components, (1) a learning goal. (2) a set of mathematical tasks, and (3) a
hypothesized learning process. Whereas the specification of the learning goal
generally precedes the specification of the tasks and hypothesized learning process,
these latter two components necessarily co-emerge. The learning process is at least
partially determined by the tasks used and the tasks used must reflect conjectures
about the possible learning processes. The design approach outlined here provides a
conceptualization of the design process with respect to these two components.
I briefly summarize the theory behind our approach to task design in the
following way. (For greater detail, see Simon, et al, 2010; Simon & Tzur, 2004;
Simon, Tzur, Heinz, & Kinzel, 2004; Tzur & Simon, 2004.) The pedagogical goal is
to promote particular mathematical concepts. These concepts are understood as
learned anticipations. Given an appropriately designed series of tasks, students can Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
503
call on available activities, attend to the effects of their activity, and come to an
anticipation of the effects of that activity – the development of a new abstraction. In
the next section, I provide an example to concretize these ideas and follow that with a
discussion of the key steps in the design process.
Instructional Example
In this section, I present an instructional example from a one-on-one teaching
experiment. The purpose of the teaching experiment was to promote and analyse
students learning of new concepts (making of an abstraction) as they engaged in
mathematical activity. Towards this end, we engaged her in a sequence of tasks and
restricted the researcher's role to probing thinking and initiating subsequent tasks.
The student, Erin, (one of three that participated in the study) was an
undergraduate prospective elementary teacher. Pre-assessment showed she lacked
understanding of both the meaning of fraction division and the invert-and-multiply
algorithm with which she was familiar. In sessions prior to the one described here, we
worked on the meaning of fraction division.
The goal of the session described here can be articulated at two levels of
specificity. First, we wanted her to reinvent a common denominator algorithm for
division of fractions. More specific in terms of the understanding involved, we
wanted her to understand the invariance of division with respect to variation in the
common units of the dividend and divisor.
The task sequence, developed by the author, began with division-of-fraction
word problems whose dividend and divisors had common denominators. Erin was
asked to solve them by drawing a diagram. She was able to solve the first task without
difficulty ("I have 7/8 of a gallon of ice cream and I want to give each of my friends a
1/8-gallon portion. To how many friends can I give ice cream?"). The task sequence
progressed to word problems in which the dividend and the divisor still had common
denominators, but the divisor did not divide the dividend equally and then to similar
tasks presented using only as number expressions (e.g., 8/5 ÷ 3/5 =). Erin's solution
process can be summarized as follows (actions for 8/5 ÷ 3/5 in parentheses):
1) Draws the dividend (draws 2 whole rectangles divided into fifths, shades
2/5 of one rectangle leaving 8/5 unshaded) (Figure 2).
2) Identifies groups the size of the divisor (circles each 3/5).
4) Counts those groups (counts 2 groups).
5) Identifies the remainder – the ungrouped part of the dividend (r = 2/5).
6) Identifies the fractional part of the quotient by determining the fraction of
the divisor represented by the remainder (2/5 is 2/3 of 3/5).
After a number of such tasks, the researcher changed the nature of the task.
He gave Erin a task and announced that the numbers were too "messy," that she
would not want to draw a diagram. The first such task was 23/25 ÷ 7/25. Erin made it
clear that she did not know the answer and the researcher encouraged her to talk
through a diagram solution without actually drawing. This she was able to do without

difficulty and arrived at the answer. The following task was 7/167 + 2/167. Again, Erin did not know the answer and solved the task by doing a mental run of her diagram drawing strategy. Finally, the researcher gives her 7/103 + 2/103 (same numerators as the previous task
52
). Erin responded with the answer "three and a half"

52
The fact, that this problem had the same numerators as the previous one, was not pointed out to Erin.Theme D – M. Simon
504
and explained that she did not need to use the denominator. When pushed to justify her claim, she drew a rectangle divided into seven boxes and argued that she could group them into groups of two parts regardless of the size of the parts that were represented. An additional task verified that Erin did not over-generalize to tasks that did not have common denominators and that she could convert to common denominators to use her reinvented algorithm (make common denominators and divide the numerators). Assessment the following week convinced us that she retained her algorithm, she could justify it, and she could use the same reasoning to think about the invariance when composite units were involved (e.g., why 2400 divided by 400 is equal to 24 divided by 4).
Simon et al (2010) gives a more detailed look at the data, analysis, and explanation of Erin's learning. My focus here is the abstraction that Erin made. That abstraction became evident when Erin quickly gave the answer. So what did Erin abstract? Erin abstracted that regardless of the size of the parts (assuming common denominators), the quotient would always be the same and would be equal to the quotient of the numerators.
Readers at this point might be tempted to argue that Erin just saw a number pattern. However, remember that up to this point in the teaching experiment, Erin had not seen two tasks with the same pair of numerators. Thus, there was no pattern to observe. The first time she encountered the situation she anticipated the result.
53
Furthermore, her conclusion was not only about the task in question. She now knew that she could find the quotient of any division of fractions involving common denominators solely by dividing the numerators. And, she was able to justify her conclusions using an improvised diagram related to her diagram drawing. These three indications make it clear that the anticipation in question was conceptual in nature and not due to noticing a pattern in the numbers.
The Design Approach
The first two steps in our design approach are the first two steps in most instructional design that is aimed at conceptual learning. We assess student understanding and articulate a learning goal
54
for the students relative to their current knowledge. It is
after these first two steps that our approach diverges.
Our third step is to specify an activity or activity sequence that students currently have available that can be the basis for the abstraction specified in the learning goal. We attempt to identify an activity that can result in an anticipation that is the particular abstraction intended.
55
The fourth step is to complete the hypothetical
learning trajectory, that is, to design a task sequence and related hypothesized learning process. The task sequence must both elicit the intended student activity and lead to the intended anticipation on the part of the students. The hypothesized learning

53
Simon (2006) presents a distinction between reflective abstraction and empirical learning processes. I have argument that Erin's learning was the result of reflective abstraction as there was no empirical pattern to observe.
54
Articulation of conceptual learning goals is a problematic issue not covered here. It is a theoretical and empirical challenge to specify learning goals in a way and level of specificity that it adequately guides instructional design (as well as instruction and assessment).
55

505
process must account for not only the overt activity of the students, but the mental activities that are expected to accompany those overt activities. I will not focus on steps beyond step 4 (e.g., symbolizing, introducing vocabulary, discussing justification), because again they are common to many approaches.
I will now use the example of the division-of-fractions task sequence to illustrate steps three and four of our task design approach. The consideration of what activity we might elicit begins in a way that is similar to Realistic Mathematics Education (Gravemeijer, 1994), a consideration of students' informal strategies. Whereas RME focuses on developing progressively more formal solution strategies, our approach is focused on developing concepts by developing anticipations from those activities.
56
In many of our design situations, we have a specified learning goal and then endeavor to identify an available activity that could be used. Our example of division of fractions illustrates a design in which there was an interaction between step two, setting the learning goal, and step three, identifying a useful activity. When considering students' informal strategies and considering diagram drawing, we realized that students' informal diagram solutions would lead more naturally to (support development of anticipations related to) a common-denominator algorithm for division of fractions than an invert-and-multiply algorithm. Thus, the goal not only affected the identification of the activity, but the activity available affected the specific goal towards which the design was oriented.
57
The challenge then was to construct a hypothetical learning trajectory. We began with division of fractions word problems and followed them up with numerical tasks (no context) to elicit a diagram drawing activity sequence like the one that Erin used (outlined above). Once the student is using the intended activity sequence, the task sequence must be designed to provoke the particular anticipation (abstraction). For this purpose we used larger numbers for the denominators and invited mental runs of the diagram drawing activity (which was a change in the activity from the researchers' perspective). The use of mental runs was intended to provoke two types of changes in the student's thinking. First, it is intended to help the student foreground the key quantitative relationships. For example, in the diagram solutions, the student first focused on how to create the number of equal parts in the rectangular unit. At least as much attention was likely to have been paid to that phase as to counting parts in order to circle a divisor shaped group or counting the number of groups. In the mental runs, the student can dispense with the first step by simply announcing, "I would draw twenty-three twenty-fifths." The second intended consequence of shifting to mental runs was to create a need on the part of the student to invoke concepts and mental operations that are critical to the concept being developed. In Erin's mental run she had to use whole number division to find out how many divisor-sized groups are in the dividend, whereas in her diagram solutions, she could simply count the number of groups she had in front of her. At the point at which Erin was doing the mental runs, she was engaging in the activity that could lead to the intended

56
Although there are often overlaps in what is learned by students using these two approaches, I emphasize here the differences in the primary aim and the theory built to achieve that aim. We definitely build on aspects of RME, particularly their use of model of becoming model for (Gravemeijer, 1994).
57
The target algorithm is not itself a conceptual learning goal. We still needed to specify the understanding involved ("to understand the invariance of division with respect to variation in the common units of the dividend and divisor"). However, I wanted to use the process of coming to the goals to illustrate how the knowledge/activities available can influence the goals that are set. Theme D – M. Simon
506
anticipation, she was comparing multiplicatively the number of parts in the dividend with the number of parts in the divisor. Thus, the diagram drawing activity provided an important step towards this activity, but was unlikely to lead directly to the intended anticipation, because the student did not need to conceptualize the multiplicative comparison.
Doing a couple mental runs did not in itself lead to the intended anticipation. The researcher at that point posed a task with the same numerators as the previous task. The purpose of this particular task was to increase the possibility that the student would see the commonality in her activity and, as a result, anticipate that the answer had to be the same and realize that it was not dependent on the value of the common denominators. So how do we explain the resulting change in thinking?
As mentioned earlier, in doing the mental runs, Erin was able to give minimal attention to establishing the dividend – she merely needed to state that she would draw it. This initial statement established the size of the parts, so that (just as in the diagram drawing) she could focus on the number of parts of that size available and the number of parts of that size in a group. Thus, she naturally, without necessarily making a conscious decision, paid particular attention to how many total parts and how many parts in a group. This focus of attention (Simon, et al, 2010) was not because she considered the denominator unimportant, but because she had established the size of the parts and was anticipating her next step, a computation involving these two quantities. In the third task of this set, when Erin was faced with a second task with the same pair of numerators and different common denominators, she realized that she was about to enact the same activity as in the previous task. At that moment, she also realized why the size of the common denominators did not change the quotient. This was an example of Erin's reflection on her (mental) activity. That is, she perceived the commonality in her activity in the two cases that led to an abstraction. This abstraction was an anticipation about fraction division (and division more broadly). She now anticipated that the division of fractions with like denominators is equivalent to the division of the numerators.
Conclusions
Our task design approach is an emerging one. Three are aspects of it that we highlight here and others whose articulation will require additional analyses. I highlight here two features of our task design approach that can be seen in the example provided above. First, the approach provides a theoretically based strategy for promoting specific mathematical understandings. It contrasts with strategies in which students must solve novel problems to progress (or hear the solutions of more able peers). Although mathematics teaching cannot cause learning, it is an approach that involves engineering task sequences so that participating students predictably develop the ability to make the new abstraction. Second, the learning goal is not to learn to solve the tasks, as it is in many approaches. The tasks are made to elicit activities that the students already have available. Erin was able to solve all of the tasks prior to making the intended abstraction. Further, she was not consciously trying to find an easier way or to invent an algorithm. Her learning was a product of reflection on her activity across a sequence of tasks.
Let us examine some of the implications of this approach to task design.
1. By using a design experiment (teaching experiment) methodology, involving
design and implementations cycles using this design approach, there is an opportunity Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
507
to understand in greater depth the interplay among goal-directed activity, reflection, and conceptual learning. (This is discussed in depth in Simon, et al, 2010.)
2. This approach potentially provides a way to design task sequences for concepts that students traditionally do not learn well. These tend to be concepts that many students do not spontaneously reinvent in problem solving situations and concepts of which they do not develop deep understanding by being part of a class discussion with more knowledgeable students. The approach focuses the instructional designers on identifying key activities that are likely to afford the intended abstractions for abstractions that were not readily made.
3. Small group work using task sequences of the kind discussed here can lead to somewhat different class discussions. If students are making the new abstraction as a result of their engagement with the task sequence, discussions can focus more on articulation of the new idea, justification, and establishing the idea as taken-as-shared knowledge.
4. The approach has potential to address issues of equity in two ways. First, many students who have conceptual gaps early on seem to never recover. This design approach provides a methoddology for building up the specific experience, based on students' currently available activities, needed to make particular abstractions. Second, success in promoting the new abstractions during small group engagement with the tasks can lead to a greater number of students participating in and benefiting from the class discussions that follows. The underlying hypothesis here is that students who abstract ideas themselves, based on their work with the mathematical tasks, tend to learn the concepts in a more powerful way than those who follow the explanation of their more able peers offered in class discussions.
One final point that was discussed briefly at the beginning of this paper is the relationship of our approach with mathematical problem solving. The approach that I have described and exemplified does not focus on students developing their problem solving abilities. Rather it focuses narrowly on the development of mathematical concepts. Developing problem solving abilities is a key part of mathematics education. One could argue that conceptual understanding and problem solving are the two wings of mathematics education – students cannot fly without effective use of the two together. Students do learn concepts through problem solving lessons. Our approach is in no way intended to minimize the importance of lessons in which that is the case. Rather, our approach provides an additional tool that has the potential for success in areas where mathematics education has been less successful. One open question is how to use this tool in conjunction with the powerful tool of problem solving lessons to maximize the learning of students.

An Instructional Design Collaborative in One Middle School
Michelle Stephan
University of North Carolina Charlotte
Didem Akyuz
Middle East Technical University
This article presents the principles for instructional design within collaborative communities in one middle school. During the study, members of the Collaborative engaged in creating and implementing a hypothetical learning trajectory and associated sequence of instructional tasks to teach integers in a middle grades classroom. During implementation of the trajectory, the members of the Collaborative played different roles in task design depending on their background. In this paper, we expand on the varying contributions that teachers, researchers and other educators make during design and implementation of rigorously designed instruction. We also document the artifacts and practices of design that led to increased teacher engagement and learning.
Keywords: Realistic Mathematics Education, Emergent Perspective, Integers, Teacher Research, Hypothetical Learning Trajectory
In 2009 an Instructional Design Collaborative was formed at a middle school (12-14 years old) in suburban Florida, USA. This Collaborative was comprised of a middle school teacher who was a former university professor, a doctoral student from a local university, two middle school mathematics teachers, and one special education teacher. The primary purpose of the Collaborative was to design and implement an instructional sequence for integers that was inspired by Realistic Mathematics Education Design Theory. All five Collaborative members participated daily in the design, implementation, and revision of all instructional tasks.
Design principles and task definition
All tasks designed by the Collaborative used the instructional design theory of Realistic Mathematics Education (RME) as the basis for creation. In RME, the focus is on the development of a sequence of tasks, not stand alone mathematical problems. Therefore, tasks are defined as problematic situations that are experientially real for students in that the dilemma that they encounter in the problem can be experienced as real by them. Furthermore, each task must be phenomenologically rich in that it lends itself to be mathematized (organized mathematically) by students. RME instructional sequences are guided by the following three design principles:
510
Heuristic one: Guided reinvention
The sequence of instructional tasks should be designed to encourage students' reinvention of key mathematical concepts. To start developing an instructional sequence, the designer first engages in a thought experiment to envision a learning route the class might invent with guidance of a teacher (Gravemeijer, 2004). It is here that knowledge of the history of mathematics as well as prior research concerning students' invented mathematical strategies can be used. Since students do not have the time to invent the intended mathematics in the same way as mathematicians originally did, the teacher must help students re-invent these ideas in shortened time periods using carefully sequenced problems and tools.
Heuristic two: Sequences should be experientially real for students
The starting points of instructional sequences should be experientially real in that the students are able to engage in personally meaningful activity (Gravemeijer, 2004). Often, this means grounding students' initial mathematical activity in experientially real scenarios (which can include mathematical situations). While many textbook authors see the value of using realworld problems in instruction, RME goes beyond simply situating mathematics in the real world. Rather, instructional tasks draw on realistic situations as a semantic grounding for students' mathematizations and activities are sequenced so that students will organize their activity within the realistic context to re-invent important mathematics.
Heuristic three: Emergent models
Instructional activities should encourage students to transition from reasoning with models of their informal mathematical activity to modeling their formal mathematical activity, also called emergent modeling (Gravemeijer & Stephan, 2002). During the transition from informal to formal, the designer/teacher supports students' modeling by introducing or using student created tools, such as physical devices, inscriptions, and symbols that can be shared by students to explain their mathematical reasoning.
Guided by the three heuristics described above, the designer creates an instructional sequence while at the same time envisioning a path that the class may follow as they engage in the tasks (Gravemeijer & Stephan, 2002). The anticipated path has been labelled a hypothetical learning trajectory in that the designer makes conjectures about the mathematical route the class, as a community, will travel, including the mathematical goals and tool-use, as they engage with the instructional tasks and anticipates the means by which the teacher can support that route. After implementation, the designer analyzes the collective learning of the class and revises the instructional sequence accordingly. Since the former professor had multiple experiences designing instruction based upon RME, she created an integer HLT for the Collaborative.
Epistemological theory
The authors use a version of social constructivism, called the emergent perspective (Cobb and Yackel, 1996), to situate their interpretation of classroom events. The emergent perspective claims that learning is both an individual, psychological process and a social process, with neither taking primacy over another. In other words, a student's mathematical development occurs as he participates in and contributes to the mathematical practices of the classroom. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
511
In particular, to document how the HLT was realized in implementation, the two authors conducted an analysis of the collective learning of the classroom (Stephan & Akyuz, 2012). They found five mathematical practices that emerged as students interacted with the sequence of instructional tasks designed by the Collaborative. T-tests indicated that the students in the first author's class made statistically significant gains in their understanding of integer subtraction, a finding that is rare in integer research.
The Collaborative experiment
Integer concepts and operations is an extremely difficult content area for students to learn with meaning. Additionally, research indicates there is no agreed upon method for teaching integers conceptually. The textbook that had been adopted by the teachers' school did not support students learning integer operations with meaning, so Collaborative members decided to create their own instructional sequence. Their motivation was primarily pragmatic in that their prior students merely memorized the rules for operating with integers. Based on the tenets of RME, they created a first draft of a sequence that used net worth, assets and debts as the realistic context for exploration.
In the first phase of instruction the teachers introduced students to the notion of net worth and posed problems that encouraged students to think about possessing assets and debts, and the effect it has on one's financial situation. Here it is intended that students construct the idea that a net worth is an abstract quantity, not a concrete entity that can be counted like money, but rather the "status" of one's financial value. Net worth is contextually rich for exploring integers in that not only can net worth represent an object with positive and negative properties and can be ordered on a number line, but net worth can also be transformed by actions (add or subtract) to produce new net worths. These actions and their results can also be inscribed on a vertical number line.
Phase Two envisions students using statements about assets and debts to solve problems in which they find and compare net worths to each other. For example, students are given a listing of the assets and debts of two people, and asked to find and compare their net worths. The goal that the teachers conjecture will become taken-as-shared is to see which person is worth more than the other. Students typically create different strategies for finding net worths, such as 1) finding the total assets then total debts, and the difference between them, and 2) adding assets and debts one at a time until finished. Students' reasoning as they compare two net worths provides the opportunity to introduce a vertical, empty number line (VNL). For example, the teachers pose tasks that asked students to place the net worth of Jackson ($10,000) and Hayden (-$45,000) on a VNL and to find how much they differ by.
Up to this point, the tasks use the words "asset" and "debt" to represent the positive and negative nature of integers, respectively. Phase Three involves vertical mathematization, scaffolding students' symbolizing from reasoning with unsigned to signed integers. To this end, activities are posed that introduce assets and debts with the + and - signs rather than the words "asset" and "debt." Some net worth statements are designed intentionally so that a third strategy might emerge, that of cancelling assets and debts that are equal, and working with the remaining assets and debts.
The Fourth Phase seeks to confront the conceptual stumbling block involving why two negatives make a positive. At this point, transaction activities are enacted to help students build on their intuitions to construct an imagistic basis for operations. Students are to judge the effect that various transactions will have on a net worth. These tasks are written to encourage students
512
to create negative and positive signs as both a process and object where the first sign signifies an action/transformation and the second represents the status of the quantity (negative/debt or positive/asset). Thus, - (-100) is read as "taking away a debt of $100" and - (+90) as taking away an asset of $90. Students are asked to judge whether or not the symbols signify what they called a "good decision", one that makes the net worth get better or a "bad decision", one that decreases the net worth.
The Fifth Phase incorporates tasks that encourage students to find the effect that various transactions have on a person's net worth. These tasks are called transaction tasks because they involve taking a person's original net worth, performing a transaction on it (like adding a debt) and determining his new net worth. While some students might perform erroneous calculations, teachers can expect "going through zero" to become taken-as-shared. For example, if the task is to find out what happens to Chris' net worth ($1000) if she takes away an asset of $1500, the teachers can re-introduce the empty number line (VNL) to make students' going through zero strategy more visual for the other students (Chris will have to pay off $1000 to get to $0 and she will still be in debt $500). In this way the VNL re-emerges in the class from student thinking as a model of transactions on net worths. Later, it might evolve to become a model for the formal integer operations of addition and subtraction in less context-dependent problem situations.
In the Sixth Phase, some activities require students to determine the results of various transactions including multiple ones like 100 - 2(-50). At first the problems are posed in context and move towards number sentences. To formalize the rules for integer operations, students are asked to list various transactions that could have taken place to make Chad's net worth go from $10,000 to $12,000. Students will write + (+2000) as the unknown transaction, - (-2000) or others like - (-1000) - (-1000).
Analysis of the varying Collaborative members' roles in task design
The Collaborative is comprised of five members: two mathematics teachers (McManus and Dickey), one special educator (Smith), one doctoral student (Akyuz) and a mathematics teacher with RME experience (Stephan). The Collaborative met one week before instruction began and then almost daily throughout the implementation.
Role 1: Anticipating supportive mathematical imagery
In the first Collaborative planning meeting, the HLT was introduced by Stephan. Since teachers did not have previous experience related with HLTs, the overarching sketch of the intent of the sequence was discussed by Stephan. In doing so, she elaborated the imagery, tool-use and potential discourse that could be supported over time. Even though the teachers learned about the HLT in the first meeting, they made important contributions based on their previous experiences. For example, the imagery of "pay off" came out in the meeting from one of the mathematics teachers, McManus:
McManus: When you say she has lower net worth, it means net worth is worse because she has assets, she can cash them all and pay off all debts and be still be in debt...I wonder if there is anything important, mathematically speaking,in paying it off?
Stephan: Two things I can come up with. One is when we get to integer operations and let's say we got $600,000 and pretend there is a transaction $900,000 ...she goes into debt 300, 000

dollars.
McManus: Because 600,000 goes to zero on the number line, you only have enough to go to
zero but there is still more left over. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
513
Smith: Or I only have this much to pay off but I still owe this!
McManus: That is all related with the number line idea we try to develop later.
Stephan: That whole going under zero that took the math community so long to get.
In this excerpt, the mathematics and special education teacher contributed to the HLT by
suggesting that students might employ a "pay off" imagery as they make sense of going below
zero. Stephan connected their imagery with the difficulty mathematicians had with negative
numbers. The mathematics teacher illustrated his understanding of the intent of the instruction by
relating his imagery to the inscriptional device (VNL). This example shows that the mathematics
and special education teachers played an important role in suggesting student imagery that might
emerge during the course of instruction. Stephan played the role of tying their contributions to
the intent of the sequence as well as grounding their notions in the history of the discipline.
Role 2: Creating challenging formative assessments
Another way in which the members of the Collaborative participated in task design
involved creating tasks that would cause cognitive conflict in their students as well as cause
students to analyze the thinking of others. In one of their planning meetings, the teachers
reported that their students were having difficulties with the notation used with the VNL. Ms.
Smith was the first to suggest creating what they typically called a "Sam and Sue problem." This
type of problem usually listed at least two fictitious students' solutions and the class had to
decide which one they agreed with and why. Mr. McManus seized on Smith' suggestion.
McManus: What if we had a couple of number lines with the stuff on it incorrectly and had a
story and say "which number line tells the story?"
The teachers worked collaboratively and created the task pictured in Figure 1. The story
focused on three imaginary students named Larry, Curly and Mo, who had used a VNL to solve
a problem in which a person originally had a net worth of $4000 but added a debt of $8000. The
students were asked to decide which students' VNL was the most accurate.
Figure 1: The formative assessment task
This example illustrates the role that the teachers took in planning meetings. In other
words, for them, planning meetings consisted of bringing in student data from class that day to
discuss next moves in instruction and possibly creating a new task to address issues that had
arisen. The task described above was completely motivated by the classroom teachers and
incorporated the heuristics of RME. Theme D – M. Stephan & D. Akyuz
514
Role 3. Using their mathematical knowledge to alter the instructional sequence
Sometimes members' contributions were of a matheamtical nature and questioned gaps
in the HLT. In a different planning meeting, Mr. McManus shared a concern that he would like
to assess his students' current understanding of the meaning of a negative net worth and that 0 is
not a negative number. In the excerpt below, the Collaborative discusses this issue which then
provokes a change in the instructional sequence.
McManus: I want to be sure that when I put a problem up there, all the kids realize that zero is
not same as negative numbers. Then they understand the abstract value; you can go below zero
and it makes you go in more debt.
Akyuz: Are you going to make them compare negative numbers also?
McManus: Yes… I think you cannot compare negative numbers until they conceptualize net
worth as abstract value.
Stephan: Because if you cannot conceptualize anything below zero [as objects in their own
right], you will have difficulty with that [ordering negatives]. I am really rethinking the order
of sequence now. I think the page after this…we need a number line here. I really think so
because even with concept of integer, forget operations right now, it is a big deal to order
those numbers on the number line.
Dickey: I want to see order on the number line. I want to see that - 4000 is below - 1000 and I
want them to see that, too.
Stephan: I think we need to have a page asking students to order a bunch of positive and
negative numbers. And then we may ask how much Juli's worth more than Deanna? And then
operations. This way, they can start making objects out of distances from zero and they might
also start thinking about those pay off ideas again.
During the discussion McManus stated that he wanted to know if his students were able
to understand the difference between negative numbers and zero as well as other negative
numbers. He stated that he wanted the students to be able to conceptualize negative numbers as
abstract objects. In this case, the role that the mathematics teacher played was to bring in his
knowledge of mathematics to question a gap in the HLT. For her part, Akyuz suggested that the
order of negative integers in relation to positives and zero ought to be assessed. Stephan agreed
and contemplated one of the Collaborative's first changes in the HLT. As a consequence of this
interaction, the Collaborative created tasks that asked students to show two people's net worths
on a number line and find out how much more one net worth was than the other (see Figure 2).
Paris' Net Worth is in the red -$20,000.
Nicole's Net Worth is in the red -$22,000.
Who is worth more? By how much?
Use the number line to show your solution.
Figure 2: Ordering and comparing net worthsMargolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
515
Role 4. Working and revising already created tasks or the sequence of the instruction
Besides creating new tasks, the members of the Collaborative also contributed to the
instruction by revising the tasks that had already been created by Stephan before the study
started. In other instances, their contributions served as a catalyst for re-ordering certain tasks
within the sequence. For example, in one of the meetings we changed the order of the
instructional sequence as necessary based on the teachers' reported interactions with the
students. Originally, after the "good and bad decision" where the students decided whether a
given transaction was good or bad, the instructional sequence followed with the net worth
trackers that included vertical number lines and the transactions below them without linking
them to the context (see Figure 3).
However, since students were not naturally using the VNL to compare net worths, we
decided to pose transaction word problems before the Net Worth Trackers (e.g., Donald has a net
worth of -$5000. A debt of $3000 is taken away. Is this good or bad? What is his net worth
now?). We changed the order because we expected students to get incorrect answers to the word
problems and that this would motivate them to want to structure their reasoning using a VNL.
Then, students would naturally see the need for reasoning with a more structured tool (VNL)
when they worked the word problems.
In summary, the Collaborative members' roles emerged in a variety of ways throughout
the implementation of the instructional sequence. We have pointed to at least four different ways
that they participated including anticipating supportive mathematical imagery, creating
challenging formative assessments, using their mathematical knowledge to alter the instructional
sequence, and working and revising already created tasks or the sequence of the instruction.
Additionally, one of the teachers contributed her knowledge of students with disabilities to the
creation of the tasks. The former professor's role included preparing the HLT and supporting
instructional tasks. The doctoral student also contributed in these ways, but brought more RME
and mathematics education literature into the discussions. It is interesting to note that during the
implementation of the instruction, the practitioners began to discuss more theoretical issues (e.g.,
imagery and abstractness of negative numbers) while the researchers began to think more about
teaching practices (e.g., were state standards covered, formative and summative assessments).
The work of creating and implementing a sophisticated sequence of mathematical tasks provided
them the opportunity to marry theory and practice in a very genuine way.
Figure3: Net Worth Trackers
Artifacts that supported teacher engagement and learning
There are many artifacts that are used or produced in the process of conducting
classroom-based research: an HLT (hypothetical learning trajectory), research articles, an Theme D – M. Stephan & D. Akyuz
516
instructional sequence, formal and informal assessments, interviews with students, state
standards, and instructional frameworks. The artifact that was reported by teachers as most
useful in shaping their actions and learning during the collaborative was the instructional
sequence itself. They argued that whenever they felt confused about the trajectory of their class,
they always had the sequence to go back to as a tool that could re-orient them to their
mathematical goals and to the expected reasoning of students. Often, our team meetings would
begin by working through the activity sheet that would be used in the next lesson. This activity
always led us to discuss students' current and possible future reasoning and how we might
support that with discourse, tools and gestures. Interestingly, teachers argued that the absence of
a teacher's manual was instrumental in their learning since they were forced to create a lesson
image for themselves rather than rely on an image from a book.
Of middle importance to teachers was the HLT (the conjectured learning route of
students) and the assessments. The HLT was important to them at the outset as a way to orient
themselves to the route that we expected students to take; however, teachers did not refer back to
the HLT as the experiment progressed. Rather, their conversations always folded back to the
activity sheets from the sequence, probably because the sequence was a more concrete
manifestation of the trajectory, whereas the HLT is more abstract. On the other hand, both design
researchers rated the HLT highly, probably because they were in charge of designing the
instructional sequence and utilized the HLT more before and during the experiment as a way to
keep in mind the goals of the instruction. With regard to assessments, teachers relied heavily
upon assessments, including student classwork and homework, but not as much on the more
formal unit test at the end of the sequence. Teachers commented that assessing student thinking
and discussing it with peers on a daily basis was an essential practice in supporting the
implementation of the instructional sequence.
Teachers rated the state standards, research articles, student interviews, and instructional
plans, as having little impact on their implementation of instruction and their learning. Since the
instructional sequence was already written, the teachers said they trusted that the designer,
Stephan, had incorporated the state and county requirements within the sequence. The articles
were not useful for teachers in this instance primarily because there is very little research on how
students conceptualize and learn integers. The researchers agreed with this and rated the research
on integers very low. In other cases, when the research focuses on how students think about the
content or how teachers implement sound instruction, teachers acknowledged that the articles
might be more valuable.
Practices that supported teacher engagement and learning
The practice of gathering data on students' conceptions, analyzing it, and using this data
to determine the task to be used the next day became a central practice of the teachers in this
collaborative. In addition, teachers engaged in the activity of lesson imaging in which we chose
the task(s) to be used in class, anticipated the diversity of ways in which students would engage,
and imagined how the whole class discussion would ensue, a practice we call lesson imaging
(Schoenfeld, 2000). In fact, the teachers rated lesson imaging as the second most important
activity in which they engaged during the project. They made a distinction between lesson
imaging and lesson planning, with the latter being the act of scheduling which activities to do
throughout the week. The teachers argued that lesson imaging is a practice that helped them
envision how students would be solving problems and how to capitalize on that in order to have
powerful mathematical discussions in which objectives were met. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
517
A third practice that emerged in a profound way among our team was collaboration.
Teachers placed the influence of this practice as number one in their own learning and success in
their classroom. They remarked that as powerful as lesson imaging is, it is not as effective in a
social vacuum; other teachers are sometimes able to anticipate student strategies that they had
not thought of or can think of better ways to engineer the whole class discussion than they would
have alone. Additionally, the presence of the experienced researchers in the collaboration was
critical to their success according to them. They recognized that they probably would not have
engaged in lesson imaging or daily reflection if not for the researchers lending their expertise and
leading the meetings.
The effects of participating in the collaborative were sustainable for these teachers as
they continued to reflect daily, lesson image and collaborate in years after Stephan's support was
directed elsewhere. In addition, the teachers involved in this project have become model
mathematics teachers for our school.
Implications of the work on different communities
The work of the Design Collaborative reported in this paper impacted a variety of
communities including students, teachers, educators, and administrators. First, their daily
reflection, planning and designing led to an increase in both students' state test scores as well as
their knowledge of integers more specifically (Stephan & Akyuz, 2012). Designing and testing
instructional sequences requires daily formative assessments in order to revise and strengthen the
tasks in real time. Thus, with input from a variety of classroom teachers, students received
instruction that addressed their immediate needs rather than waiting until the end of the unit and
re-teaching.
A second community that was influenced by their work was the teacher population at
both the Collaborative's school as well as teachers from around the state. Other mathematics
teachers at the Collaborative's school had the opportunity to work as a part of the Collaborative
if they desired. Other math teachers joined the team during the last two years as full participants
and learned about instructional design processes, analyzing student learning on a daily basis to
inform instruction and assessment. Members of the Collaborative were called on by their
administrators to lead Lesson Studies with their math colleagues.
Administrators, who held district level positions with supervisory responsibilities across
10 other middle schools, learned of this Collaborative and invited them to present their integer
work and collaboration practices to various school groups. In this way, the instructional design
and planning practices (including cognitive interviews and daily planning) were made available
to district level administrators, principals, assistant principals and teachers from other schools.
Another community that was affected by the Collaborative's work was the teacher
education population. At the time that the Collaborative was testing and revising the integer
instructional sequence, several mathematics education professors visited the classroom to
observe students as they participated in the instruction. In addition, one professor stayed after
class occasionally to question one teacher about her rationale for decisions she made during
instruction.
Finally, this design work has the potential to impact both teacher educators and
researcher/designers by the fact that several articles have been and will continue to be published
about their work. Already, the teachers from the Collaborative have published an article that
describes the circumstances that supported and constrained their work as a community of teacher
learners (Stephan, Akyuz, McManus & Smith, 2010). Akyuz documented the planning and Theme D – M. Stephan & D. Akyuz
518
classroom practices of student-centered teachers (Akyuz, 2010). Stephan and Akyuz have
published the instructional sequence and the learning of one classroom as they engaged in the
instruction in a prominent mathematics education journal (Stephan & Akyuz, 2012). Finally, the
work of a mentor teacher in guiding novice student-centered teachers to incorporate inquiry
practices into their teaching repertoire will be published within the next year. These articles have
the potential to inform researchers, designers, and teacher educators.

Mind the gap : Task design principles to achieve conceptual
change in rational number understanding
Wim Van Dooren
University of Leuven, Belgium
Xenia Vamvakoussi
University of Ioannina, Greece
Lieven Verschaffel
University of Leuven, Belgium
In this paper we focus on the problem of conceptual change in
the shift from natural to non-natural numbers. We discuss students'
difficulties in this area and present a mathematics textbook analysis to
show that this problem is not taken into consideration in instruction. We
discuss a number of principles for instruction stemming from the
conceptual change perspective to learning and present a number of
experimentally tested tasks, designed on the basis of these principles.
These tasks were used to investigate and/or to induce conceptual change
in the number concept. We argue that such tasks are of value from the
point of view of instruction.
Keywords: Rational number understanding, conceptual change
Difficulties in understanding rational numbers
Mastery of the rational numbers represents an important aspect of mathematical
literacy. However, learning about rational numbers presents students with many
difficulties, mostly when the required reasoning is not in line with their prior knowledge
and experience about natural numbers (see Ni & Zhou, 2005, for a review).
In comparing decimals, students judge for instance that longer decimals are
larger, thus responding that 2.12 > 2.2 (Resnick et al., 1989); in comparing fractions
they think that a fraction gets larger when one of its parts gets larger, resulting in
errors such as 2/5 < 2/7 (e.g., Ni & Zhou, 2005). Students also extend the meaning of
operations from natural to non-natural numbers. For instance, seeing multiplication of
natural numbers as repeated addition leads to the idea that multiplication makes
bigger, which has been shown difficult to overcome (Greer, 1994), even in adults
(Vamvakoussi, Van Dooren, & Verschaffel, in press). Finally, the dense ordering of
rational (and real) numbers is difficult for students to grasp (e.g., Vamvakoussi,
Christou, Mertens, & Van Dooren, 2011, Vamvakoussi & Vosniadou, 2004, 2010;)
58
.

58
An order ≤ on a set X is dense if, for all x and y in X for which x < y, there is a z in X such
that x < z < y. Unlike the integers, the rational numbers as well as the real number are densely ordered.
The real numbers are, in addition, continuous. Theme D – W. Van Dooren, X. Vamvakoussi, & L. Verschaffel
520
Students initially respond that there are no other numbers between two given
pseudosuccessive numbers (e.g., 0.005 and 0.006 or 1/2 and 1/3). Later, they refer to
some intermediate numbers, but still do not accept that there are infinitely many.
Theoretical framework
Several researchers have argued that many of students' difficulties with
rational numbers can be explained from a conceptual change perspective on learning
(e.g., Ni & Zhou, 2005; Smith, Solomon, & Carey, 2005). Within this perspective, we
adopt a specific theoretical frame, namely the framework theory approach to
conceptual change (FTatCC, Vamvakoussi & Vosniadou, 2010), because it proposes a
number of specific and testable principles for the design of instruction and tasks
(Greer & Verschaffel, 2007; Tsamir & Tirosh, 2007). Originally developed to account
for the challenges that students face in regard to science learning, the FTatCC has
been fruitfully applied in the past few years in the domain of mathematics learning
(e.g., Greer & Verschaffel, 2007; Verschaffel & Vosniadou, 2004). Based on
evidence from cognitive-developmental research, the FTatCC assumes (Vosniadou et
al., 2008) that young children organize their everyday experiences in the context of
lay culture from an early age in domain-specific conceptual structures, termed
framework theories. These initial theories constitute explanatory frameworks that are
generative: They underlie children's predictions and explanations regarding
unfamiliar situations in a relatively coherent way. The incompatibility between the
background assumptions of students' initial theories and the scientific ideas to which
they are exposed mainly via instruction, is assumed to be a major source of
misunderstandings and errors for students. Regarding the development of the number
concept, the FTatCC assumes that, before they are exposed to rational number
instruction, students have formed a rather coherent domain-specific, naïve theory of
number—i.e., a complex system of interrelated ideas and beliefs—based on their
extensive experiences in the natural number domain. This theory shapes their
expectations about what counts as a number and how numbers are supposed to
behave. From the students' point of view, numbers are essentially discrete counting
numbers and are grounded in additive reasoning (Vamvakoussi & Vosniadou, 2011;
see also Ni & Zhou, 2005; Smith et al., 2005).
The FTatCC assumption about the structure and content of students'
knowledge of numbers—before they are exposed to non-natural number instruction—
implies that the shift from natural to non-natural numbers is a slow and gradual
process that is difficult to accomplish and requires substantial instructional support. A
factor contributing to this difficulty is that students are typically unaware of the
background assumptions of their framework theories and thus do not perceive the
necessity to re-evaluate or revise them. The FTatCC predicts that, instead, students
enrich via the use of additive learning mechanisms their knowledge base with new
incompatible information about numbers provided through instruction, thus creating
misconceptions such as the ones described above.
Instruction design principles
The conceptual change perspective on learning and instruction has been traditionally
associated with the cognitive conflict teaching strategy. This strategy has been subject
to criticisms and is now acknowledged as a potentially useful approach provided that
it is used with caution and only as one out of several other alternatives (Vosniadou,
Ioannides, Dimitrakopoulou, & Papademetriou, 2001). Indeed, there is a number of Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
521
different principles for the design of instruction stemming from the conceptual change
perspective on learning (Greer & Verschaffel, 2007; Vosniadou et al., 2001;
Vosniadou & Vamvakoussi, 2006; Vosniadou, Vamvakoussi, & Skopeliti, 2008). We
will refer here to the ones that are mostly relevant for the purposes of the present
paper. We note that, as such, these principles are not unique to the conceptual change
perspective on learning, in particular to the FTatCC. We stress, however, that the
principles have a very specific focus, namely to address the problems arising from the
incompatibility of prior knowledge with the intended new mathematical knowledge.
This particular focus has implications also for the implementation of principles in the
design of tasks, as we will illustrate in the following sections.
Take students' prior knowledge into consideration
There are several ways for prior knowledge to be taken into consideration in
instruction. This principle refers to the necessity to acknowledge the potentially
adverse effect of prior knowledge, in cases when it is not compatible with new
information coming from instruction. This requires that teachers, curriculum
designers, and textbook authors can identify the points where conceptual change is
necessary, and that they are informed about students' potential initial understandings.
Let us present an example that is related to our discussion in the next section. Prior
knowledge and experience about natural numbers can be used to introduce nonnatural numbers. In fact, it is commonly used when, for instance, fractions are
introduced via their part-whole aspect, or when decimals are presented as whole
numbers with a change of units. On the contrary, the differences between natural and
non-natural numbers are not explicitly addressed. However, downgrading the
differences and focusing on the similarities between natural and non-natural numbers-
-with a view to build on students' prior knowledge--creates many problems in the
long run, as discussed in the first section.
Facilitate students' metaconceptual awareness
As pointed above, students are typically not aware of the background assumptions of
their framework theories of numbers (e.g., that numbers are essentially discrete) and
this hinders conceptual change learning. It is thus important to create opportunities for
students to externalize their ideas, compare them with their peers', and reflect on
them. This can be done in learning environments that foster group discussions,
particularly when students are engaged in tasks that involve modelling a situation or
dealing with external representations. This brings us to the next principle.
Use models and external representations
Again, this principle is not unique to the FTatCC. However, it is important to note
that from the FTatCC perspective, taking into consideration students' prior knowledge
and how it may influence their interpretations of a situation also applies in the case of
models and external representation introduced in instruction. Consider, for example,
the (real) number line. It is a powerful representation for numbers, but it is also
known to be difficult and even misleading for students. For instance, conceptualizing
the number line as a ruler may lead students to believe that there is a finite number of
numbers in a given interval.
Foster analogical reasoning
Analogical reasoning, in particular cross-domain mapping, is considered an important
mechanism for conceptual restructuring. This is because the comparison between two Theme D – W. Van Dooren, X. Vamvakoussi, & L. Verschaffel
522
domains may highlight their common features, reveal unnoticed commonalities, and
allow for the projection of inferences from one domain to the other. In the process, representation of one or of both domains may occur to improve the match, which may
lead to conceptual restructuring. Consider, for example, the complex interplay
between the domain of continuous magnitudes and the domain of number that, in the
course of the historical development, resulted in the re-conceptualization of the notion
of number, as well as of continuity (Vamvakoussi & Vosniadou, 2012).
In the following, we present a textbook analysis showing that the problem of
conceptual change in the number concept is not taken into consideration in
instruction. Then we present examples of tasks that are grounded on the above
principles and have been experimentally tested with respect to their potential to
induce conceptual change learning.
A textbook analysis
A central theme in the task design principles mentioned above is that students need to
be pointed explicitly to differences between natural and rational numbers. To see to
what extent this currently happens, we did an analysis of the three most frequently
used primary school mathematics textbook series in Flanders, Belgium. More
specifically, the teachers' manuals from year 2 to 6 were analysed, as these included
student materials and several additional clarifications and background information.
The units of analysis were the lines in the teachers' manual that in some way
dealt with rational numbers (i.e. fractions, decimals, negative numbers). For every
line, it was determined whether and to what extent it made reference to differences
between natural and rational numbers, or to similarities between them. In cases when
such a difference or similarity was pointed out, it was moreover coded whether this
happened in an implicit or in an explicit way. Finally, it was also coded for what
aspect (the way to determine the size of a rational number, the effect of operations
with rational numbers, the representation of rational numbers, or the density of the
rational number system) the difference or similarity was referred to.
The results showed that the textbooks were very comparable in their
treatment of rational numbers. With respect to the size of rational numbers, none of
the textbooks explicitly referred to the fact that rules that are valid to determine the
size of natural numbers do not hold for rational numbers. While most observations
referred to differences between both kinds of numbers, they were all implicit. Such an
implicit reference is for instance a number line showing the location numbers 0.6,
0.75, and 0.8. Students can derive that even though 75 is larger than 6 and 8, 0.75 is
still between 0.6 and 0.8, but it is not explicitly pointed out.
With respect to representations, all textbooks referred to differences merely
in implicit ways (such as pointing out that 2/4 = 1/2 without explicitly pointing out
that any rational number can have infinitely many different representations).
For the domain of operations, both similarities and differences between
natural and rational numbers are pointed out, about two thirds are similarities. An
example is that a decimal number like 0.72 is written as 72 tenths in order to do
operations with it (such as halving or doubling). Only one textbook explicitly
mentions that teachers should explicitly address the idea in students that division will
lead to a smaller result, and this happens only at one moment in the fifth year.
Finally, the aspect of the density of the rational numbers is hardly dealt with
at all in the three textbook series. In the few cases where it is addressed, this happens Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
523
in an implicit way, mostly by pointing out that an interval between two given numbers
on a number line can be "stretched" after which more numbers can be found, as
illustrated in Figure 1. It is however not explicitly pointed out that infinitely many
numbers can be found in any interval or that the stretching can be infinitely repeated.
Figure 1. Implicit reference to the density of the number line in a fifth grade textbook
Tasks to investigate and induce conceptual change
In the following we present specific tasks that were employed in
experimental settings with a view to investigate secondary students' understandings
of the density property of rational (and real) numbers, and to explore possibilities for
effective teaching of this counter-intuitive notion. The design of these tasks drew on a
series of studies from the FTatCC that focused on students' understanding of density
as a paradigmatic case of the problem of conceptual change in the development of the
rational number concept (Vamvakoussi & Vosniadou, 2004, 2010; Vamvakoussi et
al., 2011). In line with the FTatCC principles, the design of the tasks was informed by
empirical evidence about students' pre-existing ideas and typical misconceptions
regarding the notion of density in arithmetical, as well as geometrical contexts. This
evidence can be summarized as follows: a) the idea of discreteness is robust both in
arithmetical and in geometrical contexts, b) students are more inclined to accept that

there are infinitely many points on a segment, than that there are infinitely many
numbers in an interval, c) accepting that there are infinitely many intermediates
(numbers or points) does not imply that one understands that these can never be found
one immediately after the other, d) students do not "see" the rational numbers set as a
unified system of numbers but rather as consisting of unrelated sets of numbers (e.g.,
integers, decimals, fractions), which has implications on their judgments about the
number, as well as the type of numbers in an interval. In line with the FTatCC
principles, the tasks refer to the cross-domain mapping between continuous
magnitudes, in particular the straight line, and numbers. This cross-domain mapping
is deemed crucial for instruction-induced conceptual change in the number concept
(Vamvakoussi & Vosniadou, 2012). It also underlies a representation of numbers,
namely the (real) number line that is commonly used in schools settings.
In line with the FTatCC principles, using, evaluating, comparing and
constructing representations of numbers and the number line, lie at the heart of the
sequence of tasks designed by Vamvakoussi, Kargiotakis, Kollias, Mamalougos, and
Vosniadou (2003, 2004) (Table 1). These tasks were experimentally tested in two
different settings, both allowing for expressing one's ideas, and discussing and
evaluating others' ideas. Specifically, 30 9
th
graders were split in two groups who
worked on the tasks in pairs. Each pair presented their results to their fellow students
and they were discussed. One 45-minute session was devoted to each task.
Meanwhile, the control group (14 9
th
graders) worked in their classroom, with paper
and pencil, and the results were presented orally and then written on the blackboard Theme D – W. Van Dooren, X. Vamvakoussi, & L. Verschaffel
524
by the researcher. The experimental group (16 9
th
graders) worked in Synergeia, a
software designed to support collaborative knowledge building that provides a
structured, web-based work space in which documents and ideas can be shared and
discussions can be stored. These participants had constant access to their peers'
answers, could write comments on them, and respond to comments. Both groups
received the same pre- and a post-test with tasks on the density of numbers. They
were also interviewed after the intervention. The experimental group improved
significantly more in its performance on density tasks than the control group.
Moreover, the experimental students displayed greater metaconceptual awareness of
the change in their ideas about numbers before and after the intervention. It appears
that exchanging ideas on the particular tasks in a structured environment with the
features of Synergeia was more profitable for students than the whole class discussion
(Vamvakoussi et al., 2003, 2004).

Task Goal	
1. What do you know about the real number line? Describe as good as you can. Read and comment upon the answers of your fellow students.	Express prior knowledge about the real number line
2. We often use the term "the set of real numbers". Suppose someone tries to understand what we mean by that. Could you draw a picture to help him/her understand?	Construct a representation for real numbers
3. We have been talking about two different representations of real numbers: A "formal" one, which we usually use at school, and a second one, which was proposed in our discussion and you seem to find adequate. Could you find a solid reason why we should prefer one over the other?	Compare two different representations
4. Imagine that you can become as small as a point of the number line. Then you could see the other points up close. Suppose that you are on the point that stands for the number 2.3. Can you define what point is the one closest to you? Describe in words or by drawing a picture.	Construct a representation for the number line

Table 1: Working with representations of numbers and the number line: A sequence of tasks
Vamvakoussi and Vosniadou (2012) further elaborated on the cross-domain
mapping between numbers and the line. In line with the FTatCC, they designed a text
that a) provided explicit information about the infinity of numbers in an interval, b)
made explicit reference to the numbers-to-points correspondence, and c) used a
bridging analogy (the number line as a rubber line) to convey the idea that points (and
numbers) can never be found one immediately after the other. The excerpt regarding
the bridging analogy reads:
The mathematical number line is a strange object. You can imagine it as a rubber
band that never breaks, no matter how much you stretch it. Place numbers
between 0 and 1, until it looks like you have used all the available points. If you
stretch the rubber band, then you will find out that between the points that looked
as if there were the one next to the other, there are more available points,
corresponding to more numbers. This procedure can be repeated infinitely many
times- don't forget that your imaginary rubber band never breaks!
Vamvakoussi and Vosniadou tested experimentally the value of the "rubberline" text as compared to two other texts that contained the explicit information and Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
525
examples of intermediate numbers, or figures illustrating the examples. Six classes of
8
th
and 11
th
graders (one experimental class per grade), in total 149 students received
a pre-test with density tasks in a arithmetical and a geometrical context, were
administered the corresponding text, and then received a post-test containing all the
tasks of the pre-test, and 5 additional tasks that examined whether students were able
to deal with the no-successor aspect of density (Figure 2). All groups profited from
the explicit information about the infinity of numbers presented in the text. However,
the experimental group (8
th
and 11
th
graders) outperformed the other groups in the "no
successor" items of the posttest, and were more consistent in providing correct
answers and justifications for their answers.
Figure 2. Example of a "no-successor" task in a geometrical context

Concluding thoughts

We stress that these tasks come from experimental studies aiming at testing very
specific hypotheses, and not in the first place at creating optimal learning
environments. As researchers in (the psychology of) mathematics education, being
mostly funded to conduct fundamental research, we are not primarily concerned with
the development of tasks that can be directly used in classroom teaching, as we
mainly aim to analyze and understand students' difficulties in learning particular
concepts starting from a certain theoretical stance. Still, we are convinced that our
perspective may have an added value for task design. We consider task design an
important part of the design of instruction. The tasks presented here were designed on
the basis of specific theoretical principles stemming from a conceptual change
perspective to learning and instruction. Furthermore, these tasks are empirically
tested, also with respect to the conditions under which they can be useful for teachers
as well as students.
We suggest that using tasks that prompt students to evaluate, compare, and
construct representations (in this case, of numbers) is informative for teachers, in the
sense that it provides valuable information on students' thinking. In particular, tasks
that were presented as "thought experiments" (e.g., task 4 in Table 1; see also Figure
1) were extremely informative for students' ideas on counter-intuitive notions, which,
were not easily accessible via verbal descriptions. On the other hand, the examples
presented here indicate that, if such tasks are embedded in a learning environment that
is supportive of structured interaction among students, then they may facilitate
conceptual change learning. We also provided evidence that even a typical school
task, namely extracting information from a text to answer related questions, can lead
to conceptual change learning gains, depending on the kind of information that is
provided in the text. Specifically, information that bridges between students' initial Theme D – W. Van Dooren, X. Vamvakoussi, & L. Verschaffel
526
ideas (e.g., the segment as a "necklace of beads") and the intended mathematical
notion (e.g., the segment as a dense array of points) appears to facilitate the grasping
of counter-intuitive ideas.
We believe, therefore, that the principles and tasks as elaborated above are
interesting from an instructional point of view, and may eventually inspire the
development of learning environments. Our textbook analysis – which shows a very
large gap with the tasks and principles elaborated above – even strengthens this claim.
Finally, we must stress that the FTatCC is in first instance a cognitivelyoriented theory. Of course, students' affect, motivation and beliefs also play an
important role in the learning processes to obtain conceptual change, but they are
beyond the scope of this paper.

Features of task design informing teachers' decisions about goals and pedagogies

Peter Sullivan
Monash University, Australia
Yudong Yang
Shanghai Academy of Educational Sciences, China

Based on their mathematical goals for their students, teachers choose or

design tasks and sequences of tasks, select media for presenting tasks to students and for students to communicate results, plan pedagogies associated with realising opportunities in tasks, determine the level of complexity of tasks for their students including ways of adapting for them, and anticipate processes for assessing student learning. Each of these decisions is influenced by teachers' understanding of the relevant mathematics, by earlier assessments of the readiness of their students, by the teacher's experience or creativity or access to resources, by their expectations for student engagement, by their commitment to connecting learning with students' lives, and informed by teachers' awareness and willingness to enact the relevant pedagogies. This working group invites contributions from researchers and teachers who have considered such issues from the perspective of task design. The intention is to synthesise what is known about teachers' decision making about tasks, and to offer suggestions about task design for teachers, teacher educators, task designers, text and resource authors, and curriculum developers.
Among the questions that might be considered by authors contributing to the working group and which can be addressed by submitted papers are:
• How do features of design influence teachers' decisions to use particular tasks/sequences, or adapt them, or create their own?
• How do features of tasks/sequences influence teachers' choices about their potential for their class, including the media used for communication about the task?
• How does the design process influence teacher decisions about tasks within sequences?
• How do design considerations facilitate teacher adaptation of tasks/sequences to their students' experiences?
• How does feedback from classroom implementation of tasks/sequences inform future decisions on task design and use?
• How does collaboration between teachers, or between researchers and teachers, influence design of tasks/sequences?
• What are the implications for initial teacher education in task design?
• What is the effect of different cultural backgrounds on teachers' knowledge or belief on tasks and task design? Theme E – Introduction

Teachers and researchers collaborating to develop teaching through problem solving in primary mathematics
Mike Askew
Monash University, Melbourne
Lisa Canty
Our Holy Redeemer Primary School, Melbourne
In this paper we focus on collaborative research developed between the staff of a primary school and a university researcher/task developer. The paper draws on findings from the first cycle of research which used a collection of tasks (word problems) and examined how teachers worked with and developed the tasks as springboards for developing students' reasoning in mathematics, as applied to the modelling of additive situations. The tasks were presenting in ways that introduced teachers to the broad principles underpinning the design of the tasks but not the specific intentions behind any one particular problem. This, we argue, encouraged the coming together of the teachers and researcher as a community of learners with teachers adapting and developing the tasks in ways that they saw fit to work with their particular learners. This approach also led, however, to tasks being appropriated in ways that may not have matched with the intentions of the designer: rather than this being an obstacle, it led to rich discussions around the nature of teaching and learning. We argue for the need to consider how tasks are mediated both between task designers and the teachers and between the teachers and learners and to accept that the appropriation at each of these 'interfaces' is open to variation in interpretations, and that working with such variation can lead both the development of pedagogical content knowledge and to student learning. Hence, rather than trying to construct tasks that are 'teacher-proof', working with the fuzziness of appropriation can be a strength.
Keywords: word problem solving, pedagogy, mediation, community of inquiry
Introduction
Problems are key tasks in mathematics education and there is growing support and evidence for the effectiveness of teaching mathematics through problem solving (National Research Council, 2001). This, however, poses challenges to teachers, particularly in primary (elementary) classes. One particular challenge is how teachers can support students to create representations that will help them find problem solutions and the pedagogical decisions involved in using and building upon these representations to make explicit the mathematics inherent in particular problems. Theme E – M. Askew & L. Canty
532
We report here on a teaching experiment in a primary school that involved working with teachers to use problem solving as a starting point through which to help students, aged five to eleven, understand additive reasoning. We examine a double loop of appropriation: the first loop of appropriation of tasks (problems) and representations by teachers when working with a University developer/researcher and the second loop of appropriations that students made in working with the tasks and representations as introduced by the teachers. Through our examination of this double loop of appropriation we aim to answer the key question of:
How were the design features of the tasks appropriated by teachers and in the light of this appropriation what pedagogical decisions were the teachers prompted to make?
In answering this question we seek to examine not only how this type of task design rests on the interplay between artefacts, tools and mathematical knowledge but also on the complex relationship and interface between the task designer/researcher and teachers and between teachers and learners.
In our initial working together (teachers and designer/researcher) several themes emerged that we explore in this paper and that we are looking at in more depth as the work moves into study of developing multiplicative reasoning. The bulk of this paper is jointly constructed, but there are specific observations included from the perspective of the designer/researcher (Mike, first named author) and the teacher initiating the work in the school (Lisa, second named author): where this is the case we present these observations as quotations from one or other of the authors.
Background to the project and the roles of the authors in the design and implementation of the tasks
The work reported here arises from collaboration between a University researcher and the staff of a local primary school. The teaching and learning leader in the school (Lisa) approached the university researcher (Mike) seeking professional development for the school. Although the school's results for mathematics were relatively high, students' scores on assessments of problem solving were consistently lower than scores on items assessing 'pure' computation. The staff had put in place various pedagogies to try and improve students' attitudes towards problem solving and their ability to solve problems, including the explicit use of heuristics but this did not appear to be impacting on standards.
Lisa: Until recently, teachers have presented learners with word problems and asked them to identify the relevant information and then use some strategy, (draw a picture, make a list, work backwards, etc.) to determine the appropriate calculation to use to solve the question, by being asked, for example, do we add or subtract to determine the answer? We observed that students were getting confused by focusing on the numbers in the problem rather than the context, which in turn was leading to overgeneralisations, such as if the numbers in the problem were, say, 9 and 27, then the answer would be 3 regardless of the question. Students could confidently identify key words such as "more" but again a focus on the numbers given was leading to the assumption to always, say, add. Analysis of assessment results pointed to lower success rates in word problem solving which was in direct contrast to the generally high results in pure number algorithms without context.
The university researcher agreed to work with the school but to treat the approach as one of building a community of joint inquiry into teaching and learning about problem solving, rather than 'delivering' professional development to the staff.
At the time of writing one initial cycle of inquiry into learning about problems Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
533
involving additive reasoning has been completed. The approach taken was relatively informal in terms of data collection as the initial emphasis was on building trust and ways of working together. The cycle of working together has comprised:
• Staff and researcher meeting for a two-hour session after school during which models of working with addition and subtraction problems were introduced and jointly explored and the principles behind the design of the problems (as set out below) shared and discussed.
• Teachers devoting at least one lesson a week to these problems over six weeks.
• Researcher and teaching and learning leader meeting mid-cycle to discuss the progress and to plan the next meeting.
• A half-day second meeting with all the staff to which teachers brought artefacts produced by the children when solving problems and shared how they had incorporated the problems into their teaching.
• The designer/researcher visiting and observing the problem solving lessons.
Task design features
In line with others (Christiansen & Walter, 1986) we use 'task' to be what learners are asked to do and 'activity' as the subsequent mathematical objects that emerge from engagement in the tasks and through the interaction between participants and resources/representations. Drawing on variation theory (Runesson, 2005) the mathematical object(s) which learner activity enable to emerge can be both direct and indirect. The direct object here was to solve particular word problems, with a first level indirect object of the classification of problems (and thus improve learners' problem solving) and a second level indirect object of developing understanding of the nature of additive reasoning (and thus improve learners' understanding of mathematical structure). To promote the emergence of these different mathematical objects the task design features co-ordinated several different aspects, two of which are focused on here: the structure of additive problems, models and representations for solving problems. A third main feature was the choice of contexts through which to frame the word problems. Extensive use of humour and fantasy was made of here, for reasons similar to those set out by Zazkis and Liljedahl (2009) but it is beyond the scope of this paper to discuss this in detail.
Classification of word problems
The word problems were initially designed by adapting the Cognitively Guided Instruction framework (Carpenter, Fennema, Franke, Levi, & Empson, 1999).
Problems were written (by the first author) with the intent of exemplifying one of three types of addition/subtraction root problems:
• Change – problems where an initial quantity is increased or decreased;
• Compare – problems with two distinct quantities to compare, one of which is larger or smaller than the other;
• Part-part-whole – problems based around a set comprising two distinct subsets.
All teachers in the school were provided with a collection of these problems, loosely organised into year levels, in a variety of forms, including resources that could be projected onto a whiteboard, or printed off, and versions of the problems that adapted to make similar problems but involving different numbers.
The problems had been previously published (Askew, 2005) and as such were accompanied with booklets providing explicit guidance on the classification and Theme E – M. Askew & L. Canty
534
suggested teaching approaches. However it had become clear that although the problems were designed with the above framework in mind, in practice, when discussing problems with teachers and students and discussing where they might fit in the framework did not always result in a particular problem being matched back onto the category that was originally designated. In the light of this inherent ambiguity in the classification of the problems less specific guidance was provided for the teachers in this project: they were left to decide on what the problems exemplified either through discussions with other colleagues or with the students. Thus the intent was that the framework would (a) help teachers make pedagogical decisions about the choice of problems to present to learners and (b) provide a common language for teachers to talk about problems, both amongst themselves and with learners, and also provide a common focus within and across the years.
Models and representations
The work of Carpenter and colleagues has also demonstrated that within this framework for additive reasoning problems the structure of particular problems affects the level of difficult (for example 'change' problem where the 'start' is unknown being cognitively more challenging than those where the final result is unknown). In the light of this a second task design feature was to introduce particular representations to scaffold the move from a word problem into a mathematical model. Rather than have different models for the different types of problems (which would presuppose that the classification of a problem into one of the three types needed to precede the setting up of the model) the use of a 'bar' diagram was chosen as a core representation that could used in all three types of problem. The choice of this model was based in the consideration of not only what artefacts and tools would classroom help learners to solve the specific problems but also, through reasoning about the types of problems, develop awareness of mathematical structure. In other words, the classification of the problems and the setting up of a model were not seen as two distinct, sequential stages but each supporting the other. Artefacts and tools are typically interpreted as having a concrete or virtual 'embodiment', with language regarded as something supporting and developing artefact and tool use. In this project we used two types of artefacts/tools used to support teachers and students. Using a "bar" diagram where, given three numerical elements in a problem, one of which is unknown, helps the problem solver to decide which is the unknown and to use this not only as a bridge into a solution method but also to think about the structure of the problem and thus became a tool for thinking with (Gravemeijer & Stephan, 2002). For example, given a problem such as:
Hamsa had 12 muffins. After Hamsa got some more muffins, she had 21 muffins.
How many muffins did Hamsa get?
A model could be set up thus:
Figure 1: Representing an additive word problem Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

535
Emergent findings
Our interest is in examining a 'double loop' of appropriation: first, how
teachers initially appropriated the classification and representation and the influence
of this on the way these were turned into pedagogical tools and second, the
subsequent appropriation of the classification and representation by the students. Here
we focus in the main on the first of these - teachers' appropriation.
Teachers' appropriation of and confidence in working with the tasks.
Our epistemological position is that mathematical understanding and knowledge
building arises from meaning making activity - with the emphasis on both the
meaning and the making. Meaning does not inhere in words - "compare problems' do
not 'exist' outside the collection of problems to which this label is attached - and the
meaning making comes about through the use of artefacts (classification labels in this
case) to think about the problems. Thus the classification of the problems was not
seen as a definitive or definite but as a means of provoking discussion about the
underlying structure and treating problem solving as a meaning making activity.
Lisa: The classification of additive problems into the three types was beneficial in
two clear ways. The first was in the initial process of identifying the fact that a
problem required additive reasoning. Second it enabled students to have a
stronger framework upon which to represent the known pieces of information.
Representing the second known piece of information in a problem and knowing
how this related to the first known piece of information was the challenging step
and could lead to some confusion. The framework provided a tool that assisted in
the completion of this sense making.
The teaching and learning leader also reported that this approach led to a
wealth of discussion between teachers and, in her experience, some of the most
extended professional dialogue about the nature and content of the mathematics
teaching that she had experienced during her time at the school.
The problems as originally published were organised in groups of three
around one of the problem types, with the level of difficulty of the actual calculation
being within what might be expected for the age of the pupils. Having solved three
problems the expectation was that teachers would discuss with the pupils what types
of problems these were. Thus variation (Runesson 2005) in the design of the problems
was deliberately based around keeping, initially, the underlying structure of the
problems constant and varying the quantities. In the project the teachers became
confident in adapting this proposed approach: as they and the students became
familiar with thinking about the types of problem, so the teachers felt confident to be
flexible:
Lisa: Initially teachers were using all three of the same type problems from the
one page, (all change for example) and students successfully solved these together
with teacher direction and also independently in pairs. When instruction moved to
another type of problem, this success pattern was continuing. When teachers
observed that students were becoming competent in solving the three "types" of
problems an assessment was given to review application of this new process. We
found, however, that some students tended to apply the process needed to
successfully solve the first question to all following problems even if these were
of different types rather than selecting appropriate processes for each one. A
successful experience in the first question where students knew they had "got it"
inadvertently led to using the same reasoning for all following questions. This
tendency to "overgeneralise" a known process to different types of problems is
typical of what we had noticed previously of our students' learn one "rule" and Theme E - M. Askew & L. Canty
536
apply it all contexts. And, as before, students weren't always attending to the
contextual situation, again manipulating the numbers to get a desired or expected
answer regardless of what the question was asking. After much discussion and
error analysis of student work in our professional learning teams staff decided to
"pick and mix" to encourage the identification or classification of the problem
type as well guiding more attention to the context.
Teachers' appropriation of and work with the representations
Assumptions of 'transparency' in the use of representations
After introducing the 'block' diagrams to the teachers, as Lisa explains, these were
not initially found to be helpful by all students.
Lisa: The introduction of the block (bar diagram) to students had the intention of
providing a means to arrange the relevant information in a relational manner.
This visual, as we initially interpreted it, was intended to scaffold student thinking
of what we know and how that information related to what we were looking to
find out. Teachers modelled the representation by drawing the complete diagram
and then inserting given values in appropriate places on the diagram. Students, in
pairs, attempted new problems using the bars as a bridging tool to determine the
appropriate calculation. This was not totally successful with all students. Some
students had difficulty identifying the relationships between the numerical
information and using this to place the numbers on the diagram appropriately.
What was tending to happen was for them to use the bars as simply another way
to lay the numbers out, much as one might be told to write the answer in the box.
Thus some learners would write the two given numbers in the short bars and the
answer in the third, longest bar, irrespective of the relationship between the
numbers. If the underlying calculation was to find the difference between, say, 15
and 40 they would record this as
15 40
25
Figure 2: Representing (incorrectly) the difference between 15 and 40
Even correct representations were non-proportional making it more challenging to
conceptualise the relationships. (For example a problem involving, say, 6 and 24,
would show these represented by the same size bar because of the pre-drawing of
the whole diagram.)
As the staff discussed what was happening here it became clear that the learners
interpretation of the diagram in a 'fill in the boxes' sense could be linked to
modelling of the diagram by (some) teachers as a whole rather than building it up
sequentially. Following rich professional dialogue between staff in a formal and
informal manner, sharing the work samples, (moderation) and further dialogue
with Mike, teachers went back to the classrooms to integrate the process of
building the diagram one part at a time. Students now were challenged to think
about how we could adjust the process of building the visual framework to better
represent the problem. Giving the control back to the students to see if they could
improve our process enabled them to review and reflect on their own thinking and
innovate to assist success rates. Such ownership of the learning enhanced creation
of new and shared knowledge. Teachers also noted a significant improvement in
student's meta-language used to discuss their thinking processes, thus allowing
self recognition of mistakes/successes and the reasoning to support their answers.
Mike: Looking back I can see how the way I introduced the diagrams to the staff
would have affected their appropriation of them and in turn how this played out in
classroom. I had prepared a 'sorting' activity based on a collection of problems.
The collection was based on the Carpenter and Fennema classification with
variation in what was unknown creating a dozen or so problems. After sorting and
classifying the problems, I had pre-prepared a set of block diagrams to fit with the Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
537
problems. Although we had a rich dialogue around which diagram might go with
which problem, I did not engage the teachers with constructing the diagrams and
so the points that subsequently emerged in classrooms were not anticipated or
addressed.
Thus assumptions of 'transparency' of representations were made in both
aspects of the double appropriation loop: assumptions of transparency by the
researcher and (both similar and different) assumptions made by the teachers. We
argue, however, that rather than this being a difficulty that could have been 'smoothed
out' by more attention to detail in setting up the work, that working through the
differences resulted in a deeper understanding of the role of the representations by
both the teachers and by the students.
Lisa: The diagram became even more valuable in that it now provided a process
through which to present known information in such a way as to illuminate what
is required in order to calculate what is not known. The process of drawing these
bars, one bar at a time was also valuable as it pushed the students to discuss and
to analyse where the second bar of information needed to be placed relative to the
first (next to it or below/above and so forth) as well as representing this
information in correct proportion to the first piece of unknown information.
But it also went beyond this in promoting a focus on the proportional relationship
between the two pieces of information that were known as well as the relationship
between them and what was unknown. For example if one was faced with a
problem where 6 apples were combined with 5 apples, the bar that represented the
6 apples needed to be slightly longer than (6/5 of) the bar that represented the 5
apples. And the bar representing the 6 and 5 apples combined together would be
as long as the two other bars combined. Thus the representation suggested that
this value was going to be in the vicinity of double 5 (10) and double 6 (12). The
diagram came to also act as a de-facto 'checking' tool.
Conversions between representations as a linear process
In the discussion in the reporting back meeting several issues emerged but one in
particular concerned the interplay between the three aspects of context, representation
and numerical equation. It became clear that a popular interpretation was that these
were three stages to move through, rather than complementary representations that
might be moved back and forth between. Thus once a model had been set up the
problem context could be 'set aside' and the model treated as the primary
representation that could then be worked with to set up the symbolic. This is
consistent with a traditional view of word problems and the contexts therein being
regarded as 'immaterial' and 'hollow' vehicles for mathematical calculation: that the
context had little to do with the abstract mathematics. In fact, in designing the
contexts for the word problems considerable care and effort had been taken to choose
contexts that might support mathematising, for example throwing competitions to
provoke comparing, or homework being destroyed as a context for change.
As mentioned, a further design feature was that the problems were not
necessarily intended to be 'realistic' or 'relevant' (the realistic-ness or of contexts to
individual learners being problematic) but rather to be engaging, particularly through
the use of humour and fantasy contexts. Feedback from the staff and children was that
everyone had enjoyed the humour thus embodied and a 'playful' approach had been
invoked, but this may also have inadvertently reinforced the perception of the
contexts only being there as window dressing to be discarded as soon as possible.
Mike: During my visit to the school one lesson was observed that reinforced this
impression of a linear movement from context to diagram to symbols. The context
of the problem was two characters involved in a domino stacking competition
with questions around the differences in the numbers of dominoes successfully Theme E - M. Askew & L. Canty
538
stacked. Some of the Grade 5 students working on this were experiencing
difficulties over producing an appropriate model for the problem: several children
were putting the two quantities together end to end and representing the missing
amount as the total rather than setting up a compare model. In the discussion that
the teacher had with the class about which of these was the appropriate model, no
reference back to the context of actually stacking things up and comparing the
heights was made: the discussion was focused around the models and the numbers
- the context was not used as a way into setting up the context.
Again this has been treated as a focus of discussion in the meetings between
researcher and staff and as the work moves into multiplicative reasoning this is an
aspect that explicit attention is being paid to.
Implications of the work reported in the paper on different communities
The first implication is that word problems can provide tasks that teacher and students
not only find engaging but also which can give rise to purposeful mathematical
dialogue and meaning making.
Lisa: Initial responses from students have been most positive - they, informally,
have reported engagement with the problems, a delight in the humorous nature of
them and pleasure in discussing and exploring the possible underlying structures.
Whether this has resulted in gains on solving word problems in other situations,
most notably national tests, will become clearer as the study unfolds. Teachers
involved so far reported a shift in perspectives on the teaching of word problems
and an awareness of the meaning making processes.
Second, the introduction of a framework for working on and with the tasks, and
treating this as a joint endeavour has promoted teacher inquiry and collegiality
Lisa: As an integral part of the performance and development culture of the
school, staff observe each other's lessons within and across the levels. This direct
observation leads to a structured discussion between the staff members about the
learning taking place: as all staff have responded to the professional development
and focus on problem solving so positively along with a growing relationship of
trust, in this context observation and feedback should prove highly beneficial.
A further question is how the publication and presentation of such tasks
might be done in ways that provoke similar responses without the presence of a
researcher. While publishers might take note of the decision not to supply teachers
with the 'key' to what type of problem each word problem was meant to exemplify, in
the absence of the discussion around the design principles and the revisiting of these
to refine the meaning, then the tasks alone may simply result in a set of 'dull' word
problems.

Conflicts in designing tasks at collaborative groups
Jonei Cerqueira Barbosa
Federal University of Bahia (Brazil)
Andreia Maria Pereira de Oliveira
State University of Feira de Santana (Brazil)
This is a theoretical paper in which some categories are proposed
to analyse conflicts in designing tasks in collaborative groups composed
of academics and schoolteachers. Based on insights from our own
experience in a collaborative group that designs tasks for other teachers,
and by using concepts of Basil Bernstein's theory, we propose five arenas
of conflicts between academics' and teachers' in collaborative groups
while they are producing tasks.
Keywords: Teachers, Academics, Collaboration, Tasks, Conflicts
Introduction
Task design in teacher education is a visible theme in literature (e.g.,
Zaslavsky & Sullivan, 2011). Let us follow the wide definition proposed in the ICMI
Study 22 (ICMI, 2012): "anything that a teacher uses to demonstrate mathematics, to
pursue interactively with students, or to ask students to do something" (p. 10). Some
studies suggest tasks do not determine teachers' actions (Remillard, 2005), but tasks
provide opportunities and limitations for teachers' and learners' actions (Remillard,
2005; Watson & Mason, 2007; Sullivan, Clarke & Clarke, 2009).
In this paper, we are interested in tasks designed by collaborative groups. This
collaborative group may be defined as one which brings together school teachers and
academics (Levine & Marcus, 2010). In this case we use the term academics to denote
those who work at university institutions conducting research, teaching or
developmental programmes. We were convinced by Jaworski's (2011) argument that
"teacher educator" is not the best term since we are interested in characterising the
partnership between academics and teachers.
Evidence suggests collaborative groups have positive effects on teachers' and
students' learning (Levine & Marcus, 2010; Jaworski, 2005, 2011; Ferreira & Miorim,
2011). Despite different understandings of teacher learning (Borko, 2004; Adler &
Davis, 2006; Ball, Thames & Phelps, 2008), we wish to be explicit about our point of
view: teachers' learning is related to changes in patterns of participation in the
classrooms (Borko, 2004). There is not enough space here to develop this topic, so we
ask the reader to consider our point of view when we talk about teacher learning
throughout the paper.
In collaborative groups, teachers have an active role in choosing what to do.
Every participant has an opportunity for mutual learning, i.e., academics may learn
from teachers, and vice-versa. Despite the term "collaborative", Jaworski (2005, Theme E - J. Cerqueira Barbosa & A. M. Pereira de Oliveira
542
2011) and Zaslavsky (2008) identified tensions between teachers' and academics'
knowledge in designing tasks as they may present opposing points of view. This
finding suggests that collaborative groups are also a terrain for conflict (for now, let
us consider the term "conflict" intuitively). The same insight came to us from our own
experience in a collaborative group that we discuss below.
Conflicts are likely to emerge in designing tasks in collaborative groups, since
it involves the partners making decisions from different perspectives. For instance,
researchers' opinions may reflect their theoretical preferences whereas teachers may
express their opinions in terms of their own experiences in school contexts. In this
paper, we will focus on the role of conflict in designing tasks in collaborative groups.
As part of an ongoing research project, our theoretical contribution is based on
concepts from Basil Bernstein's theory (Bernstein, 1990, 1996). In order to build our
argumentation we mention studies reported in literature and our experience in a
collaborative group.
Initially we present a conceptualisation of collaborative groups. Subsequently,
we introduce the collaborative group that we were part of and an exemplary task
designed by the members of the group. Finally, we suggest five arenas of conflicts in
designing tasks inside collaborative groups.
Collaborative groups
Collaborative groups may work in different forms, and also represent
different types of learning (Levine & Marcus, 2010). Although not using the term
"collaborative", Jaworski (2005) explains the key characteristic of an inquiry
community composed of academics and teachers, which is that it requires us all to
trust and have confidence in working together. It suggests that members recognise
their different expertise and they share them in order to achieve a goal, which is in
line with what Wagner (1997) calls co-learning agreement. Ferreira and Miorim
(2011) make a distinguishing point for collaborative groups:
[It is] a group in which participation is voluntary, in which all individuals
involved search for professional growth, share trust and respect, support the group
work, engage in a common purpose, all the while creating and sharing meanings
about what they are doing, about their lives and professional practices (p. 138).
These authors state that not every group should be recognised as collaborative.
The authors call into question the nature of participation, which is expected to be
voluntary. As a result, a compulsory developmental programme should not be
understood as collaborative at all, since teachers cannot choose whether they want to
take part in or not.
In some sense, collaborative groups are also regulative on what is moved or
not to classrooms. Following this view, collaborative groups may be considered part
of what Basil Bernstein (1990, 1996) calls pedagogic recontextualizing field. The
function of this field is to move texts produced in the scientific areas (for instance,
Mathematics, Mathematics Education, and so on) and relocate them for instance into
classrooms. As collaborative groups focus on ways of improving teaching and
learning mathematics, they have a regulative action onto classrooms.
In the above paragraph, we mentioned the term "texts", which is a key concept
in Bernsteinian theory. Here, texts refer to all communicative actions, which may be
oral, written, gestural, and so on (Bernstein, 1990). A task is itself a written text,
whereas designing tasks requires participants to use different types of texts. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
543
Collaborative groups establish a pedagogic relationship, but not with fixed
positions between who teaches and who learns (using Bernsteinian terminology,
between transmitters and acquirers). Both teachers and academics may interchange
the position of transmitters and acquirers at different times since the relationship is
based on mutual learning. We name this as floating positions in collaborative groups.
This does not mean that the pedagogic relationship is unstable, but floating positions
is its way of being, its nature, if we ensure the principle of mutual learning in the
group.
As pedagogic practice, every collaborative group has its own principles that
regulate its functioning. Bernstein (1990, 1996) points out two main features of
pedagogic practices: classification and framing. The first one regulates what is
legitimate to communicate, the second regulates how to communicate. Then by the
co-learning agreement, and as long as the collaborative group is going on, participants
address the principles that regulate the relationship between them.
As a pedagogic relationship, collaborative groups may also experience
conflicts. Jaworski (2005), for instance, reports a conflict between teachers and
academics in a collaborative group. While teachers were reporting they use inquirybased tasks in classrooms as additional to the curriculum, the academics were
emphasizing them as being curriculum-related. Piazza, McNeill, and Hittinger (2009)
refer to two sources of conflict in teacher communities: beliefs about subject matter
and the purpose of education. Conflict is not negative, with some authors viewing it
as a source of learning (Jaworski, 2005; Zalavsky, 2008; Piazza, McNeill & Hittinger,
2009). Moreover, conflicts may tell us about the nature of collaborative groups and
their internal dynamics.
Through Bernsteinian lenses, we see conflicts in collaborative groups as an
expression of the space that insulates original contexts of academics and teachers.
Even engaged in mutual learning, the participants are likely to make public their
views grounded in either university communities or schools, respectively, be they
academics or teachers.
Mutual learning does not remove horizontal hierarchies among the
participants. Let us imagine a collaborative group in which a well-respected academic
takes part in that. In such a case, the voice of the academic may be stronger in the
group than other participants. The same may happen to an experienced teacher who
has a higher expertise about anticipating students' actions. Their respective arguments
may be more vocal than others, and so reducing the opportunity for others to engage
in dialogue.
An example
At the end of 2010, we invited Master and PhD students, prospective and
experienced teachers to join with us to form a collaborative group with the purpose of
designing mathematical tasks for school students' and teachers' use. Participation was
voluntary, and the group was composed of 25 participants in all. It was called
Mathematics Education Watch (Observatório da Educação Matemática, in Brazilian
Portuguese) and is known by the acronym OEM.
The main aim of the OEM was to design a kind of written task referred to as
educative curriculum materials by Remillard (2005). Educative curriculum materials
are those that aim at both students' and teachers' learning (Remillard, 2005).
Remillard in turn uses the term "curriculum materials" for those designed only for
student learning. The adjective "educative" added to the term means that there is Theme E - J. Cerqueira Barbosa & A. M. Pereira de Oliveira
544
some support for teachers to use the task. Then, the main motivation in organising the
OEM was to bring together teachers' and academics' expertise to assure that the
materials would be informed by teachers' know-how.
The group focused on the geometry competences recommended by Brazilian
official documents (BRASIL, 2008). The whole group was organised in seven
subgroups, and each one included, at least one academics (Master and PhD students
were also considered academics), one experienced and one prospective teacher.
Figure 1. Group picture taken after a regular meeting.
The group decided on the following phases to design educative curriculum
materials:
(1) to review literature on teaching and learning of geometry;
(2) to draft curriculum materials;
(3) to review and refine the curriculum materials;
(4) to use the materials in the OEM teachers' classrooms and to record the
implementations;
(5) to design the educative curriculum materials;
(6) to review and to refine them;
(7) to make them available on the Internet for other teachers.
At the time this paper was written, the group was starting phase 5.
Collaborative task design and the associated conflicts
Zaslavsky (2008) has shown that the cycle of designing, implementing and
modifying is an effective way of supporting teacher learning. Also this is a rich
opportunity for us as academics to learn more about school mathematics and how
teachers position themselves, which may ultimately help us to improve the ways of
supporting teachers.
Alro and Skovsmose's book (2002) was influential within the group, and we
decided to design investigation-based tasks. Figure 2 is an example of a task designed
by a subgroup, and refined by the whole group. This task is to be used with the
software Geogebra, which is familiar to the teachers who are involved in the OEM.
The task in Figure 2 can be described as curriculum materials, because at this stage it
is only focused on supporting student learning. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
545
Figure 2. Task designed at the OEM (translated from Brazilian Portuguese).
The process of producing tasks provides an opportunity for many discussions
within subgroups, as well as the group as a whole. From this experience, we noted
some conflicting points of views about decisions to be made for the task. In
Bernsteinian terms, our interpretation was the conflicting messages were aligned to
the different settings participants originally belong to.
In a Bernsteinian analysis, the interest is upon discursive control. In his words:
the focus is on how power and control are translated in principles for pedagogic
communication (Bernstein, 1996). As previously noted, collaborative groups also
represent pedagogic practice based on mutual learning. As a consequence, there are
principles that regulate what the participants communicate to each other. It is possible
that the control is weaker than other contexts in which transmitter and acquirer have
fixed positions. However, it does not mean absence of control, which is operated
among and by the participants.
Conflicts about the features of a task should be viewed in terms of agents
addressing different principles of pedagogic practice. For instance, the academics
might share their theoretical views in the group. By doing this, they select what to
say, and also how to build their argumentation to be effective in that context. This is a
sort of recontextualization (Bernstein, 1996) operated by academics from scientific
field to a setting - in case, a collaborative group - in the pedagogic recontextualizing
field. In turn, teachers' arguments might be based on their experience in schools. Also,
they select what to say and how to do it as they recognise the setting has a particular
set of principles. In Barbosa (2013), it was called reverse recontextualization, where
legitimate texts move from classrooms to the pedagogic recontextualizing field.
In some sense conflicts in collaborative groups may be framed as the
encounters between texts that evoke principles from other two fields (scientific field
and classrooms). The same sort of conflict could arise with relation to official
pedagogic recontextualizing field, that one represented by state (Bernstein, 1996).
Generally conflicts in designing tasks may refer to different dimensions, all of
them related to what to select to be approached in the task and how to do that (a very Theme E - J. Cerqueira Barbosa & A. M. Pereira de Oliveira
546
Bernsteinian point of view). Let us use the term arena to refer to the scope of a
conflict, a disagreement, i.e., the subject of the conflict. From our experience in the
OEM, and based on Bernsteinian lenses on discursive control, we shall suggest five
possible arenas of conflicts for task design in collaborative groups: context, use of
language, structure, distribution and subjects. These arenas of conflicts are analytic
categories proposed to analyse conflicts in collaborative groups when they are
engaged in decision making in the design tasks. The categories may be considered
part of what Bernstein (1996) calls languages of description. The function of the
languages of description is "to produce a specific text and translate these referential

relations into theoretical objects or potential theoretical objects" (p. 133).
The arena of context refers to the mathematical context of tasks. Alro and
Skovsmose (2002) theorise three possibilities for mathematical tasks: reference to
pure mathematics, semi-reality, and reality. We may consider two extremes – pure
mathematics-based and reality-based tasks – and many possibilities between. In this
case, the conflict of context arises when participants are discussing the adequacy of
the context for a task to achieve its learning goal. In producing the task in Figure 2,
for instance, the argument that a reality-based task would be more motivating for
students came into conflict with the argument that this sort of context, in the case,
could cause difficulties for learners.
The arena of language refers to the level of rigour tied to the task. In Figure 2,
the rigour is expressed through the use of some terms and, in particular, at question 6,
an algebraic representation is required. The level of rigour could be weaker or
stronger than that, and it also gives room for conflicting arguments while designing
tasks.
The arena of structure refers to the degree of openness in tasks. If we have a
look at task in Figure 2, we may note that the auxiliary questions follow a sequence
that scaffolds students' actions. The task could be much closer, if more auxiliary
questions were posed to guide students' actions. Also, the task could be much open,
for instance, if the question was only put in terms of investigating the relationship
between the number of sides of a polygon and its number of diagonals. Then, those
conflicts may be positioned between two extremes: closed-end and opened-end tasks.
The arena of distribution refers to what is expected to teach in a task. It refers
to selecting content to be focused on tasks. For instance, in the task of Figure 2, a
conflict could happen between two possibilities: the task should focus on the
relationship between number of sides and diagonals, or on other regularities. The
control on what is explored by students while they are approaching an open-ended
task is unpredictable. Stein et al. (2000) classified them in high or low levels, as they
require memorization or investigations and explorations, respectively.
Finally, the arena of subjects refers the way the task positions students and
teachers. In a closed-end task, the teacher is expected to keep themselves far from
students' doings on the task, once this is very structured. On the other hand, in an
opened-end task, teachers are expected to interact more with students, as the task
itself does not have many scaffolds. So every task suggests a level of insulation
between students and teacher (at least, an expectation).
The five arenas of conflicts suggested above are expected to work as tools to
analyse conflicts in decision making in the design of tasks within collaborative
groups. Note that conflicting arguments in each arena is characterised in terms of a
continuum, which means arguments may be positioned at any point of the segment
(Figure 3). Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22

Figure 3. Diagram representing arenas of conflicts in designing tasks inside
collaborative groups.
As a result, the resulting task holds the markers of the conflicts
inferred from an analysis on the task (Barbosa, 2013). Then the diagram in Figure 3
may be useful to analyse conflicts in a setting of task design, and also to analyse tasks
themselves.
Final remarks and implications
In this paper, we attempt
conflicts in collaborative groups while they are designing tasks. Instead of
only for agreements within col
conflicts represented by opponent po

A dialogue between cultures about task design for primary
school
Maria G. Bartolini Bussi
University of Modena and Reggio Emilia (Italy)
Xuhua Sun
University of Macau (China)
Alessandro Ramploud
University of Modena and Reggio Emilia (Italy)
The aim of this paper is to exploit intercultural dialogue to
analyze two cases of task design (or, better, re-design) for word problems
in different cultural traditions (the Eastern one, within the Confucian
Heritage Culture, CHC, represented here by China and the Western one,
represented here by Italy). By means of two paradigmatic examples, one
developed in Italy and one in China, we aim at showing, on the one hand,
the effects and advantages of intercultural dialogue and, on the other hand,
the need to take into account and to respect culturally rooted pedagogies,
avoiding uncritical transfer from one culture to another.
Keywords: word problems, problems with variation, primary school,
intercultural dialogue, addition/subtraction
Introduction
Word problems are a special kind of tasks, presented all over the world, in

mathematics textbooks to link numbers to real life objects and situations. They are the heirs to ancient traditions of mathematical texts, existing in all cultures. In this paper, we consider, as a paradigmatic case, problems for early childhood classroom to be solved by addition and/or subtraction, although some observations and examples are more general.
After reviewing some literature about word problems in mathematics education in China and in the West, we present a special kind of word problem taken from Chinese textbooks, i.e. problems with variation (biànshì problems).
Then we illustrate how the meeting with the Chinese tradition has suggested to a group of Italian researchers (including primary school teachers) to re-design (and test in the classrooms) a rich system of problems with variation. On the one hand this redesign is in order to meet needs emerging from Italian school practice , and to tailor classroom activity to their system of beliefs, on the other hand. Conversely, the meeting with the Western tradition has modified some principles in the Chinese approach to problems with variation, enriching the original concept based structure and offering new criteria for task re-design.
Closing remarks summarize authors' contributions to the following questions (concerning themes C and E of the Study): Theme E – M. G. Bartolini Bussi, Xuhua Sun & A. Ramploud

C1) How do curriculum expectations influence authors' design principles?
C2) How does an intention to promote change influence design?
C3) How do cultural considerations about instruction and pedagogy influence design?
E1) How does collaboration between teachers, or between researchers and teachers, influence design of tasks/sequences?
E2) What is the effect of different cultural backgrounds on teachers' knowledge or belief on tasks and task design?
Some literature about word problems
A short review of Chinese literature
Taoism has had profound influence on Chinese culture. The central Taoism idea of the evolution of events as a change process and the acceptance of the inevitability of change reveal the ideologies of "grasping ways beyond categories"; "categorize in order to unite categories" (以法遇释, 以类相比). In China, for 5000 years, mathematics knowledge was elicited by word problems, which stems from the "Shu" (术) spirit (similar to "general methods") in the problem-oriented tradition from Oriental mathematics , "… to produce new methods from word problems, promote them up to the level of general method, generalize them into 'Shu,' and deploy these 'Shu' to solve various similar problems which are more complicated, more important, and more abstruse" (Wu & Li, 1998). Impacted by the idea of "grasping ways beyond categories"; "categorize in order to unite categories", word problems in ancient China were organized into different categories in terms of situations or algorithms. For example, Jiǔzhāng Suànshù (九章算术) , the most classic literature of Chinese mathematics, used 246 word problems to spread mathematical knowledge.
The tradition of categorizing word problems did not go on when Chinese curriculum on mathematics knowledge was totally borrowed from the West in 1878, where word problems, labelled as "application problems" ("应用题"), played a role of knowledge application, not introducting original knowledge. In 1929, the first formal curriculum standard, since new China was founded, primary school arithmetic syllabus (draft) ((小学算术教学大纲(草案)), claimed that "application problems are the important part and should be covered about half of the arithmetic contents" (Wang, 1996), which has remained unchanged as basic requirements of elementary curriculum for 80 years at least. In 1952, application problems in the first official textbook for whole country were categorized into simple application problems and complex application problems. Since 1958, application problems have not been organized by their categories but by their application content for the reason that knowledge system is required as a curriculum framework. Although application problems in textbooks were not organized by their categories again, their teaching organization stressed not a single problem but a group of problems with variation. Following the thousands-years-traditions "categorize in order to unite categories", one distinctive instruction feature of word problems is to develop the ability to identify the category of word problems (识类) belonging to and discern different categories (归类), namely, discern the invariant elements from the variant elements between problems and recognize the "class" every problem belong to. This pedagogy is generally called as biànshì (变式) in Chinese, where "biàn" stands for "changing" and "shì" means "form", can be translated loosely as "variation" in English (Sun, 2011). Some categories of biànshì are the following (examples follow): Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
551
OPMS (One Problem Multiple Solutions), where, for instance, the operation to solve the problem is carried out in different ways, with different grouping and ungrouping: 8 + 9 = (8+2) + 7; 8 + 9 = 7 + (1 + 9) and so on.
OPMC (One Problem Multiple Changes), where in the same situation some changes are introduced.
MPOS (*M*ultiple Problem One Solution), where the same operation can be used to solve different problems, as in summary exercises (Sun, 2011).
To sum up, in Chinese mathematics education problem variations aim to discern, compare the invariant feature of the relationship among concepts and solutions and provide opportunities for making connections, since comparison is considered a pre-condition to perceive the structures, dependencies, and relationships that may lead to mathematical abstraction (Sun, Wong, & Lam, 2007).
A short review of Western literature
Different strands (and a different pedagogy) emerge in the literature on word problems. In this paper we mention only some strands.
The cognitive analysis of word problems (see different contribution in Carpenter, Moser, & Romberg, 1982) focuses on the difficulties met by students in understanding the problem and looking for effective solution strategies and has produced well established categorizations likely to be employed in educational setting (e.g., the well agreed categorization of additive problems into combine, change and compare).
The didactical analysis of word problems (see different contributions in the recent volume by Verschaffel et al., 2009) criticizes the stereotyped and not realistic features, highlights the distance with modelling activity and focuses on the negative effects of word problems on students' sense making capabilities. Actually, there are examples of word problems which suggest uncritical applications of rules. There is the famous case (ibidem, p. xii) concerning the age of captain: "On a boat there are 20 sheep and 6 goats. How old is the captain?" The findings show that many students would respond to such question by adding the numbers of sheep and goats.
Some literature on word problems is strongly related to the early development of algebraic reasoning that may build a bridge between the two cultures (e.g. Ofir & Arcavi, 1992, Cai & Moyer, 2008).
Examples of Chinese problems with variation
The introduction of subtraction in the first grade by problems with variation
Fig 1. Mathematics Textbook Developer Group for Elementary School, 2005, vol. 1
Chinese textbook authors never separated the subtraction concept from addition. Theme E – M. G. Bartolini Bussi, Xuhua Sun & A. Ramploud
552
Whenever there is addition there is subtraction (Yang Hui, 1274, in Siu, 2004, p. 164).
Figure 1 shows a paradigmatic example of problem variation: Xiao Ming folds a pink paper crane; xiao li and xiao hua fold two blue paper cranes. How many paper cranes do they fold? There are 3 paper cranes. Xiao ming takes a paper crane. How many paper cranes does he leave? The answers are: 1+2=3, 2+1=3, and 3–1=2. The drawing intends to help learners to recapitulate the relationship of addition and subtraction, and the meaning of "equal" from the problem set 1+2=3, 2+1=3, 3–1=2.
The problem sets hinges on exemplifying relationships rather than objects and reflects the mathematical structure underlying the problems in this respect. The addition concept is different from that of subtraction, which belongs to a different category. Yet in the sense of part-part-whole we can combine these two concepts into one category and understand the ancient idea of "grasping ways beyond categories"; "categorize in order to unite categories.
A summary system of problems with variation in second grade
First solve the nine problems below. Then explain why they have been arranged in rows and columns in this way, finding relationships
(1)In the river there are 45 white ducks and 30 black ducks. All together how many ducks are there?
(2)In the river there are white ducks and black ducks. All together there are 75 ducks. 45 are white ducks. How many black ducks are there?
(3)In the river there are white ducks and black ducks. All together there are 75 ducks. 30 are black ducks. How many white ducks are there?
(1) In the river there is a group of ducks. 30 ducks swim away. 45 ducks are still there. How many ducks are in the group (at the beginning)?
(2) In the river there are 75 ducks. Some ducks swim away. There are still 45 ducks. How many ducks have swum away?
(3) In the river there are 75 ducks. 30 ducks swim away. How many ducks are still there?
(1) In the river there are 30 black ducks. White ducks are 15 more than black ducks (black ducks are 15 less than white ducks). How many white ducks are there?
(2) In the river there are 30 black ducks and 45 white ducks. How many white ducks more than black ducks (How many black ducks less than white ducks)?
(3) In the river there are 45 white ducks. Black ducks are 15 less than white ducks (white ducks are 15 more than black ducks). How many black ducks are there?
Table 1. Beijing education science research institute and Beijing instruction research center for basic education (1996), vol. 4, p. 88. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
553
This is a system of nine problems concerning addition and subtraction, where the organization in rows refers to the already mentioned combine, change, compare categorization and the organization in column refers to the same arithmetic operation (either addition or subtraction, see MPOS above). In each row there is a problem (in the shaded cell) and two variations (see OPMC above). It is taken from a Chinese second grade textbook. The task is very complex and requires the students not only to solve each problem but also to explain why the nine problems have been arranged in this way. Each problem is associated with a graphic scheme, that models on one or two lines the relationship between quantities. Such graphic schemes for both additive and multiplicative problems had been introduced systematically by Davydov (1966) in his algebraic approach to quantitative reasoning and relationships and are used in some countries of the CHC area, such as mainland China, Japan, Singapore. In a study carried out in Italy, we first used it in teacher education as a prompt to challenge teachers' beliefs (Bartolini Bussi et al., 2011; Bartolini Bussi et al., 2012); later a redesigned task was proposed to Italian students (several experiments from grade 2 to grade 5) in order to foster the approach to algebraic reasoning as soon as possible.
Task re-design in Italy and Hong Kong: hint at two case studies
A transposition of problems with variation in Italy
Needs in school practice
In Italy, in spite of the different suggestions of the Standards and Programs (http://www.mathunion.org/icmi/other-activities/database-project/introduction/italy/) where the focus is rather on the sense making of a situation and on modelling (mathematization), it is very popular strategy among teachers to suggest "cues" in the problem text in order to detect the operation to be used. For instance, in a popular website (http://www.lamaronca.it/), for additive problems, teachers are instructed to invite students to underline words like "aggiungere" (adding), "in tutto" (in all), for addition, and words like "togliere" (remove), "restare" (remain), "in più" (more), "in meno" (less) and so on for subtraction. Without careful control, this cue might lead randomly to either right or wrong choices. Consider for instance the two texts with the same implicit question: "how many candies does John have?".
"John has 5 candies and Anna gives him 2 more candies"
"Anna has 7 candies, 2 more than John".
In spite of the same question and of the same cue, in the former case the direct reference is to addition and in the latter to subtraction. The confusion is reinforced by the fact that in Italian "più" is also the wording of "+" (plus), that is the special sign for addition. The two situations might be related to each other highlighting unknowns: 5 + 2 = ? and 7 = ? + 2.
but teachers are not encouraged to link addition and subtraction. They are rather encouraged to follow the principle one-thing-at-a-time and to practice addition for months before introducing subtraction. A very popular series of exercise books (http://www.erickson.it/Ricerca/Pagine/Results.aspx?k=matematicaimparo&start1=1, Matematicaimparo) contains even two different booklets (with different authors), one for addition and one for subtraction problems. The above practice has the effect to produce very poor performances in the solution of arithmetic problems in the national

assessment carried out at the end of the second and fifth grades. Theme E - M. G. Bartolini Bussi, Xuhua Sun & A. Ramploud
554
Task re-design
Re-design concerns the task of the Table 1. Teachers-researchers who have
collaborated in the pilot study have not implemented the same Chinese task, but have
re-designed it to tailor it to the Italian tradition and to their individual teaching styles
and systems of beliefs.
Three main changes were introduced:
1) the single task has been transformed into a set of several tasks;
2) classroom work was organized according to a sequence inspired by the
theoretical framework of semiotic mediation after a Vygotskian approach (Bartolini
Bussi & Mariotti, 2008):
a) individual or small group solution of each row of problems followed by the
invention of three problems similar to the given ones, to foster the awareness
of the problem structure;
b) collective discussion of the findings, with teacher's orchestration.
Moreover the solving graphic schemes (at the beginning) were removed and
introduced later, after thorough exploration and solution of the problems, as students
were not familiar with such schemes. In this way the use of a graphic scheme was
acknowledged by students as meaningful and not perceived as an automatic answer to
a given task. In this way the task (originally developed in China within a teacher
centered and textbook centered tradition) was modified to fit a dialogic approach
where teaching and learning are considered the two sides of the same collaborative
process.
In the same way, multiplicative problems with variation were introduced as
from the third grade in several classrooms. (Bartolini Bussi et al., 2011). The project
is in progress and involves nearly 100 teachers from September 2012.
A modified approach to problems with variation in Hong Kong
Needs in school practice
Inspired by the Western tradition of phenomenography and pedagogy of variation
(Marton & Booth, 1997) and theory on the process of mathematization (National
Council of Teachers of Mathematics, 1989), Chinese researchers found that a focus
on dealing with concepts and deriving a structure among these concepts is not
sufficient; there is also a need to pay attention to two important processes of
mathematization, induction from real life contexts and application to different
contexts, that were introduced into the tradition of bianshi problems.
Task re-design
In a structured set of bianshi problems two types of "contextual variation"
were proposed "inductive bianshi" and "application bianshi". These two types of
variation should play a role to extend and enrich the use of mathematic (structural)
variation by appropriating relevant real life contexts. The use of inductive bianshi
begins with a real life context in which the established concepts are carefully
embedded and unfolded in a set of problems that leads to the new concept to be
established (the deepening bianshi); and using application bianshi provides new
contexts (even created by students) for students to connect (or apply) different
acquired concepts (the widening bianshi). Examples associated with this approach to
the division of fractions are reported by Sun (2007) and Wong, Lam, Sun, & Chan
(2009).Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
555
Closing remarks
The two cases of the last section have been developed independently by the authors in
Italy and Hong Kong before having the occasion to discuss with each other. In both
cases a task re-design had been started to answer needs coming from school practice
and from theoretical and pedagogical backgrounds, on the one hand, and prompts
from the other cultural tradition, on the other hand. In particular, in both cases the
needs for change (questions C1 and C2) were in the foreground, because of the
awareness that existing practice did not meet the intended curriculum expectations. In
both countries (question E1) collaborations between researchers and teachers were
realized, although with different modalities (see below).
In general, the Chinese literature on word problems as tasks is focused on
teaching, e.g. the preparation of good textbooks according to the intended curriculum
and the study of effective lessons which are structured around textbooks, whilst the
Western literature on word problems as tasks is focused on learning, i. e. the analysis
of difficulties met by students to interpret the task or to make sense of the problem
situations in mathematics. These differences have effects on the researchers' and
teachers' conception of task design (and re-design). For instance, Chinese teachers
generally have limited space to re-design tasks due to the fact that Chinese curriculum
evaluation (exam) is unified by government and curriculum content is required to
follow strictly the unified standards and the unified textbooks. In Italy teacherreasearchers have more freedom to design tasks and to devote some sessions to pilot
teaching experiments like the ones mentioned in this paper. In both cases, the
culturally rooted pedagogies were essential to re-design tasks: in Italy teachers
disassembled Chinese tasks to introduce collective discussions orchestrated by the
teacher; in China induction from real life contexts was put within the variation
scheme.
The questions C3 and E2 are surely the trickiest to be addressed. We give
some elements to support this claim, although it is not the scope of this paper to
address the general comparison of cultural traditions that encompasses the issue of
word problems as tasks (for a general discussion, see Xie & Carspecken, 2008).
Word problems have been part of the historical development of mathematics
in China and in other parts of the word as well. As Gerofsky (2009) claims, nonrealistic word problems are a written and pedagogical genre that expressed generality
through exemplification and have played an important role in all the pre-algebraic
societies. From these shared roots two cultural traditions developed in different ways.
In China the superb development of Algebra (maybe the main contribution of Chinese
scholars to mathematics) was not accompanied by a parallel theoretical approach like
Euclid's one; in the West the assumption of Euclid's Elements as the paradigm for
mathematics development gave for many centuries a different status to practical
mathematics (e.g. commercial arithmetic) from where the Western tradition of algebra
was later nurtured.
Mathematization became a key point in both traditions, although in different
periods. The focus on mathematization started in the West at the beginning of 19
th
century when the teaching of natural sciences was introduced systematically in
schools and gave rise in 1983 to the International Community of Teachers of
Mathematical Modelling and Applications that addressed criticisms of stereotyped
word problems and influenced the development of mathematics curricula,
(http://www.icmihistory.unito.it/ictma.php). The expansion to China is more recent Theme E - M. G. Bartolini Bussi, Xuhua Sun & A. Ramploud
556
although Chinese educators were exposed to Western influence for decades (e.g.
Dewey, Smith, Freudenthal, see Wang, 2013, p. 38 ff.).
Hence, task re-design considered in this paper took place in different cultural
traditions. It had in both cultures the advantage of respect the local pedagogical and
theoretical roots and to exploit perspectives from the other culture. Our attitude was,
in both cases, similar to the one described by Jullien (2008) in the case of
philosophical dialogue between China and the West:
This is not about comparative philosophy, about paralleling different conceptions,
but about a philosophical dialogue in which every thought, when coming towards
the other, questions itself about its own unthought (Jullien, 2008, p. iii, our
translation).

Scaffolding Tasks for the Professional Development of
Mathematics Teachers of English Language Learners
Haiwen Chu
Quality Teaching for English Learners, WestEd
This article outlines a design framework for classroom exemplars
to be used in the professional development of mathematics teachers of
English Language Learners. This framework shapes activities built
around mathematical practices to scaffold student engagement in
interactive tasks that foster their emerging autonomy. Empirical results
from applying this framework to design teacher apprenticeship is
reported. Data includes both professional development institutes and
instructional coaching cycles. Results suggest trajectories for teachers'
shifting understanding of conceptual, academic, and linguistic goals as
they appropriate a pedagogy of promise that fully develops the potential
of all ELLs.
Keywords: English language learners, scaffolding, interaction, lesson
design
Introduction: Challenging and Supporting English Language Learners
In the United States, English Language Learners (ELLs) are a rapidly growing
population, increasing by 51% in the past decade. Policy at the federal level has
positioned ELLs through a deficit lens as "Limited English Proficient". Mainstream
pedagogical approaches have remained simplified and simplistic, emphasizing
vocabulary terms taught atomistically. Within the high-stakes environment of
standardized assessments, simplification and accommodation for ELLs might be
necessary and appropriate (e.g., Sato, Rabinowitz, Gallagher, & Huang, 2009). The
classroom environment, however, offers broader and more varied opportunities for
students to learn important mathematics with use value beyond the classroom and to
interact with teachers and their peers. Just as ELLs need support in meeting the
challenges of conceptual understanding, procedural fluency, and language
proficiency, their teachers also must navigate national shifts in academic needs,
emphases, and practices. Rather than lowering the cognitive demands of tasks
(Henningsen & Stein, 1997), mathematics teachers must find multiple approaches to
provide ELLs with temporary support as they engage with mathematical ideas and
with their classmates and they develop their autonomy.
As the Quality Teaching for English Learners (QTEL) intiative at WestEd,
we engage teachers in professional development workshops and cycles of
instructional coaching through a whole-school model. QTEL employs a pedagogical
design framework across multiple disciplines. Our work entails the design of fully
articulated lessons which use scaffolding tasks, activities that invite and structure peer Theme E - Haiwen Chu
560
support to develop students' independent abilities. Lessons form the basis of sitebased workshops for teachers. Teachers then apprentice in cycles of disciplinary
coaching. We nurture teachers' growing expertise in setting conceptual, academic,
and linguistic goals and their effective planning and implementation of lessons that
challenge and support ELLs.
This article is organized as follows. First, I define classroom-based,
interactive scaffolding tasks. I then describe the interlocking sets of principles that
guide the design and sequencing of these tasks into coherent lessons. Third, I report
empirical findings from practitioner research conducted during the first of a three-year
partnership at two secondary schools. I conclude with directions for further research
and development based upon these design principles.

Defining classroom-based, interactive scaffolding tasks
Classroom-based, interactive scaffolding tasks are drawn from research on second language acquisition. Although these tasks are compatible with mathematical tasks (e.g., Henningsen & Stein, 1997), I focus on meeting the specific needs of ELLs for pedagogical scaffolding and the authentic use of language in interaction.
Ellis (2003) frames the analysis of tasks along five dimensions: 1) goals, 2) input, 3) conditions, 4) procedures, and 5) predicted outcomes as product and process. Goals define general purposes and target competencies. Input and conditions are linked: input is the information given including the modality (e.g., oral or written descriptions, or mathematical representations), while conditions are how information is either split or shared among students. When information is split there is an information gap (Gibbons, 2009). Students possess or are given pieces of information which they must put together through communicating with one another in order to complete the task. Procedures give students discourse moves and participation formats, such as working in pairs, taking explicit turns, or using specified language. Predicted outcomes include products such as materials students will write or draw and the linguistic or cognitive processes the task is intended to engender in students.
The QTEL approach emphasizes not just individual tasks but repeatable tasktypes with similar structures. Through regular participation, ELLs gain familiarity with the structure of a task-type, and therefore shift focus away from following instructions toward understanding new concepts (Walqui & van Lier, 2010). For example, the Compare and Contrast task-type has the goal of identifying similarities and differences between two mathematical objects or situations. As inputs, students are given a matrix as a graphic organizer. The two columns are headed by descriptive titles and the three to six rows are labelled with focus questions. The conditions are split or shared. One way to split information is to have one student report to another as an expert on a particular case. Alternatively, students could share information, going back and forth as they fill out cells of the matrix. Procedurally, students take turns filling out the matrix, orally stating what they are writing down. Once the matrix is complete, students take turns orally pointing out similarities and differences, using the appropriate formulaic expressions such as, "One difference between these two functions is..." Finally, students write a summary of key similarities and differences. The predicted product includes a completed matrix and summary statements of key similarities and differences. The predicted process includes noticing similarities and differences and expressing them orally as well as in written form.
These five analytic dimensions more fully specify the task-types described by Swan (2007), which emphasize goals and predicted processes. These task-types Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
561
include: classifying mathematical objects, interpreting multiple representations, evaluating mathematical statements, creating problems, and analyzing reasoning and solutions. A "classifying mathematical objects" task provides students with multiple mathematical objects to sort, either by excluding an "odd one out" or by placing cards containing the objects into a table with given headings for rows and columns. A "multiple representations" task has students match cards containing tables, graphs, and equations. These tasks specify inputs.
Focusing attention on the conditions and procedure ensures that English language learners receive peer support through structured interaction. For example, we use a task-type called "Sort and Label". We stipulate the condition that knowledge of what is written on different cards, while ultimately shared publically, is rationed out sequentially. Information is gradually revealed to the whole group as students take turns drawing one card at a time from a stack, reading out loud or describing what is on that card. Students use targeted formulaic expressions to offer and justify tentative groupings. This procedure distributes participation more evenly. Patterns emerge as cards are placed on the table in an order that is not predetermined. Without this condition, both students and teachers will shuffle around cards wordlessly, with only a few stating reasons after the fact. Further, this task-type can be more cognitively demanding than "classifying mathematical objects" because the categories are not given in advance, and must instead by devised, discussed, and agreed upon by students working as groups.
These five analytic dimensions provide explicit invitations for ELLs to engage with mathematical concepts and procedures as they participate fully in classroom interactions. For the remainder of this article, I use "task" as shorthand for these classroom-based scaffolding tasks that require, specify, and support peer interaction.
Design principles for tasks, lessons, and units
The design of tasks is guided by a framework on three different levels. First, five Principles for Quality Teaching of English Learners address general pedagogical features of the classroom environment. Backwards design emphasizes that all planning must begin by articulating conceptual, academic, and linguistic goals. Finally, an architecture of three moments assists teachers in deconstructing broad goals into connected intermediate objectives that flow together smoothly. This framework thus provides nested layers, including outcomes with the Principles, a process with backwards design, and an architecture with three moments.
Principles of Quality Teaching for English Learners
Five Principles guide the design of instructional experiences for students: 1) academic rigor; 2) high expectations, high support; 3) quality interactions; 4) language focus; 5) quality curriculum (Walqui & van Lier, 2010). In work designed to last three years, each year focuses on different Principles. During the first year, our whole-school coaching model highlighted three Principles: academic rigor, quality interactions, and language focus.
Academic rigor considers the extent to which students acquire deep disciplinary knowledge, use higher order thinking skils, and develop central and generative concepts and skills. This aspect maps well to the construct of the cognitive demand of a mathematical task (Henningsen and Stein, 1997). Within workshops, Theme E - Haiwen Chu
562
teachers have engaged in sorting tasks by cognitive demand and then constructing variations that amplify the level of academic rigor.
Quality interactions include both interactions between the teacher and students as well as those between students as peers. These interactions must be sustained and reciprocal so that the teacher is not the sole authority who asks questions and then evaluates students' responses. Rather, students should respond to each other directly, elaborating on their own ideas, qualifying or extending them, and sharing responsibility for negotiating validity. As they co-construct new understandings, students generalize, evaluate, and connect their ideas to each other, reflecting and revising each others' ideas. These quality interactions take place not only in whole-class discussions when students or groups share work, but are infused into students' participation in tasks working in small groups or pairs. This Principle is embedded in the specification of the inputs, conditions, and procedures associated with tasks.
Further, teachers must sustain a language focus by providing students with opportunities to use disciplinary language authentically. Therefore, teachers need to have pedagogical content knowledge of language to provide students with clear and purposeful explanations of the metalinguistic knowledge that will assist them in completing a task, such as false cognates or mathematical language functions. Further, language can be viewed as performance, including disciplinary subgenres and language functions such as proving, providing counterexamples, and generalizing. Building on an approach of message redundancy, teachers should not simplify the language associated with a task, but rather amplify through extralinguistic and paralinguistic cues. Finally, in terms of correctness, teachers should judiciously select feedback focusing not on perfect usage or grammar, but on language production that meets the goals of the task (cf Moschkovich, 2012).
Backwards design
Consistent with the Understanding by Design framework (Wiggins & McTighe, 2005), the design of scaffolding tasks begins with identifying goals at the level of the lesson or unit. To meet the needs of English language learners, it is essential to clearly identify not only disciplinary or conceptual goals, but also academic and linguistic goals (Walqui & van Lier, 2010).
Conceptual goals emerge from the discipline of mathematics, and are often associated with the conceptual understanding and procedural fluency that underpin teaching mathematics for understanding (e.g., Kilpatrick, Swafford, & Findell, 2001). Academic goals are generative and span multiple school disciplines. These usually require higher order thinking: generalizing, synthesizing, and comparing and contrasting. These academic goals are aligned with both the National Council of Teachers of Mathematics Process Standards as well as the Standards for Mathematical Practice from the Common Core State Standards in Mathematics. For instance, to "model with mathematics" students need to engage in generating, applying, testing, and revising mathematical representations as they relate to real-world scenarios.
Linguistic goals can be considered on two levels. At a broad level, each unit, lesson, and task has specific language functions or genres as its objectives. For example, comparison and contrast is a language function that applies not only to mathematics but any academic discipline. Providing counterexamples is a language function that is more specific to mathematics. This approach to language views proof, for instance, as a specific genre with its own rules, conventions, and structures Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

about which students need explicit instruction. Further, the genre of proof itself has subgenres: a proof by contradiction reads differently than a constructive proof or an existence proof. These differences can be understood in terms of language functions.
On a narrower level, specific swatches of language are necessary to accomplish various language functions. These formulaic expressions are used not as individual words but flexible grammatical structures. For example, "9 is odd, but not prime" is an instance of a formulaic expression useful for giving counterexamples. The expression is like a mathematical formula in that different objects or predicates can be substituted into the positions marked in italics. ELLs in particular need explicit instruction about the formulaic expressions appropriate to mathematical language functions. It would be difficult to devise counterexamples and to communicate them to the classroom community without these linguistic structures.
While it is possible to articulate and define these different goals separately in developing teachers' expertise, in well-designed instruction the goals converge and support each other. Academic goals are the generalizations and transfer of disciplinary goals, and language is a medium for both. Focusing on goals and increasing their challenge is essential in expanding teacher expertise. Setting these goals and objectives for units and lessons is a means of specifying the more general Principles of academic rigor, quality interactions, and language focus.
Lesson architecture in three moments
A typical "traditional" lesson sequence is explanation, example, exercise (Swan, 2007). The teacher gives a general explanation, demonstrates a worked example, and then students engage in repetitive practice of the target procedure. Curricula based upon NCTM Standards such as the Connected Mathematics Project focus on a single, central problem set in a real-world context and follow a "three phase" model: Launch, Explore, Summarize (Lappan et al., 2009). In the Launch phase, students are introduced to the problem and certain key contextual features or mathematical relationships can be explained. Students work in small groups to solve the problem using their own methods in the Explore phase. In the Summarize phase, the teacher orchestrates a whole-class discussion in which different solution methods are publically shared, compared, and contrasted.
By contrast, an architecture in three moments provides a more flexible structure: 1) preparing learners, 2) interacting with the concept, and 3) extending understanding (Walqui & van Lier, 2010). When directed toward a mathematical problem set in a real-world context, Preparing, Interacting, and Extending are compatible with Launch-Explore-Summarize. The more flexible architecture of three moments, however, offers three additional benefits: broader notions of prior knowledge and explicit attention to transitions from everyday to academic language, more flexibility in terms of building students' procedural fluency with embedded opportunities for reflection and interaction, and a clearly delineated, more varied set of options for extending understanding.
The Preparing Learners moment has three possible functions in the lesson. First, it articulates a focus on key understandings for the lesson. Second, the tasks bring to the surface students' prior experiences and knowledge with the objective of narrowing these contributions toward the lesson objective. Finally, the teacher can introduce essential understandings as reflected by key vocabulary terms, presented in context. For example, students can engage in a Think-Pair-Share. The prompt is kept as general as possible to appeal to students' personal experiences rather than their Theme E - Haiwen Chu
564
mathematical opinions. For example, students might be asked to tell a story about how they had to balance something, in preparation for a lesson about the arithmetic mean as a balancing point. Students have a few minutes to think individually, before they take turns with a partner sharing responses. The teacher then leads a whole-class discussion, calling individuals to share what their partners said. The teacher then summarizes these experiences and connects them explicitly to the mathematical topic of the lesson. In contrast with the Launch phase's focus on a a single mathematical problem set in a real-world context, other tasks, such as ones that involve sorting mathematical objects or representations, function well in the Preparing moment.
As students are interacting with the Concept, they engage in three processes: deconstructing, reassembling, and connecting different aspects of the central concept of the lesson. Although compatible with the "Explore" phase of investigating a central mathematical problem, this moment can address procedural fluency. For example, students work in groups of four to carry out an Algorithm in Four Steps. In this task-type, students play the roles of different steps of a procedure, such as finding the slope of the line between two points. After completing a case or problem, students rotate roles so that each gets a chance to play each of the four steps. In contrast with the typical "exercise" part of a lesson, students are collaboratively engaged in interaction structured to heighten awareness of the interdependence of steps.
Another suitable Interacting task-type is a Jigsaw Project. Students convene in expert groups to learn about a particular case or solve a problem, becoming experts and answering common focus questions that cut across the different cases. These focus questions cannot just be factual and isolated, and should cohere to require students to negotiate, discuss, and select in expert groups. Students then return to base groups to report their findings. Base groups use a graphic organizer similar to a Compare and Contrast matrix. The focus questions allow the base group to see connections, such as different proofs of the Pythagorean theorem or different realworld instances of unit rate.
Finally, as the lesson moves toward Extending Understanding, students are invited to work in three ways: to apply the concept to novel real-world applications, to connect to other concepts or algorithms previously studied, or to re-present their

understanding in new genres and formats. This moment also includes having students
create their own problems and solve those created by their peers (cf Swan, 2007).
Reflecting on one's own process of thinking and the relative usefulness of different
representations is also appropriate in this moment. The Collaborative Poster task-type
has students work in groups of four to create a poster, with the condition that each
student uses a different color marker. A good prompt requires students to make a
choice as a group, such as only choosing one type of representation from among
tables, equations, or graphs, in order to compare two different linear functions.
Tracing teacher engagement and growth trajectories
After the first of three years of whole-school coaching and professional development
across the disciplines at two secondary schools, three phases in growth among
mathematics teachers have begun to emerge. First, are shifts in teachers' professed
beliefs, priorities, and approaches. Next, teachers adopt tasks wholesale during
coaching. Third, teachers have begun to adapt tasks in planning units and lessons.
When first working with the design framework and tasks, teachers respond
most frequently and extensively to three features. First, teachers express appreciation
for how tasks specify clearly outlined roles for students and how the interaction is Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
565
structured. They contrast this approach with the "bare" problems provided in
textbooks or other curriculum resources, or generic roles for collaborative work (e.g.
recorder, materials manager, etc). Second, teachers respond positively to notions of
language which look beyond vocabulary toward language functions and linguistic
goals in lesson planning. Many teachers say that they had not been given other tools
beyond generic state-based language proficiency standards, or that they have
previously focused only on definitions-centered vocabulary. Finally, within the
context of planning, teachers focus on the Extending moment and developing
flexibility in selecting from the multiple tasks appropriate to that moment. This focus
on Extending is particularly important given the lack of closure that is often
characteristic of many mathematics lessons in the United States.
Within coaching cycles, initially teachers often place undue focus on tasktypes as the end goal rather than as a means for achieving outcomes such as quality
interactions. This emphasis is perhaps a consequence of previous district-wide
mandates which evaluate teachers based upon implementation of specified strategies.
Modeling specific tasks in coherent instructional sequences by the coach facilitates
both teachers building belief in their students and their technical knowledge for
implementing specific tasks and transitions between tasks. A key insight that many
teacher reach through practice is that language development is not spontaneous but
occurs within the context of planned scaffolding.
Simultaneously, teachers see how the language modeled for students
facilitates their conceptual development, and they begin to select and model
appropriate formulaic expressions and genres for their students. Teachers begin
develop their capacity to enact the Principle of language focus as they become aware
of how many mathematical tasks need to be further unpacked for ELLs. A common
example is around the prompt to "summarize". Students typically produce a narrative
recount of the procedure, or a laundry list of responses to specific questions, rather
than a coherent summary oriented toward goals and methods that generalize. Once
they have unpacked the complex processes and structures involved in summarizing,
teachers can apply the process to other common but complicated commands, such as
"explain" and "justify".
Teachers' initial misfires reflect their emerging understanding of the
rationale for procedures in task-types as connected to more general goals. Often,
teachers create opening prompts that are too narrow, or after students share responses
do not efficiently focus students' contributions toward the key ideas that connect
directly with the mathematical topic. Successful openings require both pedagogical
content knowledge and implementation skills. For example, in a lesson on solving
equations by undoing, one teacher gave an example response to a Think-Pair-Share
prompt a story of making a mistake with a baking recipe. Because this modelled
example would require redoing rather than undoing, many examples students
subsequently provided did not move toward the idea of inverse operations, and the
intended question of the order in which operations would need to be undone. By
engaging in reflection during coaching, teachers produce prompts that start more
broadly and focus more narrowly. Through coaching, teachers have the chance to
revise their lessons the same day. They thus can examine and reflect upon how
changes in the clarity of directions or the inputs or conditions of the task affect
student outcomes.
The refinement of teachers' choices can be traced in the quality of the focus
questions that they generate for Jigsaw Projects and Compare and Contrast Matrices.
Generic graphic organizers for comparing and contrasting two cases may be Theme E – Haiwen Chu
566
organized like a Venn diagram and do not have focus questions. Similarly, teachers
often initially misunderstand the rationale for focus questions, omitting these
questions, asking questions that are too general or do not apply to individual cases
(e.g., "How are they the same?"), or barraging students with recall questions that do
draw focus toward key ideas. Over time, teachers have developed questions that are
both better phrased individually as well as coherent and well-sequenced as a whole.
Indeed, with more experience with this design framework, teachers begin to
engage in a form of "task problematization" (Sierpinska, 2004). Not only are there
possible variations on the mathematical question but the other aspects of the design of
the task, including inputs, conditions, and procedures. Teachers begin to reflect on
the flexibility in choosing similar but subtly different task-types as appropriate to
different moments in the lesson and trade-offs between slightly different goals. In
particular, teachers gravitate toward the tasks that involve algorithms, whether in the
format of a group task as an Algorithm in Four Steps or in Comparing and
Contrasting two different algorithms, such as for computing the median. Reflective
coaching discussions with teachers about algorithms probe the dual demand for
procedural fluency and conceptual understanding. For many teachers, the explicit
modeling provided by scaffolding tasks in which students interact as they carry out
different steps of procedures is an accessible entry point to providing ELLs with
multiple algorithms which they will eventually be able to select from strategically. In
this manner, the scaffolding embedded in well-designed tasks allows teachers to
increase the academic rigor, or cognitive demand, of classroom activity.
Conclusion: Future directions for design and research
These emerging trajectories for teacher growth suggest three areas for further research
and efforts in task design, starting from the level of individual teachers and extending,
through coaching relationships, to the level of groups of math teachers working at the
same school. 1) How do individual teachers engage with different aspects of the
design framework and make connections across different components? 2) How does
this design framework function as a coaching tool to foster teachers' development? 3)
To what extent can this design framework serve as a common language as teachers
collaborate with one another? While the design framework has so far served
primarily as a means to design lessons for the purpose of professional development,
handover would suggest that teacher-created lessons could also be eventually used for
this purpose. Further in depth observational studies of student-to-student interactions
would also be appropriate on the way to evaluating the extent to which shifts in
teachers' practices around task design and implementation affect student outcomes.

We describe an experience in task design within an in-service secondary
mathematics teacher education program in Colombia. Following a model known
as didactic analysis, a team of researchers, educators, mentors and practicing
teachers worked together in designing, implementing, assessing and
reformulating secondary school mathematics tasks. We present here the main
features of the framework on which the program is based, identify some of the
characteristics of the experience lived by trainees, educators and researchers on
task design during the first implementation of the program, and analyse the
trainees' assessment on their own proposals of tasks and on the contribution of
the program on their task design competencies.
Keywords: teacher training; task design; task implementation; crosscommunities
Law sets curriculum autonomy in Colombia. Schools and teachers are fully responsible for
curriculum design and development in all areas. Schools are expected to produce curriculum
planning for each course and academic period and teachers are usually autonomous for
designing and implementing the lessons they are in charge of. They often do so by producing
what is known as "teaching guides": sets of tasks that they design or copy from different
resources, and propose to students. Most pre-service teacher education programs in Colombia
do not prepare future teachers in task design nor other practical questions; instead, they are
based on theoretical approaches to education.
In this paper, we describe an experience in task design that emerges from an inservice teacher education program in Colombia, known as MAD (Master in Didactic
Analysis). It is based on a model—didactic analysis— that enables trainees to design,
implement and assess sequences of tasks on specific topics for which a constructivist view of
students' learning is assumed (Gómez, 2007). Based on this model, a group of researchers,
educators, mentors and in-service mathematics teachers have worked together in MAD. We
use the term task as "anything that a teacher uses to demonstrate mathematics, to pursue
interactively with students, or to ask students to do something" (ICMI Study 22, 2012, p. 10). Theme E – GEMAD
570
In what follows, we describe the main features of the framework on which the
program is based, identify some of the characteristics of the experience lived by trainees,
educators and researchers on task design during the first implementation of MAD, and
analyze the trainees assessment on their own proposals of tasks and on the contribution of
MAD on their task design competencies. In the final section, we reflect on the role of the
different agents in the program.
Framework
MAD is a master's degree in mathematics education for in-service secondary mathematics
teachers. We assume a functional view of school mathematics in MAD. This vision puts the
focus on the usefulness of the mathematical concepts for solving problems in a variety of
contexts. Students are expected to use their mathematical knowledge for this purpose. They
are expected to develop their own cognitive strategies, manage different representations of
the mathematical concepts, choose the best solution strategies, argue about their decisions
and communicate fluently their thinking processes. This functional view of school
mathematics is coherent with a constructivist approach to students' learning and can be
implemented with different pedagogies. MAD does not explicitly promote any of them, since
each trainee and his context impose their own restrictions. Nonetheless, there are some
implicit methodological principles: it is considered that the good tasks are those that promote
the active implication of students, imply the development of strategic knowledge for problem
solving in a diversity of contexts, and require that students make decisions and justify them.
MAD is based on a model known as didactic analysis (Gómez, 2007; Lupiáñez,
2009). This model is a conceptualization of the activities that the teacher has to do in order to
design tasks that seek to promote students' learning on a mathematics topic. It is organized
around four interrelated analyses: subject matter, cognitive, instruction, and performance
analysis. The didactic analysis begins with the identification of the student's knowledge for
the topic at hand (see Figure 1). With this information, and taking into account the global
planning of his course, the teacher determines the mathematics content he wants to work on
and the goals he wants to achieve (Box 1 in Figure 1). The next step involves the subject
matter analysis (Box 2), in which the teacher stresses the relationship among concepts,
highlights its multiple representations, and distinguishes the phenomena from which they
emerge. This information is used in the cognitive analysis, in which the teacher describes his
hypothesis about how students construct their knowledge. The cognitive analysis involves the
establishment of learning expectations, and the identification of the skills, reasoning, and
strategies necessary to achieve those expectations, and of the difficulties, mistakes and
obstacles students might face. This information allows the teacher to carry out an instruction
analysis: the identification and description of the tasks that can be used in the design of the
teaching and learning activities that will compose the instruction in class (Box 3). During the
implementation, these tasks should mobilize students' knowledge in order to generate
cognitive conflicts and promote the construction of meaning using the materials and
resources available (Box 4). In the performance analysis the teacher observes, describes, and
analyzes students' performance in order to produce better descriptions of their current
knowledge (Box 5). After this process, the teacher can review the planning in order to
improve the sequence of tasks for future implementations. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
571
Figure 1. Diagram of a didactic analysis cycle
In this approach, trainees are expected to develop a deep enough knowledge of the

topic so that they can support the choices and decisions they make for their lesson plan (Charalambous, 2008). This is a topic-specific knowledge that trainees are expected to develop by performing a series of activities during their training and contributes to the development of their didactic knowledge (Box 6).
Didactic analysis is a cyclic process in which trainees analyze a school mathematics topic with the purpose of designing tasks that provide the learning opportunities required for students to achieve the learning expectations. Trainees make decisions in different moments and with different purposes. When they describe in detail the topic from the mathematics point of view (the concepts and procedures involved, the forms of representing those concepts and procedures and the ways in which the topic organizes the phenomena that give sense to it), they produce and organize information about the topic that allows them to make decisions about those aspects that they consider relevant, about how to formulate and specify the learning expectations, about the capacities that can be used for characterizing those learning expectations, and about the mistakes that students can make when solving tasks related to the topic. The information that trainees produce form those decisions are the basis for further decisions about their anticipations about how students' learning can develop when they solve the tasks (Gómez & González, 2009). This process is based on a procedure that allows trainees to produce the learning paths of the tasks. Tasks' learning paths are a useful tool for assessing the effects of reformulating or extend the original tasks. For instance, trainees can make decisions about the material and resources that can be more effective for achieving the learning expectations, when they analyze the implications of their use in the learning paths of the new tasks. Based on the information about the capacities that characterize the learning expectations, trainees can establish the complexity of the tasks proposed and make decisions about how those tasks align with students' previous knowledge and about how to sequence the tasks. Trainees can also make decisions about the most

effective ways of grouping the students and about how to foresight the teachers' performance when students begin solving the tasks and encounter difficulties. In summary, didactic analysis provides trainees with a systematic procedure for analyzing a school mathematics topic and sequentially making decisions that enable them to deepen in the different aspects of the topic and design and assess the tasks with which they pretend to contribute to the achievement of the learning expectations.
Since the information that trainees produce with the didactic analysis is complex and plentiful, when they make decisions, trainees might give priority to some decisions over others. For instance, they might focus on the treatment of the students' mistakes, so that their decisions will focus on ways of facing students with those mistakes and helping them to overcome them. For instance, they might concentrate on the search of representations, resources and possible teachers interventions that can help students overcome their mistakes and difficulties. In the empirical experience that we describe below, we show the concrete decisions that were made by a group of trainees in MAD.
MAD is set up from a social perspective of the trainees' learning (Gómez & González, in press). Trainees are organized in groups of 4 or 5 teachers. Each group has a mentor that accompanies it during the program's two years duration. Each group selects a school mathematics topic on which it will work during the program. The program is composed of 8 modules, two modules per semester. Each module begins with one week of face-to-face instruction in which the educator in charge of the module presents its theoretical basis and introduces the four activities that the groups have to carry out. Each activity spans over two weeks and requires the groups of trainees to analyze or produce information on their topic from a given perspective or with a given purpose. For instance, in an early activity, the groups produce the information concerning the representation systems of their topic. Later in the program, they analyze, in another activity, the role that the teacher had during the implementation of the tasks. For each activity, the groups produce a draft of their work at the end of the first week. They then receive comments on this draft from their mentors, and produce a final version of their work that they present to their pairs, the educators and mentors at the end of the second week.
Experience
In this paper, we report on MAD's first implementation that took place during 2010 and 2011. The 26 teachers that participated in MAD were working in public and private schools of Bogotá (Colombia) and its surroundings. They were organized in 6 groups that worked on the following topics: integers, linear equations (2 groups), straight lines in the plane, and trigonometric ratios (2 groups).
The design, analysis and selection of tasks are processes that span over the whole program. It begins with a first selection of tasks that is refined and improved with new ideas and analysis proposed by educators and mentors. The different activities of the modules structure this process. Once the groups have a tasks sequence that is ready to be taken to class, the groups implement, collect information on its implementation, analyze that information in order to assess the sequence's design and implementation, and make improvement proposals for future implementations. In what follows, we show a summary of the process for the specific case of Group 5, whose topic was trigonometric ratios. This group designed a sequence of five tasks distributed in 12 lessons. The first selection of tasks was Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
573
guided by activities in which the group set up the learning goals, the contents they expected to cover, the materials they wanted to use and the context (personal, scientific, etc.) in which they wanted to place their proposal. This group focused the design of their tasks in the use of materials and resources, some of which were elaborated by the group itself. The group used the materials and resources for bringing together the tasks characteristics that they considered important for students' learning:
Materials and resources play an important role in our task sequence because they allow us to motivate students in working with mathematics; they facilitate the achievement of the learning expectations; they promote mathematical communication and the construction of arguments; and they put into play different systems of representation.
Their pedagogical decisions focused in two aspects: (a) the grouping of students and (b) the communication in class. They proposed to use the tasks with different types of students' groupings: heterogeneous groups of three students (with high, medium and low achievement), big group, and, less frequently, individual work. In order to promote the classroom communication, they decided to use the following strategy: at the beginning of each task, the teacher shares its goals; then he induces students to create their solving strategies in small groups; the groups present their strategies and argue in favor of them to the whole group; once the task is finished, the teacher gives students follow-up and feedback on their performance. These decisions were guided and founded on their functional view of school mathematics and on the group's aims of contributing to the development of students' argumentation and justification competencies.
In what follows, we show in detail the design process of one of the tasks, named The streetlight height. In the following excerpt, Group 5 describes the task's features based on the subject matter analysis they have previously realized.
We expect students to find the streetlight height by using trigonometric ratios, without direct measures. The task covers a conceptual content that includes elements and properties of right triangles and trigonometric ratios. It involves also some procedures: (a) identifying regularities and patterns, (b) formulating equations, (c) using the functional language trigonometric ratios, and (d) situations solving. The task design includes working guides, goniometers made of set squares of 45° and 60°, protractor, calculator and a metric strip. The task refers to a personal situation.
In MAD, once the groups make the first task proposal, educators and mentors introduce new elements of analysis. That is the case, for instance, of considering the concrete capacities that can be activated with the task or the mistakes that students can make when solving the task. The groups characterize the task in terms of these new elements. For example, once Group 5 produced a list of 35 capacities and 12 mistakes for their two learning goals (that we do not have space to include here), they produced a table in which they related the learning goals, the tasks in their sequence, the capacities that each task could activate and the mistakes that students could make when solving each task. Table 1 shows an excerpt of this analysis for Group 5.
Goal Task Capacities Mistakes
2 Streetlight 1, 7, 3, 8, 12, 14, 17, 33, 35 2, 5, 7.3
Table 1. Relationships among learning goals, task, capacities and mistakes Theme E - GEMAD
574
This information led them to modify the task's wording and to determine how to implement the task in class:
Before starting working with the task, the teacher explains the use of the goniometer. In the first phase, the teacher asks students to go the location in the school where the streetlight is and to calculate its height with the instrument. The goals of this phase of the tasks are twofold: (a) that students recognize the use trigonometric ratios for measuring unreachable distances and (b) that they connect the elements of the instrument with the particular situation at hand in order to represent it and calculate the distance. The students are asked to record their observations in the working sheets provided, including the steps that they took for calculating the length and a graphical representation of the situation. They produce a poster to share their work with the class group.
Once they produced the final design of the tasks sequence, the groups implemented them in class. The following are two excerpts of the balance that Group 5 made of this phase of the process.
One of the minor changes that we made during the implementation of the tasks sequence concerned the time foreseen for each session. For most tasks, the time required was greater than we expected. We can claim that the Streetlight height task was effective as it was designed because we verified that students activated the capacities that we expected. Furthermore, we observed that they also activated capacity 17 that was not expected by us. On the other hand, we established that capacities 12 and 35 were explicitly activated on a given moment of the task's development, but that they were also present along the task, since students permanently used the trigonometric vocabulary and verified the relevance of their results, when measuring and making calculations.
On the basis of this kind of analysis, Group 5 decided the following improvements for the Streetlight height task:
(a) to include instructions for the construction of the goniometers; (b) to incorporate an activity for measuring lengths that can be found directly and to use the trigonometric ratios to corroborate the results; (c) to show the diversity of theodolites that can be found, with a brief explanation of each one; (d) to ask students to select the theodolite that they think is best suited for each situation, and (e) to ask questions that can lead students to look for tools that are different to those proposed and to include new strategies of solution.
Trainees' assessment of the program
In the final part of the program, the groups of trainees that participated in MAD performed a SWOT analysis (Strengths, Weaknesses, Opportunities, Threats) of their work and made a personal assessment of the program and their participation in it. We reviewed these analysis looking for the common themes that characterized what the groups of trainees appraised as the most salient features of their work and the most important influences of the program in their capabilities for designing, implementing and assessing tasks. We consider that the trainees' claims represent those features of MAD and their work that highlight the differences between what they usually do in class and what they actually did when planning, implementing and assessing their tasks during the program. We found several themes that were mentioned by most groups. In what follows, we identify and exemplify the most frequent ones. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
575
Features of the work
All groups centred the assessment of their sequence of tasks in terms of its contribution to the achievement of the learning expectations and the overcoming of the students' errors and difficulties. They also claimed that the designed tasks were adapted to the context. The Colombian curriculum guidelines underline the importance of problem solving in context and, hence, of tasks that lead students to solve and interpret mathematical problems in a variety of situations. Trainees claimed that one of the salient features of their tasks was the fact that they were mathematical problems set in varied non-mathematical contexts that contributed to their students' proficiency in problem solving. As Group 1 explained: "the use of tasks in context favored the achievement of the learning expectations proposed because the situations in the tasks were close to the everyday life of the students." Similarly, all group of trainees mentioned the importance of the use of materials and resources (i.e., Cabri, Geogebra, Hands on Equations) in their tasks design and implementation. Their statements make us think that they do not usually introduce those resources in their teaching: "when designing the materials with which we developed our task sequence, we found that they have a great potential for other topics and school grades" (Group 5).
All groups of trainees mentioned the importance in their tasks' design and implementation of using multiple ways of promoting collaborative work in class. They recognized the benefits of having students working in pair or groups and of generating class discussion among them. Some groups of trainees also mentioned the relevance of foreseeing the teachers' reactions to the students' performance in class, particularly to students' mistakes. The assessment made by Group 1 sustains such claim: "We acknowledge the benefits of the groupings proposed for students' work in class. For instance, as a consequence of the interactions produced, the students were able to strengthen their argumentative capacities for validating their results." Similarly, Group 2 claimed that "the tasks sequence involved a methodology that supports constructive learning of individuals and groups because it contributed to create a ZPD and strengthen the establishment of agreements when taking decisions concerning the challenges that were proposed."
The groups of trainees also mentioned some of the problems and deficiencies of their tasks. The most common shortfall referred to their mistakes when foreseeing the time required for implementing the tasks as mentioned by Group 5 above. On the other hand, some

groups recognized that their students did not understand properly the wording of some of
their tasks or that the tasks did not generate the student's performance that they were
expecting. They recognized that, in some cases, they incorrectly assumed that the students
had the previous knowledge required to face the tasks. For example, Group 3 acknowledged
that "the wording of the instructions in one of the tasks was another weak point [of our task
sequence]. This situation affected the time required for the task and the understanding that
students developed when solving it." This assessment led them to propose new or modified
tasks for a future implementation of the sequence.
Influences of the program
The groups of trainees highlighted the impact of MAD in their competencies for designing,
implementing and assessing sequences of tasks. Trainees stated that the program provided
them with tools for assessing how the tasks' design could achieve the planned learning
expectations and how the tasks' implementation did in fact achieved them. Group 5 claimed Theme E - GEMAD
576
that "the didactic analysis procedure lead us to be really conscious of the importance of
planning a task sequence and assessing its relevance and effectiveness. We know better about
the mathematics that our students should learn and how they should learn them. We
recognize now that students' learning depends on the tasks they solve and that the teacher is
the main responsible of that learning." In other words, the groups recognized that the
program (a) provided them with a better preparation for developing teaching innovations
based on a structured method; (b) encouraged them to reflect on their own practice; (c)
showed them how to track the results of their lessons; (d) questioned their meanings of
knowing and learning mathematics; and (e) motivated them to modify their role as teachers.
The groups also reported that the program led them to introduce several data gathering
instruments (some of them previously unknown to them--like the students' dairies and
observation tables) that allowed them to properly assess the students' performance when
solving the tasks. They also recognized that they did not have enough time for performing
those procedures and analyze the information gathered.
Across-communities
The design and implementation of the program was a joint venture among researchers,
educators, mentors and in-service teachers. Researchers have been working for several years
on the development of the didactic analysis model and on a model for conceptualizing the
trainees' learning of it. Some of the researchers were also educators in the program.
Educators as a team have worked on the design of the program following the models
proposed by researchers. They also implemented the program working hand in hand with
trainees. This collaborative work was set up through a mentoring process in which mentors
(the educators) interacted with their group of trainees weekly. Trainees' work informed
researchers on the framework and principles, educators on their teacher education program
design and implementation, and mentors on their performance. This joint venture has evolved
beyond the program, as this paper shows. Teachers, educators and researchers have created a
working group (that signs this paper), which continues working on mathematics task design
an implementation. Some of the near-future results of this collaboration is a book with the
reports of the groups' work in the program (Gómez, in press), the support of an international
publisher for the publication of a set of teaching guides based on the groups' program's work,
and the teaching of a course in the Colombian mathematics education congress.
MAD has generated several research studies in which researchers, educators and
teachers have also collaborated. That is the case of studies in which we have explored, for
instance, the teachers' learning of specific aspects of the program (Gómez & Cañadas, 2012;
Suavita, 2012), the role of mentors (Arias, 2011), or the impact of the program in institutional
planning (Gómez & Restrepo, 2012).

Designing Professional Tasks for Didactical Analysis as a research process

Joaquín Giménez
Universitat de Barcelona
Vicenç Font
Universitat de Barcelona
Yuly Marsela Vanegas
Universitat de Barcelona

In the present paper, we show a process of designing, assessing
and re-designing (following DBR methodology) professional tasks for
preservice mathematics teacher training for Secondary School, based on
Ontosemiotic perspective for cognition and mathematical instruction
(OSA) and the correspondent reflective analysis about associated
professional practices. Such a process has been carried out during three
consecutive years in the context of the Master's degree for training
teachers of mathematics in Spain. The study shows how the successive
revisions promote growing depth analysis in the teaching school practices
of the future mathematics teachers.
Keywords: Professional tasks, design based research

1. Presentation

In this paper, we show a part of a wider investigation in which we analyze
the design of professional tasks in the teachers' formation of Secondary Mathematics
Teachers. We focus on the role of design based research (DBR) and teaching
experiment (Gravemeijer, 1998) analyzing the planning cycle and redesign of our
training process in successive phases, aiming the growing and building knowledge for
teaching (Zaviaswski & Sullivan, 2011) by future teachers. We explicitly focus
ourselves in recognizing factors that promote the feedback in the design of
professional tasks for development of the of didactic analysis competencies of the
future mathematics secondary teachers. Our intention is that they can develop
sequences of suitable tasks and to be able to re-plan their own designs of school tasks.
This work has been carried in a funded Research Project (Assessing and developing
professional competencies in mathematics and didactics during initial Secondary
Mathematics Teacher Training courses) being the first two authors of this work
members of the team who implemented the course. The professional tasks have been
evaluated and re-designed by the whole research team during the period 2009-2012.
In our study we call professional task those tasks that we propose to the
future teachers in order that they realize didactic analysis and develop their didactic
analysis competencies understood as the ability for designing, applying and Theme E - J. Giménez; V. Font; Y. Marsela Vanegas
580
evaluating sequences of learning by means of didactic analysis techniques and quality
criteria. The aim is to establish cycles of planning, implementation, evaluation and
proposals for improvement. It is also assumed that one could identify criteria and
indicators regarding the development of this competence and how it relates to the
other professional competencies required by future secondary school mathematics
teachers. This assumption is related to the question: How might professional
mathematical tasks being designed in order to make best use of the opportunities for
being a teacher as teacher enquirer? (Mason & Johnston-Wilder, 2004).
Our main aim is to investigate how the process of building a sequence of
professional tasks (so called formative cycle from now) promotes and generate
feedback in the development of the didactic analysis competence of the future
teachers within the context of teacher training courses. Such above mentioned
development, it is stated when future teachers incorporate and use tools for the
description, explanation and process valuation of mathematical school
teacher/learning practices. By using our professional tasks design as a design based
research cycle, we also want to improve a teacher as teacher-researcher of their own
practice. We will show later, examples of professional tasks and reflections of the
future teachers on having solved them, that have served to provoke successive
feedback that have allowed to improve the sequence of tasks, and to make it
increasingly effective.

2. First year design. Building a formative cycle

In the frame of the Project of investigation mentioned, we design and
implement diverse formative cycles as teaching experiments for developing
transversal competencies as cittizenship, digital competency, didactical analysis, and
others. In particular, in this presentation we discuss a part of a cycle of formation,
named of "Didactic Analysis "articulated across diverse subjects of the courses. The
development of the cycle has been based from the beginning in considering six big
types of professional tasks:
a) Analysis of practices, objects and mathematical processes.
b) Analysis of didactic interactions, conflicts and norms.
c) Valuation of tasks and classroom episodes using criteria of didactic
suitability or quality.
d) Planning and implementation of a didactic unit in their period of
practices.
e) Analysis and valuation of the suitability of the didactic implemented
unit.
f) Offer of a well-taken improvement of his didactic unit, for a future
implementation. This proposal is realized in Master's final Work.
During the first two types of tasks (a - b) it's expected to appear and discuss
tools for a descriptive and explanatory analysis that serves to answer "what happens
in the classroom and why?" (Font, Planas y Godino, 2010). The analysis and
description of the mathematical activity is realized using the theoretical constructs
proposed for OSA. In this perspective (Godino, Batanero y Font, 2007), mathematical
activity plays a central role and is modelled in terms of systems of operative and
discursive practices. From these practices the different types of related mathematical
objects emerge building cognitive or epistemic configurations among them (see two
internal hexagons in Figure 1). Problem-situations promote and contextualize the
activity; languages (symbols, notations, and graphics) represent the other entities and Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
581
serve as tools for action; arguments justify the procedures and propositions that relate
the concepts. Lastly, the objects that appear in mathematical practices and those
which emerge from these practices might be considered from the five facets of dual
dimensions. Both the dualities and objects can be analyzed from a process-product
perspective, a kind of analysis that leads us to the processes shown (decagons in
Figure 1).
During the following type of tasks (c - f), we present theoretical tools
(suitability criteria, according Godino, Batanero y Font (2007) for a valuated analysis
serving to answer "what could we improve?" These criteria are as follows: Epistemic
suitability refers to the extent to which the mathematics taught are 'good
mathematics'. Thus, in addition to the specific content of the curriculum the
institutional mathematics on which it is based are also used as a reference. Cognitive
suitability reflects the degree to which the teaching objectives and what is actually
taught are consistent with the students' developmental potential, as well as the match
between what is eventually learnt and the original targets. Interactional suitability
relates to the extent to which the forms of interaction enable students to identify and
resolve conflicts of meaning, and promote independent learning. Mediational
suitability refers to the availability and adequacy of the material and temporal
resources required by the teaching/learning process. Affective suitability reflects the
students' degree of involvement (interest, motivation, etc.) in the study process.
Ecological suitability refers to the degree of compatibility between the study process
and the school's educational policies, the curricular guidelines and the characteristics
of the social context, etc.
Figure 1. Onto-semiotic representation of mathematical knowledge (Godino, Batanero y
Font 2007)
We understand that the study of descriptive and explanatory analysis for a
didactical situation is necessary to argue based valuations (Pochulu y Font, 2011).
Methodologically, the research is mainly qualitative in nature as the purpose
is to describe the development of competence in didactic analysis among aspiring
secondary school mathematics teachers, from the University of Barcelona (Spain).
The data were collected from the video recorded observations, sorting sheets
produced by the teacher trainers and their reflections at the end of the workshops and
using the documentation housed in the Moodle platform (slides, reading material,

tasks and the students' responses to them, and questionnaires and the students' responses to them) and printed material. The samples were intentional. During all these academic years, in general, these students vary in the amount of mathematical

knowledge they have, and they hold certain conceptual biases regarding the teaching and learning of mathematics.
It was selected an initial task in which students confront a short case study about proportional reasoning, using transcripts of a classroom situation. Such an initial tasks (type a; non-theoretical), introduce the students for reading and analysing the classroom example, by using their previous knowledge and beliefs of didactic analysis. During the first task, future teachers did naif comments about a proportion class. It's easy for them to identify mathematical objects but it's difficult for them to recognize all the processes involved in the task. When they analyze interactions, they focus on leadership and teacher interventions (Task b). It's difficult for the future teachers to identify epistemic conflicts and norms. In such first analysis each group of future participant teachers used just implicitly some of the levels of analysis proposed by OSA (described in Font, Planas y Godino, 2010): Analysis of mathematical practices; Analysis of objects and mathematical processes activated by these practices; Analysis of didactical interactions and conflicts; Identification of systems of norms conditioning and making possible instructional process; Valuating didactical suitability of instruction (Font, et al., 2012). In the class debate it was observed that, though every group did not use all these levels of didactic analysis, it is possible to see how the student group as a whole has contemplated the five levels of analysis. The tasks (a-b) were considered fruitful, so they were conserved for new implementations, but they should be completed by means of the 'other voices' technique (Garuti & Boero, 2002).
Later, in the different subjects of the Master, the students realize other analysis of practices, objects activated in the above mentioned professional practices (problem, definition, proposition, representation and argument) and mathematical processes (type a). Observing the analysis realized by the future teachers some difficulties appear: (1) Difficulties to distinguish between concepts and definitions, (2) Duplicity between definitions, propositions and procedures; (3) Duplicity between propositions and thesis of arguments; (4) The description of practices is overlapped by the configuration of objects and by the description of processes, (5) Difficulties to observe and to catalogue mathematical processes, etc.
It also had been designed and implemented tasks (type b), with protocols served to show constructs as cognitive and semiotic conflicts, epistemic obstacle, types of norms, interactive, patterns of models of management, etc. After first year of experience we found that protocols were statics. For the next year it was decided to use videos and corresponding transcripts. After that it was analyzed a class about equations by applying suitability criteria (task type c). The students star by analyzing mathematical practices, objects and processes. Then the teacher develops an example in which it was revised suitability construct. After that the future teachers reflect, improve and refined their analysis by using the notion of epistemic suitability. Nevertheless, it's still difficult for the students to identify some semiotic conflicts.
Next it was proposed a task of planning and further implementation of a didactic unit in their period of practices (task type d). When doing the analysis and valuation of the didactic implemented unit (task type e), future teachers found that their planning was conditioned by the school plans in which they did the practices. As a consequence it was difficult for them to identify the epistemic consideration implicit by the school teacher proposal.
The future teachers had a few autonomy to apply in the design and implementation many learned knowledge. This aspect was considered a difficult problem to solve during redesign process because of institutional framework for the

proposal, which did not deal a selection of schools. The tasks type (e) and (f) are considered activities producing the feedback for future teachers and trainers.
According to task type e, it was found a superficial use of theoretical tools for valuing teaching practices, due because we had short time to discuss after school practices and a need for more discussion about suitability criteria, and analysis based upon previous experiences. This aspect should be promoted in a redesign.
Positive results and some feedback from the first year are explicitly observed (when analyzing task type e). It was decided to redesign task type a, by emphasizing the analysis of processes. Another aspect to consider when redesign is to find so enough rich episodes which serving to propose different typologies to profit a short time available, instead of using different episodes in each task. It was also observed that some of the final practices' works (task type e) and master's thesis (task type f) were found so rich to be considered as episodes to be incorporated in a later redesign processes.
3. Second year redesign. Improving process analysis
It was decided not to do important changes of the cycle itself for the second year Project. As an important example for the redesign, we consider enlarging task type (a) and (b) by using a new video source. In such a new task (type a) it was proposed the observation of three short ways of introducing perpendicular bisector with 12-13 years old students, by observing three different teachers. The main idea is to present a discussion about the different practices, objects and mathematics processes and to introduce a reflection associated to how each of these classes contribute to introduce different kind of epistemic configurations and objects (see hexagons in figure 2) associated to three different definitions.
Figure 2. Epistemic Configuration of classroms for teachin g perpendicular bisector
It was observed that both first and second teachers did classical proposals and management about the content and the classroom. The third teacher proposal is innovative not only because of the management but mathematically as a way of changing the regular use of mathematical content as a change of configuration of practices, objects and mathematical processes by using a non-routine task (Tzur, Sullivan, & Zaslavsky, 2008). The class started by presenting a contextualized problem, driving to the division of a desert in a set of regions. Future teachers observed interpretation processes, communication of didactical and mathematical meanings, etc. Furthermore it appears a reflection about distinguishing complex

processes from simple processes and also a general reflection about the idea of processes itself.
During the second year, the tasks designed had achieved the effect of improving their analysis of practices, objects and mathematical processes and mainly about processes (Font, et al. 2012). In this improvement, it was judged a crucial role of dynamic videotapes to analyze the visualization of professional didactical processes. On the other hand, they were introduced selected episodes of students' from previous years that were considered as a short distance from prospective teachers' perspectives. We still detect that the future teachers applied epistemic suitability criteria, by means of superficial explanations, short justifications, etc. Therefore, it's needed to improve future teachers' justifications about mathematical and didactical quality of their practices as a basis of the second redesign.
4. Third year redesign. Conectness and representativeness
Epistemic suitability criteria explained for years 1 and 2 were basically sustained in the idea of representativeness, understood as a degree, of representation of learned meanings representing relations to referenced meanings. Due to the superficiality of some students' works during the moment to apply such criteria, it was decided to do an extensive study about how the students have been applied epistemic suitability criteria in their final masters' thesis (to see if they have been used the representativeness criteria, introduced some personal proposals, etc). As a consequence, the changes proposed for the third year were the following: (1) To join the categories for epistemic suitability from OSA with categories from the quality for mathematics instruction given by Hill (2010). In such a way, it was introduced new criteria for valuing mathematical quality as it is: mathematical richness, coherence, errors, etc. (2) To select new case studies from previous years students with more wide and complex explanations than the previous case studies used en year 1 and 2. The aim was to connect echoes and voices to produce more consistent arguments (Garuti & Boero, 2002) to justify mathematical quality of didactical sequences.
A prototypical example of this new task (type c) is a case based analysis upon a student that planned a sequence with 7
th
grade (13-14 years old students) for Thales theorem. The main idea is to use as a new task, a voice of a previous future teacher M that analyzed her own practice about Thales Theorem after the school practice during the course 2010-2011. It was observed that M did a personal final analysis in which she said "...Additionally, we have tried to establish connections either with the concepts of the unit (relating as an example, Thales with similar triangles; similar triangles with similar figures, and so on) as with other subjects (for example, to compute the measure of a columns with mirrors, Snell's law of refraction, relating phisical concepts to mathematical concepts)... So, in conclusion...my epistemic configuration was right" (St. M; final report of practice and master's thesis, 2011).
The student M did not really a real good mathematical connection (Figure 3).
We use such mistake to introduce our new professional task. In such task (type c) we presented three documents: (1) tasks proposed by M to explain Thales theorem in her proposal for school practice; (2) the analysis of epistemic suitability about M proposal, and (3) a textbook in which it was ensured the representativeness of epistemic configurations for Thales Theorem having a coherent connection (see figure 3). When doing the task it was promoted a discussion to understand the idea of representativeness (by using epistemic configurations 1 and 2) and the idea of

coherent connection by using triangles in Thales position. The textbook sequence follows the order: Thales, triangles in Thales position, and after that, similarity triangles.
Epistemic Configuration EC1
Thales Theorem
Epistemic Configuration
EC2
Similar triangles
Concepts: point projection; segment projection; Triangles in Thales position
Properties:
Version 1. Segments determined by parallel rights over two secants are propotionnal.
Version 2: Two triangles in Thales position have proportional sides and equal angles.
Procedures Find fourth proportion
Argument: Comprovation of Thales Theorem; justification that triangles in Thales position have proportional sides, by using Thales theorem twice.
Problems
(1) Find one out of four segments determined by parallel rights over two secants (contextualized / decontextualized)
(2) Indirect computation of unknown measures, using Thales Theorem
Concepts/definitions:
similar triangles (similar triangles have proportional sides (def) and equal angles.)
Properties: similarity criteria
Procedures: Find fourth proportion
Arguments:
Comprovation of four proportional sides and equal angles
Figure 3 Left. Two connected configurations in the textbook.
Figure 3 Right. Comparing representativeness and connectness for M and the textbook presented by the trainer.
The aim of this professional task is to recognize a deep level of analysis from such previous prospective teacher's practices (Choppin, 2011). Thus, the future teachers learn from this analysis, the idea of connecting two epistemic configurations. At the end of the third year experiment, we found the students being more carefully presenting their didactical unit as a result of such deeper analysis.
More aspects were observed in this third year, when we analyze final work of future teachers and we found better results than previous years. Just some aspects had been presented in this paper because a lack of space.
5. Conclusions. Perspectives
As a result of our study, we have analyzed in depth what we nominated professional tasks to promote competency of didactical analysis. It was useful for such analysis the levels of didactical analysis proposed by OSA. We assume the power of analyzing case studies based on texts from previous years' students. In fact, it explains the complexity of analysis that the teacher should realize to value his/her own practice to go beyond from narratives and descriptions. We are centered specially in how successive redesign contribute to have better feedback about the analysis of

processes and valuing quality using notions of representativeness, connection and coherence. One of our conclusions is that to reflect about mathematical quality it's needed that the future teachers use theoretical powerful elements (Krainer, 1993). We value that some students explicit that by doing master's degree work, "we had been developed our competence of didactical analysis". On the other hand, we recognized the final master degree as the starting point for developing research competency for future teachers. In fact, it gives opportunities for students learning and recognizing problems of their professional context (Giménez, Font, Vanegas y Ferreres, 2012).

Following our perspective we intend to see didactical analysis beyond the banality, considering classroom situation as an integral but dynamic system evolving in time, promoting autonomous mathematical thinking and independent validation of its results as future teacher (Laborde, Perrin-Glorian, Sierpinska, 2005).
Our major conjecture in terms of designing didactical sequences of professional tasks for prospective teachers, is that we need epistemic and cognitive analysis not only to criticize each task itself, but to adapt its connections as best as possible to the didactic analysis results. In fact, suitability criteria used for redesigning the tasks (considered as teaching experiments and corresponding case studies) has anticipatory purposes as hypothetical trajectories, but also helps to improve didactic training trajectories. It's important for our task analysis to identify difficulty factors providing frameworks for hypothesizing instructional designs inspired by levels of suitability.
The relevant aspects for our task design proposal are: (1) To understand the redesign process as a teaching experiment, assuming the noticing process (Mason & Wilder 2002) when doing didactic analysis. (2) To use suitability criteria for building and analyzing professional tasks and sequences; (3) To have in mind ethical perspectives of hearing the voice of the prospective teachers as self regulating process. (4) To consider the need for a collaborative research team for redesigning process.
After three years of experience, we assume the difficulties of the future teachers for having a deep reflection upon their proposals (Leikin, 2009) but we consider that our training cycle give opportunities to improve such issues.

Designing Rich Numeracy Tasks

Merrilyn Goos

In Australia, numeracy is regarded as a general capability to be developed across the whole school curriculum, not just mathematics. This paper draws on a research study that aimed to help teachers in ten schools design numeracy tasks and implement investigative numeracy pedagogies across the middle school (Grades 6-9) curriculum. Teachers were introduced to a rich model of numeracy that gives attention to real-life contexts, application of mathematical knowledge, use of representational, physical, and digital tools, and positive dispositions towards mathematics. These elements are grounded in a critical orientation to the use of mathematics. The paper identifies ways in which collaboration between the researchers and teachers influenced the design of numeracy tasks.
Keywords: Numeracy; Teacher development; Influences on task design

Numeracy is a term used in many English-speaking countries to denote the capacity to deal with quantitative aspects of life. It is often considered to have a similar meaning to terms such as quantitative literacy (Steen, 2001) or mathematical literacy (OECD, 2004). For example, Steen proposed that the elements of quantitative literacy include: confidence with mathematics; appreciation of the nature and history of mathematics and its significance for understanding issues in the public realm; logical thinking and decision-making; use of mathematics to solve practical everyday problems in different contexts; number sense and symbol sense; reasoning with data; and the ability to draw on a range of prerequisite mathematical knowledge and tools. Some of these elements are visible in the PISA definition of mathematical literacy as: an individual's capacity to identify and understand the role mathematics plays in the world, to make well-founded judgments, and to use and engage with mathematics in ways that meet the needs of that individual's life as a constructive, concerned and reflective citizen. (OECD, p. 15)
Steen (2001) argues that, for numeracy to be useful to students, it must be learned in multiple contexts and in all school subjects, not just mathematics. In Australia, support for this challenging notion has come from several sources. A recent national review of numeracy education undertaken by the Australian government recommended that numeracy be recognised as "an across the curriculum commitment" (Council of Australian Governments, 2008, p. 7). In addition, the newly developed Australian Curriculum this country - identifies numeracy as one of seven general
across all discipline content (Australian Curriculum, Assessment and Reporting Authority, 2012). However, the new curriculum documents do not provide teachers with detailed guidance in recognising the numeracy demands of the subjec
teach, in designing tasks and learning sequences that embed numeracy across the curriculum, or in making decisions about pedagogies that support numeracy learning. This paper draws on data from a one year project that helped teachers to design numeracy tasks and implement numeracy pedagogies across the school curriculum in Grades 6-9. It was conducted before the release of the Australian Curriculum, with the intention of developing and testing a theoretically informed model of numeracy that could guide teachers' curriculum planning, task design, and pedagogical decision making in the context of an existing state

591
A numeracy task should require application of mathematical knowledge. In a
numeracy context, mathematical knowledge includes not only fluency with accessing
concepts and skills, but also problem solving strategies and the ability to make
sensible estimations (Zevenbergen, 2004).
A numeracy task should promote positive dispositions – such as confidence,
initiative, and a willingness to apply mathematical knowledge flexibly and adaptively.
Affective issues have long been held to play a central role in mathematics learning
and teaching (Leder & Forgasz, 2006), and the importance of developing positive
attitudes towards mathematics is emphasised in national and international curriculum
documents (e.g., National Council of Teachers of Mathematics, 2000; National
Curriculum Board, 2009).
A numeracy task should involve using tools. Sfard and McClain (2002)
discuss ways in which symbolic tools and other specially designed artefacts "enable,
mediate, and shape mathematical thinking" (p. 154). In school and workplace
contexts, tools may be representational (symbol systems, graphs, maps, diagrams,
drawings, tables), physical (models, measuring instruments), and digital (computers,
software, calculators, internet) (Noss, Hoyles, & Pozzi, 2000; Zevenbergen, 2004).
Because numeracy is about using mathematics to act in and on the world,
numeracy tasks should be embedded in a range of contexts (Steen, 2001). These
contexts may be drawn from real life or curriculum areas other than mathematics.
Numeracy tasks should develop a critical orientation in students since
numerate people not only know and use efficient methods, they also evaluate the
reasonableness of the results obtained and are aware of appropriate and inappropriate
uses of mathematical thinking. Numeracy tasks could ask students to evaluate
quantitative, spatial or probabilistic information used to support claims made in the
media or other contexts. They could also encourage students to consider how
mathematical information can be used to manipulate, disadvantage or shape opinions
about social or political issues (Jablonka, 2003).
The design of rich numeracy tasks according to the principles outlined above
is not sufficient to enable learning. We argue that teachers also need to adopt
investigative pedagogies to fully realise the numeracy opportunities that such tasks
afford. Diezmann, Watters, and English (2001) define mathematical investigations as
"contextualized problem solving tasks through which students can speculate, test
ideas and argue with others to defend their solutions" (p. 170). We consider this
definition applies equally well to numeracy investigations.
The numeracy model was used in three ways: (1) to analyse the numeracy
demands of the South Australian school curriculum (Goos, Geiger, & Dole, 2010); (2)
to support teachers' curriculum planning (Goos, Dole, & Geiger, 2011); and (3) to
trace changes in teachers' understanding of numeracy (Goos, Geiger, & Dole, 2011).
This paper is primarily concerned with (2), and it extends our previously published
analyses by focusing on the design of numeracy tasks and implications for pedagogy.
Project Overview
Teachers were recruited from ten schools with diverse demographic
characteristics: four primary schools (Kindergarten-Grade 7), one secondary school
(Grades 8-12), four small schools in rural areas (Grades 1-12), and one school that
combined middle and secondary grades (Grades 6-12). Each school nominated two
teachers, thus ensuring that participants could collaborate with a colleague in their
own school as well as teachers from the other schools. They included generalist Theme E – M. Goos, V. Geiger, S. Dole
592
primary school teachers who taught across all curriculum areas as well as secondary
teachers qualified to teach specific subjects (mathematics, English, science, social
education, health and physical education).
There were three elements to the research plan: (1) an audit of the middle
years curriculum to identify the numeracy demands inherent in all curriculum areas;
(2) three whole-day professional development workshops at the beginning, middle,
and end of the project; and (3) two daylong visits to each school for lesson
observations, discussion of planning documents and teaching approaches, and audiorecorded interviews with teachers and students. The overall project design is
summarised in Table 1. More details on data collection and analysis methods can be
found in Goos, Dole and Geiger (2011).

Table 1. Project Design
Influencing the Design of Numeracy Tasks
We claim that there are several aspects of the project that influenced the
design of rich numeracy tasks and enactment of associated investigative pedagogies.
The first was the numeracy model itself, the elements of which provided a set of
principles for task design. The second was our numeracy audit of the South Australian
Curriculum Framework, which identified distinctive numeracy demands for each
school subject taught in Grades 6-9. For example, the subject called Society and
Environment is organised into four strands: time, continuity and change; place, space
and environment; societies and cultures; and social systems. The numeracy audit
found that data analysis and spatial sense are the most relevant elements of
mathematical knowledge for this subject. Contexts for numeracy development
included the study of social, economic, political and ecological systems. Students
were expected to develop dispositions enabling them to "to be active citizens who can
make informed and reasoned decisions and act on these" (DECS, 2005, p. 291). The
use of tools such as maps, measuring instruments, online data sources, and
spreadsheets for collecting and analysing information was vital to learning in this
subject. The goal of enabling students to participate as ethical, active and informed
citizens, requires development of a critical orientation to viewing information and
interpreting data. Presenting the audit findings to teachers was intended to raise
awareness of their subject's numeracy demands. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
593
The third influence on task design was the way in which the research team
used the three workshops to (1) immerse teachers in numeracy tasks we had created,
(2) model investigative numeracy pedagogies, (3) guide the analysis of tasks using the
design principles provided by the numeracy model, and (4) invite the teachers to
practise designing their own numeracy tasks. For example, in the first workshop we
engaged teachers in cross-curricular numeracy investigations suitable for use with
middle years students. These included investigations of Barbie dolls' physical
proportion (with links to the health and physical education curriculum), the
occurrence of the Golden Rectangle in art, design and nature (linked to the arts and
design studies curricula), and planning for participation in the Tour Down Under, a
bicycle race similar to the Tour de France (linked to the society and environment
curriculum). In the first round of school visits we found little evidence of a critical
orientation in the lessons we observed. In interviews with teachers it emerged that
they were unsure about how to embed this element of the numeracy model into their
planning and practice. Therefore, at the second workshop we presented a range of
stimulus materials drawn from print and digital media sources and asked teachers to
work together to develop these into tasks that would promote a critical orientation in
their students, without losing sight of the other elements of the numeracy model. In
both workshops we provided a task design/analysis template that listed each element
of the numeracy model, asked how the task developed numeracy with respect to each
element, and invited teachers to identify school subjects that could provide a context
for using the task.
The fifth influence on task design was the researchers' provision of in situ
feedback to teachers during school visits. We were able to suggest ways of modifying
tasks used in the lessons we observed to give greater prominence to elements of the
numeracy model that appeared to be under-represented. The final influence on task
design was the structured sharing of practice by teachers at the second and third
workshops. At the second workshop all teachers were asked to bring evidence of one
task or lesson sequence they had tried with their class, to describe to the whole group
how the task had been implemented and how well (or not) it had worked, explain
what they learned from this experience and how they would use this evaluation in
their subsequent planning. This workshop provided an opportunity for teachers to see
how colleagues in other schools went about designing rich numeracy tasks. At the
third and final workshop, and as a result of our analysis of school visit data, we
invited four teachers who exemplified different types of professional learning
trajectories to report on their experiences. One of these is the teacher whose
abbreviated case study is presented below to illustrate how she made decisions about
the design of numeracy tasks with an investigative flavour. Although this project
emphasised numeracy across the whole school curriculum, the example below shows
how numeracy tasks can be designed within mathematics.
Teacher Decision Making about Task Design
Maggie taught mathematics and science at a large secondary school in a rural
town. She was in only her second year of teaching. The class with which she worked
for this project was a Grade 8 mathematics class.
First school visit
Initially Maggie struggled to come to grips with how to highlight the
numeracy within mathematics, but she decided to focus on teaching mathematics in Theme E – M. Goos, V. Geiger, S. Dole
594
real life contexts that would be of interest to her students. She planned a task based on
the television program The Amazing Race. Students worked for 3 weeks in the
computer laboratory to complete the task, which involved organising an adventure
holiday around the world, given an itinerary and a budget of $10,000. They also had
to complete a number of challenges for which they earned an additional $2000 each.
The challenges, which included Diving with Sharks in Cairns, Skiing in Switzerland,
and visiting The Roman Colosseum, had a focus on using directed number in context.
In The Roman Colosseum challenge students were also required to use formulas in the
context of comparing areas of the Colosseum and the Melbourne Cricket Ground, as
well as looking at exchange rates and converting between currencies.
Members of the research team observed the second lesson of this unit.
Students appeared motivated and well prepared, and they were able to explain the task
to us when we questioned them. Maggie noted that some previously disengaged
students were interested in the task, while a few others remained aloof. Some students
seemed so engaged that they acted as though the task was real; for example, when
Maggie asked one boy "Where are you up to?", he replied "I'm on my way to Paris!".
This task placed mathematics in the real life context of an adventure holiday.
It targeted mathematical knowledge of directed numbers and operations with integers
(money calculations), using digital (internet) and representational (charts, tables)
tools. We did not observe teacher actions that promoted positive dispositions towards
numeracy, but students were clearly motivated and confident in tackling the task and
trying out different combinations of flights and accommodation bookings that would
fit within their budget. A critical orientation does not seem to have been built into
this task. However, after the lesson we suggested to Maggie that this orientation could
be promoted via questioning, such as that we observed when Maggie helped a student
compare advantages and disadvantages of booking cheap backpackers'
accommodation. In this way we attempted to show how the numeracy model
informed not only task design but also teachers' pedagogies.
Second school visit
When interviewed before the lesson observation, Maggie said she had given
a lot of consideration to the types of tasks she wanted to design for the second
research cycle. She was dissatisfied with the length of the Amazing Race
investigation, as this tended to discourage some students and to make it difficult to
complete for any who missed some lessons. As a result of our emphasis in the second
workshop on developing a critical orientation, she also decided to give more attention
to this element of the numeracy model in designing the next investigation,
Approaches to a Healthy Lifestyle, which comprised a number of smaller tasks.
In one task, students investigated the relationship between the heights and
walking speeds of everyone in the class. The mathematics embedded in the
investigation included elements of collecting, representing, reducing and analysing
data. In the lesson we observed, students were to make scatter plots using Excel in

order to determine whether there was a pattern in the data they had collected. In
earlier lessons they had collected height data and calculated the mean, median and
mode. In another lesson students had marked out a 40 metre section of a 100 metre
running track and then found the time it took to walk this distance. With this
information students had calculated their walking speeds in metres per second, metres
per minute and kilometers per hour. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
595
Students all appeared engaged with the task and each group or individual
produced a scatter plot, although the appearance of the graphs varied depending on
the scales chosen or on the choice of variable for the x and y axes. Most students were
able to describe a general trend in the data and use this to make a prediction about
what Maggie's walking speed might be, based on her height. Interestingly, many
students gave most attention to their own data point within the scatter plot with
comments such as "This is me (pointing at the appropriate data point) and "This is
how tall I am and how fast I walk". Using personal data seemed to be effective for
engaging students with the task. From a student's perspective, the activity was about
them and how they compared to the rest of the class.
Students expressed surprise that the scatter plot was not linear, so that taller
people did not necessarily walk faster. Maggie challenged them to explain why this
should be the case. Some groups suggested that alternative variables – with associated
alternative hypotheses – should be explored, including, for example, the relationship
between walking speed and leg length or between walking speed and stride rate. One
group suggested there might be a stronger relationship between a person's height and
their maximum walking pace rather than their natural walking pace.
Maggie chose an engaging context that made use of students' personal details
to introduce the mathematical knowledge that was used in this lesson. The use of
personal data encouraged positive dispositions towards involvement in and
completion of the task. This task required knowledge of how to produce a scatter plot
from a data set using Excel and the capacity to make predictions from trends in the
data. Maggie asked students to use representational tools such as scatter plots and
digital tools in the form of computers and Excel. By challenging students to explain
the variance in their data from the anticipated linear relationship, Maggie introduced a
critical orientation to the task. A critical orientation was evident in most tasks in the
Approaches to a Healthy Lifestyle investigation. For example, in the culminating task
students were to compare data on the number of overweight and obese Australians in
various age groups, and make an argument for whether or not the government needed
to introduce a healthy eating policy for South Australian schools.
Implications and Concluding Comments
The work we reported here has implications for teachers, researchers, and
curriculum developers. First, it provides some evidence that a focus on task design,
when supported by a theoretical model of numeracy that is readily accessible to
teachers, can influence teacher learning and development. For example, when Maggie
reflected on what she had learned during the course of the project, she identified her
readiness to make use of more extended tasks when teaching mathematics. However,
she tempered this view by arguing that tasks needed to be made up of self-contained
sub-tasks that allowed students to move towards smaller achievable goals. For her, the
level of engagement she observed while students were working on numeracy
investigations was a compelling case for their inclusion within mathematics classes.
Nevertheless, other teachers in the project found it more difficult to decide "how
long" a numeracy investigation should be to allow students enough time to explore all
aspects of a task without losing interest, and how much guidance to give students in
structuring the investigation.
A challenge for researchers is to design larger scale studies that do not
simply rely on recruiting more schools or teachers. This is the case for most
educational research and is not unique to our project. To tackle these challenges we Theme E – M. Goos, V. Geiger, S. Dole
596
are currently conducting a follow up study that aims for both scale and sustainability
by developing numeracy curriculum leadership within schools, so that the numeracy
model and associated task design principles become integrated into schools' planning
processes for implementation of the new Australian Curriculum.
The current version of the Australian Curriculum offers some support for
recognising the numeracy demands of different school subjects, for example, by
providing a numeracy learning continuum together with icons and filters that link
numeracy capabilities to relevant curriculum content. However, additional
opportunities for developing students' numeracy capabilities are invisible unless one
knows how to "see" them and how to design and implement tasks for classroom use.
The numeracy model and ways of working with teachers outlined in this paper may
prove useful in supporting teachers to fulfil the numeracy intentions of the Australian
Curriculum.

Task design: Supporting teachers to independently create rich tasks

Libby Knott
Washington State University, Pullman, WA, USA
Jo Olson
Washington State University, Pullman, WA, USA
Anne Adams
University of Idaho, Moscow, ID, USA.
Rob Ely
University of Idaho, Moscow, ID, USA.

Teachers want to be able to create opportunities for generalizing
and justifying for their students; however, they often lack the skills and
the time needed. We attempt to investigate this issue by addressing the
question: How can we help teachers use their textbooks to create tasks
that provide opportunities for students to justify, and afford teachers
opportunities to push students to consider different cases and ultimately
engage in generalizing? We define task design to include the activities
engaged in with teachers that enable them to independently create tasks
that afford students these opportunities. We engage in a design-based
methodology with cycles to refine this process.
Keywords: Rich tasks, task design, design cycle, generalizing,
justifying

Introduction

Intellectually, teachers, mathematics educators, and mathematicians would
agree that it is important for students to generalize and justify. In recent years,
teachers have begun to ask students to explain their thinking. Teachers and students
often understand this request to mean, What steps did you use? This is one type of
explanation, but it is not sufficient for helping students to gain mathematical insights
that lead to deep understanding. Driscoll (1999) suggested that teachers need to ask
questions that prompt students to reflect on the mathematical ideas used in their
solution strategies and consider whether the strategies can be generalized. Stein,
Smith, Henningsen, and Silver (2000) suggest that teachers need to use rich tasks that
maintain cognitive demand by pressing students to make generalizations and justify
their solutions. Both of these suggestions assume that teachers have tasks that lend
themselves to acts of generalizing and justifying that go beyond finding the solution
of a problem. Lampert (1990) highlights the importance of the task itself, "it must be
a problem that will engage all students in making and testing hypotheses ... and push
them to think about when and whether it holds true in a larger domain." (p. 40). Theme E – L. Knott and al.
600
Taking time for students to make hypotheses and explore them is a tension for
teachers when they are concerned with covering the curriculum and loss of control
(Zaslavsky, 2008). The question arises, how can we help teachers use their textbooks
to create tasks that provide opportunities to students to justify, and afford teachers the
opportunity to push students to consider different cases and ultimately make
generalizations?
Making Mathematical Reasoning Explicit (MMRE) is a five-year NSF funded
project in which teachers attend three summer institutes and participate in school year
professional development. In this context, we examine the transformation of
instruction from a model where the goal of learning is to arrive at a correct answer, to
instruction with the goal of engaging students in the process of doing mathematics.
Lakatos (as cited in Lampert, 1990) described doing math as "the zig-zag path of
discovery between conjecture, justification, and revision of conjecture or modification
of assumptions that one must necessarily negotiate when engaging in this kind of
mathematical activity." (p. 40). Our first task was to work with teachers so that they
better understood the process of doing mathematics where generalizing and justifying
were the norms. Second, we gave them two simple routines to use that provided them
opportunities to elicit students' observations, explanations, and justifications. Third,
we asked them to create a task that would prompt students to generalize or justify.
This paper examines the fourth phase of our work, which helped them to use
their textbook as a source for developing rich tasks that engaged students in this zigzag path of discovery. Our research question is: What are the essential features of task
design that teachers need to attend to when modifying their existing curriculum to
engage students in learning new content in ways that require generalization and
justification? In this paper, we define task design to include the activities that we
engaged in with teachers, so that ultimately, they are able to independently create
tasks that afford students the experience of doing mathematics.

Literature Review

Literature on teacher change suggests that for teachers to enact new
pedagogy with different mathematical goals, they must rethink and revise their beliefs
and practices in light of research on teaching and learning (Cross, 2009). In addition,
to make this change, teachers need to consider the instructional goals demanded by
the new Common Core Mathematics Standards, create a different learning
environment that encourages students to engage in a different kind of learning,
establish new classroom norms where argumentation is central to the lesson, and use
discourse in which teachers no longer control the discussion through recitation. An
additional component of such change is task design.
A review of the literature on mathematics tasks revealed research on
characteristics of rich tasks, ways to maintain the cognitive demand of the task, and
examples of rich tasks that could be used in classrooms. However, we found scant
research that described how to help teachers design tasks. We define a rich task to be
one that is complex, non-algorithmic, and non-routine, allowing for multiple
strategies and representations and no single pathway to a solution. Any solution to a
rich task is not just an answer to be circled, not even simply a description of the
strategy or reasoning used to arrive at such an answer. It affords students
opportunities to generalize and justify that go beyond finding the answer. It includes
the justification for the strategy or reasoning used to arrive at an answer; an
explanation of why this particular approach is valid. Our literature review begins with Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
601

a discussion of the importance of generalizing and justifying and ends with additional comments about rich tasks.
NCTM (2000, 2009) and Common Core State Mathematics Standards (2010) emphasize the importance of reasoning and justification in learning mathematics. Generalization can be thought of as the heart of mathematics (Mason, 1996). There is consensus among mathematicians that generalization is a process that serves to create new knowledge for an individual and for the mathematics community at large (e.g., Polya, 1957; Harel & Tall, 1991;Dreyfus, 1991; Ellis, 2007). In much of reform mathematics, there is an inherent tension between this process of doing mathematics and the actual product of the mathematical activity. Polya describes the process of doing math as making a tentative generalization from an observation that is tested and revised for different cases. Justification is the tool by which a generalization is verified. Justifications validate claims, provide explanations, create a context for insights or discoveries, and develop structures to systematize knowledge (de Villiers, 1999; Hanna 2000). Clearly, the acts of generalizing and justifying are intertwined and essential to developing mathematics.
The ICME 11 Topic Study Group 34 (2008) describes the nature of tasks and task design as "not merely … 'things to be done' but as crucial in framing subsequent mathematical activity. Identifying relations between task structure, tool use, and mathematical activity can inform the design and analysis of tasks, and also gives insight into the nature of engagement and learning which takes place while tasks are being carried out." (ICME 11 TSG 34, p. 1). Rich tasks are essential in providing opportunities for students to generalize and justify.
Solving a rich task includes the processes of making conjectures, arguments, justifying and generalizing. Only if a teacher establishes these processes as the acceptable socio-mathematical norms (Yackel & Cobb, 1996) for what it means to be doing mathematics in the classroom will the task provide real opportunities for students to engage in these processes. Such tasks require higher-level cognitive demand (Stein et al. 1998) and strategic reasoning to solve (Kilpatrick, Swafford, & Findell, 2001). This high cognitive demand is necessary, but not sufficient, for fostering opportunities for justification, generalization, and conjecturing in the classroom. Teachers must treat the solution to a task not as a signal to stop thinking, but as an occasion to generalize, conjecture, and ask new questions. Doing mathematics in this way requires both students and their teachers to redefine what they believe mathematics to be (Lampert, 1990).
Theoretical Framework
We draw upon sociocultural and psychological frameworks to examine the features of task design that support teachers to reconsider what it means to teach and learn and do mathematics. These perspectives allow us to work with teachers in ways that create opportunities for them to reconsider their deeply held beliefs about the nature of teaching and learning mathematics, while simultaneously providing opportunities to engage students with tasks. Deeply held beliefs about mathematics develop over a lifetime of experiences and are resistant to change. To support teacher change, we rely on concerns based research (Hall & Hord, 2010) to structure a community of practice.
A community of practice is a group of people who share a similar goal; that learning occurs through interactions among the participants (Lave & Wenger, 1991). From this perspective, the learning environment is critical. It is the place where Theme E - L. Knott and al.
602
participants share ideas, take risks, and revise their notions. In the MMRE community of practice, participants experience math in new ways, discuss the implications for teaching with different goals, and consider the impact on students' learning. New ideas are developed through dialogue that includes sharing observations, asking questions, and clarifying ideas (Lave & Wenger). This learning is a product of the group and is available for each participant to examine and compare with his/her personal beliefs. When teachers verbalize them, their beliefs are placed in the public domain where they can be examined within the community of practice. The inner and public conversations interact, creating an opportunity for change. Critical to the conversation is the reflection on new experiences and information that may conflict with existing beliefs. With repeated experiences, reflection, and dialogue, we theorize that change is supported.
To make the work of doing mathematics in new ways meaningful, teachers need to examine their beliefs about what is important for teaching and what it means to "do mathematics." Unless they are willing to undertake such change, or at least acknowledge its necessity, it will be difficult if not impossible for them to embrace the type of task design we are advocating. Further, they will be unable to implement the tasks successfully in the classroom, even when such tasks are provided for them. For teachers to teach mathematics in new ways, they need to recognize a new instructional goal, namely, traveling along the zig-zag path that leads to making generalizations and justifications. If is from this perspective that we work with teachers in the MMRE project. We found it was necessary to embark on this preliminary work prior to or concurrently with the task design that we would engage in with teachers.
Methodology
Design-based methodology with cycles frames our work with teachers. We collected baseline data through observations of teachers working in their classrooms to characterize the pedagogy that they used. Data was analyzed using constant comparative methods. We created a rubric from research on types of generalizations and justifications. It was modified as we coded observations and noted classroom examples that contained types of justifications that did not fit into our existing rubric. When we made changes to the rubric, we went back and re-coded all of the observations.
From our research on generalization, justification, pedagogy, and teacher change, we created a blueprint for what we hoped to see if teachers engaged students in generalizing and justifying as tools for learning. Using the concept of backwards design, we created learning trajectories that would move them from their current practice to a new vision of teaching. We theorized that they needed experiences for themselves in order to be able to provide opportunities for their students to generalize and justify, before they would be ready to engage in creating rich tasks themselves.
Context
In our professional development project with teachers of grades 4 through 12, in rural schools in the Pacific Northwest of the United States, our first task was to work with teachers so that they better understood the process of justifying and what was involved in creating and supporting a classroom environment where student justification was the accepted norm. We were supported in this approach by the recent adoption by 45 US states of the Common Core State Standards Initiative (CCSS, Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
603
2010). The Standards for Mathematical Practice are arguably the most important part of the CCSS in mathematics. Additionally, they provided the motivation teachers needed in order to embrace our focus on what it would look like to see students "engaged in doing mathematics" in this way. Of the eight Standards for Mathematical Practice, the ones most relevant to our work are that students should: Reason abstractly and quantitatively; construct viable arguments and critique the reasoning of others; and, look for and make use of structure.
Design cycles
We engaged in four cycles in our work to date (see Figure 1). In the first two cycles, we provided teachers with short, easily implementable ways to engage students in justifying: choral counts and strings (Chapin, O'Connor, & Anderson, 2009). Choral counts and strings are examples of pedagogical routines that support students' learning (Lambert, Beasley, Ghousseini, Kazemi, & Franke, 2010). A choral count is some number pattern, often presented as an array, which is gradually revealed to the class by the teacher. The students are encouraged to say in unison what the next number is in the array. As they begin to see patterns, both recursive and explicit, they discuss what they observe, and make conjectures about what numbers might appear in certain spots in the array, and explain why. A string is a sequence of small problems that leads to the observation of a common property or generalization. These routines were readily understood by teachers and easily incorporated into existing classroom structure. They provided a way for teachers to encourage students to begin making their reasoning explicit. We engaged the teachers in choral count tasks and strings tasks during a professional development session, and then asked them to devise their own choral counts and strings to use in their own classrooms.
Once teachers began to see for themselves that their students were not only capable of justifying, but were enthusiastic about engaging in it, they wanted our help to adapt their existing curriculum materials to provide justifying and generalizing opportunities for their students. During the third cycle, we provided examples for teachers to engage in justifying with; then we discussed how they might use these tasks to move their students towards generalizing and justifying.
Figure 1: Design Cycles with learning trajectories illustrating the connections between theory and action
In working through these tasks with the teachers as students, we modeled and made explicit for them appropriate classroom strategies - "What do you notice?"; "Tell me why you used that strategy"; not giving confirmation of the correctness of their answers but instead suggesting they discuss it with a classmate - they might use to move their students in this direction. The next step was to work with them to create their own tasks that would lead their students to generalizing and justifying. Not Theme E - L. Knott and al.
604
surprisingly, most teachers chose to develop either strings or choral count examples based on their textbook materials, replicating or imitating the work we had done with them.
We devised a strategy we termed "turning a lesson upside down", which would help teachers to start with their existing textbook and modify a task or set of tasks so that the "key mathematical idea" target of the lesson emerged from the students' own engagement with the task. This is in contrast to how their curriculum typically approaches a new concept, by explicitly stating it as an objective of the lesson, and then providing practice problems for students. The focus in this paper is on this fourth cycle - turning a lesson upside down.
Realizing that they needed our support to modify their curriculum, we worked with them in groups during the Summer Institute on "turning a lesson upside down." We made explicit for them the steps involved in turning a lesson upside down which are summarized here:
1. Select a lesson from the textbook and determine the key understanding, method, or concept for the lesson.
2. Write the mathematical idea as a generalization, or a way of thinking that allows one to see general patterns or relationships. Note: Some mathematical idea may not be treated as a generalization.
3. Determine whether the key understanding entails justification or provides a person with a tool for justifying patterns and relationships. Identify representations that can be used to justify the key understanding.
4. Find a task(s) or a sequence of problems that can be used to illustrate or develop the key understandings. Note opportunities for generalization and/or justification that could be pursued, if any.
5. Write questions that you can ask students to make their generalizations or justifications explicit.
Results and discussion
We began cycle four by providing a simple lesson on averaging that was presented in two ways. The first was following a textbook structure in which the procedure of adding and then dividing was defined. In the upside down lesson how to find the idea of averaging emerged from student investigation. The typical textbook lesson would define the average of a set of numbers to be calculated by forming the sum of all the numbers and then dividing by the number of numbers in the set. In contrast, an upside down lesson might contextualize this target idea of finding an average in the following way: Suppose that Bonita has 5 beads, Irv has 14 beads, Jacob has 13 beads and Maria has 8 beads. How could the children redistribute the beads amongst themselves so that each child has the same number of beads?
Later we showed a video that contrasted two model lessons from an elementary school classroom. The first followed a textbook structure and the second a lesson that was turned upside down. The textbook structure dictated the format: the target procedure was made explicit and then students practiced it by solving similar problems. The second lesson was turned upside down: students were given problems that were carefully scaffolded 'finding' the mathematical target, supporting student work towards providing claims, arguments, conjectures and justifications that would help to solve the problems. Both lessons used Cuisenaire rods in which a fractional part was given (the red rod is 1/3) and the problem was to find the whole. Both Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
605
lessons focused on the relationship between the part and whole. The mathematical target of the lessons was finding the whole when a fractional part was given. We watched the two lessons with the teachers and discussed the actions, observations, and explanations of the students. Not surprisingly, the students in the upside down lesson provided more explanations and seemed more engaged. We intended to compare the structure of the two lessons so that teachers could see the differences in how to construct an upside down lesson with one that followed the structure found in their textbooks. However, we did not examine the lessons' structure because of time constraints and we thought that the differences were obvious. Yes, they were obvious to us, but not necessarily to the teachers.
In addition, one group of the teachers experienced doing mathematics by actually engaging in a lesson that we had turned upside down. We scaffolded the task with a sequence of questions designed to help them find a way through the problem. Once they had spent a considerable amount of time wrestling with the ideas of the problem and sharing their solution processes and strategies with each other, we debriefed the session and made explicit the moves that we had engaged in with them as they investigated the problem. We felt we had prepared them well to begin replicating this process for themselves. But it did not work as well as we had hoped.
Analysis of the upside down lessons written by the teachers revealed that they had difficulty using the process that we had outlined. Many of them wrote key understandings that were too broad. For example, a high school teacher wanted to review division of fractions with her algebra students. The key understanding of the lesson was, "Students will find an algorithm for dividing rational fractions. They will understand why it works." This is a too big a target idea and requires more than one class period to develop. It involves understanding the process of unitizing, partitioning, and different ways to represent fractions. Clearly, we need to help teachers understand the importance of breaking down key understandings into smaller, target components and to focus on one component rather than to try and

address all of them at once.
The teacher who was videotaped had anticipated students' responses in her
two lessons. She used these responses to help plan questions and interventions that
would support students' learning. In the lessons that teachers wrote, this critical piece
of working through the lesson and anticipating responses from the student perspective
was largely overlooked. The teachers worked collaboratively to create their upside
down lessons and may have anticipated students' responses without recording them
on the lessons that they turned in. However, we noticed that in some cases the context
of the problem interfered with concepts that the teacher wanted students to investigate
and working through the problem as a student would have illuminated this disconnect.
A sixth grade teacher identified three key understanding for her lesson: (a)
Any two numbers have at least 1 number in common; (b) The greatest common factor
is the greatest divisor they share; and (c) You can find the greatest common factor by
listing and organizing factors. While all of these understandings are important, there
are too many to address in one lesson. The problem required students to construct
pages in a scrapbook:
Annika is placing photos in a scrapbook. She has eight large photos, twelve
medium photos, and sixteen small photos. Each page will have only one size of
photo. She also wants to place the same amount of photos on each page. What is
the greatest number of photos that could be on each page? Theme E - L. Knott and al.
606
She anticipated student responses by describing different ways that they could
solve the problem using manipulative (rectangles to represent the photographs),
arrays, factor trees, or organized list. However, the problem context does not make
sense. Why would anyone want to have the same number of photographs on one
page? For example, one could put two pictures on each page, but it would look funny
in a scrapbook for one page to have two large photographs and another page to have
two small ones. Here, the context of the problem did not help students make sense of
the key understandings.
Learning trajectory
To support teachers' learning we need to respect what they know and can do
well, and build on it. Teachers were able to identify lessons that had the potential to
be turned upside down and they were able to write questions to prompt generalizing
and justifying. They will use their upside down lessons with students before we meet
again. Thus, the first opportunity to help them focus on anticipating students'
responses and articulating a component of the key understanding is through reflection.
We will frame our reflection questions around these two ideas.
Summary
This is clearly a work in progress and there will be many more cycles, and
many more revisions of these cycles. It is an ongoing, lengthy process. We are excited
about sharing the next cycles in this working group as we refine and redesign tasks
that support teachers to independently create tasks that provide opportunities for
students to justify, and afford teachers the opportunity to press students towards
justifying and generalizing.

The same task? - different learning possibilities
Angelika Kullberg
University of Gothenburg
Ulla Runesson
University of Jönköping
Pernilla Mårtensson
University of Jönköping
In this chapter we focus on variation of the design and the
implementation of a specific task during three mathematics lesson in the 8
th
grade
in a learning study (Marton & Tsui, 2004; Runesson, 2008). The theme of the
lesson was division, with a denominator between 0 and 1. The teachers wanted
their students to understand that when dividing with a denominator <1, the
quotient is larger than the numerator. Four teachers collaboratively planned,
analyzed and revised three lessons in a cyclic process. The study shows that the
implementation of the task changed between the lessons. Although the same task
was used in the lessons the way it was enacted provided different possibilities to
learn.
Keywords: Tasks, variation theory, learning study, mathematics, division
Introduction
In mathematics education tasks play a critical role in the teaching and learning
process (e.g., Hiebert & Wearne, 1997; Watson & Mason, 2006; Zaslavsky & Sullivan, 2011).
Tasks can mediate important mathematical ideas for the students. In this chapter we address
the issue about the implementation of a task. What is made possible to learn from a specific
task in different lessons? The task chosen is a sequence of items of non-contextualised
arithmetic (see Figure 1). Certainly, implementation of a task can be very different in different
classrooms. What is possible for students to learn from a task, may be affected by for
instance, how the task is enacted, students' response, students' knowledge, but also what
mathematics is made explicit from the task.
It has been suggested that tasks and teaching can be designed with variation in
certain dimensions to enhance student learning. For instance, Watson and Mason (2006), who
talks about using variation as a tool for designing tasks and the role of the teacher in the this
process:
Constructing tasks that use variation and change optimally is a design project in which
reflection about learner response leads to further refinement and precision of example
choice and sequence…This process cannot be done by textbook authors working alone
under tight publication deadlines but it can be done by teachers for themselves (Watson &
Mason, 2006, p. 100). Theme E - A. Kullberg, U. Runesson & P. Mårtensson
610
In this chapter we describe such a design project; how one task was designed,
enacted and successively refined by four teachers teaching in the 8
th
grade. The task was one
of several tasks planned collaboratively by the teachers in an iterative process of planning,
analysis and revision of a single lesson about division. This form of collaboration, called
learning study, have shown that teachers become sensitive to their students' learning and that
the way they teach the topic changes due to the insights gained by student learning (Runesson,
Kullberg, & Maunula, 2011). The aim is to discuss students' possibilities to learn from the
same task enacted in three different ways. How did the teachers implement the task and what
was made possible to experience from the task by the learners?
Background of the study
The data used comes from a learning study about division. Learning study (Pang &
Marton, 2005) is a version of the Japanese lesson study model (Fernandez, 2005; Lewis,
Perry, & Murata, 2006; Stigler & Hiebert, 1999) informed by a learning theory; variation
theory (Marton, Runesson, & Tsui, 2004). The aim is to improve students' learning by a
careful and systematic inquiry into teaching and learning. The lessons are video recorded and
students' learning is mapped by analysing how they solve certain tasks before and after the
lessons. The current study lasted one semester with several pre- and post-lesson meetings
where the three teachers planned, analysed and revised the lesson plan. After planning the
first lesson together, one of the teachers conducted the lesson in his/her class. The videorecorded lesson was analysed and, from what was observed in the lesson and analysis of how
the students solved the tasks on the post-tests, changes for the next lesson were agreed about.
After revising the lesson, the next teacher taught the lesson to his/her (new) class, and after a
second revision, the third lesson was enacted by the third teacher. One of the researchers
(third author) had a supportive role in the learning study; she took part in the discussions,
recorded the lessons, conducted the tests and informed the teachers about the results.
The teachers wanted their students to learn that in division, when the denominator is
a decimal number between 0 and 1 (e.g. 24/0.8=?) the quotient is larger than the numerator.
Previous research shows that students' overgeneralisations of rules valid in the domain of
natural numbers lead to ideas like 'multiplication always makes bigger and division always
makes smaller' (e.g. 45/0.9 equals a quotient <45) (Verschaffel, Greer, & De Corte, 2007, p.
569). The teachers were aware of that the students often had this idea and planned the lesson
to overcome this difficulty. Furthermore, they wanted their students to be able to solve
divisions like 40/0.2= without having to multiply by ten (400/2=). They believed that this
strategy would help the students to solve the problem, however, without understanding the
underlying structure of division with decimals. The ideas of 'partitive division' (e.g. 100/20
seen as 100 partitioned into 20 groups) and 'measurement division' (how many groups of 20
go into 100) was introduced in all classes before the specific task was discussed (cf., Greer,
1992). The task chosen to discuss, is a sequence of items of non-contextualised arithmetic
designed by the teachers (see Figure 1). The lesson as a whole consisted of several other
tasks.
Analysing what is made possible to learn
In order to analyse the implementation of the task from the point of view of what was
made possible to learn, variation theory is used. An important idea within variation theory is
that learning implies seeing something in a new way by experiencing aspects that you have
not experienced previously. To make it possible to notice these aspects it is necessary to
experience variation (cf., Dienes, 1960; Gibson & Gibson, 1955; Watson & Mason, 2006).
The way we experience something, or how we learn to see an object in a particular way, is a Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
611
function of those aspects we notice or discern at the same time. If different individuals
experience 'the same thing' differently, they discern different aspects of the object in
question. In order to understand or see a phenomenon or a situation in a particular way one
must discern all the critical aspects of the object in question simultaneously. Since an aspect is
noticeable only if it varies against a back-ground in invariance, the experience of variation is
a necessary condition for learning something in a specific way. Four possible patterns of
variation has been identified; contrast, generalisation, fusion, and separation (Marton,
Runesson, & Tsui, 2004). In previous studies it has been demonstrated that variation theory
can be used to analyze lessons from the point of view of what patterns of variation that are
inherent in the lesson. It has also been found that this is reflected in what students actually
learn (Kullberg, 2010; Marton & Pang, 2006; Marton & Tsui, 2004). So, identifying the
pattern of variation and invariance in the lesson implies to identify what is made possible to
learn.
Here we make use of the notion of contrast, since it was shown this pattern of
variation was frequently used by the teachers. Marton et al. (ibid.) points to the importance of
experiencing contrast for learning;
"in order to experience something a person must experience something else to compare it
with. In order to understand what "three" is, for instance, a person must experience
something that is not three: "two" or "four", for example". This illustrates how a value
(three, for instance) is experienced within a certain dimension of variation, which
corresponds to an aspect (numerosity or "manyness") (p. 16).
Teaching division with a denominator between zero and one
As can be seen from Figure 1, there is a pattern of variation and invariance built into
the task. We can see that the operations vary, since there are multiplication as well as division
items. This variation makes it possible to discern differences between multiplication and
division. Furthermore, the numbers within each column vary in a certain way, starting with
larger to smaller number, keeping the number 100 invariant, making it possible to discern
what happen to the answers when different numbers are multiplied to, or divided from 100.
The numbers varied are positive integers with one or two digits and decimal numbers between
zero and one with one decimal. The numbers were chosen to make it possible to experience
differences between divisions with numbers <1. The same numbers are used in the two

columns, except for in the answers to the items. With this design the teachers wanted to make
it possible for the students to see what happened with the answer when one factor or the
denominator changed.
Figure 1. Items in the planned task. Theme E – A. Kullberg, U. Runesson & P. Mårtensson
612
In the following we show how the design of the task changed as a result of analysis
of the revised lessons, the different ways they were implemented in the lessons, and from that
draw conclusions about what was made possible to learn from the enacted task.
Differences in implementation of the task
When we analyze how the same task was enacted in the three lessons we can see that
different aspects of division are made salient for the learner. Our suggestion is that seemingly
the same task offered different learning possibilities for the students. Note, the task was
successively written on the whiteboard by the teacher, one item at a time, starting with the
first multiplication item, followed by other multiplication items, and thereafter the division
items. The order in which the items were discussed in the lesson and what the teacher made
explicit by visually pointing out is shown in Figures 2 to 4.
Lesson 1
In lesson 1 the task was enacted in a way, that from the theoretical framework taken,
only made it possible for the learners to experience that multiplication can be used to "check"
division. The teacher started the discussion about the task in lesson 1 by asking for the answer
to the item 100·20. The teacher continued with another item, multiplying one hundred with a
smaller factor, 100·4, followed by two division items, 100/20 and 100/4 (Figure 2, see 1). The
teacher pointed out that she used the same numbers in the multiplication and division items,
however nothing else was discussed. From the set of items it was visually possible to discern
that multiplying with a smaller number give a smaller answer, and that dividing with a smaller
number give a larger answer, but this was not discussed. The teacher continued with another
set of items in multiplication (2) and thereafter division (3). The items were solved, however,
with no specific discussion about what happened with divisions with numbers < 1, although
this was the intention of the task. After calculating all items the teacher said "How can we
connect these rules of arithmetic". The class came to the conclusion that multiplying the
quotient with the denominator, for example 20·5 will give the same answer as the numerator,
100 (see A). This relationship was pointed out by the teacher for all division items, namely
that the answer to a division can be checked by a multiplication.
Figure 2. The enacted task in lesson 1. The items are grouped into sections (1 to 3) to show the
sequence of how the items were presented on the whiteboard. The lines (A) show what the teacher directed the
students' attention to.
As stated earlier the enacted task only made it possible to experience a contrast
between multiplication and division by using multiplication to check a division task. At one
point the teacher said "the answers get bigger the further down one gets" in the division Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
613
column. However, we infer that this most likely was insufficient for learning what was
intended. Even if the task was designed with the intention to make it possible for the students
to discern that the quotient is larger than the numerator when dividing with a number <1, this
was not focused upon. Instead, calculations were discussed (A), and no other relationships,
patterns or numbers were discussed.
Lesson 2
In contrast to lesson 1, in the second lesson of the cycle, the designed task was
handled in a way that made it possible for the learners to experience that when the
denominator is a decimal number >0 but <1, the quotient is larger than the numerator.
Furthermore, it was made possible to experience that the product become smaller than the
larger factor when multiplying by a number <1.
In lesson 2 the teacher started the discussion together with the students about the task
by calculating the items in both sections 1 and 2 (See figure 3), starting with the
multiplication items (section1) and continuing with the division items in section 2 (Figure 3).
After doing the calculations, the teacher asked if the students could see any 'patterns' between
the items. The students identified two 'patterns. These were summarized by the teacher:
- The smaller number multiplied with, the smaller the product and the smaller number
divided by, the larger the quotient is.
The teacher explicitly the pointed at the two columns (1 and 2) comparing the
products and quotients with one another. Thereafter the teacher pointed at the quotient and the
numerator in 100/20=5 and 100/4=25 (See figure 3) and said:
-Here the quotient is a smaller number than the numerator, is it always like that?
This question made it possible for the students to experience a contrast between, on
the one hand division with numbers < 1, and on the other hand division with 1 ≥. One student
said that after zero there was a difference. Other students said that it was not the same for
numbers <1, then the quotient became larger than the numerator. The different answers "zero"
and "one" made a contrast as to where "it turned". By comparing 0 and 1, the significant
turning point was elucidated. The teacher drew a line under items with a denominator smaller
than one (F) so the contrast became visible. Thereafter, the teacher first pointed to the
denominators 1 and then to 0.5 and said:
-When the denominator is smaller than one, the quotient (pointed to the quotient) is larger
than the numerator (pointed to the numerator) (F).
Next, the teacher made a contrast between the division item 100/0.5 and the
multiplication item 100·0.5, she said "What happens with the multiplication item then?" and
the episode ended with the conclusion that the product, 50, is <100 (H). By comparing the
items 100/0.5 and 100·0.5 it was made possible to discern that quotient became larger than
100, and the the product smaller. Theme E – A. Kullberg, U. Runesson & P. Mårtensson
614
Figure 3. The enacted task in lesson 2. The items are grouped into sections (1 to 2) to show
the sequence of how the items were presented on the whiteboard. The lines (B-H) show
what the teacher pointed to and hence, directed the students' attention to.
The analysis demonstrates that, in lesson 2, relationships between the quotient,
denominator and numerator were made possible to learn by means of a pattern of variation
that elucidated how changes in the denominator affected the quotient and the numerator.
Lesson 3
In the last lesson, the task was, in the same way as in lesson 2, handled in a way that
made it possible for the learners to experience that when dividing with a number <1, the
quotient is larger than the numerator. However, more attention was paid to the items with the
denominator <1. This was done by grouping the discussion into three sequences (See Figure
4). One difference was the sequence the items (see Figure 4). The difference in sequence was
that in both multiplication and division, items with the number 0.1, was systematically
compared with the items with 0.5. This comparison made it possible to generalise both
multiplication and division items with a denominator <1.
In lesson 3 initially the discussion was about the multiplication items in section 1
(Figure 4) starting with the item 100·50 followed by 100·5, 100·1 and 100·0.5, followed by
the items in section 2; the divisions (2). After that, multiplication and division was discussed
separately. The teachers said:
-Look at the multiplication column first, do you see any pattern, anything that is the same
or different?
The students said that the smaller number we calculate with the less zeros there are
[in the product], and the smaller number there is [the product]. The teacher said:
-What are we used to get as an answer when we calculate a multiplication?
The class said that usually it is a larger number. The teacher continued:
-Is it always like that? When do we not get a larger answer?
The students answered "After one". The teacher pointed at the decimal number 0.5
and the product, and again at the product and 100 to show that the product in this case was
smaller than 100 (I). The teacher asked if that was true for all decimals (<1), and introduced
the item 100·0.1, as another example with multiplication with a number <1 (3). Thereafter the
teacher asked if the students could see patterns in the division column. The teacher said: Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
615
-What are we used to get as an answer when we calculate a division?
The students said that they were used to get a smaller answer when they divided. The
teacher asked the students if it always is like that. The teacher said:
- Do you see where it turns? Here we get a larger answer (quotient) [the teacher
pointed at 100/0.5=200 (J)], when do we not get a larger number (quotient)? Is this
true for all decimals? (J).
The teacher introduced another division item, 100/0.1. (J), to compare with 0.5.
Figure 4. The enacted task in lesson 3. The items are grouped into sections (1 to 3) to show the
sequence of how the items were presented on the whiteboard. The lines (I-J) show what the teacher pointed to
and hence, directed the students' attention to.
In the end of the lesson, not in the discussion of the specific task analyzed here,
division with two and three decimals were also introduced (10/0.02=500, 10/0.002= 5000), as
well as multiplication with two decimals (0.02·500=10).
Different possibilities to learn from the same task
The case study reported is an example of a design project where teachers' reflection
on their teaching and the learners' responses can lead to a refinement of the task design (cf.,
Watson & Mason, 2006), but also to a greater accuracy and clarity about what to point out and
make discernible to the learners. The task used in the lessons was designed by the teachers.
The teachers decided a specific pattern of variation in the task to elicit aspects of division with
a denominator <1. In the task the same number (100) was divided or multiplied systematically
with a smaller number, so the learner easier would see how the quotient or the product
changed. This was the principle behind how the task was designed. We have shown that,
when the (same) task was enacted in classrooms, the items were handled differently as regards
to sequencing, as well as aspects of the content made explicit by the teacher, and aspects
juxtaposed and contrasted. This was a result of the difference of that which was varied and
kept invariant between the three lessons. We will suggest that these, rather subtle, differences
affected what was made possible for the students to learn. So, what might be worth
considering from this example is whether it is possible to say that the learners encountered the
same task in the three different lessons or not. In one sense it was the same task, but what the
learners encountered in the lesson was different. Our interpretation is that, only in lesson 2
and 3 the teachers' intentions were brought out. As researchers and mathematics teachers we
ask ourselves if we sufficiently make use of the possibilities that are inherent in the task
(regardless of who the designer is). A lesson is indeed interactive in nature; for instance could
the teacher's and the learners' ways of questioning and responding affect how the content is
handled. So, a lesson might not turn out to be what we planned. Even if we think we have Theme E – A. Kullberg, U. Runesson & P. Mårtensson
616
clearly brought out that which we intended to, this may not be the case. One thing we think
could be learned from this study is that, if students' fail to learn, one reason could be that it
was not made possible to learn this in the lesson. What we assume the task will mediate,
might not be possible for the learners to see. Implications of this study on teachers' pedagogy,
we suggest, is that teachers need to take an active role in how the task is enacted in the
classroom. Since, we cannot take for granted that the learner discerns from the task what the
teachers have in mind. In this study the teacher in lesson 1 wanted the students to see
connections between, for instance the quotient and the numerator, however this was never
discussed or made possible for students to become aware of. In lesson 2 and 3, on the other
hand, the teachers directed their students' attention towards this. We suggest that participation
in learning study gave the teachers time for reflection over the content and tasks used, and
contributed to the teachers' awareness of the implementation of the task.

On doing the same problem – first lessons and relentless
consistency
Laurinda Brown
University of Bristol, Graduate School of Education, UK
Alf Coles
University of Bristol, Graduate School of Education, UK
In this paper, we illustrate, through stories from practice, the
view that in designing and implementing tasks, teachers have, as a base
for decision-making, the classroom cultures they have already established
with their students. These cultures are developed over time from the first
lessons with a new group. Teachers, and curriculum developers and
researchers working with teachers could be seen as leaders of change, the
teachers of the learning of their students. In the leadership of change
literature, Fullan (2008) has developed what he calls 'six secrets of
change' that shift the focus away from detailed planning to learning
through reflective action. In Secret 4, 'Learning is the work', he talks

about addressing 'core goals and tasks with relentless consistency' (p. 76).
So, once a culture in a classroom has been established, through the
relentless consistency of practices, and children know what to do to
support their learning, this, according to Fullan, frees 'up energy for
working on innovative practices' (p. 79). Evidence for establishing
classroom practices through relentless consistency that support the
continued learning of both students and teachers is given through
observations of and interviews with teachers discussing the first lessons of
a topic or with a new group of students. For these first lessons, the
teachers often use tasks that they are familiar with and have used over
many years for their first lesson with a new group to establish ways of
working in their classrooms.
Keywords: Teacher change, mathematics education, task design,
teacher decision-making, first lessons
Introduction and Background
After studying for a mathematics degree, Laurinda completed a one-year postgraduate teacher education course (PGCE) and began teaching at a secondary school
(11-18 year-old students) where, 14 years later, she was head of the mathematics
department. An opportunity arose to have a year's sabbatical leave working as a
curriculum developer (in fact the job title was Mathematics Editor at the Resources
for Learning Development Unit (RLDU)). Her job was working with groups of
practising teachers to develop resources either in response to government initiatives (a
top-down approach) or in response to suggestions of need from teachers (a bottom-up Theme E – L. Brown and A. Coles
618
approach). One such working group was focused on the algebraic activities that would
be useful for students to experience before they used them in the new examination
courses (GCSEs), where extended investigations were going to be used for the first
time. What was important for the editor to be aware of whilst working with the group
was the publication that would emerge that would be distributed throughout the local
education authority's schools and be on sale nationally and internationally. However,
the real task of the editor was supporting the professional development of the
teachers. Nevertheless, the resources produced, whilst being quite old now and out of
print, are still considered to be some of the best resources available (for example
Laurinda has recently been approached by the National STEM Centre in the UK with
a view to publishing Addendum to Cockcroft on-line and 6
th
dimension, Developing
Teaching Styles in A Level Mathematics (Brown, 1988) is cited in an e-book (Risps:
Rich Starting Points for A Level Core Mathematics http://webfronter.com/walthamforest/CFSMaths/mnu5/Rich_Starting_Points/images/risps_ebook_apr_07.pdf) as "A
wealth of rich and open possibilities for inquisitive mathematicians.').
Following on from the RLDU work, Laurinda became a teacher educator and
still works with the one-year PGCE course for prospective teachers. She and Alf
Coles have researched and taught together since 1995, Alf having recently completed
his PhD and joined Laurinda teaching on the PGCE course at the University of
Bristol.
Focus on professional learning or change
The job of editor at the RLDU was illustrative of a subset of Gee's (2004)
principles for task design listed in Sullivan (2011, p. 32):
- learners to take roles as 'active agents' with control over goals and strategies
- skills to be developed as strategies for doing something else rather than as goals
in themselves.
As editor working with the group of teachers, the role was to keep the focus
of the teachers on the publication. It was important that we shared ideas and also that
we tried out suggestions for tasks in the different classroom cultures of members of
the group (typically not more than 10 teachers and six meetings over eighteen
months) since the tasks that made it through to publication were able to be adapted
into different classroom cultures. For instance, for the 'function game' activity
(shared as part of the algebraic activities group mentioned above, see
http://nrich.maths.org/5531 for a short video of Alf introducing this activity to a class
as a first lesson for a block of work on functions and graphs), in the final publication
Developing Algebra, each member of the working group wrote up how they had used
the task and these write-ups were printed on a non-white paper and spread throughout
the publication. The teachers were 'active agents' in this process because in their
discussions they appreciated the power of the activity in being able to be used in
many different ways and wanted the activity to be a major part of the final
publication. Laurinda coined the phrase 'spurious purposes' (Brown, 1995) to
describe the strategy, consonant with Gee's second principle above, of having an
agreed endpoint, for example, a publication, when, for the group leader, the work is
actually in the process. Spurious purposes work as well in the classroom and are a
powerful design principle (e.g., we are going into a primary school to help the
students with their mathematics, as a purpose to get slightly older students reflecting
on what they have learnt or as motivation for low achieving older students). Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
619
Working as editor at the RLDU taught Laurinda about the importance of
teacher decision-making in adapting tasks for their own classroom. She had the
privilege of visiting the classrooms of the teachers she worked with and got into the
habit of interviewing them to gain a sense of how their different classroom cultures
had developed. The technique was honed down to interviewing teachers after they had
taught their first lessons of the year. How did they choose the tasks to do? How did
they set up their classroom cultures? The rest of this paper will initially share some
stories of practice, including ones from time Laurinda spent at Monash University,
Australia (August, 2012). Rather than searching for new and exciting problems, what
seems to be important for establishing cultures is that the teachers worked with their
students on familiar tasks that were designed to introduce their students to ways of
working that they would continue to use in future lessons. As Alf commented on the
NRich website in relation to working with the problem functions and graphs,
In the end, what I like most about this problem [function game/functions and
graphs] is its familiarity; I have worked on it with every class I have ever taught.
Rather than this becoming monotonous, it seems to mean that each new class goes
further than the one before, as I become more and more attuned to what students
say and to what possibilities there are for exploration. And I imagine this is true
for everyone's 'favourite problems' – in the end it does not matter so much what
they are as what use you have made of them. (http://nrich.maths.org/5531, 2006)
So, Alf's pedagogical decision-making, focused on the meaning making of his
students within mathematics, is supported by his history of experiences of using, in
this case, the function game. His attention is freed to work contingently with what the
students bring.
After some more stories, there will be an interlude discussing Fullan's (2008)
'six secrets of change'. If we want our teachers to develop and the children to learn
mathematics we are leaders of change and insights from the leadership of change
literature can support our awarenesses of decision making in planning and in action.
Fullan's idea of relentless consistency will then be used to reflect on the stories and,
finally, some insights into classroom practices from first-lesson interviews will be
presented.
Laurinda's Stories – narratives of practice
Story 1 (Australia): I asked a group of master's students to come to the session
prepared to tell me what they thought 'curriculum' meant and what they thought
'mathematics' was. After a discussion of how she planned what she did in the
classroom, one woman, the first to speak, said 'People Maths'. She had found Mike
Ollerton's book 'Getting the buggers to add up' and now, whatever the system or
structure in her school or in the new Australian National Curriculum, she turned her
lessons into what she called 'People Maths'. She did a couple of examples actively
with the group and I followed with a couple of active loci (stand same distance from
me; with two fixed points, stand twice as far from one point as to the other). I then
asked the group what 'People Maths' was and they came up with some thoughts that
were effectively design principles for any content.
Comment: What 'People Maths' as a design principle does is focus the beginning of
the lesson on students being active. Again, the teacher has then to work contingently
with what the children do. In working actively on the second locus, stand twice as far
from one fixed point as another, questions emerge from the group, is the locus an
ellipse? A circle? These questions, force the teacher to make decisions of how to Theme E – L. Brown and A. Coles
620
respond, given the particular group being worked with. The more familiar the actual
problem and the more familiar, in this case, the teacher is with doing 'People Maths',
the more extensive the range of options that lead to a decision being taken. The
consistency of offer of 'People Maths' also serves to set up a culture in the classroom
where the students expect to do something active and make meaning from those
actions. In such a case, within an established classroom culture, the students might set
their own goals, the teacher simply acting as facilitator.
Story 2 (Australia): In a primary classroom that I visited to observe, the teacher
picked out one of the problems from Peter Sullivan's (2004, second edition) Openended Maths Activities book, to work with her students on. It was from a section
entitled 'area':
My granny bought a square rug and each side measured 1 m. When she got it
home it would not fit into the hallway so she cut the rug up and joined the pieces
together again to make a shape that would fit. What might her rug look like now?
(p. 64)
- Who can read that problem out for us? [A volunteer reads.]
- OK, so what are the key words?
- 1 metre length
- Square
- What are we trying to do?
- Cut up the square to fill the hallway. (from my field notes, August, 2012)
At this point all the students started to work, beginning in different ways.
Nobody seemed upset by not being given dimensions for the hallway. There were
some heated arguments. For example, between two boys about the solutions they had.
Both started with Granny's rug being one square on their paper. One boy filled a
hallway that was one half of a square by two squares showing this drawing in his
book:
The other boy filled a hallway that was one half of a square by one and a half squares.
The first boy had actually cut up Granny's rug. The other boy argued theoretically,
'Granny's rug has 4 1 m sides so I need a shape with 8 half metre length sides. What
would you say next?
During sharing time, the children were used to saying what they had done
and others listened or asked questions. One boy lost us all:
- I doubled the first and halved the second .4 times 2.5, .8 times 1.25.
The teacher, myself and the other children look a bit bemused. .8 x 1.25?
Surely that can't be 1? How can we check using what they know?
It was natural for me to offer to work on this with the children. I write .2 x 5
on the board and someone says, 'that's 2 tenths'.
- What can I do with 2 tenths?
- 1 fifth. [Lots of the students look confused.]
- What's a half of 2? [I invite them to chant, all reply together.] – 1
- What's a third of 3? – 1
- What's a quarter of 4? – 1
- What's a fifth of five? – 1
- What's a millionth of a million? –1
We're all smiling now. Those of us who knew the answer began chanting
and, gradually, more of the children joined in. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
621
- What about .4 by 2.5?
- .4 is 2 fifths.
- 2.5 is 2 and a half.
- How many halves in one? – 2 [chanting again. I did not ask this time]
- How many halves in 2? – 4
- How many halves in two and a half?
This seems OK. I write one half of two over one on the board without
speaking. They will be working on fractions, decimals and percentages soon. I don't
want to get into algorithms. They see a pattern and recognize it.
- 2 fifths of 5 halves? – 1
There are giggles and the energy release that I recognize of having learnt something.
Not everyone is there. However, it's the end of the lesson. The teacher says she will
use doubling and halving as the introduction to fractions and decimals. We would do
.8 x 1.25 next. The boy who started all this comes up to me before I go for lunch with
the teacher and says he's done .8 times 1.25 that way and it works.
Comment: I can remember being amazed by the beginning of this lesson. The
question was, indeed open, and the children were well used to this way of working
because no child made a comment like "the question doesn't tell us the shape of the
corridor". There was an established process by which the children made meaning of
the question, reading it out and then identifying keywords, they then all started
exploring possibilities. The activity allowed the children to work in groups and we, as
teachers simply circulated, learning the children's responses. This led the primary
teacher to her decision, when the boy lost us, to invite me to work directly with the
group. As a secondary teacher, I was aware that these students would not have
algorithms to cope with these difficult multiplications so had to make my offerings
contingent upon what they offered me. The offer, by one child, of the fraction for the
decimal was key to me realising that the pattern could be used without the need for
multiplication of fractions in that moment. The class teacher then realised that this
experience could be motivation for a focus on fraction and decimals so that their
awarenesses could be applied. It would have been impossible for me to work in this
way with a group of students unused to tackling open questions.

Story 3 (UK, after return from travels, August 30
th
, 2012): I had a tutorial with a
Master's student who is submitting her dissertation in early September. Sitting with
her, talking, I am aware that, here it is again. In the Epilogue to her work she is
discussing her development through doing the project and articulates what are now
design principles for her teaching. I ask her if I can quote from this writing and she
agrees:
In the year since completing my research project I have further grown as a
teacher, and I am sure I will continue to do so. There are many ways in which this
research has affected my teaching directly and consciously, and I believe many
ways indirectly and possibly subconsciously. […]

With all the tasks I made sure I gave clear instructions, but only enough
instructions to understand the task. What I found crucial, was not telling the
students what to do! My year 7 class this year always wanted me to tell them if
they had finished, I never did! Each time a student asked I would ask them back
"Well, is there anything else you could do?" whatever answer they gave I said
"OK". Even when they said "no" they somehow knew they had something left to
finish so would ask their partner, or would just figure it out. Something this
simple, transformed the class, they were engaged and took ownership of their Theme E - L. Brown and A. Coles
622
work. They were completing tasks for themselves, not under my instruction. They
had independence! […]
[T]he progress I have made this year, with all my classes, and in particular one
boy has amazed me! I do not think I have done anything miraculous, mainly
consistency and praise. I have always known these two things, however, the
students eventually wore me down. This year, I have remained positive with my
students and myself within an inclusive classroom. Simple things like saying
hello to the student who I had to send out of the lesson just an hour before, meant
I was building that bridge faster and more effectively. […]
I will continue to challenge students to approach problems, systematically and
logically, in order to help prepare them for life. (McCarthy, 2012)
Comment: The Masters in Mathematics Education course at the University of Bristol
is predicated on students (who are all teachers) developing their own practice through
researching an issue in their teaching. Jen, above, describes how the process of
exploration has impacted on her own pedagogy. There seem to be some design
principles emerging, one of which, common to the primary classroom in Australia and
the secondary classroom in the UK, is 'only enough instructions to understand the
task' and 'don't tell them what to do'. It would seem also that, for the secondary
teacher in Australia , in getting her class to do 'People Maths' there would be minimal
instructions to set up the task. Given the engagement of the students, however, the
teachers know that they are setting out to challenge their students in various ways and
achieve this through sharing time and not simply giving instructions, supporting their
students' independence.
At a different level, from my experience as a curriculum developer and
teacher, I was able to offer, without prior planning, activities linked to 'People
Maths'; chanting; and, support for Master's students and PGCE student teachers.
Chanting fractions in this way, for instance, was a familiar activity. Gee's (2004,
quoted in Sullivan, 2011) principles are in operation here since, in chanting, students
are placed as 'active agents' and it is clear that the purpose of doing the work is to
support students' engagement in a wider activity. Although I had never been in
exactly these situations before, what was "the same" was working contingently with
the ideas of the group and individuals and collecting strategies linked to a label. The
teacher participants are supported in becoming more aware of their own pedagogical
principles and in recognising the power of such principles.
Fullan's secrets of change and relentless consistency
The ideas within Fullan's leadership of change literature have been developed through
the process of implementing often large-scale change. Having been a consultant on
the less-than-successful implementation of the National Numeracy Strategy in the
UK, he has since been instrumental in leading teachers in Ontario, Canada to embrace
change, raising performance in literacy in the process. The purpose of 'improving
literacy in schools in Ontario' was identified, by top managers, as a focus for
development in the whole region. The challenge was, how could teachers take
forward that agenda as their own. A structure for redoing and rethinking was centred
around a meeting, once a year, called the 'Learning Fair'. In the first year of the fair,
when teachers from schools were encouraged to share what they had learnt about
literacy, many presented something from a book, say. By the third year of the Fair,
having picked up ideas from other schools and networked, there was a noticeable
growth in the motivation of the teachers whose confidence had built and they were
creatively sharing their practices. In schools, headteachers were encouraged to form Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
623
learning communities for sharing practice where they worked alongside the teachers,
not as expert but as learner.
Fullan's six secrets of change, distilled from these experiences, place
attention not on the creation of a body of knowledge about teaching and learning, but
on processes related to supporting change. There is an acceptance that we learn
through doing when this is related to a purpose or purposes, such as implementing
change through new materials, new behaviours/practices or/and new
beliefs/understandings, in a cyclical manner. Findings are at a meta-level to the actual
content of teaching and learning. For instance, one of the secrets is 'Learning is the
work'. In Fullan's theory-in-action, evaluations of effectiveness are built in to a
process of redoing and rethinking to implement change. Learning is a process and the
system can be set up to learn through the interaction of doing and thinking, because
"you are more likely to behave your way into new ways of thinking than you are to
think your way into new ways of behaving" (2008, see web-page). Fullan discusses
the importance of 'relentless consistency" within the system, not to dampen creativity
but to allow the rethinking and redoing cycle that seems so important. In his work
with teachers, 'snapshot views" are used to support them becoming aware of their
own learning. The system supports the teachers in observing themselves.
Reflections
In neither Story 1 nor Story 2 had Laurinda planned to use the tasks that she offered
(in Story 1, the People Maths and in Story 2, the multiplications). She had, however,
as Mike Askew said in a recent conversation with Laurinda during a seminar, faith in
them that they would be productive. In Story 1, the teacher does not start with the task
when planning, she starts with an intention, People Maths. She then adapts any given
suggested task, from the syllabus or the national curriculum, to include the practice
she has faith in. As a teacher educator working with a group of Master's students,
Laurinda did not prepare a set of slides but created a space for discussion. She has
used the invitation to share what is meant by curriculum before and is always struck
by how experienced teachers have these intentions and their students know what to do
in their classroom. In Jen McCarthy's case, she is able to reflect on her journey to be
able to create the classroom culture she wants. She is now in her fifth year of teaching
and not only does she have an intention that her students will be independent, but she
also, over time, illustrates how she has made learning her task and now has the skills
to achieve this. She is clear that she will continue the process of learning. Jen is
relentlessly consistent now in not telling the students what to do.
In Story 2, Laurinda and the teacher had not planned for a lot of the
mathematical ideas that arose. The focus in the book of activities had been area,
particularly conservation of area. The level of difficulty was beyond what was
expected and the content was not focused only on area, but particularly on fractions
and decimals. The children were 'active agents' in this process. The teacher, similarly
to Jen McCarthy, did not go beyond supporting her children's understanding of the
problem when introducing it to the group. The children were well used to the
sequence of prompts: the invitation for someone to read the text; identification of
keywords; and finally, identification of the problem. Here is the relentless attention to
consistency of practice that seems to hasve opened the way for creativity. It is as if,
not having to pay much attention to the routine whilst introducing the activity, a first
lesson of a sequence frees the attention of the teacher to learn her students and the
attention of the students to work on the activity. Theme E - L. Brown and A. Coles
624
In any curriculum innovation there is the issue of interpretation. In Peter
Sullivan's book, the Granny's rug problem is defined as an open one. Given the
variety of responses, this seems clear. However, another definition of an open task
might be that it will extend people's thinking. Was it the task itself that did this in this
teacher's classroom, or the procedure established through which the children began to
engage with the activity? Another example provided by Barbara Clarke in a seminar
discussing these ideas at Monash University was that an activity was open if the
children have choices. Having watched a video of the beginning of the lesson where
Alf was teaching using the function game, there were at two contrasting views of the
task. One that it was closed because the teacher had an answer in mind and secondly
that it was open because the children had choice, they decided what the next starting
number would be, for instance. At the start of Granny's rug problem there was no
defined task to do, in that no measurements for the hallway are given. In this teacher's
classroom there were no signs of protest from the children that they did not know
what to do. So, the task remained open for the children and we, as teachers, had to
adapt to what was offered by them. What we seemed to be doing was closely
observing what the children were doing, not necessarily intervening. In the sharing
time, the move into chanting was comfortable, because it is a process that Laurinda is
able to use creatively, adapting to what is offered. In this case, the focus is on
multiplication of fractions. Laurinda could also have turned the fraction focus into a
People Maths idea. How do we make decisions about what to do as teachers? In the
moment we simply act out of all of our past experiences. So, you give me a task, no
matter how well designed and, as a teacher, I will work with it. Similarly, when the
culture of the classroom is established, even a page of calculations from a textbook
will be tackled by children such as those in Story 2, through opening up the questions
and discussing alternative strategies.
In conclusion, intentions and first lesson tasks by way of illustration
Laurinda has spent a lot of her life interviewing teachers about or running
sessions related to first lessons. First lessons both as the first mathematics lessons
taught at the start of the academic year and first lessons as starting a new area or topic
of work. Experienced teachers 'do the same problem' (see Brown, Reid and Zack,
1997) with their groups to establish a culture in which they and their students are
comfortable to act. In teaching the first lesson with a new group, established teaching
practices of teachers, which are often invisible and implicit in classrooms later in the
year because they have become part of the culture, are made visible both by the
teacher commenting on how they want the students to behave explicitly, or in telling
what happened afterwards in interviews.
Intention - story - Teacher C: I like to give things a story because I like to give the
children a natural language as a parallel to the mathematical language. I think it
allows enabling people to enter the world of maths you are talking about, then, if you
have got a story, if it's amusing or catchy in any way they might get interested in the
first place, but it does provide short simple language with which they can converse
with one another. So, it allows for group work, which is something else I think.
First lesson - activity - Teacher B: The calculation side of it is sort of trivial in a way
but the maths of it is looking at the structure, looking for a particular result, trying to
understand how the numbers arrange themselves to give you the answer that you Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
625
want. It's called difference of 3 although I'll probably run it as difference of 4. What
you do is put 4 numbers into a two by two grid. And you multiply the two top
numbers together and the two bottom numbers together. Add them together and write
down the total. Do the same with the columns. Add them to get a total. What's the
difference between the two totals? Can they get a difference of 4? 7? Whatever. I'd
like to see them asking each other "What if you try this?' type questions. It's all part
of modelling, it's what happens when you change something.
It seems to be the case that when a teacher has an intention such as 'People
Maths' or 'Story', then the actual activities used are not so important. There is a
relentless consistency in the style of teaching. Not every teacher would be
comfortable using these intentions all the time, but what does seem important is that,
over time, in the journey from prospective teacher to experienced, not only do
teachers find how they can work that allows their children to become enthusiastic
mathematicians but also that they share with other teachers so that they extend their
range of possible intentions, for example, not only story but also group work. In the
moment, any teacher simply acts contingently in response to their students' actions
within the culture that has been developed. Any task, no matter how well designed,
cannot be teacher proof, but is open to interpretation through the individual teacher's
and their students' cultural lens.
There is relentless consistency that allows the cultures to be established, but
also the creative space for both the children and teachers to continue to learn. The
teachers have a faith that these ways of working will productive. In talking about the
first lessons, the behaviours of the students that are valued by the teacher are
explicitly mentioned and would be mentioned in the classroom, as metacomments.
The ease of the arithmetic and the teacher's familiarity with the problem (adapting a
first offer of 3 to 4 suggesting consistency of problem with creative adaptation)
allowed the teacher to focus their attention on structures within doing mathematics
that they could stress during this first experience of students working with them
problem solving.
So, to sum up, a couple of design principles for teacher decision making in
relation to tasks:
- Do something that you are comfortable with that you have done many times
before to allow you to adapt and set up the rules of the community with relentless
consistency. You can then begin to learn the students. This can be comfortable either
at the level of intention or using a familiar problem, making decisions about how to
introduce the task, adapting or learning from previous experiences.
- Keep attention on the process and meta-comment about routines.

Reflections of Nigerian teachers on a learning experience designed to
develop pupils' multiplicative reasoning

Kathryn I. Omoregie
Nigeria
This paper presents the reflections of Nigerian teachers on a learning
experience which was designed to develop pupils' multiplicative reasoning. The
teachers' views indicate that the learning experience was of benefit to the pupils and
teachers.
Keywords: International education, mathematics learning, instructional aids,
mathematics tasks
The purpose of this paper is to report the reflections of a few Nigerian teachers on a
learning experience which was designed to develop pupils' multiplicative reasoning. This paper
addresses how features of design influence teachers' decisions.
Description of the tasks
An outline of the tasks which were given to the teachers to implement is shown below. The
tasks were designed by a mathematics teacher (the author). The purpose of the learning experience
was to help develop pupils' multiplicative reasoning through an approach which would be enjoyable
and interesting for young children. The tasks were written in a directed manner, in part because of
the costs involved in contacting the teachers if further clarification was required.
Exploring proportional reasoning with pineapples
Targeted year groups – Year 2&3
Duration: 30-40 minutes
Group the children in teams of 4 or 6
Materials: A4/A3 paper, scissors, ruler, and a pineapple
Prepare circles on A4 paper, about 12cm radius; divide each into eight equal sectors.
Key words: double, half, quarter, triple, third, eighth, equivalent fraction, etc. Theme E – K. I. Omoregie
628
Opener: Display one circle and present question 1
Q.1. Tami, Usman and Abby share a circular pineapple slice. It's cut into eight equal
pieces, through the middle, like this (show the picture) Tami gets one piece, Usman three and Abby
four. Danladi says that Abby got half of the pineapple slice. Show your group whether he is right or
wrong, and why.
Give one circle to each group of children. Guide children to cut out the sectors, and arrange
the four pieces Abby got – it should be evident, even without cutting, that four is half of eight, and
that the ratio of Abby's portion to the whole slice is 1:2, otherwise expressed as "Abby gets half of
the pineapple slice" Point out to the pupils that four eighths and one half are equivalent fractions.
If quite a large number of pupils are struggling at this initial point, it might be necessary to do a
whole class demonstration at the board, with a group of pupils as helpers to arrange the pieces over
a full circle.
Emphasize that the words in bold below are important to preserve the definition of the
word fraction – Equal portions are necessary. A pineapple slice representation that isn't perfectly
circular wouldn't fit the definition- hence the choice of paper circles to represent the slices. We can
also ignore thickness of the slice, since the paper is uniformly thick. Explain that other shapes can
be split into equal portions, e.g., a Kit Kat chocolate bar. Draw a rectangle, split into eight equal
sections, shade four of them. Draw one of exactly the same size and shade half of it. Again, point
out to the pupils that four eighths and one half are equivalent fractions.
Main activity
Guide the groups of children similarly, by arranging pieces, to compare Tami's portion to the whole;
and then, each portion with the others. For each portion, draw a rectangular representation of the
fraction, so that the children get used to multiple representations of the same fraction. Encourage
the children to discuss in groups, to write their completed statements, and draw pictures for each
fraction on a shared A4/A3 piece of paper. As the children get used to working with less direction,
introduce some open questions.
Examples of statements for pupils to complete – (You could modify these and add more
statements & open questions)
T:W
1:8
Tami's portion is one eighth of the whole slice.
Tami gets one eighth of the pineapple slice
The whole slice is eight times as large as T's portion
A:W
4:8
A's portion is . . . . .of the whole slice.
A gets ….. of the pineapple slice
The whole slice is 2 times/twice as large as/double . . A.'s portion
These are examples of the solutions one would expect from the pupils' comparison of each child's
portion to the others:
A:T 4:1 A's portion is four times as large as T's,
T:A 1:4 T's portion is one quarter of A's
U:T 3:1 U's portion is thrice/ three times as large as T's Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
629
T:U 1:3 T's portion is one third of U's
A:U 4:3 (slightly more difficult) U's portion is three quarters of A's
Plenary
Have each group come up to the board for a few minutes to share their pictures and
completed statements with the whole class as a small demonstration of what they have learned.
Recap the important points, check for understanding of the keywords and clear up any
misconceptions.
Snack time
Have the pineapple cut into even slices. Have one slice for each group, and guide each
group of children to share their assigned slice equally, with a grown-up at hand to help with cutting
the slices into equal sectors.
Extra Notes
Q. 2 below might be used in a follow-on lesson to reinforce what has been learned. Crosscurricular learning opportunities in science can also be explored. It might be beneficial to plan a
linked science lesson for use alongside this activity. Health science-nutritional value of fruits &
Agricultural science-types of plants are possible linked-lesson ideas.
Q2. Kore, Gbenga and Titi share a circular pineapple slice cut into twelve equal pieces. They
receive two, four, and six pieces respectively. Guide the children to do similar comparisons, using
circles split into twelfths.
A definition of tasks which encouraged looking beyond tasks to the type of mathematical
thinking and activity stimulated in the pupils (Watson et al, 2008) was adopted. It seems that a
teacher's natural intuition, influenced to some degree by the different texts read and previous
training received, informed most, if not all of the task design decisions, and that the decisions are
supported by the theories in the texts below. The following literature regarding the sorts of
mathematical thinking and activity that good mathematics tasks are aimed at generating were
consulted: (Piggott, 2004) (Piggott & Back 2004) (Watson & Mason, 2004) (Ingram & WardPenny, 2010) (Breen & O'Shea 2010).
Retrospectively, the links between the literature and the design of the tasks can be
identified: Ingram and Ward-Penny (2010) explain that it is possible for students to be 'engaged'
with a task, busy and seemingly enthused, without actually engaging with the mathematics. A
feature of this task that guards against the pitfall described is the requirement for pupils to articulate
their mathematical thinking both in writing and in speech, so that the teacher is able to check for
engagement with the mathematics.
Piggott (2004) identifies mathematical thinking strategies, some of which apply to the
tasks. They include- conjecturing/theorising, testing ideas- guessing and testing (hypothesizing),
representing information and reflecting on experience. Piggott and Back (2004) explain a concept
termed 'teaching for problem solving' – involving children in solving real problems. In the tasks,
the sharing of the pineapple slice enables pupils to apply mathematics to a real-life situation which
is relevant to children their age. Watson and Mason (2004) explain the importance of explicitly
requiring learners to reflect on their learning experience, noting that developing reflective practices
among learners is key. In the tasks, both verbal and written reflection are encouraged.
Another definition of tasks which encouraged looking beyond tasks to learning experiences
-with tasks considered as just one element of design- was also adopted (Swan, 2008a). One aim was
to create a learning experience that modelled a collaborative orientation of learning (Swan, 2008b).
Hence for the tasks, organising the children in groups of 4 or 6 was instructed. Williams (2008)
suggests that an optimal group size for interventions is a carefully chosen pair or three, and suggests
that larger groups might allow group members to get by without actively engaging with the Theme E – K. I. Omoregie
630
learning. Thus retrospectively, groups of 2-3 may have been better, depending on practicalities such
as total class size.
The learning experience was structured to encourage group discussion and foster active
student engagement, based on recommendations from studies on mathematics teaching in Nigeria
(Salman, 2009) and beyond (Krainer, 1993; Henningsen & Stein,1997). The improvement of
mathematics teaching and learning in the country has been noted as essential by researchers
(Eniayeju, 2008; Popoola, Ogini & Ojo 2011). The use of paper circles to model fractions are in
line with recommendations to encourage the use of locally available concrete materials and other
learning aids in mathematics classrooms (Afolabi and Adeleke, 2010). The use of circle sectors to
represent fractions of a whole is not new: Thompson and Saldanha (2003), for instance, in their
discussion of fractions and multiplicative reasoning, give a pizza fraction example, but the context
and the approach used in the tasks were original.
The learning experience aided the pupils in developing mental images for concepts and
encouraged the use of multiple representations (Swan, 2008b). It enabled testing by pupils of
conjectures (Pratt and Noss 2010). It also aligned with the definitions of purpose and utility
proposed by Ainley and Pratt (2005), in terms of a meaningful outcome for the pupils, and helping
them gain an appreciation of situations in which it might be appropriate to apply the skills they were
developing.
Excerpts of the reflections of teachers from four schools are outlined below. The
reflections were sent in writing-the teachers were not interviewed. In retrospect, it would have been
useful to speak to the teachers and confirm whether they carried out all the suggestions outlined in
the task.
Stone pupil) said that R(another pupil) has one out of the eight divisions of the apple she brought.
Relating fractions to actual experience or to the use of what goes on around us has really helped in
making the topic easier to explain to the pupils.
At first it looked strange to them but after proper explanation, they really understood and enjoyed
it. . . The method helps the children to understand fraction(s) better as they were responding well
to the questions asked. I used three pupils to represent Tami, Usman and Abby. One represented
Tami and I gave him one sector of the pineapple. One represented Usman and I gave him three
sectors of the pineapple. One represented Abby and I gave him four sectors of the pineapple
which meant half of the whole pineapple.
Learning fraction(s) at this level is difficult for children but with cutting and sharing, the pupils
make fun with it and enjoyed the lesson. Using resources at hand and engaging the pupils to
contribute to the lesson facilitated the class exercise and it enable(d) the pupils to understand the
topic without) stress; the method is good but expensive to implement.
Demonstration and practical aspect can be introduced in teaching maths for effective learning
because not all of the pupils have interest in mathematics. The lesson was quite interesting.
The lesson was interesting. They (the children) enjoyed the lesson because the pineapple was a
motivational material for the pupil's learning. The cutting of the circle into eight part(s) and giving
the pupils (the) puzzle to tackle on the board was quite interesting and new. It was quite an
interesting class. The class was more interesting seeing the children chanting and cheering
themselves after answering questions. It was even more fun after the whole learning period when
they had to share the pineapple amongst themselves.
From the teachers' feedback, the following link between task design features and
pedagogical choices of the teachers can be inferred (Fig 3): Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
631
Figure 3
The task type closely relates to one referred to as 'manipulating-getting-a-sense-ofarticulating' (Mason and Johnston-Wilder 2004). A pedagogical decision of a teacher was to listen
(Freudenthal 1991, Davis 1996) to the children articulating their understanding of the mathematics,
while another decision of a teacher was to increase opportunities for the pupils to actively use the
concrete objects, manipulating these to get a sense of the mathematics that they were learning
(Salman 2009).
From the reflections, it appears that the learning experience was useful to the pupils and
teachers.
It is hoped that the process outlined has the potential to contribute to the improvement of
mathematics teaching and learning in Nigerian classrooms.
Acknowledgement
I thank the following family members for liaising with Nigerian schools and teachers on
my behalf, and for general support: Mrs G. Omoregie, Mr O. Omoregie, Mr&Mrs U. Omoregie,
Mr. K. Binuyo. Sincere thanks to Ann Reeve and Dr. Afoke.

The article focuses on the design and implementation of simple
tasks in a teacher education course for mathematics teachers. It discusses
the rationale for this design including prospective teachers' difficulty in
task analysis and in-depth understanding of task specifications. Then the
effect of simple tasks is tested and exhibited through two detailed case
studies in which the implementation of two tasks is observed. The tasks
are different in nature, one is an algebraic traditional task and the other is
a geometric modeling task. Still, both share design similarity, afford many
learning opportunities, and can facilitate task design by these future
teachers.
Keywords: Task design, teacher education, modeling
Introduction
The design of good effective tasks is crucial in teacher education for two related
reasons. The teacher educator wants to use effective tasks to convey the many goals
of teacher education, and the prospective teachers need to experience good task
examples that would facilitate their own future task design.
In this article we suggest that effective tasks do not have to be complex. We
support this claim with data from the second author's doctoral research supervised by
the first author. The study informs us of the power of simple tasks through
observations and analysis of class implementation of tasks that were designed and
presented by the first author in a mathematics teacher education course. The simple
design of these tasks is intended to serve as a relatively easy model supporting teacher
pedagogical decision making in class,
Although the design of tasks is going to be a major part in their practice,
prospective teachers cannot be expected to be good tasks designers without getting
some support through specially designed instruction. This has become evident to us
when we asked our students in a teacher education course to compare two tasks. One
of the tasks involved cutting greeting cards (this task is described further on in the
first case study) and the second involved pouring beer from a container into cans. The
main and relevant difference between the problems involves the rigidity of the
cardboard versus the "flexibility" of liquid. This feature results in different types of
"remainders", as the rigid material does not allow remaining scraps to be put together
(unlike a situation such as cutting cookies with "flexible" dough). This difference
leads to fitting very different mathematical models. Yet, instead of identifying this Theme E – I. Peled & A. Suzan
634
feature, the students suggested some minor characteristics such as the fact that one
problem is two dimensional and the other is in three dimensions.
This task analysis difficulty strengthened our motivation to design simple
tasks and to make our design principles explicit to our students. It can be said that the
nature of our tasks became a part of the didactical contract in the course.
Further support for the need to stay simple involves the type of change we try
to achieve through the tasks. Often, as teacher educators, we aim at changing
prospective teachers' conceptions. With some of our goals such changes can be more
easily acquired when task context involves simple situations. Peled and Balacheff
(2011) discuss characteristics of task examples that aim to promote a shift from a
problem solving perspective to a modeling perspective. They use simple word
problems in an effort to promote teacher understanding of the meaning of fitting
mathematical models in different types of situations. The authors claim that the use of
these simple problems instead of complex modeling problems helps avoid teacher
resistance to problems that are very different from what they use traditionally, and
that it helps focus on the main current goal.
Theoretical background
As mentioned in the introduction, the design of tasks in teacher education has to take
into account prospective teacher resistance to change. This is not surprising when we
become aware of the strength of teacher beliefs investigated in many studies in
teaching mathematic and other subjects as well (Stuart & Thurlow, 2000; Kagan,
1992; Brown, Cooney, & Jones, 1990).
According to Piaget (1985), a change in knowledge and new learning can
occur through the creation of discomfort (disequilibrium, in Piaget's terms) with
existing knowledge or beliefs, leading to an effort to make some adjustments that
would restore the state of equilibrium. Following this recognition, Zaslavsky (2005)
designed tasks that were aimed to create uncertainty. Similarly, in our own work
(Peled & suzan, 2011), we describe the effect of a task that was designed to create a
cognitive conflict, a discomfort that was supposed to lead to abandon intuitive
knowledge for the sake of using formal knowledge. However, we found that creating
a conflict is one thing and resolving it is something else. That is, as suggested and
identified by Limon (2001), the design of good tasks has to obey certain conditions in
order to create a meaningful conflict leading to conflict resolution.
When teacher educators use tasks that create cognitive conflict to facilitate
desired changes in prospective teachers' conceptions, they can, at the same time,
acquire two other important goals. The students, the prospective teachers, can learn
that tasks that lead to a cognitive conflict can be effective means for facilitating their
own future students' learning. In addition, as described by Peled and Suzan (ibid),
becoming aware of the power of intuitive knowledge over their own performance,
teachers might become more sensitive to their students' difficulties. As analyzed and
discussed by Jaworski (1992), developing this sensitivity is a central teacher
education goal.
As can be seen, cognitive conflict tasks can aim at different types of
knowledge. They might have mathematical, pedagogical or psychological goals.
Peled and Balacheff (2011) discuss the use of such tasks to acquire epistemological
goals in the case of learning and understanding issues of modeling.
Modeling, as defined by Peled (2010) in more relaxed terms, is the process of
fitting a mathematical model to a situation described in a given problem. This process Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
635
includes the analysis and organization of the given situation before any
mathematization is done. Most of the studies on modeling (for example: English &
Watters, 2005; Lesh & Doerr, 2003) involve quite complex problems some of which
are termed MEA (model eliciting activities). These problems involve an extensive
situation analysis and their main purpose is developing modeling skills, i.e. the ability
to analyze, represent, and make autonomous decisions and choices of representations
and mathematical tools.
Following a theoretical analysis of modeling (Peled and Bassan, 2005) and
with the goal of developing teacher insights about the process of fitting a
mathematical model rather than developing skills, Peled and Balacheff (2011)
discuss (as mentioned in the introduction) the rationale for using problems that are not
as complex as MEA.
In this study we observe the effect of simple tasks that have been designed to
make a change in different types of teacher knowledge.
Procedure
The study was conducted in a university teacher education course taken as a part of a
mathematics teacher certificate program. The 24 students participating in the course
were in the third and last year of their undergraduate studies towards an academic
degree in mathematics.
The first author, a researcher and teacher educator, was the course instructor.
She designed the course with the purpose of promoting student meta-cognitive
perspective of teaching and learning and with the pedagogical approach of "not
telling" in the spirit of Lampert (1990). Using a design experiment methodology, as
described and used by Cobb et al. (2003), she has kept reflecting on the effect of tasks
through several years of conducting the course, redesigning new tasks or modifying
existing tasks accordingly.
The second author participated in all class sessions, recorded them and took
notes. Student homework and their final course assignment were also collected and
analyzed. She also met with the instructor and took notes of the instructor's
explanations for task goals and task design.
The implementation of each of the course tasks included a sequence of
activities. Each task started with a problem that the students were asked to solve in
class, and sometimes solve again at home. This activity was followed by class
discussion and by individual reflection that was given as a homework activity.
Results
The findings presented in this article are a part of the findings reported in the doctoral
dissertation. We focus on two of the course tasks, where each task includes a
sequence of activities, as mentioned above. The research questions refer to the nature
of the tasks and to their effect. We analysed the learning opportunities created by each
of the tasks, and within each task we identified the added value of the reflection
activities that followed the problem. We also analyzed the nature of the tasks and
identified some general design similarities.
The two problems that start each activity sequence are a geometric problem,
involving a print-shop where the workers are cutting greeting cards from a cardboard,
and an algebraic problem where show tickets of different prices are purchased.
The first problem, the greeting cards problem presented in Table 1,
originated in a graduate course where students interviewed print-shop workers on the Theme E – I. Peled & A. Suzan
636
situation described in the problem. While the students thought that they should divide
the area of the cardboard by the area of the greeting card, the print-shop workers used
a different mathematical model depicted in Figure 1.
How many small 6 cm X 8 cm greeting cards can be cut
from a 65 cm X 85 cm piece of cardboard?
Table 1: The Greeting Cards Problem
Using a symbolic formulation, the mathematical model used by the workers
involved taking the maximum of the value of [L/l]x[W/w] and the value of ,
[L/w]x[W/l], while the students used an area division model, [S/s], which is much less
appropriate in this situation.
Figure 1. Print-shop worker options for cutting greeting cards.
The goal of this relatively simple modeling situation was to develop
understanding of the idea of fitting a mathematical model in a given situation. The
implementation of the problem resulted in the construction of a wide range of models.
About 40% of the students suggested a model that was close or identical to the area
division model. A solution of this type is, most likely, an indication of an automatic
identification of the problem as an area problem without making an effort to represent
and analyze the situation by, for example, making some drawing of the cardboard and
cards.
In the following activity students were asked to generalize their models in
order to increase their awareness of the different parameters that were involved. As a
result about a quarter of the students shifted to a better model. The discussion that
followed these two activities, problem solution and problem generalization, created
many learning opportunities that cannot be detailed in this short paper. They include
awareness of problem features (simple and yet eliciting different models that can be
compared), mathematical knowledge (use of mathematical representations, concept of
area), pedagogical and psychological knowledge (misconception of over-linearity),
and epistemological (developing meta-understanding of fitting a mathematical
model).
The second problem, the show tickets problem presented in Table 2,
originated as a result of an error made by very few students when asked to solve a
similar problem without a request for multiple solutions. Most of the students chose x Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
637
to stand for the value that was the described reference, and solved the problem
correctly. The few who failed chose x to stand for the less convenient value. As a
result of their choice, they had to convert the given relationship between the values. In
making this conversion they wrongly asserted that: If A is by K percent smaller than
B then B is by K percent bigger than A. Obviously, this is a wrong generalization of
"regular" number relations.
Mary took her daughter and her neighbour's daughter to a show. Her
neighbour wanted to pay for the show's ticket but Mary did not remember the
exact price.
She knew the total sum was 143 IS and that a child's ticket was 20% cheaper
than an adult's ticket.
Help Mary figure out the child's ticket price. You are requested to do it in
two ways, each time using a different value (adult's ticket price, child's ticket
price) to be represented by the variable x.
Table 2: The Show Tickets Problem.
The original purpose of the modified task was to "not tell" students of their
mistake but give them a chance to become aware of it on their own. However, further
experience with the multiple solutions version made us aware of the many goals this
problem together with its following activities can achieve.
While a conventional problem version resulted in avoidance of the need to
make a percentage relation conversion, the multiple solutions version forced all the
students to face the conversion difficulty. As a result, 20 out of 24 (83%) solved the

non-routine and less convenient alternative incorrectly, asserting that if the child's ticket is 20% cheaper than the adult's ticket, then the adult's ticket is 20% more than the child's ticket. Since this alternative led to an incorrect solution while the convenient route resulted in a correct solution, these students realized that they have two different solutions and therefore something must be wrong.
Thus, most of the class experienced a cognitive conflict situation. However, as it turned out, conflict resolution did not occur spontaneously. A class discussion that immediately followed resulted in partial improvement. As depicted in Figure 2, only about a third (6 out of 20) of those who faced a conflict, managed to resolve it.
Figure 2: Conflict and (very partial) conflict resolution. Theme E – I. Peled & A. Suzan
638
The analysis of learning opportunities created during the activity sequence and especially during the discussion reveals the many goals that can be promoted through this one simple task. Similarly to the first task, the learning opportunities consisted of mathematical, psychological, and pedagogical goals. The teacher educator seized the opportunity to talk about cognitive conflict in general, making the students aware of what they experienced. Since they also experienced difficulty in conflict resolution, this pedagogical and problematic issue could be demonstrated through their own work and thus better understood.
The discussion brought up student realization of the strong power of intuitive knowledge. Some students explicitly expressed their increased sensitivity and understanding towards their future students' mistakes in view of the fact that in spite of their mathematical knowledge they themselves failed to resist incorrect intuitions. As stated by one of the students:
I personally felt uneasy because I am supposed to know this subject very well and solve this problem easily. Suddenly I got stuck and the solution wasn't so easy and fluent as I expected. Now I realize that if I, who master this subject, got confused, it can certainly happen to my own students too. We, as teachers, shouldn't be upset with them when it happens.
In addition to discussing the task as an example of a cognitive conflict task, students were also made aware of its simple design. The modification of a conventional algebraic problem into an effective interesting task required only a simple addition of a request to solve the problem in two ways.
Conclusions
Our study suggests that prospective teachers can benefit from experiencing simple tasks. This assertion is tested and confirmed in the article through the observations made in a teacher education course conducted in the spirit of a "not telling" approach. Through specially designed tasks, prospective teachers were expected to undergo knowledge change in their mathematical, pedagogical, psychological and epistemological knowledge.
The two case studies presented in the study involve two different tasks. The analysis of learning opportunities in both tasks has shown that not only did each task achieve its main goal, but also that in spite of the relatively simple formulation of the problems, many additional goals could be achieved. This fact was explicitly discussed with the prospective teachers. The intention was that they would experience examples of pedagogical decisions in task design and would become more confident that the task of task construction is within their limits. Of further help was the extensive discussion of the use of cognitive conflict to promote learning. The self experience of change and learning as a result of working on a simple task that triggers the emergence and resolution of a cognitive conflict is expected to make these task design principles a part of their teaching repertoire.
Thus, we believe that the exposure to simple problems and the explicit discussion of problem features created an opportunity for developing task design skills. Although this skill was not tested, students' awareness of task design characteristics was exhibited in their discussions. As mentioned in the introduction, the design of course tasks using explicit design principles became a part of the course didactical contract. As a result, when a new task was presented, students could tell that even though it looked simple, they could expect it to run deep leading to interesting and significant learning. Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.

Engaging teachers in the web of considerations underlying the design of tasks that foster the need for new mathematical concepts or tools: The case of calculus

Gila Ron
Technion – Israel Institute of Technology
Orit Zaslavsky
New York University and Technion – Israel Institute of Technology
Iris Zodik
Technion – Israel Institute of Technology

This paper reports on a design experiment, within which the design principles emerged in an iterative way, through examples, expert comments, reflections, and revisions. The focus for this part is on the design considerations of tasks that problematize the use of students' existing mathematical tools and set the grounds for learning about new (for the students) tools. Having gained insights ourselves, we built on our experiences to involve teachers in similar considerations. It turned out to be a way of thinking that teachers had not experienced before, nor were they aware of the possible web of considerations that underlie design issues related to specific choices of examples for tasks that aim at preparing the grounds for a new mathematical concept. We argue that this kind of thinking is not sufficiently attended to, yet should be part of teachers' knowledge for teaching mathematics.
Keywords: task design, teacher education, calculus.

Introduction

Typically, the process of task design is often a 3-stage hierarchical process that includes: 1. Stating goal(s) and connecting the task to the goal(s); 2. Designing a generic task that addresses these goals; and then (when applicable) 3. Carefully choosing the specific examples to "plug in" the generic task. Teachers usually are not engaged in this full process, and mostly make choices about existing tasks in textbooks, rarely with some (minor) modifications.
In this process, the specific examples can change dramatically the quality of the task, its connection to the goals, its target audience, how it may unfold in the class, etc. Analysing the subtle anticipated differences between various versions of the same generic task that only differ along the specifics chosen, and making judicious choices of the specifics of a task, is an important element of desired teacher knowledge and practice that our study aims at developing. In this paper we focus on a particular goal for teaching mathematics, namely, preparing the grounds for introducing a new mathematical concept or tool. More specifically, we illustrate this Theme E – G. Ron, O. Zaslavsky & I. Zodik
642
approach and way of working with teachers through the concept of the derivative as a tool for detecting the behaviour of a graph of a function.
Throughout the school years, teachers are often faced with the task of presenting mathematical concepts that are new to their students. To do this meaningfully, it is important to create the need for the new concepts that are introduced. We base our stand on the necessity-based approach to learning (Harel, 2007). That is, it is important to help teachers learn to problematize the situation for their students. One way to do this is with the use of carefully designed tasks.
This constitutes a challenge for teachers and teacher-educators, because on the one hand, we often want to point to the limitation of existing tools for a particular purpose, while we need to maintain the usefulness and merits of the existing tools for other purposes (otherwise students will believe that much of what they learn will need to be abandoned in the future). We do not want students to feel that what they have learned so far becomes useless as they progress in the study of mathematics. Thus, the progression from existing tools/concepts to new tools/concepts should lead to an extended mathematical 'toolbox'.
From a design perspective, with respect to tools, we would like teachers to be able to design tasks that foster discussion of the merits and limitation of existing as well as new tools. For example, using a function table to sketch graphs (of functions) is useful for certain functions (e.g., linear functions) and certain properties. However, when we move to the study of more advanced functions (e.g., higher degree polynomial functions), we need to introduce the concept of derivative. But even then, tables still have a significant role. Clearly, derivatives can help detect significant turning points in a graph, which could get lost using an arbitrarily constructed table. However, derivatives may also serve as a tool to construct a more useful function table, thus, they support the value of function tables, so that students do not have to abandon this tool (function table) when more advanced tools (derivatives) are introduced.
In our study, the design principles emerged in an iterative way, through examples, expert comments, reflection, and revisions. Interestingly, we experienced a certain degree of tension in attempting to satisfy some guiding principles. Having gained insights ourselves, we built on our experiences to involve teachers in similar considerations. It turned out to be a way of thinking that they had not experienced before, nor were they aware of the possible web of considerations that underlie design issues related to specific choices of examples for tasks that aim at preparing the grounds for a new mathematical concept/tool. We argue that this kind of thinking is not sufficiently attended to, yet should be part of teachers' knowledge for teaching mathematics (Ball & Hill, 2009; Hill, Ball, & Schilling, 2008; Silverman & Thompson, 2008).
We turn to a detailed example from calculus, that illustrates the web of considerations that teachers should be able to employ – some more general, and some very specific and detailed. We then move to a report on teachers' actual thinking and experiences related to this example.

An analysis of the design process of a task for students

Initial Assumptions and Decisions

As the first step of the design process, aimed at introducing the concept of derivative, we adapted a generic task that relies on students' prior experiences with Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
643
function value tables. Variations of this type of task can be found in some textbooks. The structure of the task that we developed is presented in Figure 1. Note that we build on students' prior experience in using symmetrical tables for sketching graphs. To turn this into a task for students, a teacher would need to choose the specific function f.
The next level of design requires a choice of the type of function f that would be used for this task. It makes sense to use a cubic function, assuming students do not have any prior image of how the graph of a cubic function should look. Choosing a quadratic function for this purpose would not be equally appropriate for the stated goal, as the behaviour of its graph can be deduced by other considerations (e.g., symmetry). Actually, it is possible to sketch a rather accurate graph of any quadratic function with the use of a table and the special symmetrical properties of the function (that is one of the reasons that many secondary mathematics curricula include the quadratic function as part of algebra while the cubic function is part of calculus). We assume that after dealing with quadratic functions, students are familiar with the concept of an extreme point of a function, at least at an intuitive level. At this stage, by an accurate sketch of a graph of a function we mean a graph that captures all its extreme points, as well as its increasing and decreasing domains (clearly, moving further on, we can increase the accuracy, by detecting inflection points and concave and convex domains as well. At that stage, a similar approach can be applied to the introduction of the second derivative).
Figure 1: A generic task for students aimed at evoking some limitations of a function value table
The teachers with whom we worked, who had not experienced careful design considerations before, maintained that any cubic function could serve equally well for this task. However, this level of design calls for more refined considerations. In other words, once we decided to use a cubic function of the form: f(x)=ax
3
+bx
2
+cx+d, a≠0,
the question remained: what specific values would be good to choose for the

parameters a,b,c,d given the goals of the task? This level of detail is not commonly Theme E – G. Ron, O. Zaslavsky & I. Zodik
644
addressed and was completely unfamiliar to all the teachers in our study. We turn to
the description of some of these refined considerations.
What specific function should we choose?
For brevity, we present only part of the web of considerations that could and
should be employed. After several deliberations and iterations, we presented teachers
with the following three possible functions that could serve for the task (Figure 2).
(1) (2) (3)
Figure 2: Three cubic functions to consider for the generic task for students
All three functions belong to the following sub-set of cubic functions:
f(x)=ax
3
+cx+d, a≠0. This choice was guided by our knowledge of the properties of
such functions. In particular, we considered the following two properties significant
from a design standpoint:
1. Although the function is not linear, its specific parameters should give
students, at first, the (wrong) impression that it is linear, when they
use familiar tools.
All three functions have an inflection point on the y-axis.
For all of them, any choice of symmetrical values for the table, of the form
x=-k, 0, k (k≠0), results in 3 co-linear points on the graph that could create
an illusion of linearity for students who complete the first function-value
table in Figure 1.
2. The graph of the function should be 'manageable' for students to
sketch, in the sense that the parts containing critical points can fit
easily in a regular notebook page.
For all three functions, the critical values to which students need to pay
attention are small enough so that the graphs can be sketched in students'
notebooks in a homogenous coordinate system; no need to worry about
scaling. The possibility of sketching the graphs in a homogenous
coordinate system eliminates distractions by technical aspects of graphing.
f x)(x 3x
3
= −)(2 1
3
f x = x − x +)(2 5.1 1
3
f x = x − x +Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
645
Moreover, being able to sketch the graphs in a homogenous coordinate
system is important in the context of developing the initial notion of
derivative, so that examining the slopes at different points on the graph can
be done visually without the need for any calculations.
Figure 3 presents an analysis of the three functions, from mathematical and
pedagogical perspectives. It conveys the complexity of considerations surrounding the
choice of a specific function for the task (in Figure 1). It raises the difficulty to
recommend one answer to the question: Which function (of the three) should we use
for the above task? The answer depends amongst others on the level of the students,
and on the teacher's goals and intentions beyond this task.
(1) (2) (3)
The function has 3
intersection points with the xaxis, all of which can easily be
found algebraically.
• For strong students, this may
not be a good choice, since
they could immediately see a
way to detect the entire
behavior of the graph by
solving the equation: x
3
-3x=0
and making intuitive
inferences.
• For weaker students, who are
not likely to be able to solve
this equation, it could be
better to begin by asking
them to find where the
function is positive and
where it is negative. This
builds on what they are able
to do, and the need for new
tools arises when asked about
extreme points of the
function.
• Choosing this function for
the task can be an advantage
if the teacher intends to use it
later to illustrate a full
analysis of the graph of a
function that includes finding
the (exact) intersection points
with the axes.
• In terms of the goal of the
task, the fact that the extreme
points are detected by the
function value table may
leave students with the
impression that there is no
real need for new tools.
At this stage, students have
no way to find the
intersection point of the
function with the x-axis.
• An advantage for choosing
this function is that students
are not likely to anticipate
that there are extreme points,
thus, this finding will
surprise them and reinforce
the need for new tools.
• Although this function can
serve to raise the need for
new tools, it would not be a
good one for illustrating later
a full investigation of the
graph of the function that
includes finding the extreme
points of the function.
• An advantage of this function
is that students are not likely
to find the extreme points by
checking various (arbitrarily
chosen) values in the table,
as the x-coordinates of the
extreme points are irrational.
Using the values -1,0,1 (or
actually any table with just
integers) gives the impression
that the function is an
increasing function.
• This may help achieve the
goal of the task.
• This function lends itself to a
gradual realization of its
properties: first students see
that it is not linear, then -
that it is not an increasing
function, and later - that
points that seem as extreme
points are not.
At this stage, students have
no way to find the
intersection point of the
function with the x-axis.
• An advantage for choosing
this function is that students
are not likely to anticipate
that there are extreme points,
thus, this finding will
surprise them and reinforce
the need for new tools.
The x-coordinates of the
extreme points are rational
numbers that can easily be
detected when extending the
values in the table (to halves).
• An advantage of this function
is that the values in the
extended table are all
integers (or other easy-tohandle numbers); this makes
the calculations easier and
reduces distractions that
complicated calculations may
cause.
• In terms of the goal of the
task, the fact that the extreme
points are detected by the
function value table may
leave students with the
impression that there is no
real need for new tools.
Using the values -1,0,1 (or
actually any table with just
integers) gives the impression
that the function is a
decreasing function.
• This may help achieve the
goal of the task.
f x)(x 3x
3
= −)(2 1
3

Figure 3: An analysis of the three cubic functions under consideration
In terms of teacher education and teacher knowledge, it is not about finding
the right function, but about helping teachers make judicious decisions that are based
on careful analysis of affordances and limitations that are entailed in the choice of a
specific function. Yet, weighing all the considerations for each of the three functions
(Figure 3), it seems that all round function (2) may be more advantageous than the
other two.
Teachers thinking about the design of such tasks
The setting and research instrument
A group of experienced secondary mathematics teachers were given a written
questionnaire, in two parts. Some were also interviewed about their responses. The
first part of the questionnaire presented the task (Figure 1) with function (2), and
prompted teachers to examine the merits of this task, analyse its advantages and
disadvantages, and reflect on their own practice with respect to the use of similar
tasks that have the same goals. This part of the questionnaire also included a question
about desirable considerations the teachers would (or actually do) take into account
when choosing a function for this or for a similar task.
For the second part of the questionnaire we collected the considerations
teachers wrote in the first part, and prepared a list of these considerations; for each
consideration the teachers were asked to state whether they agree that it is desirable
and why. In addition, we had conversations with some of the teachers, to better
understand their thinking.
Main findings
Most of the teachers' responses indicated that they had not come across such
subtle considerations prior to our study. The questions evoked their awareness to the
need to address the issue of limitation of a table for sketching graphs of functions in a
more sophisticated and rich way than they encountered both in their practice and in
professional development frameworks.
The considerations the teachers suggested included properties of a function
that they thought would make it a good choice for the task, e.g.: 'a function that is
unfamiliar to the students'; 'a function with more than one extreme point'; 'a function
that is not symmetrical'; 'a function that is not special'; 'a function that the
coordinates of its extreme points do not appear in the table'; 'a function for which it is
hard to detect immediately its intersection points with the x-axis and thus its extreme

points cannot be inferred instantly'. Interestingly, none of the teachers mentioned at
all consideration 1 and 2 above, which could be viewed as critical.
There were teachers who stated that they do not use such tasks (as the one in
Figure 1 above). The main claim was that although this is a significant activity,
curriculum constraints do not permit spending time on such a task. Some maintained
that it is sufficient to build on students' (drill and) practice, because when you
practice enough problems with derivatives, then students gain understanding that the
derivative is zero at an extreme point. Clearly, this implies that for some teachers the
necessity principle is not part of their thinking.
Several teachers claimed that they rely on textbooks and that it does not
matter what function is chosen. The three specific examples (of the cubic functions)
in our study appeared to most teachers the same, for the purpose of the task; analysing Margolinas, C. (Ed.). (2013). Task Design in Mathematics Education. Proceedings of ICMI Study 22 . Oxford.
647
the subtle differences and how they impact the task was totally new to them. Through
drawing their attention to the differences between the three functions in terms of their
specific affordances in addressing the goal of the task, and to the merits and
limitations of each example in terms of its learning potential for their students, they
felt they were able to make more judicious pedagogical decisions/choices, while
before - they were not aware of or able to see such distinctions.
Conclusion
The mathematical and pedagogical analysis presented above point to the
wealth and complexity of considerations underlying what teachers' decisions with
respect to task design for their students could and should be, in general, and for tasks
that address the need for advanced tools for sketching graphs, in particular. Based on
some empirical evidence, our study establishes the need to work with teachers in
ways that develop and expand their pedagogical toolbox and encourage them to build
on it when they design and make choices regarding specific tasks for certain purposes.
In this paper we focused on the purpose to establish the need to expand new tools.
This approach can be applied to other purposes and topics. While the scope of the
study may seem narrow, it can be generalized, to other similar situations (e.g., other
tools/concepts that need to be introduced) as well as to a more general level that deals
with working with teachers on the significant of choice of the specific examples for a
task, or in other words - how going into details could make a huge difference.
One of the goals of teacher education is to prepare teachers to consider
alternatives (Zaslavsky and Sullivan, 2011). We view task design as a fruitful site for
considering alternatives. It is not enough to support a specific choice. There is value
in considering other possible choices, and by that - crystalizing and refining the
criteria for such choices.
The approach we describe moves from finding the 'right' choice to realizing
that it is a give and take situation. Each choice has its merits and its limitations.
Articulating these merits and limitations is part of what teachers should experience
and what teacher education programs should foster.

the theory of realiStic
mathematiCS education
Paul Cobb, Qing Zhao &Jana Visnovska,
Vanderbilt University
Abstract: This article focuses on the critical role of design theory in our work as mathematics educators. We give
particular attention to a specific design theory, Realistic Mathematics Education (RME). We first clarify the enduring
contributions of RME to design in mathematics education and then discuss three adaptations that we made to RME
theory while conducting a series of classroom design experiments. The first of these adaptations involves taking a broader
perspective on the means of supporting students' mathematical learning to include both the organization of classroom
activities and the nature of classroom discourse. The second adaptation involves a change in orientation that acknowledges
the mediating role of the teacher. The goal of instructional design then becomes to develop resources that teachers can
use to achieve their instructional agendas rather than to support students' learning directly. The third adaptation again
centers on the teacher and concerns the potential contribution of designed instructional resources as a means of supporting
teachers' as well as students' learning.
Keywords: design research, instructional design, design theory, Realistic Mathematics Education, mathematics teaching
and learning.

Our focus in this article is on the critical role that
design theory has played in our work as mathematics
educators. To ground the discussion, we give particular attention to a specific design theory that we found
especially useful in our work over the past 15 years,
Realistic Mathematics Education (RME) developed
at the Freudenthal Institute in the Netherlands. We
first outline the type of research in which we engaged
when we first began to appropriate ideas from RME
design theory. Against this background, we clarify
the significance that we attributed to RME theory at
that time and then move to the present in order to
discuss our current views of the contributions of this
design theory. In the second part of the paper, we
focus on three adaptations we have made to RME
theory as our theoretical position and research interests have evolved over time. The first of these adaptations involves a broadening of our perspective on the
means of supporting students'mathematical learning
to include both the organization of classroom activities and the nature of the classroom discourse. The
second adaptation involves a shift in our orientation
as instructional designers such that our goal when
developing sequences of instructional activities is
no longer to support individual students' learning
directly. We now consider the mediating role of the
teacher as crucial and view ourselves as developing
resources for teachers to use to achieve their instructional agendas. The third adaptation again centers on
the teacher and concerns the potential contribution
of instructional sequences as a means of supporting
teachers' as well as students' learning.
the contributions of rme
RME is rooted in Freudenthal's (191 ;
193) interpretation of mathematics as a human
activity. In Freudenthal's view, students should be
given the opportunity to reinvent mathematics by
organizing or mathematizing either real world situations or mathematical relationships and processes
that have substance for them. In developing this
position, Freudenthal emphasized that the material
students are to mathematize should be real for them.
It is for this reason that approach is called Realistic
Mathematics Education. Freudenthal considered 106
leArning FroM And AdAPting the theory oF reAlistic MAtheMAtics educAtion
Paul Cobb, Qing Zhao &Jana Visnovska
mathematizing to be the key process in mathematics
education for three reasons. First, mathematizing is
a major activity of mathematicians. Second, mathematizing fosters applicability by familiarizing
students with a mathematical approach to everyday
settings. Third, mathematizing relates directly to
the idea of reinvention, a process in which students
formalize their informal understandings and intuitions. Freudenthal argued with considerable force
that mature, conventional symbolizations should
not be taken as the instructional starting point. He
was particularly critical of this practice and termed
it an anti-didactic inversion because the process by
which the mathematicians developed mathematics
is turned upside down (Freudenthal, 193). For
Freudenthal and for researchers and instructional
developers who subsequently elaborated his ideas,
the goal of mathematics education should be to
support students' mathematical learning as a process
of guided reinvention.
Positive Heuristics for Instructional Design
To provide a context for the subsequent discussion, we first outline the type of research we were
conducting at the time that we became aware of RME
and began to focus explicitly on issues of instructional design. This research involved conducting a
series of year-long design experiments in US secondgrade and third-grade classrooms with seven- and
eight-year-old children. One of our goals in conducting these experiments was to extend the constructivist teaching experiment methodology developed
by Steffe and his colleagues to the classroom (Cobb
& Steffe, 1983; Steffe, 1983; Steffe & Kieren, 1994;
Steffe & Thompson, 2000). In a constructivist
teaching experiment, the researcher typically interacts with a small number of students one-on-one
and attempts to precipitate their learning by posing
judiciously chosen tasks and by asking follow up
questions, often with the intention of encouraging
the student to reflect on his or her mathematical activity. The immediate purpose when interacting with
the participating students is to study the process by
which they reorganize their mathematical reasoning.
The larger purpose when conducting a retrospective
analysis of the teaching sessions is to develop conceptual models composed of theoretical constructs that
can be used to account for the mathematical learning of other students (P. W. Thompson & Saldanha,
2000). As a consequence, although the researcher
acts as a teacher when conducting an experiment
of this type, the primary emphasis is psychological
and centers on the analysis of students'mathematical
reasoning. The development of instructional designs
is, in contrast, of secondary importance.
Our primary focus when we extended this methodology to the classroom remained consistent with
Steffe's emphasis on developing explanatory theoretical constructs rather than on formulating instructional designs. In particular, we gave priority to the
development of an interpretive framework that would
enable us to situate students' mathematical learning
within the social context of the classroom (cf. Cobb
& Yackel, 1996). This was the case even though

we had developed a complete set of instructional
activities during a design experiment conducted
in a second-grade classroom. Constructivism and
the related theories on which we drew provided us
with a number of negative heuristics that ruled out
a range of approaches to instructional design. For
example, we rejected what Treffers (198) termed
structuralist approaches to design in which physical
materials and graphics are developed that, for the
adult, embody the mathematical relationships that
are the target of instruction. However, the positive
heuristics that guided our development of instructional activities were global in nature. For example,
the constructivist perspective to which we subscribed
at that time oriented us to view mathematical learning as an activity in which students reorganize their
activity to resolve situations that they experience
as problematic. The instructional activities that we
developed were therefore designed to give rise to a
range of mathematical problems as students interpreted the activities at a variety of levels of sophistication. We also drew on neo-Piagetian analyses
of social interactions (Doise & Mugny, 199) and
viewed classroom social interactions as a potential
means of supporting students' progressive reorganization of their mathematical reasoning. In particular,
we conjectured that interactions in which conflicts in
students' interpretations became apparent would give
rise to learning opportunities for them, and that they
might reorganize their reasoning as they resolved
these interpersonal conflicts. As a consequence, the
structure of classroom activities in the second- and
third-grade design experiments involved the students leArning FroM And AdAPting the theory oF reAlistic MAtheMAtics educAtion
Paul Cobb, Qing Zhao &Jana Visnovska
10
first working in pairs to complete instructional activities and then participating in whole-class discussions
of their interpretations and solutions.
It was not until we first began to learn about RME
theory that we came to realize that our attempts at
instructional design were, in comparison, inadequate and that we needed to develop a more systematic approach. Our interest in RME design theory
was first inspired by Adrian Treffers's (198) book,
Three dimensions: A model ofgoal and theory description in mathematics instruction - The Wiskobas Project.
Treffers's intent is this book was primarily theoretical
in that he schematized two decades of instructional
design work and classroom experimentation, in the
process teasing out a number of positive heuristics
for instructional design in mathematics. Against the
background of our research at the time, the design
heuristics that Treffers illustrated by describing
several instructional sequences were a revelation.
It was apparent from Treffers's account that RME
was a detailed, empirically grounded design theory
that was compatible with our constructivist perspective on mathematical learning. For example,
RME's basic tenets of mathematics as a human activity and of mathematical learning as the progressive
reorganization of activity were both consistent with
our general viewpoint. In addition, we valued the
manner in which RME placed students' mathematical reasoning at the center of the design process
while simultaneously proposing the specific means
by which the development of their reasoning could
be systemically supported. Furthermore, Treffers's
account of RME clarified that the purpose for
conducting design experiments was not limited to
developing explanatory constructs, but could also
include developing, testing, and revising instructional sequences.
These insights led us to realize that we had
attempted to study students' mathematical learning in situations in which we had not necessarily
provided adequate supports for learning. The design
decisions that Treffers illustrated served to emphasize a relatively fine-grained level of detail that
had been absent in our prior work. The types of
design decisions that we especially noted included
both the careful selection of the problem situations
that were used during the first part of an instructional sequence and the explicit attention given to
the design of non-standard notation schemes as a
means of supporting students' reorganization of
their mathematical activity. In addition to taking
account of specific aspects of RME theory, we also
learned an important methodological lesson from
Treffers's presentation. The heuristics on which we
had relied were relatively global in nature because
we had derived them from a general background
theory. In contrast, the specific design heuristics
that Treffers outlined had emerged from and yet
remained grounded in the activities of designing
and experimenting in classrooms.
As these reflections make clear, there was much
that we could learn by becoming familiar with the
general orientation to design inherent in RME.
However, we were also aware that RME cannot be
reduced to a set of heuristics. It is a sophisticated set
of practices that have been developed by a community of designers and researchers over an extended
period of time. Gravemeijer (1994) clarifies why the
process of developing and revising designs in the
RME tradition cannot, in principle, be completely
codified. In reflecting on his activity as an instructional designer, Gravemeijer argues that designer's
activity resembles that of a bricoleur:
A bricoleur is a handy man who invents pragmatic
solutions in practical situations…[T]he bricoleur
has become adept at using whatever is available. The
bricoleur's tools and materials are very heterogeneous:
Some remain from earlier jobs, others have been
collected with a certain project in mind. (p. 44)
From the sociocultural perspective, this is an
excellent characterization of creativity and invention
(cf. Cole, 1996). Novelty and originality are seen to
be historically and culturally situated from this perspective and to involve the adaptation and reconfiguring of resources from a range of disparate practices
(cf. Emirbayer & Mische, 1998 ; Holland, Skinner,
Lachicotte, & Cain, 1998 ; Varenne & McDermott,
1998). Inspired by Gravemeijer's characterization
of design, we have in fact described our own efforts
to develop theoretical constructs that enable us to
situate students' mathematical learning within the
social context of the classroom as a process of bricolage in which we drew on and adapted ideas from
a range of theoretical sources for pragmatic ends
(Cobb, Stephan, McClain, & Gravemeijer, 2001).108
leArning FroM And AdAPting the theory oF reAlistic MAtheMAtics educAtion
Paul Cobb, Qing Zhao &Jana Visnovska
This portrayal of RME as an evolving set of
interrelated practices implies that it is one thing to
attempt to understand a particular approach to design
by reading about it and quite another to engage
competently in the process of developing designs. As
a consequence of reading books by leading contributors to RME (e.g., Gravemeijer, 1994 ; Streefland,
1991 ; Treffers, 198), we became reasonably proficient at commentating on the design theory. However,
we had to co-participate in the process of formulating, testing, and revising designs before we became
able to develop adequate designs for supporting
students' mathematical learning. In this regard, an
ongoing collaboration with Koeno Gravemeijer in the
course of which we developed several instructional
sequences proved to be crucial. With hindsight, we
view our collaboration with Gravemeijer as a process
of apprenticeship in which we were legitimate peripheral participants in the RME research community
(cf. Lave & Wenger, 1991). In the course of this
apprenticeship, we consciously adapted several of the
ideas that we appropriated from RME while pursuing
a number of other interests. In the remainder of this
article, we first step back from our personal involvement in RME to consider its enduring contributions
to design in mathematics education and then discuss
three of these adaptations.
enduring Contributions
In our view, RME theory makes an enduring
contribution to mathematics education by offering
a viable solution to a long-standing problem that
was first delineated by John Dewey. In contemporary accounts, Dewey is frequently characterized
as a strong advocate of open-ended, project-based
approaches to instruction. It is true that Dewey
condemned the predominant instructional practice of
his day that promoted rote learning at the expense of
a deep understanding of disciplinary ideas. However,
as Prawat (1995) documents, Dewey was equally
critical of unstructured project-based approaches
in which students are encouraged to pursue their
own interests (Westbrook, 1991). He argued that
these two general instructional approaches constitute opposite poles of a dichotomy between disciplinary content on the one hand and students' current
understandings and interests on the other. A primary
goal of both his educational philosophy and his work
at the Laboratory School that he established at the
University of Chicago was to transcend this dichotomy. In this regard, he anticipated a central issue
with which mathematics educators continue to
struggle. Ball (1993) articulated this issue succinctly
when she asked:
How do I [as a mathematics teacher] create
experiences for my students that connect with what
they now know and care about but that also transcend
the present? How do I value their interests and also
connect them to ideas and traditions growing out of
centuries of mathematical exploration and invention?
(p. 35, italics in the original)
The originality of the solution proposed by
RME stems from the manner in which this perennial problem is reframed. For RME designers, the
challenge is not that of directly connecting students'
understandings and interests with the ideas of the
discipline. Instead, it is to support the progressive
development of students' mathematical reasoning so
that they can eventually participate in established
mathematical practices that have grown out of
centuries of exploration and invention. The metaphor inherent in the RME approach is that of continually building up towards substantial participation in
established mathematical practices rather than that
of attempting to directly connect or bridge between
students' current understandings and the established
mathematical ideas and traditions that constitute
students' intellectual inheritance.
This orientation has become routine for RME
designers and is captured by three central tenets of
the design theory. The first of these tenets is that the
starting points of an instructional sequence should
be experientially real to students in the sense that
they can immediately engage in personally meaningful mathematical activity (Gravemeijer, 1990 ;
Streefland, 1991). For the designer, the immediate
goal is that students' interpretations and solutions
should lead to the development of informal ways of
speaking, symbolizing, and reasoning across a range
of initial instructional activities. Treffers (198) calls
this process of negotiating and generalizing informal
solution processes horizontal mathematization.
Thompson (1992) indicates the significance of this
first tenet from a constructivist perspective when he
observes that "if students do not become engaged leArning FroM And AdAPting the theory oF reAlistic MAtheMAtics educAtion
Paul Cobb, Qing Zhao &Jana Visnovska
109
imaginistically in the ways that relate mathematical
reasoning to principled experience, then we have
little reason to believe that they will come to see
their worlds outside of school as in any way mathematical" (p. 10). This tenet is also consistent with
recommendations derived from investigations that
have compared and contrasted mathematical activity
in the classroom with that in out-of-school situations (e.g., de Abreu, 2000; Masingila, 1994; Nunes,
Schliemann, & Carraher, 1993; Saxe, 1994).
The second central tenet is that in addition to
being experientially real to students, the starting
points should also be justifiable in terms of the
potential end points of the learning sequence. This
implies that the informal ways of speaking, symbolizing, and reasoning established during the initial
phase of an instructional sequence should constitute
a basis for a progressive process of vertical mathematization. However, as Treffers makes clear, students'
increasingly sophisticated mathematical reasoning
does not become decoupled from the starting point
situations in this process. Instead, these situations

should continue to function as paradigm cases to
which students can fold back (Pirie & Kieren, 1994),
thereby anchoring their reasoning. This latter requirement is consistent with analyses that emphasize
the important role that analogies (Clement & Brown,
1989) and metaphors (Dörfler, 2000; Presmeg, 199)
play in mathematical activity.
The third tenet focuses on the means of supporting the process of vertical mathematization and it is
here that the general approach of building up towards
substantial participation in established mathematical
practices becomes evident. One of the primary means
of support involves activities in which students create
and elaborate symbolic models of their informal
mathematical activity. This modeling activity might
involve making drawings, diagrams, or tables, or
it could involve developing informal notations or
using conventional mathematical notations. This
third tenet is based on the conjecture that, with the
teacher's guidance, students' models oftheir informal
mathematical activity can evolve through use into
models for more general mathematical reasoning
(Gravemeijer, 1999; Gravemeijer, Cobb, Bowers, &
Whitenack, 2000). This transition involves a shift
such that ways of symbolizing initially developed to
mathematize informal activity subsequently come
to support more general mathematical activity in a
range of situations. In practice, the approach of building up from students' initial informal activities to
conventional ways of symbolizing involves both the
judicious selection of instructional activities and the
negotiation of successive ways of symbolizing. As
part of this process, the teacher attempts to achieve
his or her instructional agenda by capitalizing on
students' contributions and by introducing ways of
symbolizing that fit with their reasoning at particular
points in an instructional sequence.
This third tenet of RME is consistent with Sfard's
(1991 ; 1994) historical analysis of several mathematical concepts including number and function
(cf. Gravemeijer et al., 2000). Sfard contends that
the historical development of mathematics can be
seen as a long sequence of reifications, each of which
involves the transformation of operational or process
conceptions into object-like structural conceptions.
She argues that the development of ways of symbolizing has been integral to the reification process.
However, she is also careful to clarify that it is the
process of reasoning with symbolizations, not the
symbolizations themselves, that are reified during a
model-of to model-for transition. This emphasis on
activity serves to differentiate approaches based on
RME from approaches that involve a so-called modeling point of view (e.g., Lesh & Doerr, 2000). In these
latter approaches, a model is considered to capture
mathematical structures or relationships inherent in
starting point situations. In contrast, models as they
are characterized in RME originate from students'
ways of acting and reasoning with tools and symbols
in the starting point situations. Although this distinction is subtle, it has important implications for design
in that the focus is on students' anticipated interpretations and solutions rather than on the features of
instructional activities per se.
The attention that RME designers give to the development of ways of symbolizing suggests a possible
point of contact with Vygotsky's cultural-historical
theory of development. Semiotic mediation and the
use of cultural tools such as mathematical symbols
constitutes one of the two mechanisms that Vygotsky
contended drives conceptual development, the other
being interpersonal relations (Davydov, 1995; van
der Veer & Valsiner, 1991 ; Vygotsky, 198). The
differences between RME and Vygotskian approa-110
leArning FroM And AdAPting the theory oF reAlistic MAtheMAtics educAtion
Paul Cobb, Qing Zhao &Jana Visnovska
ches center on the contrast between the metaphors
of building up towards substantial participation in
established mathematical practices and of connecting
students' current understandings with established
mathematical ideas. In Vygotskian theory, learning
in instructional situations is viewed as a process of
transmitting mathematical meaning from one generation to the next. Within this perspective, symbols are
sometimes called carriers of meaning and are treated
as primary vehicles of the enculturation process (van
Oers, 1996). This formulation does not, of course,
imply a crude transmission view of communication. Instead, the fundamental claim is that students
develop particular mathematical conceptions as they
learn to use conventional symbols while engaging in
particular sociocultural activities (Davydov, 1988). In
this scheme, the teacher's role is frequently characterized as that of relating students' personal meanings
to the cultural meanings inherent in the appropriate
use of conventional symbols. The teacher's role
might therefore be characterized as that of introducing conventional means of symbolizing and relating
them to students' mathematical activity (cf. Davydov
& Radzikhovskii, 1985; Tharp & Gallimore, 1988).
In contrast to the sociocultural framing of
instructional design as the transmission of mathematical meaning from one generation to the next, RME
designers frame the fundamental design challenge
as that of supporting the emergence of mathematical meaning in the classroom. This orientation is
apparent in both the means of symbolizing developed
in the classroom and in the characterization of the
teacher's role. As is the case in Vygotskian approaches, RME acknowledges that the teacher is an institutionalized authority in the classroom. Further, the
teacher might, on occasion, express this authority in
action by introducing means of symbolizing as he or
she redescribes students' contributions. However, it
is apparent from the third tenet of RME that these
means of symbolizing are not restricted to conventional mathematical symbols. Instead, the designer
draws on both historical analyses and analyses of
students' informal mathematical reasoning to invent
means of symbolizing that students, at a particular
point in their development, might see as reasonable to
use to achieve their mathematical goals (Gravemeijer,
1994). The resulting instructional sequences therefore involve the establishment of non-standard
means of symbolizing that are designed both to fit
with students' informal activity and to support their
development of more sophisticated forms of mathematical reasoning. These means are, in effect, offered
to students as resources that they might use as they
solve problems and communicate their thinking. In
this approach to design, symbolic means are developed to support students' progressive reconstruction
of cultural meanings (Gravemeijer, 1994).
adaptations
We now consider three adaptations we have made
that build on the RME approach to design. In doing
so, we draw on a recently completed classroom design
experiment that focused on the teaching and learning
of statistical data analysis at the middle school level.
We give an overview of the design experiment as we
discuss the first adaptation that involves broadening
our perspective on the means of supporting students'
mathematical learning. As we illustrate, this broader
perspective enables us to view classrooms as activity
systems that are designed to support the participating
students' learning of significant mathematical ideas.
Classrooms as Activity systems
Background to the design experiment
The design experiment on which we will focus
was conducted in a US seventh-grade classroom with
29 12-year-old students and focused on the analysis
of univariate data. The experiment, which was
conducted in collaboration with Koeno Gravemeijer
and Erna Yackel, lasted 12 weeks and involved 34
classroom sessions of approximately 40 minutes in
duration. A member of the research team1
served
as the teacher throughout the experiment. As part
of the process of preparing for the experiment, we
identified both the instructional starting points and
prospective endpoints. The interviews and whole
class performance assessments that we conducted
to determine the starting points indicated that, for
most of the students, data analysis involved "doing
something with the numbers" by manipulating
them in a relatively procedural manner (McGatha,
Cobb, & McClain, 2002). For example, many of
the students simply calculated mean of every data leArning FroM And AdAPting the theory oF reAlistic MAtheMAtics educAtion
Paul Cobb, Qing Zhao &Jana Visnovska
111
set when attempting to solve each task posed irrespective of whether the mean would give them useful
insights into the problem. Our analysis of these interviews indicated that the students did not view data
as measures of aspects or features of a situation that
had been generated in order to understand a phenomenon or make a decision. We concluded from these
assessments that our immediate goal should be to
influence the students' beliefs about what it means to
do statistics in school such that they would begin to
analyze data in order to address a significant question
rather than simply perform calculations and follow
conventions for drawing specific types of graphs.
The identification of prospective instructional
endpoints involved delineating what Wiggins and
McTighe (1998) term the "big ideas" that are at the
heart of a discipline, that have enduring value beyond
the classroom, and that offer potential for engaging students. The overarching statistical idea that
emerged from our synthesis of the research literature
and our analysis of the interviews and classroom
performance assessments was that of distribution.
One of primary goals for the design experiment was
therefore that the students would come to view data
sets as entities that are distributed within a space
of possible values (Hancock, Kaput, & Goldsmith,
1992 ; Konold & Higgins, 2002; Konold, Pollatsek,
Well, & Gagnon, 199 ; Wilensky, 199). In the
approach that we planned to take, notions such as
center, spread-outness, skewness, and relative density
would then emerge as ways of characterizing how
specific data sets are distributed within this space of
values (Bakker & Gravemeijer, 2004; Cobb, 1999 ;
McClain, Cobb, & Gravemeijer, 2000). Furthermore,
various statistical graphs or inscriptions would
emerge as ways of structuring data distributions in
order to identify relevant trends or patterns. Thus,
consistent with the third tenet of RME, we viewed
the students' development of increasingly sophisticated ways of reasoning about data as inextricably
bound up with their development of increasingly
sophisticated ways of inscribing data (Biehler, 1993;
deLange, van Reeuwijk, Burrill, & Romberg, 1993 ;
Lehrer & Romberg, 1996).
Interviews that we conducted with the 29 students
shortly after the design experiment was completed
indicate that we had some success in achieving
these goals. The interviews included tasks in which
the students were asked to compare graphs of two
unequal data sets that corresponded to histograms
and to box-and-whiskers plots. A significant majority
of the students did so by developing relatively sophisticated arguments that involved reasoning about the
data in terms of relative rather than absolute frequencies. In this regard, Konold et al. (199) argue that
a focus on the rate of occurrence (i.e., the relative
frequencyl of data within a range of values is at the
heart of what they term a statistical perspective. As
the arguments that most of the students formulated
in the interviews involved comparing the graphs
in terms of the proportion of data within various
ranges of values, it would seem that they were in the
process of developing this statistical perspective. It
is also worth noting that when we began a follow-up
design experiment with some of the same students
nine months later, there was no regression in their
statistical reasoning (Cobb, McClain, & Gravemeijer,
2003). The students' progress at the beginning of this
follow-up experiment was in fact such that they could
all interpret graphs that corresponded to histograms

and to box-and-whiskers plots in these relatively
sophisticated ways within the first three or four class
sessions of this follow-up experiment.
The retrospective analyses that we have conducted
of the design experiment to account for the process
of the students' learning and the means by which
it was supported highlighted the important role of
the instructional activities and the tools the students
used to analyze data sets. However, these analyses
also indicate the importance of two means of support
that are not typically considered by instructional designers. These additional means of support concern the
organization of classroom activities and the nature of
the classroom discourse (Cobb, 1999; McClain et al.,
2000).
Instructional activities
One of the primary commitments that we made
when we developed the instructional activities
was that students' activity in the classroom should
involve the investigative spirit of data analysis from
the outset. This implied that the instructional activities should involve analyzing data sets that the
students viewed as realistic for purposes that they
considered legitimate. As a consequence, most of the 112
leArning FroM And AdAPting the theory oF reAlistic MAtheMAtics educAtion
Paul Cobb, Qing Zhao &Jana Visnovska
instructional activities that we developed involved
comparing two data sets in order to make a decision
or judgment (e.g., analyze the T-cell counts of AIDS
patients who had enrolled in two different treatment
protocols). From the midpoint of the experiment,
the students were also required to write reports of
their analyses for a specified audience (e.g., the chief
medical officer of a hospital in the case of the AIDS
data). This requirement reflected the observation that
data are typically analyzed with a particular audience
in mind almost everywhere except in school (cf.
Noss, Pozzi, & Hoyles, 1999).
Tools
The students used two computer tools that were
introduced sequentially during the experiment to
analyze data sets and thus complete the instructional
activities. As these tools have been described extensively elsewhere (e.g., Bakker & Gravemeijer, 2003;
Cobb, 2002; McClain, 2002), it suffices to note that
they provided the students with a variety of options
for organizing graphical inscriptions of data sets. Our
intent in designing the tools was that they should
fit with the students' reasoning when they were first
introduced and that they should support the reorganization of that reasoning as the students used them.
Consistent with RME's focus on students' activity,
we did not attempt to build the statistical ideas we
wanted the students to learn into either the instructional activities or the computer tools in the hope that
they might come to see them. Instead, we focused
squarely on how the students' use of the tools would
change the nature of their activity as they analyzed
data and thus the types of statistical reasoning that
they might develop.
Organization ofclassroom activities
In considering the third means of support, the
organization of classroom activities, we began to
broaden our purview beyond the issues that typically
concern instructional designers. One of goals when
planning the organization of classroom activities was
to ensure that the students would come to view data
as measures of an aspect of a phenomenon rather
than merely as numbers relatively early in the design
experiment. To this end, the teacher introduced each
instructional activity by talking through the data
generation process with the students. These conversations often involved protracted discussions during
which the teacher and students together framed the
particular phenomenon under investigation (e.g.,
AIDS), clarified its significance (e.g., the importance
of developing more effective treatments), delineated
relevant aspects of the situation that should be
measured (e.g., patients' T-cell counts), and considered how they might be measured (e.g., taking
blood samples). The teacher then introduced the data
the students were to analyze as being generated by
this process. The resulting organization of classroom
activities, which often spanned two or more class
sessions, therefore involved (a) a whole-class discussion of the data generation process, (b) individual or
small-group activity in which the students usually
worked at computers to analyze data, and (c) a
whole-class discussion of the students' analyses.
In organizing the classroom activities in this
manner, we conjectured that as a consequence of
participating in the discussions of the data generation process, data sets would come to have a history
for the students such that they reflected the interests
and purposes for which they were generated (cf.
Latour, 198 ; Lehrer & Romberg, 1996; Roth, 199).
As it transpired, this conjecture proved to be well
founded. On the first instructional activity in which
the students used a computer tool to analyze data,
approximately half of the students calculated means
by hand and selected the data set with the larger
mean. However, in the third instructional activity,
all the students used the computer tool to identify
differences in the data sets that gave insight into the
question they were investigating. We interpreted this
observation as indicating that doing statistics had
come to involve actually analyzing data within the
first week of the design experiment (Cobb, 1999 ;
McClain et al., 2000).
In accounting for the effectiveness of the data
creation discussions, it is important to note that the
teacher did not attempt to teach the students how
to generate sound data directly. Instead, she guided
the development of a classroom culture in which a
premium was placed on the development of databased arguments. This observation indicates that
the concluding whole class discussions in which the
students explained and justified their analyses also leArning FroM And AdAPting the theory oF reAlistic MAtheMAtics educAtion
Paul Cobb, Qing Zhao &Jana Visnovska
113
played a crucial role. It was as the students participated in these latter discussions that they first became
aware of the implications of the data generation
process for the conclusions that could legitimately
be drawn from data.
Our overriding concern as we prepared for these
discussions in the classroom was that mathematically
significant issues that advanced the instructional
agenda would became explicit topics of conversation.
To this end, the teacher and a second member of the
research team circulated around the classroom while
the students were working at the computers to gain
a sense of the various ways in which they were organizing and reasoning about the data. Towards the end
of the small-group work, they then conferred briefly
to develop conjectures about mathematically significant issues that might emerge as topics of conversation in the subsequent whole-class discussion. Their
intent was to capitalize on the students' reasoning by
identifying data analyses that, when compared and
contrasted, might give rise to substantive mathematical conversations. To the extent that the teacher
succeeded, students' participation in the discussions
would serve as primary means of supporting their
progressive reorganization of their reasoning and
thus their gradual induction into the values, beliefs,
and ways of knowing of the discipline.
We should clarify that our intent in giving these
illustrations from the statistics design experiment has
not been to argue that this particular organization of
classroom activities should be applied more generally.
The crucial contribution of the initial data generation
discussions would, for example, appear to be specific
to our focus on statistical data analysis. Instead, our
purpose has been to demonstrate the importance of
attending explicitly to the organization of classroom
activities as a primary means of supporting (or inhibiting) students' mathematical learning. In our view,
the organization of classroom activities is an integral
aspect of an instructional design.
Classroom discourse
In discussing the potential contribution of whole
class discussions, we stressed the importance of
ensuring that significant mathematical issues that
advance the instructional agenda emerge as topics
of conversation. The final means of support that we
identified when analyzing the statistics experiment
focuses on the nature of classroom discourse. To
clarify this means of support, we extend a distinction that Thompson and Thompson (1996) make
between calculational and conceptual orientations
in mathematics teaching by differentiating between
calculational and conceptual discourse. We should
stress at the outset that calculational discourse
does not refer to conversations that focus on the
procedural manipulation of conventional tools
and symbols whose use is a rule-following activity
for students. The solution methods that students
explain as they contribute to calculational discourse
might in fact be self-generated and involve relatively sophisticated mathematical understandings.
The contrast between calculational and conceptual
discourse should therefore not be confused with
Skemp's (196) well-known distinction between
instrumental and relational understandings. Instead,
the distinction concerns the norms or standards for
what counts as an acceptable mathematical argument. In calculational discourse, contributions are
acceptable if students describe how they produced
a result and they are not obliged to explain why
they used a particular method. In contrast to this
exclusive focus on methods or solution strategies,
the issues that emerge as topics of conversation in
conceptual discourse also include the interpretations
of instructional activities that underlie those ways of
calculating and that constitute their rationale.
As an illustration, the computer tool that the
students used to analyze the data on the two AIDS
treatment programs provided students with a variety
of options for organizing axis plot inscriptions of
the patients' T-cell counts (i.e., the T-cell counts for
each treatment were inscribed as dots located on
an axis of values). The least sophisticated of these
options involved dragging a bar to a chosen location
on the axis, thereby partitioning the data set into
two groups. As shown in Figure 1, the number of
points in each group was shown on the screen and
adjusted automatically as the bar was dragged along
the axis. A calculational explanation of an analysis
conducted to determine which treatment program
was more effective involves describing the specific
steps taken when conducting the analysis. For a relatively unsophisticated analysis in which the bar is
used to partition each data set, the students might 114
leArning FroM And AdAPting the theory oF reAlistic MAtheMAtics educAtion
Paul Cobb, Qing Zhao &Jana Visnovska
simply explain that they placed the bar at a particular value and then report the number of points
above and below this value in both data sets. As it so
happened, three of 14 groups of students conducted
analyses of this type. In each case, they placed the
bar so that what they called the "hill" in one of the
data sets was mostly below the bar, and the "hill" in
the other data set was mostly above the bar.
Experimental Treatment
Traditional Treatment
Figure 1. The AIDS Data Partitioned at T-cell counts of525leArning FroM And AdAPting the theory oF reAlistic MAtheMAtics educAtion
Paul Cobb, Qing Zhao &Jana Visnovska
115
A conceptual explanation of these solutions would
involve describing not merely the steps of the analysis
but also the reasons for carrying them given the issue
under investigation, that of judging the effectiveness of

the two treatment programs. In giving explanations of
this type, the students who participated in the design
experiment clarified that they placed the bar at a particular location in order to highlight and quantify a qualitative difference between the two data sets, the location
of the "hills." A retrospective analysis of video-recordings of all classroom sessions indicates that the interventions the teacher made to support conceptual explanations of this type also contributed to the students'
development of relatively sophisticated explanations
in which they compared data sets in terms of relative
rather than absolute frequencies (Cobb, 1999).
Our experiences in both this and a number of other
classroom design experiments lead us to conclude that
discussions in which the teacher judiciously supports
students' attempts to articulate their task interpretations
can be extremely productive settings for mathematical
learning. As these articulations focus on the reasoning
that lies behind solution procedures, students' participation in such discussions increases the likelihood that
they might come to understand each other's reasoning.
Had the discussion in the design experiment classroom
remained calculational, students could only have
understood each other's explanations by creating a task
interpretation that lay behind their use of the computer
tool entirely on their own. In contrast, the students'
participation in conceptual discourse provided them
with resources that supported their understanding of
other's explanations and thus their reorganization of
their initial interpretations of tasks. These resources are
not limited to what is said but also include inscriptions
and notations that are pointed to and spoken about (cf.
A. G. Thompson, Philipp, Thompson, & Boyd, 1994).
In the statistics design experiment, for example, the
graphs that the students developed as they used the
computer tools were integral to communication as well
as to their individual reasoning. This interdependency
of tools and discourse indicates the systemic nature of
the various means of support that we have discussed.
The classroom activity system
As the case of the statistics design experiment
indicates, the four means of support that we have
discussed are strongly interrelated. For example, the
statistics instructional activities as they were actually
realized in the classroom depended on talking through
the data generation process, the computer tools that
the students used to conduct analyses, and the nature
of the subsequent whole class discussions. It is easy
to imagine how the instructional activities might be
realized differently if the options for organizing data
on the computer tool had consisted only of conventional statistical graphs, or if there had been no whole
class discussions and the teacher had simply graded
the students' reports of their analyses.
In light of these interdependencies, it is reasonable to view the various means of support as
constituting a single classroom activity system. This
perspective is compatible with Stigler and Hiebert's
(1999) contention that teaching should be viewed as
a system. In making this claim, Stigler and Hiebert
directly challenge analyses that decompose teachers'
instructional practices into a number of independent
moves or competencies. They instead propose that
the meaning and significance of any particular facet
of a teacher's instructional practice becomes apparent
only when it is analyzed within the context of the
entire practice. In a similar manner, the four means
of support that we have discussed should be viewed
as aspects of a single classroom activity system (Cobb
& McClain, 2004). Instructional design from this
point of view therefore involves designing classroom
activity systems such that students develop significant mathematical ideas as they participate in them
and contribute to their evolution.
This systemic perspective sits uncomfortably
with approaches to design that focus exclusively on
instructional activities and tools. These formulations
focus on selected aspects of the classroom activity
system in isolation, in the process casting instructional activities as the cause and learning as the
effect. From the systemic perspective, conjectures
about what students might learn as they use tools to
complete instructional activities are, at best, metonymies for more encompassing conjectures about
what students might learn as they participate in an
envisioned classroom activity system. This broader
perspective brings other aspects of the classroom
activity system to the fore as an explicit focus of
design, thereby enabling the designer to consider
how proposed instructional activities and tools might 116
leArning FroM And AdAPting the theory oF reAlistic MAtheMAtics educAtion
Paul Cobb, Qing Zhao &Jana Visnovska
be realized in the classroom. In addition, this perspective highlights the central role of the teacher in
orchestrating the organization of classroom activities
and in guiding the negotiation of norms of mathematical argumentation. A second adaptation that
we have made to the RME approach to instructional
design emphasizes the crucial contribution of the
teacher.
Designing Resources for Classroom teaching
Instructional designers typically assume that
they are developing instructional activities and associated resources to support the learning of individual students. In doing so, they justify instructional
sequences in terms of a hypothetical learning trajectory that focuses on the development of individual
student's mathematical reasoning. As a consequence
of our experience of developing and refining instructional sequences while conducting classroom design
experiments, we came to view this exclusive focus
on individual students' reasoning as problematic for
two reasons. First, our work in classrooms led us to
question justifications cast exclusively in terms of
individual students' mathematical reasoning for the
straightforward reason that, in any classroom, there are
significant qualitative differences in students' thinking
at any point in time (Cobb et al., 2001). To capture this
diversity in students' reasoning, it would be necessary
to formulate multiple learning trajectories. However,
an approach of this type leads to our second concern
about an exclusively individual perspective, namely
that it is unmanageable for the teachers. It is unrealistic to expect that teachers will be able to formulate
and continually update learning trajectories for every
student, or even for several groups of students, and use
these multiple trajectories to inform instruction. As an
alternative to an exclusively individualistic focus, we
have found it useful while working in classrooms to
view a hypothetical learning trajectory as consisting
of conjectures about the collective mathematical development of the classroom community. This proposal
constitutes the second adaptation that we made to the
RME design theory.
This adaptation has methodological implications
for the analysis of classroom data.
2
The adaptation is
also pragmatically significant and brings the teacher
into the picture. In particular, the purpose of instructional design becomes that of developing resources
for the teacher to use to support students' learning,
rather than to develop instructional activities that
are intended to support students' learning directly.
We illustrate this point by returning to the statistics
design experiment. We noted that one of the commitments we made when we developed instructional
activities during this experiment was that students'
activity in the classroom should involve the investigative spirit of data analysis from the outset. A second
commitment was that significant mathematical issues
that advanced the instructional agenda should emerge
as a focus of conversation during the whole-class
discussions of the students' analyses. The challenge
for us as instructional designers was therefore to
transcend what Dewey (1951/1981) termed the dichotomy between process and content by systematically
supporting the emergence of key statistical ideas while
simultaneously ensuring that the analyses the students
conducted involved an investigative orientation. This
is a non-trivial issue in that inquiry-based instructional approaches have sometimes been criticized for
emphasizing the process of inquiry at the expense of
substantive disciplinary ideas. In approaching this
challenge, we viewed the various data-based arguments that the students produced as they completed
the instructional activities as a primary resource on
which the teacher could draw to initiate and guide
whole-class discussions that focused on significant
statistical ideas. As a consequence, we did not merely
attempt to design instructional activities that would
be accessible to multiple individual students who may
differ in terms of level of statistical sophistication. Our
goal when developing specific instructional activities
was also to ensure that the diverse ways in which the
students analyzed data would constitute an instructional resource on which the teacher could capitalize
to support the learning of entire class.
The achievement of this design goal required
extremely detailed instructional planning. However,
rather than attempting to influence each individual
student's reasoning in a specified manner by developing particular instructional activities, we attempted
to anticipate the range of data-based arguments that a
group of students might produce as they completed
specific instructional activities. Our discussion of
seemingly inconsequential features of task scenarios
and of the particular characteristics of data sets were
therefore quite lengthy as minor modifications to an leArning FroM And AdAPting the theory oF reAlistic MAtheMAtics educAtion
Paul Cobb, Qing Zhao &Jana Visnovska
11
instructional activity could significantly influence
the types of analyses the students would produce and
thus the resources on which the teacher could draw
to further her instructional agenda. For example, in
developing the AIDS instructional activity, we purposefully constructed data sets with a significantly different number of data points so that the teacher could
initiate a comparison of analyses that were based on
absolute and on relative frequency. In doing so, we
paid particular attention to the characteristics of the
task scenario in which the inequality in the size of
the data sets would seem reasonable to the students.
As a result of this detailed preparation, a number of
mathematically significant issues emerged during the
whole-class discussion of the AIDS data set, including
the contrast between absolute and relative frequency,
the interpretation of data graphs corresponding to
box-and-whiskers plots, and the use of percentages to
quantify the proportions of a data set located in particular intervals (Cobb, 1999; McClain et al., 2000).
It is apparent from this illustration that our instructional agenda included a concerted effort to support
the students' transition from additive to multiplicative
reasoning about data. However, we did not attempt to
achieve this goal by somehow causing the individual
students to make this transition as they completed
certain instructional activities. Instead, we attempted
to develop instructional activities that would result in
a range of solutions on which the teacher could capitalize as she planned whole class discussions. We therefore viewed ourselves as developing resources that the
teacher could use to achieve her instructional agenda.
Looking beyond the statistics design experiment, we
attribute a central, mediating role to teachers more
generally and in fact view them as co-designers of the
classroom activity systems that constitute the immediate social situations of their students' mathematical
development. It should be clear from the illustrations
we have given that the role we envision for the teacher
is relatively demanding and requires considerable
knowledge and judgment. The third adaptation that we
discuss takes these demands seriously and focuses on
the possible means of supporting teachers' learning.
supports for teachers' Learning
Our characterization of the teachers as co-designers implies that high-quality mathematics teaching
is a generative, knowledge building process in
which teachers learn about their students' mathematical reasoning and the means of supporting its
development as they analyze, adapt, test, and refine
instructional sequences that have proved effective
elsewhere (cf. Franke, Carpenter, Levi, & Fennema,
2001). As Gamoran et al. (2003) observe, this form
of instructional practice is complex, demanding,
uncertain, and not reducible to predictable routines
(cf. Ball & Cohen, 1999 ; Clark, 1988 ; Lampert,
2001; McClain, 2002; Schifter, 1995; Smith, 1996).

Teachers need considerable support as they learn to
adapt instructional sequences to the contingencies
of their classroom while at the same time placing
students' reasoning at the center of their instructional decision-making. The third adaptation that we
propose focuses on what is involved when designing
instructional sequences so that they support teachers'
as well as students' learning.
In our view, teachers' implementation of an
instructional sequence is necessarily a process of
conjecture-driven adaptation. In taking this stance,
we follow de Certeau (1984) in contending that an
artifact such as an instructional sequence developed
by one group is necessarily reshaped and transformed
when others use it. Wertsch (1998) extends this
argument by contending that this is the case even
when the users attempt to comply with the designers' intentions. To paraphrase Wertsch, teachers
necessarily adjust an instructional sequence to the
actual circumstances that they encounter even when
they attempt to remain faithful to the designers'
intentions. Aspects of these circumstances that
significantly influence teachers' instructional practices include the institutional constraints that they
attempt to satisfy, the formal and informal sources
of assistance on which they can draw, their students'
prior instructional histories, and the instructional
materials and resources that they use as the basis
for instruction (Ball & Cohen, 1996 ; Blumenfeld,
Fishman, Krajcik, Marx, & Soloway, 2000 ; Brown,
Stein, & Forman, 1996 ; Confrey, Bell, & Carrejo,
2001; Feiman-Nemser & Remillard, 1996; Gamoran,
Secada, & Marrett, 2000 ; Nelson, 1999 ; Rowan,
1990; Senger, 1999; Stein & Brown, 199 ; Tharp &
Gallimore, 1988).
de Certeau (1984) and Wertsch (1998) take
their argument one step further by proposing that 118
leArning FroM And AdAPting the theory oF reAlistic MAtheMAtics educAtion
Paul Cobb, Qing Zhao &Jana Visnovska
when teachers attempt to use instructional materials
developed elsewhere, a second process of creation or
production is involved. In our view, this perspective is
potentially productive for teacher professional development because it orients us to focus our efforts on
supporting teachers' development of the personal and
social resources that would enable them to adapt the
designed instructional sequences in ways to support
their students' learning of significant mathematical
ideas. This perspective is also useful for research on
teacher professional development in that it orients
us to explain why teachers adapt instructional
sequences in particular ways by understanding their
evolving instructional practices as they are situated
in particular institutional settings.
We can best illustrate the third adaptation that we
made to RME theory by referring to a teacher professional development experiment
3
conducted with a
group of middle-school mathematics teachers who
taught 12- and 13-year-old students. The statistical
instructional sequence that we developed in the prior
classroom design experiment served as one of the
primary tools that we used to support the teachers'
learning. It is important to note that the retrospective
analyses that we conducted of the classroom design
experiment justify the instructional sequence in terms
of (a) a substantiated trajectory for students' mathematical learning, and (b) the documented means of
supporting learning along that trajectory. If we had
justified the instructional sequence solely with traditional experimental data, the teachers would know
that this sequence had proved effective elsewhere but
would not have access to the underlying rationale that
would enable them to adapt it effectively to their own
instructional settings. In contrast, the type of rationale
that we developed constitutes a potentially important
resource for teachers as they adapt, test, and modify
the instructional sequence in their classrooms. Our
intent in the professional development experiment
was therefore to engage teachers in activities that
would enable them to reconstruct the rationale for
the instructional sequence.
As an illustration, we engaged the teachers in a
variety of activities that focused on how to conduct
data generation discussions. As we noted when
discussing the statistics design experiment, data
generation discussions play a significant role in
shaping the ways in which students interpret data.
Early in our collaboration, the teachers recognized
that data generation discussions were an important
aspect of instruction. However, it became apparent
that, from their perspective, effective instructional
activities involved a scenario that was immediately
interesting and personally relevant to students. For
example, the teachers considered that instructional
activities that involve soft drinks or roller coasters
were instructionally more promising than those that
focused on issues of broader social significance (e.g.,
AIDS). They therefore understood the importance
of data generation discussions primarily in terms
of capturing students' interest so that they would
engage in instructional activities. It was also apparent
that, from the teachers' perspective, data generation
discussions made little if any contribution to the
ways that students interpreted and analyzed data.
During our ensuing collaboration with the
teachers, we engaged them in a number of activities that focused on data generation discussions.
This approach was reasonably successful in that the
teachers came to view a broader range of problem
scenarios as potentially productive and saw it as their
responsibility to develop the significance and relevance of problem situations with students. Towards
the end of our collaboration with the teachers, there
were strong indications that the teachers had become
aware that the students' understanding of the process
by which the data were generated influenced how
they interpreted and analyzed the data. In particular,
they explicitly linked the issues that they addressed
while conducting data creation discussions to
students' subsequent analyses. This development
would have been unlikely had we not made the rationale for the instructional sequence an explicit focus
of professional development activities.
Methodologically, the perspective we have illustrated on teacher learning and implementation
offers the prospect that research on teacher professional development might become a design science
characterized by tightly integrated cycles in which
designs for supporting teachers' learning are developed, tested, analyzed, and modified. The products
of teacher development research of this type might
include prototypical sequences of activities and
resources for teacher-researcher collaboration
together with a rationale that is cast in terms of (a) the
actual learning trajectory for a professional teaching leArning FroM And AdAPting the theory oF reAlistic MAtheMAtics educAtion
Paul Cobb, Qing Zhao &Jana Visnovska
119
community, and (b) means by which that learning
can be supported. We speculate that the rationales
of this type will enable other researchers and teacher
educators to adapt the prototypical sequences to the
specific settings in which they are collaborating with
teachers in a conjecture-driven manner.
conclusion
In the first part of this article, we emphasized the
value of the positive heuristics for design proposed
by RME. These heuristics have not been derived from
a general background theory but instead they are
empirically grounded in the activity of developing,
testing, and revising specific designs in classrooms.
The enduring contribution of RME resides in the
solution that it proposes to the perennial question of
how to induct students into established mathematical
practices while simultaneously taking their current
understandings and interests seriously. The approach
proposed by RME involves continually building up
towards substantial participation in established
mathematical practices rather than attempting to
directly connect students' current understandings to
established mathematical ideas and traditions.
Against this background, we discussed three
adaptations that we have made to the RME approach
to design. The first adaptation involves broadening the
means of supporting students' mathematical learning
beyond instructional activities and tools to include
the organization of classroom activities and the
nature of classroom discourse. These various means
of support are strongly interrelated and can be viewed
as aspects of an encompassing classroom activity
system. The goal for instructional development is
therefore to design classroom activity systems such
that students develop significant mathematical ideas
as they participate in them and contribute to their
evolution. The second adaptation emphasized the
critical role of teachers as co-designers of classroom
activity systems. The purpose in developing
instructional activities and tools is not to support
individual students' mathematical learning directly.
Instead, it is to develop resources that teachers
can use to achieve their instructional agendas by
capitalizing on students' diverse interpretations and
solutions. The third adaptation took account of the
demands of the envisioned role for the teacher and
concerned supports of teachers' learning. We argued
that the implementation of instructional sequences
necessarily involves a process of adaptation. The
goal for teacher professional development should
therefore be to support teachers' development
of the personal and social resources that enable
teachers to adapt instructional sequences in ways
that enhance their students'mathematical learning.
This orientation offers the prospect that research
on teacher professional development might become
a design science that involves developing, testing,
and modifying designs for supporting the learning
of professional teaching communities and the
participating teachers.120

The teacher and the tool: instrumental orchestrations
in the technology-rich mathematics classroom
Paul Drijvers & Michiel Doorman & Peter Boon &
Helen Reed & Koeno Gravemeijer
Published online: 14 July 2010
The Author(s) 2010. This article is published with open access at Springerlink.com
Abstract The availability oftechnology in the mathematics classroom challenges the way
teachers orchestrate student learning. Using the theory of instrumental orchestration as the
main interpretative framework, this study investigates which types of orchestrations
teachers develop when using technology and to what extent these are related to teachers'
views on mathematics education and the role of technology therein. Data consisted of
videotapes of 38 lessons taught by three teachers, who also provided information on their
views through questionnaires and interviews. Qualitative analysis of these data led to the
identification of orchestration types and teacher profiles. The orchestration preferences of
the three teachers proved to be related to their views. A detailed analysis of one exemplary
episode suggests how other theoretical perspectives might complement the theory of
instrumental orchestration.

1 Introduction
In spite of technology's recognised potential for teaching and learning, its integration into
secondary mathematics education lags behind the high expectations that many researchers
and educators had some decades ago (Lagrange, Artigue, Laborde & Trouche, 2003). The
role ofthe teacher has been acknowledged as both a critical and a problematic factor in this
integrative process (Artigue, Drijvers, Lagrange, Mariotti & Ruthven, 2009; Doerr &
Zangor, 2000; Lagrange & Ozdemir Erdogan, 2009; Monaghan, 2004; Ruthven &

K. Gravemeijer
Eindhoven School ofEducation, Eindhoven University ofTechnology,
Eindhoven, The Netherlandsthennessy, 2002). It is critical in the sense that the way in which teachers approach the use
ofthechnology has major consequences for the effects ofits use in the classroom (Kendal &
Stacey, 2002). It is problematic, as teachers who do not perceive the use of technology in
their teaching as valuable for their educational goals are able to avoid it, unless explicitly
required to do so by institutional or curriculum constraints. Also, teachers often experience
difficulties in adapting their teaching techniques (Sensevy, Schubauer-Leoni, Mercier,
Ligozat & Perrot, 2005) to situations in which technology plays a role (Monaghan, 2004).
What is difficult from a teacher's perspective in integrating technology into his or her
mathematics teaching? Robert and Rogalski (2005) point out that teachers' practices are
both complex and stable. Building on this, Lagrange and Monaghan (2009) argue that the
availability of technology amplifies the complexity and, as a consequence, challenges the

stability ofteaching practices: techniques that are used in 'traditional' settings can no longer
be applied in a routine-like manner when technology is available. A new repertoire of
teaching techniques, instrumented by the available tools, has to be developed. These new
techniques are likely to be related to already existing ones as well as to the teachers'
underlying views on mathematics education (Pierce & Ball, 2009).
In order to help teachers to benefit from technology in everyday mathematics teaching,
therefore, it is important to have more knowledge about the new teaching techniques that
emerge in the technology-rich classroom and how these relate to teachers' views on
mathematics education and the role of technology therein.
2 Theoretical framework and research questions
The main theoretical perspective that informs our investigation of teacher behaviour in a
technology-rich environment is the instrumental approach to tool use, and the notion of
instrumental orchestration in particular.
The instrumental approach acknowledges the complexity of using technology within
mathematics education (Artigue, 2002). According to this approach, the use of a
technological tool involves a process of instrumental genesis, during which the object or
artefact is turned into an instrument. This instrument is a psychological construct, which
combines the artefact and the schemes (in the sense ofVergnaud, 1996) the user develops to
use it for specific types of tasks. In such instrumentation schemes, technical knowledge
about the artefact and domain-specific knowledge (in this case, mathematical knowledge)
are intertwined. Instrumental genesis, therefore, is essentially the co-emergence of schemes
and techniques for using the artefact.
Many studies focus on students' instrumental genesis and its possible benefits for
learning (e.g. see Kieran & Drijvers, 2006). However, it was acknowledged that students'
instrumental geneses need to be guided by the teacher through the orchestration
(McKenzie, 2001) of mathematical situations (Mariotti, 2002). For example, Kendal and
colleagues (Kendal & Stacey, 2002; Kendal, Stacey, & Pierce, 2004) showed that teachers
privilege certain techniques for using technological tools over others and, in this way, guide
the students' acquisition of tool mastery and their learning processes. To describe how the
teacher can fine-tune the students' individual instruments and compose coherent sets of
instruments within the classroom, thus enhancing both individual and collective geneses,
Trouche (2004) introduced the metaphor of instrumental orchestration.
An instrumental orchestration is defined as the teacher's intentional and systematic
organisation and use of the various artefacts available in a—in this case computerised—
learning environment in a given mathematical task situation, in order to guide students'
214 P. Drijvers et al.instrumental genesis (Trouche, 2004). We distinguish three elements within an instrumental
orchestration: a didactic configuration, an exploitation mode and a didactical performance.
These three elements are now described in more detail.
A didactical configuration is an arrangement ofartefacts in the environment, or, in other
words, a configuration ofthe teaching setting and the artefacts involved in it. In the musical
metaphor of orchestration, setting up the didactical configuration can be compared with
choosing musical instruments to be included in the band, and arranging them in space so
that the different sounds result in polyphonic music, which in the mathematics classroom
might come down to a sound and converging mathematical discourse.
An exploitation mode is the way the teacher decides to exploit a didactical configuration
for the benefit ofhis or her didactical intentions. This includes decisions on the way a task
is introduced and worked through, on the possible roles ofthe artefacts to be played, and on
the schemes and techniques to be developed and established by the students. Decisions on
the exploitation mode can be seen as part of the design of a Hypothetical Learning
Trajectory (Simon, 1995). In terms of the metaphor of orchestration, setting up the
exploitation mode can be compared with determining the partition for each of the musical
instruments involved, bearing in mind the anticipated harmonies that will emerge.
A didacticalperformance involves the ad hoc decisions taken while teaching on how to
actually perform in the chosen didactic configuration and exploitation mode: what question
to pose now, how to do justice to (or to set aside) any particular student input, how to deal
with an unexpected aspect of the mathematical task or the technological tool, or other
emerging goals.
In the metaphor of orchestration, the didactical performance can be compared to a
musical performance, in which the actual interplay between conductor and musicians
reveals the feasibility of the intentions and the success of their realisation.
Didactical configurations and exploitation modes were introduced by Trouche (2004).
As an instrumental orchestration is partially prepared beforehand and partially created 'on
the spot' while teaching, we felt the need to add the actual didactical performance as a third
component. Establishing the didactical configuration has a strong preparatory aspect: often,
didactical configurations need to be thought of before the lesson and cannot easily be
changed during it. Exploitation modes may be more flexible, while didactical performances
have a strong ad hoc aspect. As such, the threefold model has a time dimension.
The model also has a global–local dimension. An instrumental orchestration has a global
component, in that it is part ofthe teacher's repertoire ofteaching techniques. It also has an
incidental, local actualisation appropriate for the specific didactical context and adapted to
the target group and the didactical intentions.
Even ifthe metaphor ofinstrumental orchestration is appealing, it has its limitations like
every metaphor. Ifwe think ofa teacher as a conductor ofa symphony orchestra consisting
of highly skilled musicians, who enters the concert hall with a clear idea on how to make
the musicians play Mahler the way he himselfreads the century-old partition, we might feel
uneasy. However, ifwe think ofthe class as ajazz band, consisting ofboth novice and more
advanced musicians, and the teacher being the band leader who prepared a global partition
but is open for improvisation and interpretation by the students, and for doing justice to
input at different levels, the metaphor makes more sense. It is in the latter way that we
suggest to understand it.
Despite the potential of the instrumental orchestration model to help understand
teachers' practices in the technology-rich classroom, the number of elaborated examples of
instrumental orchestrations described in the research literature to date is limited (Drijvers &
Trouche, 2008; Trouche, 2004). Meanwhile, our goal formulated above is to find out which
The teacher and the tool 215new teaching techniques emerge in the technology-rich classroom. In terms of the
instrumental orchestration framework, one aim ofthis study is to identify different types of
orchestrations. Therefore, the first research question is:
(1) Which types of instrumental orchestration emerge in technology-rich classroom
teaching?
As a means to make this research question feasible to deal with, we limit ourselves here
to orchestrations in whole-class teaching. Of course, other organisations of the learning,
such as individual student work and work in pairs or groups, are also important, but we
address them elsewhere (Drijvers, submitted).
The process of a teacher developing instrumental orchestrations is guided by his or her
knowledge of, experience with and views onmathematics education andthe role oftechnology
herein (Pierce & Ball, 2009). This includes the teachers' own knowledge and skills concerning
the integration of technology, and their concerns about time constraints and behavioural
control. Gueudet and Trouche (2009) refer to these often implicit guidelines which drive a
teacher's choices as operational invariants. Such operational invariants can be very general,
such as 'learning takes place through interaction', or more specific to the role oftechnology,
for example 'technology offers means to improve classroom interaction'. These operational
invariants work out in types of invariant teacher behaviours, which are instrumented by the
available tools. The notions of operational invariants and teachers' views are used in this
study to interpret the information from teachers in relation to their observed orchestrational
behaviour. The second aim of this study, phrased in the introduction as the investigation of
how teaching techniques relate to teachers' views on mathematics education and the role of
technology therein, is reformulated in terms of the instrumental orchestration framework as
the following second research question:
(2) To what extent are teachers' repertoires of orchestrations related to their expressed
views on mathematics education and the role of technology therein?
The way inwhichwe answerthese questions with instrumental orchestration as a framework
canbe considered as atestregarding the suitability andvalue ofinstrumental orchestration as an
interpretative lens for research into teaching with technological tools. As such, our 'hidden
agenda' is to contribute to the development ofthis model, its evaluation in terms ofaffordances
and limitations, and its articulation with other theoretical approaches.
3 Research context
The research questions are addressed in the context ofa research project on a technology-rich
learning arrangement for the concept offunction
1
. In this project, a learning arrangement for
eighth-grade students as designed. The design was guided by Realistic Mathematics Education
principles (Gravemeijer, 1994). The arrangement, which consisted of eight 50-min lessons,
aimed at the development ofa rich function concept, whereby functions are conceptualised as
input–output assignments, as dynamic processes of co-variation and as mathematical objects
with different representations (Drijvers, Doorman, Boon, Van Gisbergen & Gravemeijer,
2007; Slavit, 1997). The design of the learning materials was directed by a hypothetical
learning trajectory, in which the expected conceptual development was guided and facilitated
1
For further information on the project, see the project website www.fi.uu.nl/tooluse/en/.
216 P. Drijvers et al.by means of activities carried out with a technological tool. An accompanying teacher guide
contained suggestions and working formats for appropriate teaching techniques and included a
planning scheme.
The main technological component of the learning arrangement is a Java applet called
Algebra Arrows. The applet was embedded in an electronic learning environment called the
Digital Mathematics Environment (DME). The applet allows for the construction and use of
chains of operations (so-called arrow chains) and provides options for creating tables,
graphs and formulae and for scrolling and tracing. The DME allows students to access their
work from any location, and the teacher to access this work in order to monitor progress
and track the conceptual development of the students. Figure 1 shows these digital tools.
The right part is the Algebra Arrows window, in which students create and use their
representations. At the left, the DME provides tasks and boxes in which the students type
their answers. The numbered circles at the bottom of the screen allow for navigation
through the tasks, the underlined one currently indicating task 2.
Besides teacher orchestration, other foci of this research project are students' learning
(Doorman, Boon, Drijvers, Van Gisbergen, Gravemeijer & Reed, 2009) and the relationships between learning outcomes and student attitudes and behaviours (Reed, Drijvers &
Kirschner, 2010).
4 Method
The intervention consisted of the implementation of the above described learning
arrangement in 29 eighth-grade classrooms in one Belgian and nine Dutch schools in
three research cycles, each consisting of a (re)design phase, a teaching experiment phase
Fig. 1 Algebra Arrows applet embedded in the Digital Mathematics Environment
The teacher and the tool 217and a phase of data analysis (Gravemeijer, 1994). In terms ofthe orchestration model, this
learning arrangement offers tools and tasks, which are part of the didactical configuration,
as well as suggestions in the teacher guide concerning exploitation modes. The teachers'
freedom, therefore, mainly concerned the configuration of the classroom setting, the
exploitation mode and the didactical performance. The resulting orchestrations are the
outcome of both the design by the researchers and the choices of the teachers themselves.
To investigate the first research question concerning the types of orchestration which
emerge in technology-rich classroom teaching, video tapes were analysed of38 lessons taught
in five classes by three female mathematics teachers who volunteered to participate in the
research project. The three were experienced teachers; however, the use oftechnology in this
specific learning arrangement was new to them. One ofthese teachers taught the arrangement
each ofthe three cycles, the others each taught it once. The three teachers were chosen so as
to have some variety in their educational level (degree for upper secondary or lower
secondary education, respectively) and school type (gymnasium or general secondary school).
For reasons mentioned above, data analysis focused on whole-class episodes in which
technologywasused. Theunitofanalysis was an episode, whichwas definedas thewhole-class
treatment of a single DME-task. If this treatment contained different orchestration types, the
episode was cut into sub-episodes, each with a unique orchestration type. In this way, a corpus
of 83 (sub-)episodes was identified. These were organised and analysed with the help of
software for qualitative data analysis
2
. The analysis was carried out in a bottom-up manner,
though partly driven by theory (e.g. Kendal & Stacey, 2002; Pierce & Ball, 2009; Trouche,
2004). Six orchestration types were identified and the corpus was coded according to this
categorization. A second coding of24 episodes (29%) was done by a co-researcher and led to
a good inter-rater reliability (a Cohen's kappa of .72).
To investigate the second research question on the relationships between the types of
orchestrations and teachers' views on mathematical learning and teaching and the role
oftechnology therein, each ofthe three teachers' orchestrations were analysed on the basis
of their observed teaching behaviours, and possible operational invariants were identified.
Then, the teachers' answers to an online questionnaire were used to obtain insight into their
self-reported views. The questionnaire consisted of 40 items on a five-point rating scale,
with the range of answers from 'strongly agree' to 'strongly disagree'. Items were derived
from previous research in this area and addressed the influence of technology on students'
learning and attitudes, on the lesson organisation, and on the role ofthe teacher (Drijvers et
al., 2007; Reed et al., 2010). Teachers' self-reported views and their observed orchestrations
were then integrated to produce a profile for each ofthe three teachers, which was validated
through a semi-structured post-intervention interview with the teacher concerned. To further
explore the value of the instrumental orchestration framework, transcripts of a limited
number of episodes were analysed in more detail.
5 Results
The results presentedbelow consist of(1) aglobal inventory ofobserved orchestrationtypes, (2)
their frequency distribution over the three teachers involved, (3) profiles ofthree participating
teachers with respect to their orchestrations and their views on mathematics education and the
role oftechnology therein, and (4) an extended analysis ofone exemplary episode.

218 P. Drijvers et al.5.1 A global inventory of orchestration types
Six orchestration types were identified through a combination oftheory-driven and data-driven
analysis; these were termed Technical-demo, Explain-the-screen, Link-screen-board, Discussthe-screen, Spot-and-show, and Sherpa-at-work. Each of these orchestration types is briefly
described in terms of the first two elements of orchestration theory—i.e., didactical
configuration and exploitation mode—and is illustrated by a short example. The localised,
ad hoc nature of the third element of an instrumental orchestration—the didactical
performance—makes it unsuitable for inclusion in this global inventory.
The Technical-demo orchestration concerns the demonstration of tool techniques by the
teacher. It is recognised as an important aspect of technology-rich teaching (Monaghan,
2001, 2004). A didactical configuration for this orchestration includes access to the applet
and the DME, facilities for projecting the computer screen, and a classroom arrangement
that allows the students to follow the demonstration. As exploitation modes, teachers can
demonstrate a technique in a new situation or task, or use student work to show new
techniques in anticipation of what will follow. As an example, teachers exploited this

orchestration type to demonstrate the technique ofmaking an arrow chain of operations, or to draw a graph and scale it with the buttons above the graph window (see Fig. 1).
Demonstration-like orchestrations are also well-known in non-technological teaching settings; however, the type of demonstration seen here is instrumented by the technical tools and also specific to the tool's opportunities and constraints.
The Explain-the-screen orchestration concerns whole-class explanation by the teacher, guided by what happens on the computer screen. The explanation goes beyond techniques, and involves mathematical content. Didactical configurations can be similar to the Technicaldemo ones. As exploitation modes, teachers may take student work as a point ofdeparture for the explanation, or start with their own solution to a task. As an example, one teacher used the inverse arrow chain ofthe square chain to explain that square roots are always non-negative numbers. Explanatory orchestrations, of course, are also used in non-technological teaching settings, where they might be called Explain-the-board. The phenomena encountered in the technological environment, however, are often different from the ones faced at the traditional blackboard.
In the Link-screen-board orchestration, the teacher stresses the relationship between what happens in the technological environment and how this is represented in conventional mathematics of paper, book and blackboard. In addition to DME access and projection facilities, a didactical configuration includes a blackboard and a classroom setting such that both screen and board are visible. Similarly to the previously mentioned orchestration types, teachers' exploitation modes may take student work as a point of departure or start with a task or problem situation they set themselves. As an example, teachers copied arrow chains from the screen to the board, often in abbreviated and more conventional mathematical forms. This orchestration type is specific to the technology used. Because transfer to paper-and-pencil is known to be a problematic issue (Billington, 2009; Bretscher, 2009; Kieran & Drijvers, 2006), this kind of orchestration was one of our a priori foci.
The Discuss-the-screen orchestration concerns a whole-class discussion about what happens on the computer screen. The goal is to enhance collective instrumental genesis. A didactical configuration includes DME access and projecting facilities, preferably access to student work, and a classroom setting favourable for discussion. As exploitation modes, student work, a task, or a problem or approach set by the teacher can serve as the point of departure for student reactions. As an example, one teacher used a screen similar to the one in Fig. 1 to discuss different ways offinding a break-even point. Ofcourse, discussing results on The teacher and the tool 219the blackboard is a common teaching strategy. The advantage ofdiscussion in a technological environment is that suggestions for different representations and techniques, as they emerge in the discussion, can be easily tried out, with fast and dynamic feedback on obtained outcomes.
In the Spot-and-show orchestration, student reasoning is brought to the fore through the identification of interesting DME student work during preparation of the lesson, and its deliberate use in a classroom discussion. Besides previously mentioned features, a didactical configuration includes access to the DME during lesson preparation. As exploitation modes, teachers may have the students whose work is shown explain their reasoning, and ask other students for reactions, or themselves provide feedback on the student work. An example of Spot-and-show is given in the episode elaborated below. In that episode the teacher spots an inappropriate answer in a student solution while preparing the lesson, and discusses it with the whole class during the lesson. As this orchestration depends on the facilities offered to the teacher to browse through the DME student work, it is technology-specific and instrumented by the DME.
In the Sherpa-at-work orchestration, a so-called Sherpa-student uses the technology to present his or her work, or to carry out actions the teacher requests. Didactical configurations are similar to the Discuss-the-screen orchestration type. The classroom setting should be such that the Sherpa-student can be in control of using the technology, with all students able to follow the actions of both Sherpa-student and teacher easily. As exploitation modes, teachers may have work presented or explained by the Sherpa-student, or may pose questions to the Sherpa-student and ask him/her to carry out specific actions in the technological environment. As an example, one teacher had students using the computer and data projector to show a family ofgraphs, explain their reasoning and change the screen as requested by the teacher. This orchestration type is described in the literature (Trouche, 2004) and was therefore derived a priori from theory rather than emerging from the data.
A reflection on this set ofsix identified orchestration types led to the distinction ofa teacherstudent dimension. In Technical-demo, Explain-the-screen and Link-screen-board, the teacher dominates the communication. Studentinputisrestrictedandtheteacherguides the interactions in an Initiation-Response-Evaluation pattern. These orchestrations can be seen as teacher-centred. In Discuss-the-screen, Spot-and-show and Sherpa-at-work orchestrations, students have the opportunity to react and have more input. Even though the teacher manages the orchestration, there is more interaction and students have more voice than in the first three orchestration types. These can therefore be seen as student-centred orchestrations.
Another remark on this inventory is that the orchestrations are not isolated, but part of orchestrational sequences, and play particular roles in such a sequence. For instance, Technical-demo was often observed to precede and prepare for a phase of individual student work, to improve the efficiency of the latter phase. Spot-and-show orchestrations, and to a lesser extent Sherpa-at-work and Discuss-the-screen orchestrations, often exploit previous student work, individually or in pairs.
In summary, six orchestration types were identified, which differ in their focus on the teacher or the student as driving the orchestration and in the degree of technological specificity: some can be seen as technological variants of regular teaching practices most teachers are familiar with, whereas others are more specific to the use of technology or to the use of the tools used in this study in particular.

5.2 Frequency distribution of types of orchestrations over three teachers

Table 1 shows the frequencies ofthe orchestration types for each ofthe three teachers and, for teacher A, for each ofthe three times she taught the lesson series. Technical-demo is the most 220 P. Drijvers et al.frequently used orchestration type. In the post-intervention interviews, the three teachers said they feltthe needto familiarise students withbasic tooltechniques, in orderto preventtechnical obstacles hindering the subsequent mathematical activities: some basic technical knowledge is needed anddemonstrations canbe an efficientmeans toprovide it. This also avoidedthe teacher having to do too much "techno trouble shooting" (Monaghan, 2004, p. 346) or acting as "technical assistant" (Lagrange & Caliskan-Dedeoglu, 2009) during the work in pairs. In the interview, Teacher C explained the importance of Technical-demo as follows:
I want to prevent students from encountering technical difficulties while they are at work withthe computer…andhaveto waitformyhelp, whereas itoften concerns aminorissue.
The Spot-and-show orchestration also occurs frequently, but is unevenly spread over the three teachers. Although all three indicated in the post-intervention interview that they appreciated the facility to browse through the DME student work while preparing the next lesson, this orchestration type was mainly exploited by teacher B, who said:
The DME is practical for seeingwhat students do –you canuse itto fine-tune yourlesson.
The teacher guide, which the teachers received before the start of the teaching sequence, contained suggestions for teaching strategies which, in retrospect, match some of the identified orchestration types. A comparison ofthe suggested orchestrations in the teacher guide with the observed frequencies in Table 1 reveals that Link-screen-board and Discuss-the-screen were not suggested in the teacher guide, but were nevertheless quite frequently observed. Sherpa-at-work, on the contrary, was suggested several times in the teacher guide but was not popular with two ofthe three teachers. This shows that teachers felt free to adapt the suggestions in the teacher guide and make their own choices independently from it. We will come back to this in the discussion section that concludes this paper.

5.3 Teacher profiles of orchestrations and views on mathematics education and technology

Table 1 reveals a number ofdifferences between the three teachers. In order to explain them, we related them to teachers' answers to the questionnaire and the post-intervention interviews.

5.3.1 Teacher A

Table 1 shows that teacher A has slightly lower overall frequencies than teachers B and C. This corresponds to the observation that she takes time for her orchestrations to play out,

Table 1 Orchestration type frequencies by teachers

Orchestration type	Teacher A			Teacher B	Teacher C		Total
	cycle 1	cycle 2	cycle 3	cycle 2	cycle 3		
Technical demo	5	3	5	2	7		22
Explain-the-screen	0	0	1	0	7	8	
Link-screen-board	3	0	3	6	0	12	
Discuss-the-screen	4	4	2	3	1	14	
Spot-and-show	0	1	2	12	2	17	
Sherpa-at-work	2	7	1	0	0	10	
Total	14	15	14	23	17	83	

The teacher and the tool Z21and does not switch between orchestrations as fast as the other teachers. Apart from Technical-demo, which was discussed above, teacher A has relatively high frequencies for Discuss-the-screen and for Sherpa-at-work orchestrations. These are student-centred orchestration types, which teacher A used to evoke interaction between the students and herself. The underlying operational invariant is that students should be given a voice and that teaching should enable students to learn through interaction. In her classroom discussions, elements such as idea generation, comparison, evaluation and filtering (Sherin, 2002) can be traced.
Teacher A's views on mathematics education and the role of technology, as she expressed it in the questionnaire and the post-intervention interview, stress the importance of interaction in the classroom. She sees technology as a means to stimulate this:
…so you can have discussions with the students using the images that you saw on the screen, … that makes it more lively.
Her observed orchestration behaviour can be related to these views. For example, her agreement with the questionnaire statement 'As a teacher, one has to tell students clearly what they should do with ICT' matches her use of Technical-demo orchestrations. She also agreed with the statements 'The use of ICT gives the teacher more possibilities to build on students' ideas during whole-class discussions' and 'The use of ICT creates shared images and experiences which one can discuss with the students', which explains her preference for student-centred orchestrations, in which discussion and interaction play important roles.
In the post-intervention interview, teacher A mentioned time constraints as the main reason not to use Sherpa-at-work in the third cycle. Technical constraints (e.g. slow internet connections during the first cycle or inappropriate classroom settings in the computer lab) also drove her choices for orchestrations, as well as practical issues such as the features of the classroom in which the lesson takes place: how are the tables arranged, how are the computers set up, is Internet access available, and so forth.
In short, the profile of teacher A is that of a teacher who prioritises student-centred orchestrations. This relates to her view on learning as an interactive process in which students should have a voice. Technology is a means to achieve this, and offers new possibilities for teaching mathematics in an interactive way.

5.3.2 Teacher B

Table 1 shows that teacher B has relatively high frequencies for Link-screen-board, and particularly for Spot-and-show. Technical-demo is not often used, possibly due to the fact that her class consisted ofhigh-achieving students who are used to working independently and therefore might not need so much technical instruction. The Link-screen-board is used to establish links between the mathematics as it is represented in the technological environment and conventional mathematical representations and techniques. The Spot-andshow orchestration is used mainly to discuss either student inappropriate answers or original and insightful solutions.
Teacher B's views on mathematics education and the role oftechnology, as expressed in the questionnaire and the post-intervention interview, stress the importance of establishing links between the DME-work and paper-and-pencil mathematics. She sees the use of technology as an effective means to achieve her mathematical teaching goals, while she recognises that knowledge thus obtained also needs to be transferred to the paper-and-222 P. Drijvers et al.pencil environment. In addition, she believes that discussing mistakes and original approaches is fruitful for learning, and that both of these are more visible within a technological environment.
Her observed orchestration behaviour can be related to these views. Her strong agreement with the statement 'Compared with paper-and-pencil, ICT makes student work more visible for me' matches with her frequent use ofthe DME's facility to browse student work while preparing the Spot-and-show orchestrations. She also strongly agreed with the statement 'ICT can help students to develop understanding', which explains her interest in the use of ICT.
In the post-intervention interview, teacher B explained that she uses the Link-screenboard orchestration to … take distance from the specific ICT-environment; otherwise the experience remains too much linked to the ICT.
Concerning Spot-and-show, Teacher B explained that many students in her class were eager to have their work shown, which was an extra incentive for her to use it. She did not use the other student-centred orchestration types, as she considered them too time-consuming and also thought they might bring about some loss of control.
In short, the profile of teacher B is a teacher who finds the mathematical content ofthe lesson to be paramount and uses technology as a means to teach this. This results in attention to the links between the DME-work and paper-and-pencil or blackboard mathematics. She likes to be in control of the situation, which made her choose mainly teacher-centred orchestration types. Even if her frequent use of Spot-and-show reflects the importance she accords to discussing misconceptions and original approaches with the students, she usually quite strongly guides the Spot-and-show orchestrations. This aspect of Teacher B's profile is illustrated in the extended extract presented in the next section, which took place in teacher B's class.

5.3.3 Teacher C

Table 1 shows that teacher C has relatively high frequencies for Technical-demo and Explain-the-screen, which are considered as teacher-centred orchestration types. The Technical-demo orchestration is used to show the students what is possible with the tool and how to use it. The Explain-the-screen orchestration is in some cases used to provide students with a good starting position for new tasks, and in some cases to explain how tasks could have been solved. The underlying operational invariants seem to include the desire to avoid technical obstacles during student computer work, and the beliefthat tasks should be clearly explained to the students, in order to foster more efficient learning activities.
In the post-intervention interview, teacher C described herself as a 'typical teacher for mid-ability students' who strongly believes that such students benefit from clear demonstrations and explanations in a structured and stepwise approach. Technology is a suitable and useful means to provide this kind of scaffolding. At the same time, she was aware that students may encounter difficulties while using technology, and wished to

prevent these as much as possible. Furthermore, she wanted to be in control of what is
happening in the classroom, and believed that more teacher-centred orchestrations support
this.
Her observed orchestration behaviour can be related to these views. She strongly
agreed with the statement 'As a teacher, one has to tell students clearly what they should
The teacher and the tool 223do with ICT', which matches with her prioritising Technical-demo orchestrations.
Teacher C was neutral on the statements 'The use of ICT provides the teacher more
possibilities to build on students' ideas during whole-class discussions' and 'The use of
ICT creates shared images and experiences which one can discuss with the students'. This
might explain her preference for teacher-centred orchestrations. Her preference for a
stepwise approach was reflected in her strong agreement with the statement 'Students
become more systematic in their approach through the work with ICT'. She explained
that she focused Technical-demo orchestrations on obstacles she experienced herself
when using the DME, and that time constraints made her avoid orchestrations such as
Sherpa-at-work.
In short, teacher C's profile shows a concern for difficulties which students may
encounter when learning mathematics, particularly when using technology, and the
conviction that clear explanations and instructions are suitable means to deal with this.
This guides her choice for teacher-centred orchestrations. She wants technology to
support a stepwise problem solving approach. Furthermore, time constraints and control
are important factors for her in making her orchestrational choices.
From the profiles described here, we conclude that the three teachers differ in their
preferences for orchestration types and that their preferences can be related to their views
on mathematics education and the role of technology therein. In fact, their views on
mathematics education and the opportunities technology offers can be seen as their
theoretical discourse that justifies their orchestrational choices and guides their operational
invariants. These choices were shown to be partially based on time constraints and concerns
about control, which is in line with findings in other studies (Pierce & Ball, 2009). Finally,
it is interesting to note that the profiles of teachers A and C reported here are close to
similar profiles from two case studies (of teacher P1 and N, respectively) described by
Ruthven, Hennessy, and Deaney (2008).
5.4 Extended analysis of one episode
So far, orchestrations have been described on a global level in order to draw up an
inventory of orchestration types. However, more detailed issues, such as the teacherstudent interaction during these orchestrations, remained unaddressed. To further
investigate the explanatory power of the notion of instrumental orchestration and of
its third element of didactical performance in particular, a number of episodes were
analysed more extensively; one exemplary episode is presented here. As the Spotand-show orchestration is highly instrumented by technology and offers interesting
interaction potential, we chose a Spot-and-show episode, taught by teacher B.
During the first two lessons ofthe learning arrangement, the notion ofarrow chains was
introduced to the students after group work on diverse problem situations involving
dependency and co-variation (see Doorman et al., 2009). In the third and fourth lessons,
students worked in pairs with arrow chains in the DME. In task 8, one of the tasks of the
fourth lesson, the designers filled the applet window with the start ofa square and a square
root chain and an empty graph window (see Fig. 2).
While preparing the fifth lesson, teacher B came upon the work of Florence (a
pseudonym) and her classmate (see Fig. 3). These two students used a Table-Graph
technique to solve this task: they added both tables and graphs in the applet window. As the
tables provide integer input values and the students did not add an input variable in the
input box, the graphs that appear are dot graphs. Then the students clicked on different
224 P. Drijvers et al.input values in the table, and observed the effects on the two corresponding dots in the
graph. This technique was used more often by these students as a means ofinvestigating the
function. In this case, this led them to think that it is 'special' that two points reflecting
function values for the same input value are vertically aligned. Their reasoning, therefore,
reads: "for the square they are all whole numbers, and for the square root they are whole
numbers and fractions. And the square of a number is always right above the root?'. The
question mark at the end indicates that the students were not sure about their findings.
Teacher B decided to treat this task, and this inappropriate answer in particular, in a whole
class discussion. The text frame below contains the verbatim transcript of this episode.
Using a data projector, the DME with the list of student pairs is projected on the wall above the blackboard.
The teacher T navigates within this list to Tim and Kay and opens their solution of task 8.
T: Here it says [points on the screen to question c using the mouse]: what do you notice? Oh yes, I
actually wanted to see quite a different one, because they had …
T quickly navigates to Florence (F) and her classmate's work. In their work, the students checked on the
Table option. This led to 'dot graphs' on the screen (see figure 2 left screen). The answer to question c,
which the students had typed in, reads:
"for the square they are all whole numbers, and for the square root they are whole numbers and fractions.
And the square of a number is always right above the root.?"
T: Look here, what this says [points at the students' answer to question c on the screen with the
mouse and follows it while reading]. For the square they are all whole numbers, okay, and for the
square root they aren't whole numbers, we agree with that too, and the square of a number is
always right above the square root.
F: Was that right?
T: I'm not saying.
St1
:
: Yes, I had that too.
T: What they say, then, is that every time there is…if I've got something here, there is something
above it, and if I've got something there, there is also something above it. [points with the mouse
at pairs of vertically aligned points in the graph] Why is it, that these things are right above each
other?
F: Well, because it…the square root is just…no the square is just, um, twice the root, or something.
St2: No.
T: Kay?
Kay: That's because the line underneath, that's got a number on it, which you take the square root of
and square, so on the same line anyway.
T: What are those numbers called that are on the horizontal line then?
St3: The input numbers.
T: The input numbers.
T: Ehm, Florence, did you follow what Kay said?
F: No, but I […]. It was about numbers and about square roots and about…
Sts: [laugh]
St: It was about numbers!
The teacher and the tool 225T: Kay said: these are the input numbers, here on the horizontal line. [moves the mouse over the
horizontal axis] And for an input number you get an output number. And that is right above it. So
if you take the same input number for two functions… [indicates the two arrow chains with the
mouse]
F: Oh yes.
T: … then you also get…then you get points above it [points at a pair of vertically aligned dots in the
graph]. So that's got nothing at all to do with the functions. It's just got to do with from which
number you are going to calculate the output value. Now, if for both of them you calculate what
the output value is for 10 [indicates 10 at the horizontal axis], they both get a point above the 10
[indicates two dots above x=10]. Do you understand that?
F: Oh yes, I didn't know that.
T navigates back to the list of student pairs.

"St1, St2, .. stands for one of the students
In analysing this episode from an instrumental orchestrationperspective, itwas recognised as
a Spot-and-show orchestration: 'Spot' because the teacher, while preparing the lesson, spotted
the inappropriate answer in the students' DME-work, and 'show' referring to the teacher's
decision to display these students' results as a starting point for whole-class discussion. The
Fig. 2 Computer task 8
226 P. Drijvers et al.teacher's phrase 'Ohyes, I actuallywantedto see quite a different one' andherdirectnavigation
to Florence's work reveal her deliberate intention to act the way she does.
The didactical configuration for the preparatory phase consists of the DME's option for
teachers to look at the students' work at any time. As a result, the teacher notices the
inappropriate answer and decides to deal with it in her lesson. Apparently, the teacher likes to
use technology for "supporting learning through analysis of mathematical discrepancies"
(Ruthven, Hennessy & Deaney, 2008, p. 312). The monitoring of students' work is
instrumented by DME-facilities that are not available to students. As the teacher finds the
computer lab not to be appropriate for whole-class teaching, the lesson takes place in a regular
classroom with a PC with DME access, connected to a data projector. The configuration
includes putting the computer with the data projector in the centre of the classroom. This
choice is driven by the constraints ofone ofthe artefacts: ifthe projector was at the front, the
projection would get too small for the students to read. The screen is projected on the wall
above the blackboard, thus enabling the teacher to write on the board, which she regularly
does—though not in the episode presented here. Both this way ofpreparing the lessons and
the setting in the classroom are observed frequently in this teacher's lessons.
The exploitation mode of this configuration includes the teacher's choice to operate the
PC herself. This, in combination with the computer being in the centre of the classroom,
results in the teacher standing in the centre of the classroom, with the students closely
around her, all focused on the projection on the wall. This exploitation mode enables
classroom discussion and student involvement.
The didacticalperformance starts with the teacher displaying the student work she had
selected to show and reading out their reasoning, while adding some minor comments
('Look here, …'). Then she reformulates the answer and asks Florence for an explanation
Fig. 3 Florence's applet screen presented during whole-class discussion
The teacher and the tool 227('What they say…'). When the explanation turns out to be inappropriate, she invites
another student, Kay, to give his explanation, and checks whether Florence understands it.
When this is not the case, the teacher rephrases Kay's explanation and once more checks
with Florence, who now says she understands, although she does not actually give evidence
ofthis. Throughout the didactical performance, the teacher uses the mouse to relate her oral
expressions to the phenomena on the screen.
The didactical performance is now considered in more detail. The starting point for
the episode is Florence's artefact-related notion: a dot graph in the applet window of
the DME suggests to her a 'special' feature of dots being aligned vertically. This is
related to the tool technique of creating a table of function values and a corresponding
graph. An understanding of the underlying mathematical concepts and meaning seems
to be lacking.
The mathematical meaning the teacher is aiming for is that the coordinates of a point of
the graph of a function reflect the values of independent and dependent variables,
conventionally represented on the horizontal and vertical axes, respectively. As a
consequence, different functions with the same input value will result in points that are
vertically aligned in the graph.
What does the teacher do to guide the learning process towards this meaning? Firstly,
she reads the students' written answer and approves parts of it that are not crucial to the
targeted understanding. However, she does not comment on the final part ofthe answer and
later says 'I am not saying' when asked if it is correct.
As a next step, she rephrases the students' answer and illustrates it with mouse
movements in the applet window, so that all students understand the conjecture made by
Florence. Then the teacher brings the relevant question to the fore: 'Why is it that these
things are right above each other?' This leads to a vague reaction from Florence. The
teacher invites Kay to explain his reasoning, which indicates that his interpretation of the
representation in the artefact is linked to his understanding ofthe meaning ofthe graph as a
representation ofa mathematical idea/concept. The teacher subsequently evokes a precision
ofthe intended mathematical meaning by asking for the type ofnumbers that is represented
on the horizontal axis. This raises awareness of the link between the arrow chain and the
graph. As a final step, the teacher checks ifFlorence understands Kay's explanation. As this
does not seem to be the case, the teacher repeats and expands Kay's reasoning in her own
words, again supporting her explanation with mouse movements on the screen. Once more
she checks this with Florence, who now says she understands. As a result, Florence and her
classmate remove the remark on the vertically aligned dots after this classroom discussion
and replace it by a remark on the increasing behaviour of the square function: "for the
square they are always whole numbers, and for the square root they are whole numbers and
fractions. The squares get higher with much bigger steps."
This analysis reveals some important strategies this teacher applies in her didactical
performance. Firstly, she evokes mathematical meaning in several ways, namely by posing
open questions, by inviting students to explain their reasoning, and by giving her own
explanations. Secondly, she uses revoicing techniques and thus 'orchestrates multiple
voices' (Forman & Ansell, 2002), while she in some cases also improves the students'
formulations and privileges specific input. Thirdly, she gives mathematical meaning to tool
techniques and mathematical representations by using the mouse to highlight parts of the
screen during her explanations. Finally, she regularly checks students' understanding. This
approach is typical for teacher B, and is consistent with the profile presented above. She
used Spot-and-show orchestration quite frequently, perceiving it as a means to enhance
student involvement and discussion, which she believes contributes to the development of
228 P. Drijvers et al.the mathematical meaning that she finds so important. Evoking mathematical meaning in
classroom discussions based on student results seems to be one of her operational
invariants.
But what about the link between instrumental orchestration and instrumental genesis? As
the episode only shows the result of students using the artefact, we do not see direct traces
of the students' instrumental genesis. We argue, however, that Florence's idea of two
vertically aligned points being special is part of her scheme of using the Table-Graph
technique to produce dot graphs. Even though her knowledge linked to this technique—the
theorem-in-action, as it is called in instrumentation theory—is inappropriate, the episode
indicates that the teacher can exploit the students' experiences—in this case those of
Florence and Kay in particular—for the purpose of attaching mathematical meaning to the
technique used. The teacher privileges the epistemic value of the Table-Graph technique
above its pragmatic value (Artigue, 2002). In her didactical performance of the Spot-andshow orchestration she put into action, she highlights the mathematical meaning of the
concept of function as it emerges from the technique. This is exactly what instrumental
genesis is about. In this sense, the lens ofinstrumentational orchestration has a great deal to
offer in this analysis. However, our analysis also reveals the importance of the interplay
between representations in the technological environment and mathematical meaning. This
suggests that the analysis could benefit from notions from semiotic mediation theory, which
stresses the mediation potential of artefacts between the learner and the mathematical
knowledge (Bartolini Bussi & Mariotti, 2008). Analyses such as those by Maracci and
Mariotti (2009) show that the semiotic mediation framework can complement theories on
instrumentation and orchestration (Drijvers, Kieran & Mariotti, 2010).
6 Conclusions and discussion
6.1 Conclusions
The first research question of this study concerns the different types of instrumental
orchestrations which emerge in technology-rich classroom teaching. The analysis revealed
six orchestration types, which are different in their technological specificity. Discuss-thescreen and Explain-the-screen can be seen as technological variants of regular teaching

practices most teachers are familiar with. More specific for the use of technology are
Technical-demo, Sherpa-at-work and Link-screen-board. Specific for technological tools
that provide the teacher with online monitoring of digital student work is the Spot-andshow orchestration. It can be concluded that the repertoire of orchestrations is diverse, that
they differ in respect to whether the focus is on the teacher or the student, and that the
orchestrations have different degrees of technological specificity. Technological and time
constraints as well as control issues may influence the choice and exploitation of the
orchestrations. Furthermore, a discrepancy was noticed between orchestrations that were
suggested in the teacher guide and orchestrations that were actually observed.
The second research question concerns the relationships between these types of
orchestrations and teachers' expressed views on mathematical learning and teaching and
the role of technology therein. The matching of observed orchestrations with data from
questionnaires and interviews reveals considerable links between the three teachers'
preferences for orchestrations and their views on what is important to achieve during
teaching and how technology can support this. We conclude that these three teachers'
choices for orchestrations are related to their expressed views.
The teacher and the tool 2296.2 Discussion
The above conclusions may inform mathematics teachers and teacher educators who are
engaged in professional development on the issue of the integration of technological tools
in teaching. With respect to these conclusions, three issues deserve further discussion: the
inventory of the six orchestration types, including its generalizability and researchers'
expectations, the relationship between orchestrational choices and teachers' expressed
views, and the explanatory power ofthe instrumental orchestration framework, including its
limitations and its articulation with other theoretical approaches.
With respect to the inventory ofthe six orchestration types, it is interesting to see that the
identified orchestrations can to a certain extent be related to 'traditional' teaching
techniques. This suggests an evolution of teaching techniques rather than a revolution.
Also, the researchers' expectations for the orchestrational opportunities the digital tools
provide, as they were sketched in the teacher guide, were to a certain extent ignored by the
teachers. They choose their orchestrations themselves, which led to discrepancies between
the researchers' prior expectations and the actual findings from observations, discrepancies
that are also reported by Lagrange and Caliskan-Dedeoglu (2009). The data suggest that the
teachers make their choices in line with their regular habits and their views on mathematics
teaching, which underpins the remark on teachers' practices as being stable, made by
Robert and Rogalski (2005) and referred to in the introduction.
For the case of spreadsheet software, Lagrange and Ozdemir Erdogan (2009) report on
the differences between teachers stressing the epistemological value oftool techniques, and
students who primarily see the pragmatic value. Similar struggles were observed in this
study, where teachers felt obliged to use technical-demo orchestrations relatively often,
whereas their primary concern was in the mathematical meaning.
The method for identifying orchestration types has its limitations, which impact the
generalizability of the results. First, the orchestration types were sometimes difficult to
distinguish. Even ifthe inter-rater reliability ofthe codings was good, it was not always easy to
decide, for example, ifa Spot-and-show orchestration gradually turned into Discuss-the-screen
or Explain-the-screen. Second, it is possible that other types of orchestrations might have
emerged in a different learning arrangement or while observing other teachers. The
observations took place during a specific intervention, consisting ofa complex and innovative
learning arrangement with which the three teachers were not familiar. This lack offamiliarity,
along with start-up problems, may have influenced their orchestration choices. Also, the time
schedule for the learning arrangement was tight, which may also have affected the didactical
performance and the decisions involved. And finally, the specific tool characteristics may have
invited (or inhibited) specific types of orchestration. For example, Spot-and-show orchestrations clearly depend on the opportunity for the teacher to access student work while preparing
the lesson.
Despite these limitations, we conjecture that the identified orchestration types also exist,
maybe in adapted forms, outside the scope ofthis study. Therefore, it would be worthwhile
investigating whether variants of the identified orchestration types can be recognised in
other settings, such as group work or individual student-teacher interactions (Drijvers,
submitted), and in learning arrangements with other types of technological tools.
Concerning the relationship between orchestrational choices and teachers' expressed
views, which was the second research focus, the data suggest that the teachers' views on
mathematics education and the opportunities technology offers can be seen as their theoretical
discourse thatjustifies their orchestrational choices and guide their operational invariants. It is
interesting to note that the teachers' views as identified in this study correspond to findings
230 P. Drijvers et al.reported elsewhere. We already mentioned the similarities between the profiles ofteachers A
and C and those of two teachers described by Ruthven, Hennessy & Deaney (2008).
Lagrange and Caliskan-Dedeoglu (2009) also mention the relationship between teachers'
expectations towards technology and their general ideas on teaching and learning.
As a limitation of the study on the relationships between orchestrational choices and
expressed views, however, we point out that the data in the study presented here are too
limited to justify claims on the teachers' operational invariants across other classes and
other kinds oftechnological tools. Furthermore, the notion ofoperational invariants in itself
might benefit from further elaboration and concretisation.
As a final point of discussion, we also wished to investigate what the framework of
instrumental orchestration offers to the analysis of technology-rich classroom teaching. If
we interpret the orchestration metaphor in terms of a jazz band with its band leader, as we
suggested earlier, we experience this framework as a productive lens through which to view
teacher behaviour. On the whole, it appears to do justice to the subtleties in the preparation
and performance ofteaching techniques. The first two dimensions ofthe model helped us to
identify global patterns in teachers' behaviours, while the third dimension of the model—
the didactical performance—turned out to be more fruitful in the detailed analysis of a
teaching episode. On a more critical note, however, one can wonder if similar results could
have been obtained in our study without the somewhat difficult vocabulary of the
theoretical framework. Furthermore, as with every metaphor, the musical metaphor has only
a limited application to educational settings. Also, we perceived a danger of sticking too
much to superficial aspects of teaching while describing didactical configurations and
exploitation modes. That is why the extension with didactical performance as a third
component was useful and allowed for more in-depth and domain-specific didactical
analysis.
As an aside, it should also be noted that, while designing orchestrations, the teacher is
also engaged in a process of instrumental genesis for accomplishing the intended teaching
task (Bueno-Ravel & Gueudet, 2007). However, the data available here do not allow us to
proceed beyond developing a state-of-the art inventory of orchestration types to observing
this process of instrumental genesis over time.
At the global level of analysis, it is worthwhile to consider the integration of the
orchestrational model with other theoretical approaches. As a first approach, Ruthven and
colleagues (Ruthven, 2007, 2009; Ruthven, Deaney & Hennessy, 2009) designed a model
with a focus on key structuring features that shape technology integration into classroom
practice. Applications of this model (e.g. see Lagrange & Caliskan-Dedeoglu, 2009) show
that it can complement and supplement the instrumental orchestration model, and may
thereby contribute to further theoretical development. A second additional approach is
Saxe's (1991) four parameter model, which centres on emergent goals under the influence
of activity structures, social interactions, prior understandings, and conventions and
artefacts. Even if it was designed for completely different purposes, several studies
successfully applied this model to frame teachers' activities in technology-based
mathematics lessons (Lagrange & Monaghan, 2009; Lagrange & Ozdemir Erdogan,
2009; Monaghan, 2004). In our own work, we used it as complementary to instrumentation
and orchestration, to capture the changing meaning students attach to existing techniques
(Doorman et al., 2009). Third, the recently developed notion of teacher resources and
documents (Gueudet & Trouche, 2009) matches well with notions on instrumental genesis
and orchestration and may be worth exploring further. Fourth and final, at a more detailed
level of analysis—for example in the exemplary Spot-and-show episode—the interplay of
tool techniques and mathematical meaning became more salient. It became clear that the
The teacher and the tool 231analysis could benefit from the semiotic mediation perspective (Bartolini Bussi & Mariotti,
2008) as an additional theoretical lens. The articulation, integration and confrontation of
these different models is a challenge for research in this domain and deserves further
investigation.
Acknowledgement We thank the teachers and students ofthe experimental sites fortheir collaboration, Sjef
van Gisbergen for his work as second coder, and the Netherlands Organisation for Scientific Research
(NWO) for supporting the research study (project no. 411-04-123).

MobileMath: exploring mathematics outside the classroom
Monica Wijers • Vincent Jonker • Paul Drijvers
Accepted: 26 August 2010/Published online: 9 September 2010
The Author(s) 2010. This article is published with open access at Springerlink.com
Abstract Computer games seem to have a potential for
engaging students in meaningful learning, inside as well as
outside of school. With the growing availability of mobile
handheld technology (HHT), a number of location-based
games for handheld mobile phones with GPS have been
designed for educational use. The exploitation of this
potential for engaging students into meaningful learning,
however, so far remains unexplored. In an explorative
design research, we investigated whether a location-based
game with HHT provides opportunities for engaging in
mathematical activities through the design of a geometry
game called MobileMath. Its usability and opportunities for
learning were tested in a pilot on three different secondary
schools with 60 12-14-year-old students. Data were gathered by means of participatory observation, online storage
of game data, an online survey and interviews with students
and teachers. The results suggest that students were highly
motivated, and enjoyed playing the game. Students indicated they learned to use the GPS, to read a map and to
construct quadrilaterals. The study suggests learning
opportunities that MobileMath provides and that need
further investigation.
1 Introduction
So far, the use of handheld technology (HHT) in mathematics education has mainly focused on traditional mathematical content, such as algebra and graphing, and took
place in regular teaching settings (Trouche and Drijvers
2010). Nowadays, however, HHT has more to offer:
handheld devices offer options for other topics, such as
geometry, and can be used outside the classroom, thanks to
wireless communication. Such extended mobile devices
also provide opportunities for game play in ways that are
new for mathematics students and their teachers. These
new features are supposed to engage students in meaningful learning, inside as well as outside of school (Gee
2003; Shaffer 2006; DeVane et al. 2008), fit into the digital
lifestyle of the new generation and are expected to have
great motivational potential. Computer games may enable
setting up rich learning environments that appeal for peer
collaboration, knowledge constructions, and new roles for
both teacher and students (Egenfeldt-Nielsen 2005).
Until today, little is known about the ways in which
these assumed potentials can be exploited for the sake of
engagement in and quality of learning. Therefore, the
overarching aim of the study that we report upon in this
paper is to explore the potential of mobile HHT for the
engagement in mathematics education, and the learning
opportunities of a geometrical out-of-school game in
particular.
2 Theoretical background
The backbone of the study's theoretical framework is
formed by notions on engagement, and on authentic and
realistic mathematics learning.
This article is based on the paper 'MobileMath: the phone, the game
and the math' (Wijers, Jonker, & Kerstens, 2008) presented at
ECGBL2008, Barcelona, Spain, 16-17 October 2008.

ZDM Mathematics Education (2010) 42:789-799
DOI 10.1007/s11858-010-0276-3Mobile gaming is a general term that covers a large
range of activities including playing casual games on
handhelds as well as playing highly interactive locationbased games on mobile devices, where real and virtual
worlds are mixed. Digital games seem to be tools for
supporting meaningful learning and engagement of students, both inside and out of school (Prensky 2001; Gee
2003; Shaffer 2006; DeVane et al. 2008). Gee (2003)
connects engagement in good video games to players being
'enticed to try' (p. 65), put in lots of effort and spend lots of
time on task. Prensky (2001) connects engagement to 'total
involvement', no off-task behavior and continuous paying
attention. He formulates the following elements that need
to be carefully designed and combined in order to create
engaging games:
• rules: provide structure and organize the game play;
• goals: motivate players;
• outcome andfeedback: inform players on the progress,
provide opportunities to learn;
• conflict/challenge/competition: make games exciting;
• interaction: social aspect.
Mobile devices provide the opportunity to actually
situate learning outside school and make it possible to
integrate characteristics of effective learning such as situated authentic learning, peer collaboration and motivational power. In the definition of O'Malley et al. (2003),
mobile learning is any sort of learning that happens when
the learner is not at a fixed, predetermined location, or
that happens when the learner takes advantage of learning
opportunities offered by mobile technologies. A key
characteristic of mobile learning is that it enables
knowledge building and constructing understanding by
learners in different contexts (Winters 2007). Research on
game-based learning suggests that the combination of
reality and virtual elements leads to a mixed reality
experience which can contribute to the students'
engagement (Schwabe & Go¨th 2005). A term used to
stress this combination is hybrid reality game (HRG), as
this type of games augments the reality by adding virtual
elements to it.
Hybrid reality games (HRGs) employ mobile handheld technologies and GPS devices as tools for
transforming physical spaces into interactive game
boards (De Souza e Silva & Delacruz 2006, p. 231).
HRGs' intrinsic motivational properties transform an
otherwise dry curriculum into something entertaining
and fun, using affordable and ubiquitous technology.
However, these types of games are more than a new
snazzy delivery vehicle for the existing content.
HRGs force players to look at familiar spaces from
unfamiliar perspectives and at content learned in the
classroom from a different viewpoint, using learning
principles such as elements of social, experiential,
and situated learning. (De Souza e Silva & Delacruz
2006, p. 246)
Of course, in serious gaming, we are interested not only
in engagement, but also in learning. To enhance the
learning effects, games need to be embedded in learning
activities (Lave & Wenger 1991). The effectiveness of
these learning activities can be stimulated if the tasks are
authentic and realistic, and can be worked on in collaboration (O'Donnell et al. 2005). Recent research has shown
that the use of mobile location-aware games can contribute
to meaningful learning on several school and academic
subjects such as history (Admiraal et al. 2007) and science
(Squire & Klopfer 2007; Squire 2008). For the case of
mathematics, the theory of Realistic Mathematics Education (RME) may help us to design meaningful learning
activities.
The theory of RME stresses that problem situations
presented in learning activities should be 'experientially'
real to students (Gravemeijer 1994) and have meaningful,
authentic problem situations as starting points. Mathematics is seen as a constructive human activity that is
driven by the act of mathematizing (Freudenthal 1991).
Freudenthal (1991) stresses the importance of guided
reinvention, which underlies the construction of knowledge as if a student reinvented it. Students' own productions and constructions play an important part in the
learning process also because they form input for classroom discussions and interactive reflection. This is in line
with a socio-constructivist perspective on learning, in
which mathematics is seen as both an individual, constructive activity and as a social practice (Cobb, Yackel, &
Wood 1992). Social interaction is seen as a necessary
condition for learning mathematics (Freudenthal 1991;
Treffers 1987, 1991).
With notions of engagement and authentic, RME in
mind, we can now phrase the central question of this pilot
study:
Can a social mobile game, based on the geographical
reality, its virtual map representation, and locationsensitive handheld technology engage 12-14 year old
students in meaningful mathematical activities?
The words 'engage' and 'meaningful' evoke the following sub-questions:
• Game play: does the game engage the students? Do
they appreciate the mixed reality experience?
• Learning opportunities: Do the students recognize the
mathematics embedded in the mobile game? Do
students feel they learned something?

1233 Methods
To address the research questions, a game called MobileMath was designed, with corresponding learning activities,
and a sequence of pilots was set up. A first pilot was held
with the teachers of the three pilot schools, followed by
three pilots with students at different schools. In all pilots,
researchers observed the team activities during the game
and debriefed the teams afterward. Observations were
made either by accompanying a team outside as a participating researcher or by watching all teams in the game in
real time on the website. Notes were made and the game
data were stored online. Players completed an online
questionnaire immediately after playing.
3.1 Design of the MobileMath game
With the design of the game MobileMath (Demeyer et al.
2008), the design team consisting of researchers on mathematics education
1
and developers of creative technology
for social innovation
2
has tried to combine principles of
RME with principles of mobile game-based learning in
order to design a mobile mathematical game, i.e. engaging
and provides opportunities for mathematics learning.

As a first design heuristic, the elements described by
Prensky (2001) guided the design of the game structure.
The players' position is to be involved into the game play
and thus should support situative, authentic and collaborative learning of mathematics. Collaboration and interaction, including both social interaction and interaction with
the tools, were realized by having students play in eight
competing teams of two students. The game rules were
designed to promote both types of interaction.
As a second design principle, the RME theory led us to
search for an authentic and realistic problem situation—
where we take the word 'realistic' as meaningful rather
than as 'from everyday life'. By incorporating students'
own mathematical constructions in the heart of the game
play of MobileMath, we wished to integrate an important
tenet of RME with principles of situated and game-based
learning.
MobileMath is designed to be a HRG. In MobileMath,
we wanted the players to be immersed in a mixed reality
game environment, in which they create virtual elements,
in this case mathematical shapes, by interacting with the
real world.
We wanted to design a geometric game. By playing the
game, students were expected to deepen their experiential
knowledge of geometrical concepts related to shapes and
orientation/navigation. This includes: properties of angles
and edges of parallelograms (including rectangles and
squares); geometrical concepts such as parallel and perpendicular; and on the boundary of geography and math:
orientation and navigation in 2D (map) and 3D (real
world). These are all topics addressed in the math curriculum in lower secondary education in grade 7 or 8. The
objectives are to learn the names of the shapes and gain (at
least implicit) knowledge of some fundamental properties
of parallelograms regarding sides being in pairs parallel
and of equal length; and angles being straight or not. In the
game, they create parallelograms and thus must use and
make explicit the knowledge of these properties.
We identified the starting point for the design of MobileMath to be the game play. The mathematical content to
be learnt would be integrated into the game in an intrinsic
way. Previous research on game-based learning has shown
that the content of a game can be integrated into the game
in an intrinsic or an extrinsic way (Kafai, 1998, 2001;
Malone and Lepper, 1987). Intrinsic integration of content
(mathematics) in a game provides students with greater
opportunities to construct new relationships with knowledge in the process of playing. In this type of games, the
educational and game components are inseparable (Klopfer,
2005). A large number of the available games for
mathematics do not reflect this design principle. By realizing this intrinsic integration of game and mathematics,
MobileMath should give students the feeling of playing a
game, and at the same time have them experiencing
another way of doing mathematics.
A second design issue concerns the location-based
character of MobileMath. It was seen as important to make
sure that every school could use the game in its own direct
environment. Players can thus use their knowledge of the
environment as well as expand that knowledge by playing
the game. Although the game is location-based in the sense
that it makes use of elements in the real world, MobileMath
is not based on one specific location, but can be played
anywhere.
3.2 Pilot with the teachers
The pilot was carried out with one geography teacher, three
mathematics teachers and one computer science teacher.
This pilot had three objectives: to test the game play with a
group of 'new' players, to prepare for the pilots with students and to discuss and co-design the educational setting.
The game test was performed with five teams, each consisting of one teacher and one researcher as participating
observer. Afterward, the teachers filled in a questionnaire
and the game was discussed with all participants. The
closing discussion, in which the tracks were viewed and the
strategies of the teams were discussed, provided opportunities for reflecting and making connections between game
1
Freudenthal Institute, Utrecht University.
2
Waag Society, Amsterdam.
MobileMath 791
123strategies and aspects of mathematics (geometry of navigation and orientation and shapes) and geography (map
skills).
3.3 Pilots with students
MobileMath was piloted in grades 7 and 8. By the end of
grade 7, all students have worked on mathematical content
related to MobileMath. This includes: navigation and orientation; measurements such as length (distance) and area;
2D shapes and their properties, especially those of specific
quadrilaterals. The construction of 2D shapes is not a core
topic in the mathematics curriculum for grade 7.
Three secondary schools (from the researchers' networks) participated in the pilot with a total of 60 students,
54 of whom filled in the questionnaire afterward (see
Table 1). All pilots were observed by at least three
researchers, notes were taken and in two of the three pilots
video recordings were made.
The pilots consisted of a whole-class introduction, one
round of game play of 1 h and a debriefing session. The
whole-class introduction focused on map reading skills,
characteristics of quadrilaterals, the game rules and the
technology of the phone. In schools 1 and 2, both a math
teacher and a geography teacher were involved. Introduction in school 1 took about 50 min, whereas in school 2
only 30 min was used. In school 3, the game was introduced by a mathematics teacher the day before the game
was played. On all schools, a designer-researcher demonstrated how to use the phone. After the introduction students played a 1-h game of MobileMath in a playing field
located around school, with a radius of 1 km. Because of
the large number of students who participated in school 1,
two rounds of game play were needed: half of the students
played the game outside, while the other half watched the
game play online in the computer room at school and kept
a log of what (they thought) was happening.
At school 1, for safety reasons, all outside teams were
accompanied by a teacher or researcher acting as a participating observer. At the other schools, the teams went
outside on their own and the teachers and researchers
observed the game play online on the game website. In a
debriefing session, the stored game data and the observation notes were used to have the teams reflect on their game
play. Two forms of debriefing were used: a debriefing
session with each team immediately upon its arrival back at
school or a whole-class debriefing session. At schools 1
and 2, both forms were used, at school 3 only individual
debriefings were held. Notes were taken during the
debriefing sessions, and in two schools debriefing was
videotaped.
4 The MobileMath game
The MobileMath game, as it resulted from the design
process, is a location-based game that can be played on a
mobile phone with a GPS receiver and Windows Mobile as
Operating System. Geometry was chosen by the team to
provide the mathematical content to be addressed in the
game.
The game can be played by two to eight teams. Each
team creates geometrical shapes on a previously defined
playing field (in the real world), using a mobile phone with
GPS functionality and an on-screen map. The size of the
playing field and the duration of the game can be set by the
first player starting the game from a mobile phone. Other
teams then subscribe to this game by choosing a team
name. Players are connected with the game space and each
other through the map on their screens. During the game,
all teams can see themselves and the others as colored dots
moving in real time in the playing field on the underlying
map. The goal is for a team to gain points by covering as
much area as possible with virtually constructed parallelograms ((including squares and rectangles). Players do this
outside by walking to locations where they place, and
virtually connect, vertices. To support the process of constructing and deconstructing quadrilaterals, auxiliary lines
are visible on screen. If the fourth vertex finishes a shape
correctly (which is evaluated by the game engine, within a
margin of about 10 m), it appears on the playing field in the
color of the team and is visible for all teams. If the fourth
vertex does not finish a correct shape, it will disappear (see
Fig. 1).
Since the shapes cannot overlap, it is possible to 'hinder'
a team by trying to create a shape within a shape under
construction.
Based on a conversion rule, each shape is awarded with
a score equivalent to its area; this score is multiplied by a
factor based on the difficulty of the construction of the
shape. The difficulty of the construction is defined by the
number of constraints. Squares having the most constraints
Table 1 Overview of the pilots
# of students Grade Male Female Voluntary? Accompanied?
School 1 28 7 17 11 No Yes
School 2 12 8 4 8 No No
School 3 16 8 11 5 Yes No
792 M. Wijers et al.
123(exact right angles and equal sides) are most difficult to
construct: the factors are 29 for a square and 1.59 for a
rectangle and 1 for any other parallelogram. The created
shapes are virtual elements added to the real world as a
kind of 'overlay' (see Fig. 2): the physical world has thus
become an interactive game board.
Deconstructing quadrilaterals of other teams is also part
of the game play and teams are rewarded points for it.
Deconstruction brings extra challenge and competition in
the game. Both construction and deconstruction require
that players use their knowledge of characteristics of specific types of parallelograms and their constructions.
Figure 3 shows the locations of the four points of
deconstruction for the parallelogram in the center. Determining the location of one of these deconstruction points
on the map as well as in the real world requires a mathematical 'construction'.
As the game proceeds, teams occupy territory with their
shapes and thus the free playing space gets smaller, which
provokes interaction between competing teams. Territory
occupied cannot be used anymore, unless the shape covering it is destroyed. Deconstruction of shapes clears space
and the deconstructing team 'steals' half the points connected to that shape from the team that created it. The
game ends after a set duration, the team with the highest
score being the winner.
The game is supported by a website on which each game
can be observed in real time online and on which the game
data are stored and can be viewed back later. These data
include the tracks of all teams, which are not visible on the
phones during game play, as well as the quadrilaterals that
remain at the end of the game.
What does playing MobileMath come down to in terms
of student actions? Students look at the map and imagine
where they want to make a shape. They walk to the location for the first vertex and then enter this location using the
phone. On the map, they see the location marked with a dot
in the color of the team. When they start walking again, to
the location of the second vertex of their imagined shape, a
line occurs on the screen connecting the first vertex with
the current (moving) team location. Once the team is at the
location they see fit as the second vertex of their shape,
they enter it and a second colored dot appears; the line
connecting the dots is now solid and is an edge of the
shape. The team now plans the location for the third vertex;
they use the map on their screen in combination with
properties of the real world. There are several constraints:
the type of shape they want to make determines whether
they will go for a straight angle or not; properties of the
terrain pose constraints as well: a vertex cannot be in water
or within a building because the students must enter the
vertex on the location itself. As soon as they start walking,

location of the fourth vertex
Fig. 2 View of a finished MobileMath game showing the created
quadrilaterals and the playing field
Fig. 3 The four deconstruction points of the parallelogram in the
center
MobileMath 793
123two dotted lines connecting the two 'set' vertices with the
current location appear on the screen (see Fig. 1).
Note that it is not necessary to walk along an imaginary
edge; the connecting line will become the edge once the
location of the vertex is 'entered'; this edge can run

through buildings or over water. After entering the location
for the third vertex, the location of the last one is 'determined': students now must go to exactly that position that
finishes the shape in a correct way. Until now, there was
always the opportunity to change the strategy. For the last
vertex, accuracy is very important. It is in this phase that
we see students using the zoom options of the game:
zooming out to see their whole intended shape, zooming in
to accurately place the last vertex and, e.g., make sure the
angle is indeed a straight one. Students walk back and forth
to fine-tune the location of the last vertex.
5 Results
In this section, we present the results based on the analysis
of the observation data, the stored game data and the data
from the online questionnaire.
The first pilot with the teachers showed that the game
play proved to be engaging, that the technology worked
well and that the rules and goals were clear. Based on the
observations during game play, the group discussion and
the data of the questionnaire, it was decided that some
elements needed extra attention when introducing the game
to the students. These included: the mathematics involved
in finding the deconstruction points, the inaccuracy of the
GPS, the 'mechanics' of the grid and the use of the map,
which is not a conventional street map. As a result, the
educational embedding was designed in the form of
teaching suggestions for a whole-class introduction focusing on the mathematics, the geography, the actual handheld
phone (HTC)—provided by the researchers—and the game
play. Also, the online evaluation questionnaire for the
students was designed based on these pilot experiences.
We present the results of the pilots with students in five
sections: (1) engagement, (2) game play, (3) technical
issues (all related to sub-question 1), (4) mathematics: the
construction process, and (5) learning opportunities (the
latter two related to sub-question 2).
5.1 Engagement
Students easily engaged in MobileMath as was observed
during all of the four games that were played: no large
technical difficulties were observed and all teams played
for the full hour.
On the questionnaire, the game was rated as being 'fun'
(see Table 2). This is supported by data from the
observations made by the accompanying researchers.
Typically, students reacted very exuberant when they
completed or destroyed a shape. This was visible in their
moves as well as in their verbal outings: ''yes, we did it''.
In an open-ended follow-up question, students were
asked to motivate their 'fun score'. The reasons most frequently given are summarized in Table 3.
The most frequently mentioned positive reason refers to
the mathematical content of the game. A sample student's
response for this is: ''The game is fun because, you learn to
use GPS and you learn to construct different shapes:
quadrilaterals, rectangles, etcetera, and at the same time
you play a game''.
5.2 Game play
Most students easily understood the goal and the rules of
MobileMath. Most of the 30 teams constructed or deconstructed at least one correct quadrilateral and scored points.
There are large differences in scores, both between the four
games as well as between the teams within one game, as
can be seen in Table 4.
Table 4 shows that the students in school 1 who played
the game in the second round did better than the students
who played in the first round. The students who played
game 2 had watched and discussed the game being played

794 M. Wijers et al.
123by their classmates on the game website. Observations
revealed that the teams in this second round were more
aware of each others locations and actions.
Six out of the 30 teams that played MobileMath scored
no points at all, which means they did not succeed in
constructing or deconstructing any shape. In game 3, more
than half of the teams (4 out of 7) did not score any points.
During this game, the weather conditions were very bad:
storm and rain. An analysis of the tracks of these teams
reveals that two of them did not seem to attempt to create a
correct shape but instead wandered of to a dry and warm
place (the nearby shopping center), while the other two
teams tried but were not accurate enough.
5.3 Technical issues
None of the students had problems using the phone.
Observations showed that most students easily interacted
within the mixed reality environment, and were able to
combine the information from the map with the information from the physical world. One team, e.g., placed the
edge they just made on screen, parallel to the street to
decide whether to go left or right.
A small number of students, however, were seen to have
problems reading and interpreting the map on screen. They
had a hard time figuring out how the map matched with
their environment. This may be partly due to the fact that
the map on screen was not a conventional street map (see
Figs. 1, 2).
The technical features 'zooming' and 'checking the
scores' were used by most students (see Table 5).
Almost all students checked the scores frequently, which
helped them to make tactical and strategic decisions, like
destroying a large shape of the leading team to steal half of
their points and take over the lead. Students who used the
zoom function mentioned several reasons for doing so.
They indicated to use zoom in during the (de)construction
process to check the accuracy of their construction. Using
the zoom-in and walking back and forth in the physical
world is required to find the proper location for a vertex or
for a deconstruction point.
Zooming out was used to get an overview of the playing
field where the locations of all teams and the shapes that
had been created so far could be seen. It was also used by
teams to check their own location, and plan their course
and actions. The inaccuracy of the GPS readings, combined
with the margins and the grid, proved to be frustrating for
some of the teams.
5.4 Mathematics: the construction process
The stored game data, especially the tracks of all teams,
show that for the creation of shapes different strategies
were employed. A first strategy is based on the (virtual)
reality of the map: students deploying this strategy used
elements from the map—like rectangular street patterns
and buildings—to identify possible quadrilaterals. A second observed strategy can be characterized as 'using
knowledge of the environment around school'—students
who used this strategy knew, e.g., where a rectangular
playground was located and used this knowledge of the
physical world, to identify and construct a shape. This
strategy in which the virtual and physical reality merges
can also cause conflicts. This happened in a team of students that wanted to make a rectangle around the sports
field near school. The students walked around it (on the
sidewalk) and 'entered' the vertices on their handheld. But
three times over when they entered the last vertex, the
game gave as feedback that their shape was wrong. Only
back at school when reviewing their tracks on the computer, they noticed that the streets around the sports field
did not form a proper rectangle; two of the angles were not
90. During the game, they did not zoom out in the virtual
layer to check their assumptions that the streets in the
physical world around the field formed a proper rectangle.
The third observed strategy is a mathematical one.
Students using this strategy made their quadrilaterals as
'free standing' shapes. Two girls even leaped over a ditch
to overcome the physical barriers of the location to finish
their shape. The tracks of teams deploying this strategy are
often not related to the edges of their shapes. They indentify locations for their vertices and use their maps only
to plan a route to walk from one to the next. For these
students, the characteristics ofthe physical environment are
hardly important for their constructions, they mainly focus
on the mathematical properties of the shapes under
construction.

1235.5 Learning opportunities
The questionnaire presented the following three open
questions related to learning and school subjects:
• Did you learn something? Illustrate.
• Is this game related to geography? If so, in what way?
• Is this game related to mathematics? If so, in what way?
Most students (78%) confirmed that they had learned
something. In the open follow-up question, the majority of
them (36 out of 42) reported what it was they had learned.
Students could list more than one example. The results are
summarized in Table 6.
An example of learning occurring during reflection-inaction is the following: Two students (a team) were creating a rectangle: after they fixated the third vertex, they
noticed that they had not created a right angle. One of the
students wanted to delete this shape because 'in this way
we cannot finish the rectangle', the other student while
looking at the screen suddenly realized that another option
existed ''we can make it into a parallelogram if we put the
fourth vertex here instead of here (pointing at the map on
the screen).''
Learning opportunities could also be identified in the
introduction and debriefing sessions as is exemplified in the
following examples:
The geography teacher introduces the map used in
MobileMath by projecting it on screen. He tells the class
that this is a very simple map on which not everything can
be recognized.
T Can you see the railway-tracks?
S1 Yes, black and white
T And the water?
S2 You see two small ferry boats on the map
T Can you name something you recognize on this map?
S3 The police station (by the icon of a flame)

T Where can I walk?
S4 On this type of lines ['roads']
The mathematics teacher introduces the shapes that can
be made in MobileMath. He uses a flexible device made of
four strips to demonstrate the shapes.
T How can you be sure if a shape is a rectangle?
Students name several properties:
• the upper side is long
• the length and width are not equal
• it has four corners
T Who can tell more about the corners?
S1 The corners are the same … same
S2 … 90 degrees
S3 … straight
T How can we make a square?
S By making the length and width equal
T What shape do you think will be easier to make in the
game: a rectangle or a square?
S1 Square: you do not have to walk that far
S2 A rectangle, the length and width don't need to be
equal
T What is easier to make: a rectangle or a parallelogram?
S Rectangle
The large majority of the students recognized the relation to geography in the use of the map or the GPS. Eight
of the 54 students saw no relation to geography. Three
students saw no relation to mathematics. Most students
specify how they observed the relation between mathematics and MobileMath: 32 students used terminology
related to constructing shapes, 4 students connected this
with the calculating of the score; 6 students (also) used
other geometrical terms such as area, angles and measurements; calculating (in general) was mentioned five
times.
Other learning opportunities were identified in the
debriefing sessions. Students explained their strategies and
constructions, referring to their tracks on the map projected
in the classroom. For example, one girl (age 13) was asked
to describe and explain her team's subsequent activities
during the game in front of the classroom. The tracks of the
team are projected as a curly line on the map (see Fig. 4).
T Where did you place your vertices to make your
shapes? [T. points to the location of the school on the
lower left of the map on the interactive whiteboard]
S [Pointing to the tracks on the map] First we made this
small rectangle here. Then we made a block around the
church. Then we made a third rectangle and a fourth
one (see Fig. 5). At the end of the game three shapes
were destroyed by other teams
Reports such as the one above led to lively discussions
between students centered around the game strategies

123employed, the mathematical 'constructions' and shapes
each team made, and around the geographical aspects of
the game. Students were able to reflect on their actions:
they indicated, e.g., why in some cases their shapes under
construction proved to be incorrect, how they tried to
'hinder' other teams and how they determined the location
of a deconstruction point.
6 Conclusion
The research questions phrased in Sect. 2 focus on the
engagement provoked by a social mobile game and its
opportunities for learning mathematics. The questions are
investigated through design and through field tests with
teachers and students. We now address the two foci of
engagement and learning opportunities, respectively.
6.1 The game play engagement
6.1.1 MobileMath characteristics
What characteristics of the MobileMath game were
important for the students' engagement? We first conclude
that MobileMath indeed fulfills the characteristics of a
HRG with its intrinsic motivational properties as defined
by De Souza e Silva & Delacruz (2006). It allows players
to create an imaginary layer on top of the physical reality
by drawing shapes. MobileMath adds a geometrical
dimension to the world which is transformed into a game
board. Observations show that for the players the physical
and digital space merge, which contributes to students'
engagement. Interaction between the teams mainly took
place in the virtual reality: they spotted each other more
easily on screen than in the physical reality. This matches
with similar results found by others Squire and Klopfer
(2007), who conclude that students 'within minutes were
diving into this mixed-reality environment' (p. 403).
A prerequisite for engagement is appropriate technical
functioning. We conclude that the technical environment of
MobileMath is user-friendly, robust and flexible enough to
be used in an actual (educational) playing setting. Students
easily used the functionality of the phones. However, the
inaccuracy of the GPS readings sometimes interfered with
and frustrated the game play. For example, what looked like
a parallelogram on screen was identified by the game as
being arectangle, or a seemingly correctly placed vertex was
evaluated to be wrong. This is in line with Schwabe & Go¨th
(2005) who discussed this type ofeffects of(in)accuracy and
concluded that for tasks that require very specific locations
the inaccuracy can cause frustration and loss ofengagement.
Other, more accurate location technologies may be preferred
in that case. For MobileMath, the margins and the grid size
built into the software need to be reconsidered.
Fig. 4 Tracks of one team after they finished the game saved on the
computer
Fig. 5 Shapes created by one team, pasted manually in the tracks to clarify the protocol
MobileMath 797
123 6.1.2 Fun and engagement
Main factors that showed to be essential in enhancing
students' engagement are clear goals, objectives, and rules,
competition and interaction, which is in agreement with the
elements identified by Prensky (2001). In MobileMath, the
goal and objectives proved to be clear. Furthermore, all
teams kept setting new goals for themselves, during the full
hour. Although they were moving freely outside of school,
most students were seen to be highly motivated and
engaged during game play, almost no off-task behavior was
observed. We can also identify the other elements: MobileMath has clear rules that structure the game, and students had no problems understanding and following these
rules. The feedback in this game is immediate: every
action, its outcome and its consequences are immediately
visible on the map on the phone. Without this immediate
feedback, the game would be unplayable.
Competition provided an important contribution to the
engagement with MobileMath. There are two elements in
the game that can be described as competitive. First, the
game in itself as a whole is competitive: students are all
competing to cover as much area as possible on a restricted
playing field, and gain the highest number of points. Second, the option of destroying shapes of others brings in an
extra competitive element. This feature proved to be very
engaging: eight students explicitly mentioned it in the
questionnaire as the main reason for the game being fun.
Also during debriefing sessions team specifically and in
much detail reported their deconstruction actions and successes. Some teams during the game even specialized in
destroying instead of creating shapes. MobileMath offers
ample opportunities for interaction. Because there was
only one phone for two players in one team, the players had
to work together. In most teams this turned out to be
positive: often the two students were seen bent over the
screen together, discussing and planning their actions. In a
small number of teams, the student carrying the phone did
all the work and the other students just walked along.
Because all students were eager to play, most students did
not let this happen.
Altogether, we conclude that with the design of MobileMath we succeeded in creating an engaging game
activity. MobileMath was showed to be an accessible HRG
with engaging characteristics such as clear goals, objectives and rules, as well as competitive and interactive
elements.
6.2 Learning opportunities for mathematics
The design of MobileMath shows that mathematics can
successfully be integrated into an engaging mobile location-aware game. Almost all students recognized the
mathematics in the game and described it in mathematical
terms. The mathematical concepts build into MobileMath
(orientation and navigation, measurement, properties and
especially 'constructions' of specific quadrilaterals) were
already partly known by the students (see Sect. 5.5).
However, in the regular curriculum, creating shapes does
not receive much attention and the bodily experience of
making shapes—as is done in MobileMath—is fully new.
MobileMath invites several types of mathematical
activity, such as the (re)discovery and use of characteristics
of squares, rectangles and parallelograms, the notice of
geometrical aspects of the world, and to combine mathematical skills.
Students (re)discovered and used characteristics of
squares, rectangles and parallelograms when they
(de)constructed these shapes. In doing so, they went back
and forth between the realities of the map and the real
world. Students needed to imagine a shape before actually
creating it. They had to mentally 'see' it on the map, and
then walk to the locations of the vertices in the real world.
Students' perception of the city changed like in HRGs and
other augmented reality games. They noticed and discussed
geometrical aspects of the world, such as if streets make
right angles or not and whether they are running parallel;
they identified blocks, buildings or other structures as
having a rectangular 'top view' on the map. Combining
math skills was needed when a team studied the map and
decided on a strategy related to their position. They had to
consider aspects such as time and distance: which distances
can be covered walking? How much time is left before the
game ends? Where will a correct shape fit, can each vertex
be reached? How long will the construction process take?
Students were also observed using mathematical skills and
reasoning when reflecting on the scores, which also
involves reasoning about area.
Observations also show that during game play students
went through micro-cycles of learning and reflection in a
natural way. For each action, they needed to reflect on the
game status, which involved taking note of the playing
field and of the characteristics of the shape they were
creating in relation to the physical aspects of the terrain.
They discussed, e.g., where to place a vertex to make sure
that the angles and the length of the edge were suited to
create the intended shape. Apart from the names of the
quadrilaterals, they frequently used mathematical terms
such as parallel, (straight) angle, straight line, perpendicular, of equal length. Because they were 'acting out' these
concepts in their movements and constructions, it is likely
that their understanding has deepened and has become
experientially real.
For the further exploitation of the mathematical aspects
of the game play, debriefing sessions are important.
Although in the pilot these sessions were very short, we
798 M. Wijers et al.
123could glimpse the opportunities these sessions have for
reflecting on the game play as well as on the math involved
and thus for promoting learning. Some work is still needed
to fully exploit this potential of MobileMath for learning.
Although, as stated before, students reported they
learned something, were able to name aspects of the

mathematics involved in the game and were seen to engage
in mathematical activities and talk, we cannot yet support
the claim that MobileMath has had a learning effect. The
fact that in MobileMath students experience mathematics
to be engaging may in itself be seen as a positive result. In
future research on MobileMath, we hope to be able to
measure learning effects, and thus show that MobileMath
can contribute to students' learning of mathematics, just as
some other digital games have proven to do (Kebritchi
et al. 2008; Rosas et al. 2003; Shin et al. 2006).

Realistic Mathematics Education Theory Meets Web Technology

Abstract
This paper about realistic mathematics education (RME) and Web technology towards
mathematics reform in Indonesia. First, reform in mathematics education is briefly
described. Second, three main components that influence the reform are discussed:
new goals, new content and new theory. Furthermore, the Dutch theory for realistic
mathematics education and its characteristics is elaborated. Finally, the ongoing study
in developing a Web-based system called CASCADE-IMEI that aims to support student
teachers to learn about RME as an innovation in mathematics education in Indonesia is
discussed.

I. INTRODUCTION

Mathematics education is changing continuously. It can be seen by a movement from traditional curricula to problem oriented curricula or application based curricula (de Lange et al. 1993). Such change or reform in mathematics education can also be seen as a shift away from the transmission of knowledge by teachers towards investigation, construction and discourse (Gravemeijer, 1997). This reform is mostly influenced by changes in ideas on goals, content and the theory for learning and teaching of mathematics.

Concerning the goals, there is a growing emphasis on the usefulness of mathematics in daily practice. This trend is fostered by societal changes. 'The coming information society poses new demands to the citizens as 'mathematical literacy'. These societal changes also have their influence on the content of mathematics education in terms of reconsideration of what it means to know and do mathematics. Mathematics is not seen as a ready-made product anymore but it is stressed on the process of doing mathematics. The notion of mastery rules and procedures of mathematics is being exchanged for the idea that students should have a deep understanding of their mathematics and should be able to explain and justify it. Finally after twenty five years of developmental research, a theory for learning and teaching of mathematics education called realistic mathematics education (RME) is evolved. RME is strongly related to the constructivist theory (Freudenthal, 1991; Gravemeijer, 1994;de Lange, 1993).

II. MATHEMATICAL LITERACY: THE NEW GOAL

Mathematics literacy is a new goal that is embedded in the new mathematics curriculum in many countries. The 'traditional goals' often only has two main elements: to prepare for the work-place and for future education; and to understand mathematics as a discipline. A new set of goals were prepared by the Commission of Standards for School Mathematics of the National Council of Teacher Mathematics. It lists ten goals, five the content goals - Number and Operations, Algebra, Geometry, Measurement, and Data Analysis and Probability - explicitly describe the content that students should learn and five the process goals - Problem Solving, Reasoning and Proof, Communication, Connections, and Representation - highlight ways of acquiring and using content knowledge (NCTM, 1989).

The mathematics literacy is further articulated by the NCTM standards by proposing five general goals for students.

• learning to value mathematics. Understanding its evolution and its role in society and the sciences.

• Becoming confident of ones own ability. Coming to trust one's own mathematical thinking and having the ability to make sense of situations and solved problems.

• Becoming a mathematical problem solver. This is essential to becoming a productive citizen and requires experience in solving a variety of extended and non-routine problems.

• Learning to communicate mathematically. Learning the signs, symbols and terms of mathematics.

• Learning to reason mathematically. Making conjectures, gathering evidence and building mathematical arguments.

These goals reflect a shift away from traditional practice; traditional skills are subsumed under more general goals for problem-solving, communication and critical attitude. III. REALISTIC MATHEMATICS EDUCATION: THE NEW THEORY

3.1 Realistic Mathematics Education

RME is a teaching and learning theory in mathematics education that was first introduced and developed by the Freudenthal Institute in the Netherlands since almost three decades. RME is mostly determined by Freudenthal's view on mathematics (Freudenthal, 1991). Two of his important points of view are: Mathematics must be connected to reality; and mathematics should be seen as human activity. First, mathematics must be close to children and be relevant to every day life situations. However, the word 'realistic', refers not just to the connection with the real-world, but also to problem situations which are real in students' mind. Second, the idea of mathematics as a human activity is stressed. Mathematics education organized as a process of guided reinvention, where students can experience a similar process compared to the proces by which mathematics was invented. In this case, the reinvention process uses concepts of mathematization as a guide.

Two types of mathematization, which were formulated explicitly in an educational context by Treffers (1991), are horizontal and vertical mathematization. In horizontal mathematization, the students come up with mathematical tools which can help to organize and solve a problem located in a real-life situation. On the other hand, vertical mathematization is the process of reorganization within the mathematical system itself. Freudenthal (1991) pointed out that horizontal mathematization involves going from the world of life into the world of symbols, while vertical mathematization means moving within the world of symbols. But he adds that the difference between these two types is not always clear cut.

Treffers (1991) classifies mathematics education into four types with regard to horizontal and vertical mathematization:

(1) Mechanistic, or 'traditional approach', is based on drill-practice and patterns, which treat the person like a computer or a machine (mechanic). In this approach, both horizontal and vertical mathematization are less or even not used.

(2) Empiristic approach, the world is a reality, in which students are provided with materials from their living world. This means that students are faced with situations in which they have to do horizontal mathematization activities. However, they are not prompted to the extended situation in order to come up with a formula or a model.

(3) Structuralist, or 'New Math approach' that is based on set theory, flowchart and games that are kinds of horizontal mathematization but they are stated from an 'ad hoc' created world, which had nothing in common with the learner's living world.

(4) Realistic approach, a real-world situation or a context problem is taken as the starting point of learning mathematics. And then it is explored by horizontal mathematization activities. This means students organize the problem, try to identify the mathematical

aspects of the problem, and discover regularities and relations. Then, by using vertical
mathematization students develop mathematical concepts.
3.2 The characteristics of RME
Historically, the characteristics of RME are related to the Van Hiele's levels of learning
mathematics. According to Van Hiele (cited in de Lange, 1996a) the process of learning
proceeds through three levels: (1) real; (2) analysis; and (3) formal.
Traditional instruction is inclined to start at the second or third level, while the realistic
approach starts from the first level. Then, in order to start at the first level; that deals with the
phenomenon that is familiar to the students, Freudenthal's didactical phenomenology that
learning should start from a contextual problem, is used. Furthermore, by guided reinvention
and progressive mathematizations (Treffer, 1991), students are guided didactically to process
as efficiently from one level to another level of thinking through mathematization.
Combining the three Van Hiele's levels, Freudenthal's didactical phenomenology and Treffers'
progressive mathematization results in the following five tenets or characteristics of RME
(Treffers, 1991):
(1) phenomenological exploration or the use of contexts;
(2) the use of models or bridging by vertical instruments;
(3) the use of students own productions and constructions or students contribution;
(4) the interactive character of the teaching process or interactivity; and
(5) the intertwining of various learning strands.
In the next sections these tenets will be elaborated. (1) Phenomenological exploration or the use of contexts
In RME, the starting point of instructional experiences should be `real' to the students;
allowing them to immediately become engaged in the situation. This means that instruction
should not start with the formal system. The phenomena by which the concepts appear in
reality should be the source of concept formation. The process of extracting the appropriate
concept from a concrete situation is stated by De Lange (1987) as 'conceptual
mathematization'. This process will force the students to explore the situation, find and
identify the relevant mathematics, schematize, and visualize to discover regularities, and
develop a 'model' resulting in a mathematical concept. By reflecting and generalizing the
students will develop a more complete concept. Then, the students can and will apply
mathematical concepts to new areas of the real world and by doing so, reinforce and
strengthen the concept. This process is called applied mathematization. The two examples of
context problems, t-shirt and soda and parent's night, are presented in the next section.
(2) The use of models or bridging by vertical instruments
The term model refers to situation models and mathematical models that are developed by
the students themselves. This means that the students develop models in solving problems.
Four levels of models in designing RME lessons can be distinguished (Gravemeijer, 1994):
(1) the situational level, where domain-specific, situational knowledge and strategies are
used within the context of the situation;
(2) a referential level or the level 'model of', where models and strategies refer to the
situation described in the problem;
(3) a general level or the level 'model for', where a mathematical focus on strategies
dominates over the reference to the context; and
(4) the level of formal mathematics, where one works with conventional procedures and
notations.
(3) The use of students own productions and constructions
Students should be asked to 'produce' more concrete things. De Lange(1987) and Streefland
(1991) stress the fact that, by making 'free production', students are forced to reflect on the
path they themselves have taken in their learning process and, at the same time, to anticipate
its continuation. Free productions can form an essential part of assessment. For example,
students may be asked to write an essay, to do an experiment, to collect data and draw
conclusions, to design exercises that can be used in a test, or to design a test for other
students in the classroom.
(4) The interactive character of the teaching process or interactivity
Interaction between students and between students and teachers is an essential part in RME
(de Lange, 1996a; Gravenmeijer, 1994). Explicit negotiation, intervention, discussion,
cooperation, and evaluation are essential elements in a constructive learning process in
which the informal methods of students are used as a lever to attain the formal ones. In this
interactive instruction students are engaged in explaining, justifying, agreeing and
disagreeing, questioning alternatives and reflecting.
(5) The intertwining of various learning strands or units
In RME (de Lange, 1996a; Gravenmeijer, 1994), the integration of mathematical strands or
units is essential. It is often called the holistic approach, which incorporates applications,
implies that learning strands can not be dealt with as separate entities; instead, an
intertwining of learning strands is exploited in problem solving. One of the reasons is that
applying mathematics is very difficult if mathematics is taught 'vertically', that is if various
subjects are taught separately, neglecting the cross-connections. In applications one usually
needs more than algebra alone or geometry alone.
For additional information about these five tenets relating to the designing lessons based on
the realistic approach see Zulkardi (1999a). IV. MEANINGFUL CONTEXT: THE NEW CONTENT
As mention earlier that the first tenet of RME is the use of meaningful context as the starting
point of instruction. The following is an example of meaningful context for concept
development that was designed for students of ages 12. This problem is very powerful due to
the its position in the curriculum and the connections to earlier as well as later activities. It is
presented in a visual way (de Lange, 1996a, 1996b):
This problem I used as an assessment problem in a workshop that followed by junior high
school teachers in Bandung. Before the problem was stated the participants were told to use
the informal method. However, it appeared that most of them (see A. Syukur's solution) solve
the problem using the formal method of linear algebra.
However, one of the teacher (see Herlina's solution) solved the problem using the informal
method.
Students of ages 12 at the school come with very ingenious and different solutions. They are
not familiar with the algebraic nature of the problem and are not hindered by this algebraic
knowledge that makes the problem so difficult to teachers. Instead of using 2a + 2b = 44 and
a + 3b = 30, they solve the problem just using common sense reasoning. Students operate
differently: These two solutions are very different in nature: the first one notices that if two t-shirts and
two cups are 44, one plus one must equal to 22. They take away one t-shirt and one cup from
the second picture which leaves two cups for 8 dollars. Done. The second solution uses
regularity as the starting point. The first picture shows 2 + 2, the second 1 + 3, so the 'third'
picture must show 0 + 4. The price belonging with the third picture must be 16, fitting in the
sequence; 44, 30, 16. The student shows good insight in where the essential part of the
reasoning takes place: after noting that 2,2 followed 1,3 leads to 0,4 he writes down: almost
ready. Exactly.
Later on students will handle in a formal way systems of equations. At that time they know
informally how to reason algebraically, to understand equations, to use the proper
mathematical notation and even to understand the concept of variable. But in this case it will
take about two years to reach that level of real mathematical understanding (de Lange,
1996b).
The second example, think about a classroom with students of 8 to 9 years of age. The
teacher introduces the 'parent night' problem to his students (see also Gravemeijer, 1994; De
Lange, 1996b):
Tonight 81 parents will visit our school. Six parents can be seated at each table
How many tables do we need?
The teacher makes a small sketch on the blackboard:
The students start to work on the problem in groups 3 and 4. The teacher walks around in the
classroom, asking small questions about the process of solving the problem. The students
were eager to engage in this process. After about ten minutes the teacher ends this part of
the lesson. Students are asked to show and explain their solution. They vary quite a bit.
Austin just copied as many as of the teacher's sketch as he needed to seat the parents: Another student, Ani, started out the same way, but after drawing two tables he shifted to
more schematic representation: a rectangle with number 6 on it. After drawing two of those
'tables' he realized that five tables would add up to 30. So, via 30 to 60 and then on to 72
and 78. And finally he added the last three chairs.
A third student, Alhariz, went a step further in mathematizing the problem. Although he also
started to draw the table from the blackboard as a model he immediately schematized the
problem and used his very recent knowledge of multiplication, by using multiplies of 6. He
wrote down: 6 x 6 = 36, then doubled the 36 to 72, and added another two tables to get a
capacity of 84.
If we look from distance at these three different solutions (and of course there were many
more) we notice a different level using 'real' mathematics in this 'real-world' problem. Many
teachers would even argue that the first solution no mathematics has been used at all. But
visualizing and schematizing are also important mathematizing tools that can be very
powerful. The third solution makes the mathematics more visible and will be considered to
have a 'higher' level.
After the whole classroom discussion without making too many explicit recommendations of
wich solution is the best, the teacher continued by presenting the next problem:
The 81 parents will be served coffee, of course. Each pot holds 7 cups of coffee. How many
pots wee need?
From a mathematical point of view exactly the same problem. Instead 81:6 we now have to
deal with 81:7. Not so for the students. In the first place the context prohibits an easy
pictorial solution: the students have a hard time drawing the coffee pots as Alhariz' s solution
shows:
Alhariz, who used the most formal solution in the table problem now goes completely to
mental arithmetic with visual support. Austin, who ad the most simple solution with the
tables, tries to use the schema again with the pots. He represents them in the same way: a
series of cups around the pot. But after two pots he seems to realize the discussion about multiplication as a means to
speed things up and he jumps to: 10 x 7 = 70 and adds: 70 + 11 = 81, which give him 12 pots.
The work of yet another student, Yan, shows a typical solution for this second round of the
parents problem:
No visualization, but multiplication. Within one lesson one can easily see the progress that the
students have made towards solving this class of real contextual problems and
mathematizing in order to develop new mathematical concepts, in this case division.
V. CASCADE-IMEI: A STUDY IN THE FIELD OF REFORM IN MATHEMATICS
EDUCATION IN INDONESIA
5.1 Mathematics Education in Indonesia need to be reformed
Based on the literature review in the preliminary study of CASCADE-MEI (see also Manan,
1998; Zulkardi, 1999b) mathematics education especially in the secondary level need to be
reformed. Nowadays, mathematics education in Indonesia is categorized into the
mechanistic-structuralist approach. While many countries already change their approach from
mechanistic-structuralistic to the new approach, realistic approach, it is clear that in Indonesia
mathematics education need to be changed as well.
As a consequence of reform, alternative curricula, alternative textbooks and teaching
materials, and alternative forms of assessment (de Lange, 1993; Van den Heuvell-Panhuizen,
1996; Fullan, 1991) are essential. Selter (1997) pointed out that these are all mediated
through the teacher, specifically through teacher's beliefs about how to organize and facilitate
children's learning of mathematics. Consequently, teachers are a key players in educational
change. In this context, teacher training (pre service as well as in service) plays a vital role.
Reform efforts will seriously be hampered, if reform in teacher training is not regarded as
being as urgent as reform at schools. This implies that reform can be started from teacher
training.
As Gravemeijer (1997) pointed out, it is not easy to support teachers in order to make our
common reform efforts successful. Teacher training should not primarily be an apprenticeship
training that provides recipes and methods that are directly applicable in the classroom, but it
should first and foremost assist prospective teachers in developing their autonomy. This
implies to support them in increasing their degree of awareness: about mathematics, about
children's mathematical learning, about the quality of teaching mathematics, and so forth
(Selter, 1997). This means that a learning environment is needed that contains supports with
which student teachers can enrich their knowledge about content as well as didactic
mathematics.
5.2 CASCADE-IMEI: Theory meets technology
Information and communication technology (ICT) tools currently permeate almost every
professional domain. Web technology is starting to get used in education as well. Teachers
can use this technology to store information such as lessons or problems, then can access
these materials from many places in the world, and discuss and share problems and
experiences after using the materials in the classroom.
CASCADE-IMEI stands for Computer Assisted Curriculum Analysis, Design and Evaluation
for Innovation in Mathematics Education in Indonesia. The main purpose of this study is to
develop a web-based system which provides resources, training opportunities and
communication tools for student teachers in Indonesia, learning RME as an innovation in mathematics education. This study builds on the previous studies about computer support
system (see Nieveen, 1997) and number of studies about realistic mathematics education
(de Lange , 1987; Gravemeijer, 1994, Streefland, 1991; Van den Heuvel-Panhuizen, 1996).
The study is guided by the following main research question:
"what role can a Web-based system play in supporting student teachers learn RME as an
innovation in mathematics education in Indonesia?"
CASCADE-MEI, a rich learning environment, will be developed based on the philosophy of
RME theory which is represented in a number of support tools such as infobase (various
topics of RME lessons, teacher guides, assessment problems and student productions),
communication tools (communication and discussion using e-mail and mailing list) and
training opportunity (a course about the introduction to the RME).
Now, this is end of the second year of a four year study of CASCADE-IMEI. A number of
mathematics lessons have been developed and researched as well as the course. These
tentative result can be seen in the Dikti homepage
(http://www.dikti.org) in the 'free space' part (see figure the Website below).
VI. CONCLUSION
In this paper the new perspective on the goals, the content and the theory for teaching and
learning of mathematics education have been discussed and illustrated. These are combined
on the ongoing study CASCADE-IMEI that uses Web technology as a tool in order to support
mathematics student teachers in teaching mathematics to the students in the school.
If the Netherlands is taken as an example of a successful country in reforming the
mathematics education in the level primary and secondary school then the following
considerations should be taken in to account:
• mathematical literacy should be added to the curriculum;
• the content of curriculum should be changed into the application based curriculum;
• mechanistic-structuralistic approach should be moved to the realistic approach; and
• teacher training (pre service and in service) should change as well.
CASCADE-IMEI is focusing on these considerations by providing a rich learning environment
using Web towards mathematics reform in Indonesia. REFFERENCES

Chapter 4
Using multimedia cases for educating the primary
school mathematics teacher educator:
a design study
Maarten Dolk*, Jaap den Hertog, Koeno Gravemeijer
Freudenthal Institute, Utrecht University, P.O. Box 9432, 3506 GK Utrecht, The Netherlands
Abstract
The overarching goal of this chapter is to better understand how multimedia video case
studies can support the professionalization ofprimary-school-mathematics teacher educators.
We investigate the use of multimedia cases to support teacher educators in learning to
mathematize and didactize and to learn how to use multimedia cases with their student
teachers. The research study has an exploratory character; we will present a framework for the
use of multimedia cases as a tentative answer, grounded in the researchers' experiments and
design activities.

Keywords: Mathematics education; Primary schools; Teacher education; Multimedia cases
Over the last decades, the so-called 'domain-specific instruction theory for
realistic mathematics education (RME)' has been developed and gradually
implemented in the Netherlands. The RME approach capitalizes on students'
input. Following Freudenthal's (1991) adage of "mathematics as a human activity',
students are encouraged to reinvent mathematics. It will be clear that this puts
high demands upon teachers. Amongst other things, they must be able to give
students construction space, provide them with open investigation activities,
allow them to share and discuss their work and particularly, consider relationships between different approaches. This in turn puts high demands on teacher
educators. For instance, the teacher educators have to help student teachers develop
a constructivist approach to teaching. They have to integrate mathematics,

1
and pedagogy, and do it in such a way that student teachers are using
their knowledge in real practice. But, how does one prepare primary-schoolmathematics teacher educators for this job?
In the Netherlands, a 2-year long 16-day in-service course exists, intended to give
beginning teacher educators a jump-start. This course has been offered and revised
many times over the last 10 years. This situation proved to offer a fruitful setting for
experimenting with the use of multimedia cases in teacher education, which is the
theme of our contribution.
In this chapter, we report on what we have learnt about the use of multimedia
cases in the course of developing this in-service course for beginning mathematics
educators. In doing so, we want to address the question of: How to employ
multimedia cases in teacher education. More specifically, our research question is:
How to employ multimedia cases to support teacher educators in learning to
mathematize and didactize and to learn how to use multimedia cases with their
student teachers? Note that our research has an explorative character; we will present
a framework for the use ofmultimedia cases as a tentative answer that is grounded in
the researchers' experiments and design activities. The justification ofthis framework
is grounded in empirically based conjectures about how participants learn and how
the suggested educational investigations or multimedia cases support this learning
process. In this respect, the design-research approach fits with the general shift in the
norms of justification observed by the Research Advisory Committee (RAC) of the
NCTM (1996). Compared to traditional research, they argue, norms of justification
have shifted from assembling facts that prove one curriculum better than another, to
providing well-substantiated theories about how these curricula work. With those
new norms of justification, they go on to say, teachers (teacher educators) have some
informative theories that they can take as a point of departure. They can take the
frameworks and theories of the researchers as conjectures, to test and modify in their
own classroom. In this manner, the teachers/teacher educators can produce their
own contribution to the development of those theories, instead of being passive
consumers of knowledge produced by others. In short, we may say that the research
we present here can be seen as a case study—on the use of multimedia cases—that is
meant to function in a similar manner as the multimedia cases themselves.
The chapter is organized in the following manner. We start by framing the issue of
the use of multimedia case studies in teacher education. Next we move to our own
research by characterizing the teacher education course in which the use of
multimedia cases is embedded. Then we describe the multimedia computer
environment that is used. This will be followed by an exposition on the research
method that can be typecast as 'design research' or 'developmental research'. The
backbone of this type of research is constituted by the learning process of the
researchers, which is described subsequently. And, we conclude the chapter with a
short reflection on our findings.
1
In this paper, didactics refers to the continental European notion of didactics: The interrelation of
teaching and learning activities and processes aimed at the construction ofan understanding ofthe subject
matter by students.
 The use of multimedia case studies in the education of teacher educators
In traditional classroom observations each student typically observes a different
classroom, and the teacher educator rarely visits any of the classrooms.
Consequently what students notice varies considerably. Even if several students
observe the same classroom each student tells a different story. This leaves teacher
educators wondering whether the students really saw the same lesson. A problem is
that live classroom observations allow neither reviewing nor thinking time,
advantages that video and written cases do offer (Dolk, Faes, Goffree, Hermsen,
& Oonk, 1996; Mousley, Sullivan, & Mousley, 1996; Lampert & Ball, 1998). Having
the lesson present 'on demand' allows students and teacher educators to share
observations and interpretations and to revisit and review the lesson several times.
As anyone who has studied videotapes of lessons knows, each viewing and each
viewer bring added dimensions to what is observed. These two alternatives for
observing and studying classroom teaching differ in at least one respect: video allows
the learner a more objective view of the classroom; written cases force the learner to
look through the lens of the describer. Compared to text-based cases, real video is
closer to experiencing the act of teaching: it is multi-faceted, and allows for different
interpretations, reflections and analyses (Lin, 2001). However, we have to keep in
mind that video too has its limitations. Video, for instance, does not reflect the
ability of an observer to be aware of several groups while attending to what one
learner is saying. Case studies have been employed since the beginning of the 19th
century, first in Law Schools, later in Business Schools. Using case studies in Schools
of Education is more recent. Text-based case studies are documents describing
exemplary real life situations. The idea is that students learn to reason about the
situation, learn to generalize their thinking, developed for one case, to form the basis
for thinking about many cases. The situation becomes a tool to think with.
An educational case study can be designed so that students can easily investigate
the information, can engage in conversation about the situation. According to
Merseth (1996), to be effective, case studies need to be situated in a real world
context, rely on research, and foster the development ofmultiple perspectives. In our
perspective, case studies must allow learners to explore the richness and complexity
of genuine teaching problems because they are situated in the real classroom
(Putnam & Borko, 2000). However, in text-based cases authors often feel compelled
to reduce the complexity of the real situation, failing to portray the full complexity,
and nuances of real teaching situations. Such cases are often fine-tuned towards the
mathematical and didactical knowledge under consideration; real education is not.
How complex real-life teaching situations can be is shown by Lampert (2001), in the
opening chapter of her book Teaching problems and the problems of teaching where
she describes how an interval of a couple of minutes during one of her lessons asked
for many considerations, reflection and decisions. In general, real teaching is messy
(Duckworth, 1987). Linear video provides more information about classroom
events. For instance, it captures some facial and verbal expressions, use of time,
involvement of the learners, and the flow of the lesson. Nevertheless, it remains
unifocal, even where there is cutting between cameras. The availability of fast
computers and multimedia software expands the possible uses of video and cases in
education. Major technological issues with video, like reviewing footage and
searching and random accessing footage in video banks, have become incidentals.
Multimedia cases provide easy access to multiple sources of information: teachers'
planning, students' work, textbooks, and background reading. This development has
made written cases obsolete. Naturally, during the last decade, the development and
use of multimedia cases in teacher education has boomed.
The use of multimedia cases creates opportunities for teacher educators to have
users construct situated mathematical and didactical knowledge. However, we are
only learning to understand how multimedia cases can be used in teacher education
and how it influences a user's construction of theoretical and practical knowledge
(Galen van, Dolk, Feijs, Jonker, & Ruesink, 1993; Dolk et al., 1996; Mousley et al.,
1996; Lampert & Ball, 1998; Lin, 2001). The question of, how to employ multimedia
case studies in teacher education, is still open.
2. The mathematics-educators course
Our research question is addressed in design experiments on the use ofmultimedia
cases that were part of a larger design effort aiming at the development of a course
on the professionalization of beginning mathematics teacher educators. We will
therefore first describe this course.
The key tenets of the course can be summarized as ''mathematizing'' and
''didactizing''. Following Freudenthal (1991), we use the verbs mathematizing and
didactizing to emphasize the process rather than the product. By using a gerund
verb form, we express a dynamically emergent view of mathematics and didactics:
one more closely akin to the process of constructing meaning. The idea of
mathematizing and didactizing implies that mathematics and didactics can and
should be learned through one's own mental activities. Learners are finding ways to
explore situations mathematically (didactically), they are noticing and exploring
relationships, putting forth explanations and conjectures, and trying to convince one

another oftheir thinking. Our participants construct didactical knowledge. Didactics need not be a ''dead subject'', developed by others. Just as with mathematizing, they can explore situations didactically, notice relationships, put forward conjectures and explanations, and try to convince one another of their thinking. They can construct didactical meaning.

2.1. RME theory

One of the central tenets of RME is that the starting points of instructional sequences should be experientially real to students in the sense that they can immediately engage in personally meaningful mathematical activity (Gravemeijer, Cobb, Bowers, & Whitenack, 2000; Streefland, 1991).

A second tenet of RME is that in addition to taking account of students' current mathematical understandings, the starting points should also be justifiable in terms

of the potential mathematical end points of the learning sequence. This implies that students' initially informal mathematical activity should constitute a basis from which they can abstract and develop increasingly sophisticated mathematical concepts as they participate in classroom mathematical activities. At the same time, the situations that serve as starting points should continue to function as paradigm cases that involve rich imagery and thus anchor students' increasingly abstract mathematical activity.

These central tenets are worked out in a domain-specific instruction theory for Realistic Mathematics Education that is grounded in numerous concrete elaborations of the RME approach. This domain-specific instruction theory can be typified by three design heuristics (Gravemeijer, 1998): guided reinvention through progressive mathematization, didactical phenomenological analysis, and emergent modeling. This theory, however, cannot be transmitted to (student) teachers in a ready-made form.

Instead, we have to create a basis for discussions on RME and on how to guide the reinvention processes of the students, by having the student teachers experience reinvention and mathematizing for themselves. The same holds for teacher educators. In addition to, experiencing this process, the course participants (teacher educators) are presented with activities like anticipating solutions of primary school students, and analyzing student work and multimedia cases.

2.2. Didactizing

In teacher education, Goffree and Dolk (1995) have identified reflection, narration and construction as being particularly important. Reflection is seen as a precondition for learning, especially for learning from one's own activities. Therefore, it is important to stimulate beginning teachers to reflect on their classroom experiences and actions. We have, however, to take into account, that the students' a priori experiences and beliefs will influence what they learn of what is taught in teacher education courses. Furthermore, they construct their own understanding of educational theory and build their own practical knowledge. Often, educational theory presented to pre-service teachers is not used in practice (Wubbels, 1992; Wideen, Mayer-Smith, & Moon, 1998). Beginning teachers find it difficult to connect the theories they studied during pre-service teacher education to their images of a teacher, to their feelings of fear, disappointment, etc., and to values embedded in everyday practice in schools, values they quickly internalize. They also tend to consider theory oflittle worth in the light oftheir personal concerns about survival in the classroom.

The problem of connecting theory to practice can be analyzed from two perspectives. One perspective is that of the difference between the knowledge scientific theories offer and the kind of knowledge teachers need. The other perspective is that of the problematic character of the use of knowledge in immediate teacher behavior. We will briefly discuss both perspectives since they constitute key elements of the rationale of the experimental course, and of the use of multimedia cases in this course.

2.3. Scientific knowledge versus practical wisdom

Korthagen and Kessels (1999) analyze what they call the gap between theory and practice, and describe an approach to teacher education that might help to link theory and practice. In their article, they go back to Aristotle's concepts of episteme and phronesis to explain the difference. They use the distinction between episteme, which they translate with ''scientific knowledge'', and phronesis, which they translate with ''practical wisdom'', to make a distinction between Theory-with-a-capital-T, and theory-with-a-small-t (Korthagen & Kessels, 1999). Episteme aims at more general knowledge about types of situations, while the emphasis of phronesis is mostly on perceiving more in a particular situation and finding a helpful course of action on the basis of strengthened awareness. This strengthened awareness of concrete characteristics in specific situations helps student teachers to discover, in the specific situations occurring in everyday teaching, which methods and strategies to use.

We consider educational theory in literature as formal knowledge, as Theory-witha-capital-T. This theory is based on formal research, applicable to a wide variety of situations, and can be characterized as ''objectively reasonable belief''. We consider theory developed by learners as theory-with-a-small-t. This theory is often still situation-specific, and related to the context in which it was developed. This theory is formed on the basis of generalization across a number of situations. It is more perceptual than conceptual. It focuses the attention of the actor in the situation on certain characteristics of the situation, characteristics important to the question of how to act in the situation.

Narrative knowledge can be starting point to theorize theory-with-a-small-t. Narratives are an account of a situation, containing affective and theoretical descriptions of the observation of that situation, and of the events and actions in the situation. An educational narrative is more than a story about the situation, it is integral to communication among educators and, as a consequence, to the development and sharing ofeducational knowledge (Gudmundsdottir, 1995; Mason, 2002).

Teachers can tell about events in the classroom in a personal manner. Their story contains their interpretation of an educational situation, including the actions of the children and the teacher. Teachers express their knowledge in these stories; it is a narrative way of knowing (Gudmundsdottir, 1995; Tripp, 1993). These stories tell as much about them as they do about the event recounted. Narratives represent knowledge that is situated and remembered in stories and that is related to real situations, but may be overlaid by theories, beliefs, attitudes, expectations, assumptions and the desire to be seen as 'in the right'. This knowledge is personal, in the sense that there is a personal history to the situation and, of course, a personal interpretation of the situation. Constructing narratives from learning experiences will help teachers to reflect on those experiences. Narratives also play an important role in the relationship between teacher knowledge and teacher behavior.

In conclusion, we may argue that student teachers will benefit from constructing narrative knowledge. Our point of departure is that multimedia case studies can

function as a mediating tool in transcending the apparent dichotomy between theory and practice and can be instrumental in helping teachers develop situated practical knowledge about teaching (compare the framework put forward at the end of this chapter). Students' and teachers' practical knowledge is often embedded in their stories about classroom situations. In our view, these stories or narratives relate to observations, interpretations and analyses of classroom events, reveal essential aspects of (realistic) mathematics education, can be theoretically charged, and are easily remembered and recalled (see Tripp, 1993; Bruner, 1996). For teacher education, developing narratives through multimedia case studies can play a central role in transcending the dichotomy between theory and practice. In principle, experienced teacher educators will gradually develop their own way of working for this.

Our starting point is the thought that if student teachers are being taught to use new media, by using new media, it makes sense to prepare beginning teacher educators similarly. Most beginning primary mathematics teacher educators are new to teacher education; they might have experiences in other types of education, in other subjects, or with students of other age groups and often, in the beginning, are not able to transfer those experiences to their new position. So an in-service course also needs to address their concerns and help them to develop knowledge and experiences for teacher education. Teacher educators, on the one hand, need to develop mathematical and didactical knowledge, and, on the other, to develop knowledge of the teaching of student teachers; specifically, they need to develop insight in ways of using multimedia case studies for the education of their students (see Mason, 1998).

2.4. Immediate teaching behavior

Most Dutch primary school teachers use mathematics textbooks for planning their day-to-day lessons. Based on the last lesson, they will decide how to continue the next day. Teachers' theoretical and practical knowledge plays a crucial role in these decisions. Also, during the lesson the teacher has to make many ad hoc decisions on how to support students in constructing mathematical knowledge (see Clark & Peterson, 1986). Often, these decisions are characterized by a lack of time to reflect on what happened and to make a conscious decision (Eraut, 1995; Dolk, 1997; Mason, 2002). Dolk (1997) calls these unconscious reactions to a situation immediate behavior. Theoretical knowledge (Theory-with-a-capital-T) will not change immediate behavior. However, we need to understand that this behavior does not arise by magic; immediate behavior is the result of Gestalts (Korthagen, 1993; Dolk, 1997; Korthagen & Kessels, 1999), it is a response to a dynamic juxtaposition ofperceptual influences. This means that it will be possible to influence immediate behavior.

With modern technology, a learning environment can be designed for students to investigate and possibly acquire practical knowledge. In such an environment, students are given the opportunity to construct situated practical knowledge in the form of narratives and to generalize this knowledge to the broader teaching context.

Theory is no longer a starting point of teacher education. Here, narrative knowledge can be acquired by investigating real teaching. This environment and the way it is used in teacher education ought to allow for the construction of theory, the consideration of Theory, and the construction of new repertoire.

2.5. Multimedia environment

In our experimental courses, we used a multimedia environment, MILE, developed by the Freudenthal Institute, which allows users to search for classroom footage in a video database, and accompanying students' and teachers' materials. MILE is a Multimedia Interactive Learning Environment for prospective primary school teachers, with content for primary mathematics teachers education programs (Dolk et al., 1996; Goffree & Oonk, 2001). It is computer based and furnishes a database of real classroom teaching open for didactical investigations. It allows (prospective) teachers and teacher educators to study many aspects of mathematics education in primary schools. The environment consists of a video database of real teaching and learning practice in primary schools, communication tools for learners, a search engine, a scrapbook, and a journal for the learners. Several lessons are available for investigations by learners, creating opportunities to develop conjectures about teachers' practical knowledge and teaching behavior and the effect of that. Also, the environment allows them to analyze students' learning over time, and to investigate parts of the process by which students develop mathematical understanding. Therefore, MILE enables learners to investigate the relation between teaching and learning in primary school mathematics lessons (Fig. 1).

Each lesson is divided into short fragments. The division is based on subject matter and pedagogical and educational points of view. Each fragment is provided with an abstract, in which the story of the fragment is told. These abstracts make it possible for learners to select relevant and smaller fragments. They can for instance select a fragment in which students are discussing a developed strategy, where the teacher facilitates a conversation on a mathematical topic or where students develop a mathematical model.

Of course, in the case of a database with more than 3500 fragments, a learner needs other entry points besides an archive. Therefore, a search engine allows the learners to search the database in several different ways. Firstly, they can search the class dialogue based on full text retrieval. Secondly, they can search the abstracts based on full text retrieval and eventually, they can search the fragments on the basis of contextualized subject matter related labels. These labels, used to classify the narratives, are based on the educational, psychological, pedagogical, and subject matter pedagogical literature.

2.6. Rephrasing the research question

The MILE software does not offer a framework for investigating these episodes, to mathematize and didactize them and construct situated knowledge. Nor does the architecture of the software offer beginning teacher educators support in using

multimedia cases in their colleges. What is needed are multimedia case-based educational methodologies. This brings us to rephrasing our research question: How to employ multimedia cases to support teacher educators in learning to mathematize and didactize and to learn how to use multimedia case studies with their student teachers.

3. Research method

Within the context of the design, trial, and revision of the course for beginning mathematics educators, the question of how to employ multimedia cases became an independent topic of research. Given the interwovenness with the course design, the research naturally took the form of design research (Gravemeijer & Cobb, 2001; Edelson, 2002). With Edelson (ibid) we may argue that there are good reasons for engaging in design research. First, design research provides a productive perspective for theory development. After all, the range and completeness of the theory are immediately tested in the design process. Incompleteness will provide the designer with conflicting guidance, exposing inconsistencies. Furthermore, designers have Fig. 1. The archive, a part ofthe MILE environment, gives an overview ofthe lessons in the digital school and of the fragments in these lessons.

practical considerations to guide them. This provides a natural focus for theory development. The second reason Edelson mentions is the usefulness of the results. The prescriptive theories that design research produces provide educators with applicable research products. And thirdly, Edelson argues, design research involves researchers in the improvement of education. Researchers can withdraw from prevailing considerations driving traditional educational designers and educators; they have the opportunity to create innovative designs.

In our conception, design research, or developmental research, as it is called in the Netherlands (Gravemeijer, 1994), is driven by the cyclic process of thought experiments and education experiments that is at the heart of educational design.

2

Each teaching experiment, i.e. each enactment of the experimental course, consisted of a chain of such micro-cycles. In our case, a thought experiment would typically concern a deliberation on how the participants would think and reason while participating in an activity that involved the use of multimedia case studies. The

corresponding education experiment would then concern the trial ofthat activity and
the interpretation of the reactions of the participants in light of what was
conjectured.
3
As a consequence, we did reconsider our design regularly during the teaching
experiment. The ongoing analyses of the participants' individual and social activity
informed new anticipatory thought experiments, in the course of which conjectures
about possible learning trajectories were frequently revised. These revisions,
however, were guided by a more robust, but potentially revisable, local educational
theory.
In our research, this (conjectured) local educational theory was cast in terms of a
framework for the use of multimedia cases that aims at helping teacher educators
construct knowledge from episodes of classroom situations. A preliminary framework emerged from the finding that observing, reflecting, generalizing, and
theorizing had become essential components of the experimental course. Once
explicated, this (conjectured) framework could be used and put to the test in the
subsequent teaching experiments—which in our case encompassed three cycles of
teaching the experimental course. In those teaching experiments, the (conjectured)
framework, on the one hand, guided the thought experiments and the interpretation
of the education experiments, but on the other hand was revised and refined on the
basis of the very same thought and education experiments—which is indicated by the
double arrows in Fig. 2.
This focus on the ongoing experimentation process emphasizes that ideas and
conjectures were modified while interpreting participants' reasoning and learning
during the teaching experiment. The empirical data on the activities of the
participants was interpreted in the light of the theoretical framework of teacher
2
As an aside, we may note that to some degree, developmental or design research, action research, and
didactical engineering are comparable. In choosing the framework and terminology of developmental
research, we follow a long Dutch tradition in research in mathematics education.
3
Compare Simon's (1995) notions of 'mathematical teaching cycle', and 'hypothetical learning
trajectory'.
education described earlier. In this respect, we can speak of testable conjectures
about both the course of participants' development and the specific means of
supporting that development. These conjectures were then modified and revised
throughout the teaching experiment. Each session constituted a design micro-cycle in
that the assumptions and conjectures proposed while planning the activities were
scrutinized in the light of actual observations.
A further aspect of the methodology concerns retrospective analyses conducted on
the entire data set collected during the experiment. This data set included field notes,
recordings of individual interviews with participants, copies of the participants'
written work, and meeting notes of the designers/researchers who taught the course.
One of the primary aims of a retrospective analysis is to support the constitution
of a revised local instruction theory (or in our case framework). This is the starting
point for the next teaching experiment. Here, the cyclic nature of the methodology,
noted on the level of instructional design micro-cycles, reappears on a broader level.
An entire teaching experiment and the subsequent retrospective analysis together
constitute a larger design cycle; a design cycle that was carried out three times in our
research (Fig. 3).

Fig. 3. Design macro-cycles.
The final version of the local educational theory (or the multimedia-use
framework) can be seen as the result of the learning processes of the researchers, founded in the reality of teaching. Similarly, we can characterize design
research as the learning process of the research team, and we would argue that
this learning process has to justify the outcome of the research project (Gravemeijer,
1994, 1998). In relation to this we can refer to the methodological norm
of ''trackability'' that is used as a criterion in ethnographic research (Smaling,
1992). This norm requires that the research is reported in such a manner that
an informed outsider could retrace the learning process of the research team. In
the next paragraph, we will describe our learning process as designer/researcher but,
due to page limitations not with the amount of detail the aforementioned norm
requires.
4. Findings
4.1. Designing a course for teacher educators with the use of MILE
The first thing the developers of the course encountered when a multimedia case
study was used was that the participants could not agree on what happened in the
footage (see Jaworski, 1988; Galen van et al., 1993). Nor was there one prevailing
approach to viewing classroom footage. Some ofthe participants felt they had such a
good overview of teaching that making notes or reviewing the footage were not
necessary. Others had made extensive notes and felt compelled to review the footage.
In the sharing after the first observation, most participants could only partly describe
the occurrences in the footage. Some were more inclined to value the teacher's
actions; others were focusing on the students. Some participants tried to stay close to
the observations; others were freely interpreting the footage on the basis of their
knowledge and personal beliefs.
In the second round, we designed a new case to make the participants-as-a-group
agree on the paraphrasing of the footage before they could interpret or analyze it.
This led to a cyclic process of viewing and discussing the footage. Each round of
discussion ended with a list of observation questions. After several rounds most
participants agreed upon the paraphrasing of the footage.
The next thing the developers noticed was that the participants preferred skipping
a discussion about their observation and analysis of the footage; they ''raced''
toward conclusions based on a mixture of theoretical and practical knowledge and
personal beliefs. Most participants tried to produce hard statements, containing
values and judgments. They were often not able to prove them. Hardly ever did their
conclusions lead to hypothesis or questions.
In the next round, we redesigned the multimedia case study framework, guiding
participants towards a more investigative analysis. After extensive observation and
discussion of the observation, we challenged the participants to analyze the footage
and propose alternative explanations, to prove and disprove these, and to formulate
investigative questions for further study.
In several cycles, several case studies were developed based on the four steps ofthis
framework: observation, paraphrasing, analysis and reflection. For example, after
observing and discussing a conversation between a student and the teacher, the
participants had to role-play the situation. Their different interpretations of the roles
and the underlying analysis of the two characters were discussed.
Over time, we became aware that this approach led the participants to develop
situated mathematical and didactical knowledge. However, they did not apply that
knowledge in their teaching of student teachers, nor did they develop theoretical
knowledge on using multimedia cases in teacher education. Furthermore, during the
four steps the participants switched constantly between discussion of the footage
from their point of view and from their expectations of their student teachers' point
of view.
These led to a redesign of our framework. We added steps to develop narrative
knowledge and to consciously expand the teaching repertoire of the participants. To
have participants construct knowledge about the framework we designed, we
designed the case to have them make the six steps twice, once at their level and then
at the level of the student teacher. Furthermore, we introduced a 'backburner': the
possibility for participants to reflect on the framework and on their learning. The
latter can be seen as some form of pro-flection, of preparing oneself to notice more
sensitively and/or to act differently in the future (see Mason, 2002).
4.2. Six-step design framework: from observing a situation to the construction of
educational meaning
Using this iterative process of experimenting, analyzing, and adjusting we
developed a six-step (Fig. 4) framework: an approach to working with multimedia
cases and to constructing mathematical and didactical meaning and repertoire in the
MILE environment. The six steps in this framework are:
1. Observing,
2. Sharing and Discussing Observations,
3. Analyzing,
4. Reflecting,
Observing
Discussing
Observation
Analyzing
Reflecting
Developing Narrative
Knowledge
Expanding the Personal
Repertoire and Generalizing
Fig. 4. Six-step design framework.
5. Developing Narrative Knowledge,
6. Expanding the Personal Repertoire and Generalizing the Situation into a Didactic
for Teacher Education.
4.3. Observing
Observation is a didactical principle (Freudenthal, 1991). Our participants need to
observe learning processes, to become aware of and report the many aspects of
teaching. As Freudenthal (1991) states, teaching and didactical experiences result
from observing learning processes. Teachers' practical knowledge and their behavior
are based on and justified by experience.
Observing is difficult. After viewing a fragment of a lesson once, participants are
often certain they can give an accurate description of that classroom episode. As
different participants share their observations, most participants have to admit that
other observers noticed things they missed. However, there is more.
4.4. Sharing and discussing observations
On the one hand, sharing and discussing are meant as stimulation to observation.
In sharing and discussing their observations, learners are encouraged to reflect on
their observational and reporting strategies, to see discrepancies between different
observations as a stimulus to observe more (better, deeper) and to question their own
observations. Not only do the participants become aware of the inaccuracy, and
incompleteness of their observations, they also become aware of the interaction
between their interpretation of the situation and their observation of the situation.
They become aware that their (un)conscious beliefs of teaching and learning, and
their educational knowledge take the form of a filter that allows only a part of the
situation to be observed, and that parts of their report of the situation are based on
their interpretations of the situation, not on the situation itself.
On the other hand, sharing and discussing the observation helps to overcome the
learning paradox—when you do not know much, you cannot see much; when you
know more, you see much more. Through comparing and discussing the
observations of peers, participants will be challenged to widen their observation
and therefore their analysis of a situation.
4.5. Analyzing
During an archaeological excavation, researchers dig up evidence of human
civilization. Later they try to reconstruct that civilization by analyzing their findings.
In the same manner, didacticians try to analyze their observations. Teacher
educators benefit from being able to analyze classroom observations and focus on
each of the three elements of the didactical triangle (the children, the teacher, the
subject matter within the contextual situation-environment and the interaction
between them). For instance, the analysis can focus on reconstructing the children's
construction of mathematical meaning. It can attempt to probe the children's
understanding of the situation. It can also focus on interaction between the
mathematical problem and the children's understanding.
These different foci help participants to understand what observations are
worth reporting, and to construct mathematical and didactical meaning for the
classroom situations. Learning to observe, report and analyze is a circular
learning process. Participants need to be able to make rich observations allowing
multiple interpretations, to be able to analyze the situation thoroughly; but to be
able to make such a rich observation, participants need to have constructed a
deeper understanding of classroom situations through ongoing analysis of those
situations.
4.6. Reflecting
Following Schon's (1983) suggestion of a conversation-with-the-situation,
participants are challenged to reflect on the situation and construct practical
knowledge from it. Reflection is seen as a precondition for the process of
constructing meaning and knowledge, especially for learning from one's own
observations and analysis. This process is based on the experiences and viewpoints of
the participant, underlining the cyclic character of this six-step approach.
4.7. Developing narrative knowledge
Students' and teachers' practical knowledge is often embedded in their stories
about classroom situations. These stories or narratives relate to observations of a
classroom event, reveal essential aspects of (realistic) mathematics education, can be
theoretically charged and are easily remembered and recalled. For teacher education,
such narratives can play a central role in intertwining theory and practice. These

narratives are more than classroom anecdotes. The latter will not support the
development of deeper understanding of the situation unless organized in
educational or psychological categories.
4.8. Expanding thepersonal repertoire and generalizing the situation into a didacticfor
teacher education
To construct theoretical knowledge through the development of narratives,
participants are enticed to generalize narratives of several analogous situations into
one encompassing narrative. By generalizing the situation and the narrative, the
participants build a personal didactical theory. Where conscious practical knowledge
can be put into words, it becomes open to examination by scholars who may then be
able to turn it into formal knowledge. At this moment in the process, we challenge
the participants to become that scholar and to examine their own theory.
At the same time, they work in classroom situations, interviewing children and
teachers, organizing mathematical investigations. This allows them to try new
classroom behavior and expand their repertoire.
M. Dolk et al. / Int. J. Educ. Res. 37 (2002) 161–178 1754.9. Cycling processes
These six steps are not independent. The arrows in Fig. 4 indicate that sets of steps
are related to other steps. The process is cyclic, observing and discussing the
observation forms the basis ofthe analysis and reflection ofthe situation. However, at
the same time, the analysis and reflection will fuel new questions for the observation.
5. Concluding remarks
In this chapter, we addressed the issue of the use of multimedia case studies in
teacher education, by investigating a specific setting—that of the professional
development ofbeginning mathematics education teachers in the Netherlands. Based
on our research, we propose a six-step framework that aims at helping the
participants develop narrative knowledge. In this manner we want to both transcend
the presumed dichotomy between theory and practice, and foster a sound basis for
immediate teaching behavior that fits the ideas of realistic mathematics education.
Our experiences with the emerging framework in our design research give us
confidence that it can work in this manner. However, for us, it is still a tentative
framework. Further research is needed, not only in our own experimental setting,
but also in different settings. At this moment, the framework as developed in this
study is being used in the development of CD-ROM learning environments.
We hope that other teacher educators and researchers will be inspired by our
account of what we learnt, and take our framework as a point of departure for more
formal research or more informal experiments on the use ofmultimedia case studies,
in other settings than the one described in this chapter. If that happened, our design
research would have achieved what we intended.

ABSTRACT The article presents a review of the competence-framed concept of
compulsory mathematics education and appropriate instruction methods, in light
of the international influences on Croatia through comparative ranking in PISA
mathematical literacy. We begin by reviewing the conceptual constructs behind social
influences on the supra-national development of the literacy/competence concept
in mathematics education and assessment, and briefly examine its components and
instructional contributions. Within this context we proceed to map past and current,
and extrapolate future, changes in the conceptualisation of school mathematics and
mathematics teaching in Croatian compulsory education, including recent empirical
findings on mathematics instruction in Croatian primary schools. The aim is to examine
social and (comparative) political influences on subject-matter and teaching of 'hard'
school subjects such as mathematics, chart Croatia's current position according to
international assessment and instructional trends, and recommend possible steps in
immediate development of educational policy.
Key words: PISA testing, competence, literacy, mathematics, instruction, problem-based
learning, compulsory education in Croatia.

1. Mathematical Knowledge, Mathematical Competence and PISA: What does
Society Want from Compulsory Mathematics Education?
When comparing the conceptual and social development of the aims of mathematics
instruction to the performance in international assessment such as OECD's PISA, the
crucial leverage is provided by the teachers' understanding of the aims of mathematics instruction and their access to and choice of practices to achieve it. As the aims
of mathematical education change under international and social exertion, can the
classroom practices, and teachers primarily responsible for it, follow? In the mid-
1990s international comparisons of educational systems and content began taking
shape (Bishop, Clements, Keitel, Kilpatrick and La-borde, 1996.), including mathematics education. In fact, 'hard subjects' such as mathematics and science education,
provided a more stable ground for comparison than the more context dependent
liberal arts education (Domazet, 2006.). Thus, PISA international assessment assumes that mathematical knowledge and skills are not culture-bound and thus are fully
internationally comparative.
In a comparative mathematics education volume from 1996. M. Niss (as cited in
Hoogland and Jablonka, 2003.:1) states that traditional goals of mathematics education had been, by then, considerably broadened to include the "essential aspects of
numeracy and "mathematics literacy" in society" (Hoogland and Jablonka, 2003.:1).
Despite that statement 'literacy' does not as yet feature strongly in the actual content
of the review. By 2003., and the next edition of the same review, the situation changes drastically. This is also the time when the international PISA assessment, which
strongly features the 'mathematical literacy' context, begins to permeate educational
development thinking in increasing number of countries. The PISA theoretical framework has many similarities with the theoretical perspective adopted for mathematics education called realistic mathematics education, which is itself rooted in H.
Freudental's ideas about mathematics teaching (Freudenthal, 1973.).
It is important to mention here that realistic mathematics education (RME) is, as a
teaching and learning theory, substantially determined by Freudenthal's view of
mathematics as a human activity connected to reality, close to children and relevant
to society (Heuvel-Panhuizen, 2003.:10). Accordingly, in addition to the use of contexts in mathematics teaching and learning, RME attached significant importance to
mathematics teaching as a process in which students develop and apply mathematical concepts and tools in a realistic problem context. As opposed to the traditional
mathematics education, such an approach presented a shift towards modernisation
of mathematics education and its current developments. Subsequently, different social influences on the broadened definition of goals of mathematics education can
be detected, from developing human capital to achieving environmental awareness
or social change (Jablonka, 2003.). Mathematical education was no longer just about
transferring the canon of 'mathematical knowledge' to the uninitiated youth, but
about satisfying broader social goals in that. And the national framework curricula
and international assessment were to reflect that aim. M. Domazet, B. Baranović, J. Matić: Mathematics competence and international...

Perhaps this trend is globally today most evident in the OECD/PISA approach (Organisation for Economic Co-operation and Development [OECD], 1999.) which includes mathematics education as one of the instruments of development of human
capital. Mathematics was not just some abstract body of knowledge, but contained
skills and a way of thinking to be applied in numerous real-life situations, professional tasks and global cooperation. Through broadening to 'literacy' applicable

in wider contexts than a classroom, mathematics education was to become more
causally relevant to raising living standards and intensification of economic activity
(development of human capital, Jablonka, 2003.).
When comparing the 'mathematical literacy' definitions of the contemporary international PISA assessment and the more traditional expectations of mathematics
education that Croatian teachers were trained in and work with, a gradual change
from abstract training in understanding of the world's deterministic regularities to
participation in a numerical-analytical society is observed. This is a reflection of the
global trend of linking mathematics education with real-life contexts, and expression of societal pressures extraneous to specific subject concept on the definition of
educational outcomes. Because existence of such pressures cannot be ignored, they
are relevant to the review of conceptual construction of a specific subject (in this
case the 'hard' subject of mathematics, cf. Domazet, 2006.) and its teaching practices,
without being used as an overall assessment of an intrinsic quality of mathematics
education in Croatia.
The most senior practicing teachers (just under 40% of overall lower-secondary
teacher population according to 2003. research, Baranović, 2006.) would have been
initially instructed that "The aim of primary mathematics education is to introduce the
students to quantitative understanding of the world, to identification of mathematical
structures that are used to describe the phenomena and the regularities in social
and natural sciences, and are applied in everyday life." (Furlan, Kaučič, Muhvić,
Podgorski, and Zadrović, 1974.:72) This definition is immediately followed by a list
of instructional tasks in mathematics which contains various forms of mathematical
knowledge and understanding but no specifics of their application in life other than
general rationality and orderly precision. At the outset of Croatian transition (1991.)
no significant content change is reported in mathematics instruction (Jakopović,
1991.), and average age of practicing maths teachers in Croatia makes this their
primary training definition (Baranović, 2006.). Some instructional changes are
advised with claims that teacher-centred lecture-style instruction cannot ensure
adequate development of youths as it 'passivises' the young person and hinders the
personality development. Although mathematical instruction is expected to prepare
students for employment and scientific and technological development of the state,
application of knowledge in students' everyday life is listed in the last place.
In a first revision of the educational content in the transitional period (Ministry of
Education and Sport of Republic of Croatia, 1999.) practical applicability of mathematical knowledge is abandoned altogether and the overall aims of mathematics
are listed purely in terms of knowledge appropriation and its application in further
learning and other natural and social sciences. Again mathematics is tasked with Sociologija i prostor, 51 (2013) 195 (1): 109-131
112

developing rational thinking, orderliness and precision of expression. Although,
of course, all of those can be applied in everyday life, there is no explicit mention
of the real-life situation or specific professional tasks. Subsequent revision in 2006.
(with PISA present on the global stage) lists the general goals of education as development of individual personalities and overall knowledge society, but no particular application of knowledge is listed (Ministry of Science, Education and Sport
of Republic of Croatia, 2006.). In mathematics instruction itself, enabling students
to join various professions, economy, use contemporary technology and become
members of contemporary society is cited, but the main goal of mathematics education is appropriation of foundational mathematical knowledge, development of
basic mathematical literacy and ability to solve mathematical problems. Application
of mathematical knowledge in everyday life is now listed higher up in instructional
tasks, right after skills in mathematical expression and numerical literacy.
Finally, the most recent reform initiated in 2011. and ongoing, justifies compulsory
mathematical education with the need to equip students to successfully participate
in the society reliant on information and technology (Ministry of Science, Education
and Sports of Republic of Croatia [MZOS], 2011.). Mathematical instruction is now
repeatedly explicitly connected to its everyday and lifelong learning application in
various forms (numeracy, spatial cognition etc.). The curriculum framework document explicitly states that through mathematical instruction " students will realise
the importance of mathematics in their daily lives, gain insight into the historical
development of the discipline, and come to understand its role and importance in
the society of the past, present, and future. [...]They will gain exposure to mathematical problems found in real, everyday situations, thus linking the discipline with
their everyday lives..." (MZOS, 2011.:80). Among the explicit goals of mathematical
instruction, appropriation of basic mathematical knowledge and skills is immediately followed by the application of mathematical principles "in various contexts,
including professional life" (MZOS, 2011.:80).
The PISA assessment on the other hand, tests for literacy defined as "an individual's
capacity to identify, to understand the role that mathematics plays in the world, to
make well founded judgments and to use and engage in mathematics in ways that
meet the needs of that individual's life as a constructive, concerned and reflective
citizen" (Organisation for Economic Co-operation and Development [OECD], 2003.:
24).
1
The new concept of mathematics as mathematical literacy is of special importance for Croatia which has recently joined the PISA assessment and introduced
changes of the mathematics curriculum as a part of the broader national curriculum
reform (2011. reform mentioned above). Joining the assessment subjects the whole
of Croatian compulsory mathematics education complex (curriculum-teachers-students-schooling processes) to rough-and-ready comparisons on global scale, which
1
Though there are definitions of mathematical literacy assessed in PISA prior to and following
the given 2003. definition, this is the one most closely related to the discussions in other sources cited in this text, as well as the one used at the outset of the 2003.-2009. period for which
some comparative results are presented below. M. Domazet, B. Baranović, J. Matić: Mathematics competence and international...
113

are more often than not one-dimensional in terms of ranking of means of assessment performance.
As such they ignore both the greater breadth of aims of school mathematics education than sole achievement of literacy in mathematics requires, and the variations in
conceptual construction of mathematics education between Croatian contemporary
textbooks and curricula on one side, and PISA educational outcomes definition on
the other. Moreover, the international assessment rationale itself assumes that different curricula affects across countries are entirely unproblematic and comparable by
simply choosing to adopt the trans-curricular character by fiat (Keitel and Kilpatrick,
1999.). Actual assessment of individual curriculum and instruction complex's performance must be aligned with explicit goals of the curriculum as they are prescribed
to teachers (cf. Schoenfeld, 2002.). Thus, for example Glasnović-Gracin empirically
illustrates the differences between goals of Croatian mathematics education as defined in in-use textbooks and curricula and PISA competences definition (Glasnović
Gracin, 2012.). Furthermore, there are empirical demonstrations of how these discrepancies between international assessment programmes (such as PISA) and different national mathematics education complexes vary between countries, making the
testing items more or less applicable to what the students were actually prepared for
through education (Schmidt, Wang and McKnight, 2005., Schoenfeld 2002.; cf. also
Mešić 2012. for related case of TIMSS international assessment).
Summarily put, what is important for our purposes here is that PISA should not be
used to indicate the overall quality of particular national compulsory mathematics
education, but its comparative output against a well-defined set of criteria, whilst noting the general influence such international assessment (and subsequent rankings
produced) has on the curricula and instruction within countries (see below). In that
light recent research findings on the state of the math education
2
indicate (Baranović
and Štibrić, 2011.) that the Croatian teachers have notionally adopted the requirement of applicability of mathematical knowledge, but still perceive the operational
components of this requirement in a traditional way.
Namely, when ranking the importance of students' learning outcomes
3
mathematics
teachers valued most highly application of mathematics in everyday life (56.0% of
2
The research we are referring to was carried out in 2010. using a random stratified representative sample of 625 math teachers (Grades 5-8) from elementary schools throughout
Croatia which is 31% of the total number of math teachers working in elementary schools
in Croatia during the data collection . The administered teachers' questionnaire covered the
following dimensions of math education: teachers' mathematics-related beliefs, importance
of students' learning outcomes that foster the development of mathematical literacy, students'
activities during math lessons, usage of teaching materials and tools, teachers' estimates of
the characteristics of the existing math curricula and teachers' perception of self-efficacy. The
research results were presented at the ECER conference, held in Berlin in 2011. (Baranović
and Štibrić, 2011.).
3
Out of 18 offered students' learning outcomes, the teachers were asked to choose 5 outcomes to which they attribute most attention. Sociologija i prostor, 51 (2013) 195 (1): 109-131
114

teachers' responses) and adoption of a positive attitude towards mathematics (55%
of responses) while most other learning outcomes, which are characteristic of PISA
concept of mathematical literacy, were ranked very low: e.g. students' reasoning
about mathematical concepts and processes (13% of responses), critical thinking
about math concepts and procedures (15% of responses), mutual communication of
ideas and results (18% of responses) etc. At the same time, and as indicated by the
operational goals of mathematics instruction above, the teachers attributed relatively
significant attention to the specific learning outcomes which are typical of traditional approach to mathematics, e.g. students' hard and thorough work during math
lessons (35.0% of responses), students' confidence in solving standard mathematical
tasks (31.5% of responses), mastering the math syllabi (32%), etc. (Baranović and
Štibrić, 2011.).
Though aimed at the 'same animal' (Niss, 2003.b:215), different historical and present-day delineations of school mathematics instruction place different emphasis
on the everyday social and professional context of the current students and future
employees and citizens. Whereas Croatian 1970s and 1980s students were expected
to be initiated into the quantitative understanding of the world, which would in part
open up the riches of natural and social scientific description of it, the 2000s global
citizens, trained in mathematical literacy, are much more focused on the judgements
about the role of mathematics in occupational and social life. This further illustrates
the difference in construction of the desired outcomes of compulsory mathematics
education through time in Croatia and globally, which also bears on the straightforward assessment performance of the student population.
M. Niss (one of the participants of the PISA conceptual team) is explicit (Niss,
2003.b:216) about the role of mathematical literacy in maintenance of, and participation in, democratic social activities, something that mathematics as pure, fundamental science is decidedly outside of. And although maintenance and participation
in the social order and societal operations will involve many mundane activities like
checking someone else's sums, Niss is convinced of the deeper role that mathematical literacy plays in a society, a role that goes back some way to the "quantitative
[and scientific] understanding of the world" (Furlan et al., 1974.:72). He says that it
has a role to play in allowing individuals to come to grips with how mankind perceives the world, its natural, social, cultural and technological aspects. "[Mathematical
literacy is an essential component] in liberating literacy and popular enlightenment"
(Niss, 2003.b:217). Again, bearing in mind that PISA does not explicitly asses the
mathematics curriculum, whose goals should be broader than the outcomes assessed by PISA programme (cf. Schmidt et al., 2005.), we note that training solely for
literacy and 'applied knowledge' can miss out on the depth and comprehensive understanding of mathematics subject matter even when achieving high performance
in assessment (Schoenfeld, 1988.).
There is a worry that 'mathematical literacy' is just 'easy mathematics', the 'mathematics for the un-mathematical'. From the perspective of the historical and social
influences on the broadening of mathematical instruction and educational aims, it
is worth heeding a statement from apartheid-conscious South Africa (Julie, 2006.) M. Domazet, B. Baranović, J. Matić: Mathematics competence and international...
115

that 'mathematical literacy', even when perceived as 'easy mathematics', is democratically enabling for a broader population. Given the stated importance of mathematics in everyday life in contemporary society it is exclusive to limit the instruction
and understanding to only those with 'mathematical potential'. Julie is adamant
that mathematical literacy, whether we like it or not, is justified by globalisation,
technological availability of access to knowledge and the "world-wide thrust for
regular testing [...] through international comparative studies". Nonetheless, even as
'literacy', school mathematics can come in empowering or disabling forms, as a tool
contributing to the participation in the spectrum of relevant global worldviews or as
just a 21st century version of basic arithmetic (Julie, 2006.). And in South Africa the
public can still remember how the latter 'lower form' of mathematics instruction was
used as a tool of discrimination and domination.
For the purposes of this paper it is worth noting the liberty to switch between the
mathematical literacy and mathematical competence. Though there might be entire
volumes dedicated to fishing out the fine details of the difference, we shall contend
here with using both to describe the mathematical ability that can be and is applied
outside the strict mathematical factual knowledge reproduction tests. So Hoogland
and Jablonka (2003.) say that various definitions of mathematical literacy relate to
an individual's capacity to understand mathematical aspects of everyday situations
and make judgements about them based on the mathematics learnt at school. As we
have seen above, PISA includes in the definition of mathematical literacy engagement in mathematics and forming of judgements of the roles mathematics plays in
current and future lives of the students. Likewise, a more socio-politically motivated
concept of competence (which in several of its European iterations explicitly includes mathematical competence) is based on the DeSeCo attempts to define 'key competences useful for a successful life for individuals and a well-functioning society',
and progresses towards, for example, "the ability to apply learning outcomes adequately in a defined context (education, work, personal or professional development)"
(Office for Official Publications of the European Communities [CEDEFOP], 2008.).
Moreover, the DeSeCo elaborates that 'competence is not limited to cognitive elements; it also encompasses functional aspects (involving technical skills) as well as
interpersonal attributes (social or organisational skills), values and ethics, attitudes,
emotions, and motivation (Rychen and Salganik, 2003.; CEDEFOP, 2008.). Indeed,
Silver (2003.:27) refers to the historical foundation of the attempts at settling the
definition of mathematical competence in the definitions of literacy, numeracy and
expertise. Silver hints at mathematical competence potentially being a wider term
than literacy, so as to include more of the academic or expert reasoning, whilst
maintaining the applicability to everyday life requirements. For the purposes of the
discussion of the innovations of teaching practices we can safely focus on the part of
competence where it fully overlaps with literacy, the part in which mathematics instruction has to focus on something more than the initiation into the academic discipline. Silver himself will warrant this with stressing the importance of examining the
application of mathematical knowledge in context of its everyday applicable use.
Niss, as one of the authors of the PISA definitions, bases the definition of mathematical competence on the supposedly more familiar notion of literacy in general (Niss, Sociologija i prostor, 51 (2013) 195 (1): 109-131
116

2003.a). Just as literacy involves the mastery of written and spoken language, a use
of language, so mathematical competence consists of the ability to understand and
use mathematics in a variety of mathematics-related contexts and situations in which
mathematics plays a crucial role. This, of course, consists of the mastery over a lot of
factual knowledge and domain-specific skills but cannot be reduced solely to those.
It is also important to note for our purposes here that there are attempts to define
competence as an "attribute of participation in an activity system" (Gresalfi, Martin,
Hand, and Greeno, 2009.; Engeström, 1993.; Greeno, 2006.; Lemke, 1990.). The purpose of introducing this dimension here is to highlight the social and cooperative
aspects of mathematical competence. The point to be emphasised following Gresalfi
et al. (2009.) is that what counts as "competent" becomes construed in individual
classrooms, and can take a different appearance from one to another. Teachers and
their own implicit definition of mathematics competence are most immediately responsible for such constructions.
With all those in mind, it is important that Croatian teachers today mostly realise the
importance of teaching mathematics for its application in life, rather than initiation
in the abstract discipline and worldview. However, beneath the surface expression
of aim to 'apply mathematics in everyday life', they show low preference for some
of the more specific learning outcomes that are characteristic of the new concept of
mathematical competence. Following the introduction of those into the new National Framework Curriculum, they should be developed in greater detail in a way that
teachers could implement in the lessons. But, as we shall see, curricular design is
less than half of the story, as instructional practices and teachers general workload
contribute to the attainment of students in standardised testing and their retention of
knowledge for application in life.
2. PISA: Testing for Life?

Through the international assessment whose outcomes are most readily presented
in the ranked form, the PISA definition of mathematical competence eventually influences, through pressures external to curriculum conception, the understanding of
mathematics to be promulgated through the individual national curricula. That is if
the participating countries want to enhance their international ranking performance,
which most undoubtedly do as a matter of prestige. In fact, as Niss (2003.b:217)
puts it, in order to comply with the PISA competition for rank "it becomes a crucial
task to find and employ new ways to define and describe mathematics curricula that
focus on mathematical competence rather than on facts and techniques". The other
possible response is to highlight inadequacies in the PISA programme itself, which
might incrementally contribute to its overall improvement, but will eventually reach
the boundaries of 'aiming at the same animal' (cf. above) and reaping the benefits
of contemporary mathematics education trends. What we are primarily interested
here is the social phenomenon of influence of PISA on national instruction practices
and curricula, whilst aware of the misalignment of Croatian compulsory mathematics
education and PISA (cf. Glasnović Gracin, 2012. and above) and the general societal influence on competence construction (cf. Domazet, 2011.; Halász and Michel,
2011.). M. Domazet, B. Baranović, J. Matić: Mathematics competence and international...
117

On the other hand, through Niss' own admission, (Niss, 2003.a:120) PISA definition
of the desired mathematical literacy is influenced by the work on the Danish national programme of mathematical competence definition, in addition to the already
mentioned RME development even further back (cf. Freudenthal, 1973. and above).
What is interesting for our purposes is to briefly survey the competence concepts
that were included in this definition, as well as the assessment practices based on
those. According to Niss, competence concept in mathematics divides into two major groups of more specific competencies. The first group consists of capability in
asking and answering questions in and with mathematics (Niss, 2003.a, p. 118): thinking mathematically, posing and solving mathematical problems, modelling mathematically, and reasoning mathematically. The second group represents capability to
use mathematical language and tools: representing mathematical entities, handling
mathematical symbols and formalisms, "mathematics" communication, and making
use of relevant and available aids and tools. These are the components closely shadowed even in the latest PISA assessment framework (Organisation for Economic
Co-operation and Development [OECD], 2009.:106-7).
These have been developed in greater detail so as to try to address many perspectives on what mathematically competent person should emulate. There is no room
here to enter into those, but what is more interesting is the ability to successfully
test for the mastery of the complex competence defined in this way. This has to be
achieved in a way to avoid the traditional and simple test of the initiation into the
academic discipline of mathematics, but also to provide the teaching process with
a realistic and reasonable outcome of instruction rather than some holistic property
which some students have and others do not. If on the PISA definition, the competence requires the ability to 'identify, understand and engage in mathematics' and
'make judgements about the role of mathematics', what is the adequate instruction
(and subsequent testing) to look like?
Niss understands, at least in part, the PISA definition as requiring the preparedness
to act mathematically on the basis of knowledge and insight (Niss, 2003.a:119).
And the test he envisages for that has to be founded on the range of the students'
competences in relation to the mathematical activities they are or may be involved
in as part of everyday life. Here he envisages the testing outcome to consist of the
three dimensions product of which is the total competence level, as the spatial
volume is the product of three spatial dimensions. The dimensions are the degree
of coverage, the radius of action and the technical level of competence activation.
What is traditionally mostly taught and tested for is the first dimension: the extent to
which the students master different aspects of the school subject's cognitive content.
But the complex notion such as PISA definition aims to test for requires the test to
vary and assess for the spectrum of contexts in which the student can recognise the
potential for and successfully draw on the different aspects of competence listed
above. Finally, in the contemporary global context, the technical level calls for the
assessment of the conceptual and technical complexity of the aids and tools the
students can depend on to activate the application of different aspects of competence
named above. Sociologija i prostor, 51 (2013) 195 (1): 109-131
118

A proviso immediately follows, that the fully adequate assessment of the possession
of competence is more than a single test can hope to achieve. But when it tries to
come even close to this, it has to provide as broad as possible a spectrum of activities in which the degree and range of competence possession can be demonstrated.
In that respect, the PISA Assessment framework envisages several clusters of tasks
in which combinations of component competences can be assessed for in different
ways: the reproduction cluster, the connections cluster and the reflection cluster
(OECD, 2009.). But the clusters also respect the hierarchy of complexity, with reflection being the most complex and the reproduction the simplest.
In this sense, the competence-based 'innovative' international framework shows clear connections to the foundations of mathematics teaching and testing: to reproduce
the basic cognitive items and skills, to make independent connections and reason
through broad reflection on the abstract knowledge in combination with the specificities of the given context. In that respect the PISA assessment presents a fine-tuning
on the base of the traditional mathematics instruction ('introduction to quantitative
understanding') that majority of Croatian teachers have been trained in.
4
In other
words, it is a question of reorienting and not rebuilding mathematics instruction.
But the degree of reorienting required can be extensive, as will be discussed below.
Although national standardised testing takes increasing importance in quantifying
and certifying educational outcomes in Croatia, the main outcome of competencebased education should still be a successful application of the competences developed to everyday life beyond schooling and assessment contexts. As has already
been mentioned above, the research among Croatian teachers reflects as much: the
highest ranking elements of mathematical competence as outcome are 'apply mathematics in everyday life' and 'adopt a positive attitude towards mathematics' showing
the teachers are aware of the trends. However, some of the operational formulations
of those outcomes, as derived from for example PISA-related definitions, enjoy a
very low preference amongst teachers (as presented above).
5
In a discussion of the effect of teachers on the international mathematics standardised assessment performance (comparisons of the performance of the East Asian and
Western students in mathematics, such as Lapointe, Mead, and Askew, 1992.; Stevenson, Lummis, Lee, and Stigler, 1990.) teachers' own competence in mathematics
and pedagogy was assumed to be a major factor in influencing student performance. However, repeated study by Leung and Kyungmee (2002.), comparing the East
4
Only the most recent generation of the practicing mathematics teachers in Croatia will have
undergone their initial teacher-training based on the more recent mathematical concept definitions (2006. and 2011.), whilst majority of the practicing teachers for their initial training
relies on the 1974. conceptualization and its 1991. and 1999. derivatives.
5
Though PISA is not the only competence-based outcome construction, it is useful here
for both its broad application and expansive examination, whilst providing an interesting
expansive international comparison and paradigmatic societal influence on national education systems. M. Domazet, B. Baranović, J. Matić: Mathematics competence and international...
119

Asian teachers from different regions (Shanghai, as presented in Ma, 1999., versus
Hong Kong and Korea) found that it was the ability to specialise in mathematics
teaching and the general workload that mostly contributed to the teachers' own
competence in fundamental mathematics and their grasp of, and subsequent ability
to freely manipulate, mathematical concepts. The advantage of Shanghai teachers,
which registered both in their students' performance in standardises testing (cf. PISA
performance overview below), but also in teachers' own test and concept manipulation performance stemmed from them teaching mathematics only and only in one
grade in a certain year, whilst bearing a lighter teaching load, allowing them to devote their full attention to preparing the particular grade's (innovative, conceptually
foundational) lessons.
The disadvantage of the other teachers assessed lead to their lower (though not
insufficient) grasp of the fundamental mathematical concepts, but more importantly,
to their reliance on traditional teacher-centred instruction that excludes the investigative navigating of students' own exploration or other instructional methods conducive to constructivist-based conception of mathematics learning and instruction.
Leung and Kyungmee (2002.) admit that there was also some attitudinal justification
for the teacher-centred procedural instruction, resting on the teachers' explicit beliefs that the problem-based learning is unsuitable for the early stages of schooling.
That basic rules and procedures have to be 'drilled' first. However, when pressed
to explain the success of the non-Shanghai East Asian students in the standardised
testing, despite the limitations their teachers face, Leung and Kyungmee (2002.) claim that fundamental conceptual understanding is not a prerequisite of a successful
practical application of knowledge. They are of the belief that successful blind task
completion through repeated practice can of its own lead to conceptual understanding at a later stage.
Be that as it may, Leung and Kyungmee (2002.) concede that only within a well
designed curriculum, such that concepts are introduced in a measured interlace
with systematically varying exercises, can such a 'practice-makes-perfect' route to
understanding and eventual competence-mastery be followed. This sees a division
of labour in mathematics instruction where the task of the conceptual innovation in
mathematics instruction is carried by the curriculum and textbook designers. The
teachers are then only asked to competently follow the curricular recommendations.
This seems to be similar to the Croatian practice, where little freedom in curricular
design is left to the teachers, and their teaching practices (as is reported below)
reflect the focus on teacher-centred instruction. Nonetheless, the international performance certified competence of the East Asian students can be attributed, at least
partly, to the competence of their teachers.
Country performances on the mathematical literacy scales can be a contested issue,
which becomes obvious from the change in the mode of presentation of the results
in PISA reports 2003. to 2009. (where bare statistical differences are replaced with
a more narrative interpretation of the individual results' importance). However, for
the purposes of this text there is no need to enter into their detailed analysis, and
it is useful to approximately focus on the mode of presentation applied in the la-Sociologija i prostor, 51 (2013) 195 (1): 109-131
120

test report (Organisation for Economic Co-operation and Development [OECD],
2010.:134) where grouping of countries is provided with respect to significance
6
of difference in score. In that respect, and regarding the literature drawn on in this
text (Leung and Kyungmee, 2002.), it is illustrative to compare the mean overall
performance of Croatian students in 2006. and 2009. to that of students from selected East Asian economies and countries consistently exhibiting a top performance,
and participating countries from the former shared Yugoslavian state (Montenegro,
Slovenia and Serbia) where structural similarities in educational goals and teacher
education may exist.
We note the limitations of the PISA testing in relation to Croatian curriculum, as well
as the variations in the assessment programme itself as described by Glasnović Gracin (2012.), but are not after relying on PISA rankings here to expose the quality of
the overall mathematics curriculum or instruction. Moreover, whilst a lot of ink has
been shed over analyses of national PISA performance and many different overall
ratings constructed, it is the simple overall rankings of the type mentioned here that
present the paradigmatic case for the international ranking pressures on the construction of national educational outcomes. This text, on the other hand does not
endeavour to enter into details of analyses of comprehensive reasons for individual
countries' performance (which would go far beyond curriculum and instruction
alone), but to describe a simple link between educational outcome definitions in
Croatian documents through time and contemporary international pressures.
East Asian countries and economies exhibit consistent performance at the top of the
scale in mathematical literacy, which has sparked research interest some of which is
drawn on below. Croatia participated in PISA assessment in 2006. and 2009., where
the latter performance results slide downwards on point scale. Although its students
performed below OECD average Croatia remains on the scale above Serbia and
Montenegro. Slovenia, which is the first former Yugoslavian country that joined the
European Union
7
, shows performance above OECD average
8
, but not as high as the
East Asian countries and economies.
6
"Significance' here refers to statistical significance as presented by the official OECD PISA
publications (OECD, 2010.).
7
Slovenia introduced reforms to primary education structure in the 1990s by extending general compulsory education to 9 years (with 6 years primary education) and outcome-oriented
national curriculum.
8
In PISA 2003. results presentation there are significant differences presented including and
excluding the Bonferroni adjustment. We have no need to enter into this level of detail of
statistical presentation here, as we are concerned only with a rough overall trend. However,
as the exact rankings of countries' performances can be a sensitive issue politically we refer

html). M. Domazet, B. Baranović, J. Matić: Mathematics competence and international...
121

Moreover, Croatian students rate mathematics among the least interesting and most
difficult school subjects. It requires a lot of their study time and effort, even though
they show awareness of its importance in both present and future life. Very few of
them are encouraged to learn more, and report being mainly passive recipients of
knowledge in mathematics lessons. Mathematics was ranked second of least liked
school subjects, mainly for being difficult and incomprehensible (Marušić, 2006.).
As stated above, also no radical changes in content and its presentation were introduced in the Croatian context, and the mathematics instruction is still primarily
teacher-centred. Although mean ranking in international assessment programmes
should not be the primary and only goal of mathematics instruction, given the
complex intersection of students' attitudes to the subject, teaching practices and curricular aims it is worth exploring the link between curriculum and instruction, and
acquisition of competence as tested by PISA (bearing in mind all its limitations and
failures, as stated above).
3. Teaching for Competence
Not only is the development of competence a recently trendy expressed goal of
schooling, it is also a conventional human need for those earnestly engaged in a
learning process. It includes understanding when, where and how to achieve certain outcomes, and feeling efficacious in performing the actions leading to them. In
this way the notion of competence is closely tied to the theories of motivation for
studying mathematics, which in turn is closely connected to the way that the content is presented to the students. To support the acquisition of competence, rather
than mastery over set tasks, communication about mathematics between teachers
and students should be significantly altered from that used in traditional classrooms (Lampert, 1991.), the instruction that provides feedback, over and above the
evaluation of testing success, should be conducted, and methods which focus on
interactive, collaborative, and investigative teaching should be employed (Sriraman
and English, 2010.). Turner et al. (1998.) show that such practices are related to
increased intrinsic motivation to learn. Moreover, to make students themselves aware of the process of development of competence as part of motivation for learning,
teachers need to provide space for students to reflect on what they do and do not
understand, including explication of reasoning behind reaching certain correct and
incorrect answers. This in turn leads to increased conceptual thinking which provides a firmer foundation for the overall competence in mathematics beyond the set
school tasks (Kazemi and Stipek, 2001.). Facilitating students' cognitive restructuring
and conceptual reorganizations that precede the school mathematics competence
development is what constructivists see as one of the teachers' core responsibilities
(Cobb, 1988.).
Qualitative study by Wilson, Cooney and Stinson (2005.) examined mathematics
teachers' experiences and attitudes concerning how teaching for understanding should be designed. The interviewees offered some insights on their own and students'
prerequisites for competence development. Former refers to teachers' need for de-Sociologija i prostor, 51 (2013) 195 (1): 109-131

122
S o c i o l o g i j a i p r o s t o r
veloping more efficient strategies for connecting and visualizing mathematics, as
well as assessing students' understanding (Wilson, Cooney and Stinson, 2005.). On
the other hand, some of the recognized strategies aimed to enhance students' comprehensiveness in learning mathematics are use of varied approaches for engaging
students in the learning process (precisely; ICT use, writing ideas, team-working,
applying mathematics, hands-on and laboratory activities etc.) (Wilson, Cooney and
Stinson, 2005.), encouraging hypothesis making plus building and defending student strategies of mathematical problem-solving (Lampert, 1991.) and discussing the
limitations of students' current methods together with finding alternatives (Cobb,
1988.). However, the overarching precondition for the successful process of competence development is a students' perception of free, safe, errors-allowing learning
environment in which they are inclined to actively participate. Alternatively, Voigt
(1985.) points out that if teachers impose methods, i.e. outline them as demands,
not suggestions, students are likely to run away from constructive learning activities
into finding whichever shorter, superficial way that leads to demonstration of mathematical behavior teachers expect (Cobb, 1988.; Schoenfeld, 1988.), not resulting in
profound understanding.
Evidently, in order to enhance the development of broadly considered mathematical
competence, various constructivist-based teaching methods should be deliberately
employed. However, if teaching strategies used in classrooms still largely fall under the scope of what is considered to be direct instruction (as it is evidenced by
numerous studies across educational settings, e.g. Malzahn, 2002; Baranović, 2006),
is it realistic to expect the development of broader, functional and 'realisitc' mathematical competence to be occurring and be apparent in the results of assessments?
As Halász and Michel report for the full spectrum of Key Competences, beyond the
normative curricular definition of the goals of mathematical instruction lies the more
difficult practical implementation resting on the change of professional behaviour
of teachers who already have deeply rooted instruction and assessment practices.
This requires classroom level innovations which still need to be implemented Europe-wide (Council of the European Union, 2010., as cited in Halász and Michel,
2011.:298). New ways of organising learning in an innovative school environment
remains a task to be completed in an implementation of the mathematical competence framework. But Halász and Michel's analysis admits that changing learning
environments is the most difficult implementation challenge. This poses system-level requirements for 'national educational innovation', but also massive investment
in teacher 'capacity development' (Halász and Michel, 2011.:303-304) so that they
become capable of adapting their classroom level practices to the educational goals
defined in the novel way.
One of the things this improvement involves, in connection with the requirement to
provide learning applicable in contexts outside classrooms, is the orientation on student-centred instruction. Depaepe, De Corte, and Verschaffel's (2007.) study particularly highlights that curricular and textbook innovation alone is insufficient to successfully implement the novel instruction approaches. Specifically, it is the
teachers
who play a very active role in the implementation of the curricular materials. They M. Domazet, B. Baranović, J. Matić: Mathematics competence and international...
123
S o c i o l o g i j a i p r o s t o r
interpret, and this may be unconscious, the new instructions through their existing
and prior knowledge and set practice patterns. Even more importantly, the demands
of the aforementioned constructivist-based instruction may be too complex for the
teachers who have been trained in the traditional delivery of mathematical concepts
and standard examples for practice. Ensor (2001.) can be drawn on to highlight and
illustrate the importance of in-service training to raise awareness of the obstacles
expected based on the previous studies, as well as the specific preconceptions that
a group of teachers situated in a particular national context may have.
There is research (Erickson, 1999.) showing that problem-based learning (PBL) strategies in classroom can assist with the added value of competence outcome, as
opposed to bare knowledge and mathematical skills developed through traditional instruction. Applying mathematics to everyday life and complex interaction of
knowledge from multitude of domains requires students to readily combine the
mathematical conceptual knowledge with the problem solving and communication
skills, creative and critical thinking skills, as well as positive attitude and values
(Tamirzi et al., 2010.:4864). Innovative teaching methods, such as problem-based
learning, have on their own not been shown to have a significant influence on conventional mathematical assessment performance compared to traditional teaching,
but have made significant difference to the mental effort invested into the real-life
mathematics problems (Tarmizi, Tarmizi, Lojinina, and Mokhtara, 2010.). Needless
to say, problem based-learning is not the only instruction strategy to be applied in
competence-oriented classroom, nor is all mathematics curricular content suitable
for problem-based instruction.
Though this does not make them an ideal candidate for raising national PISA scores,
it suggests that they can play a role in producing learning outcomes more suited to
the competence-model. Other studies (Depaepe et al., 2007.; Silver and Stein, 1996.),
performed in a longer run of lessons, suggest that there is a significant difference
even in the test performance and post-test retention in favour of the problem-based
instruction. Even more importantly, problem-based learning led to more positive
beliefs about and attitudes towards learning and teaching mathematical problem
solving, and even greater readiness to apply the problem-solving skills gained in
real-life situations. These are all important factors in both students' motivation for
adoption of mathematical content and the type of educational outcome that international assessments like PISA aim for.
Problem-based or investigative learning is a teaching method in which students
are exposed to realistic, simulated real-life problems that are ill-structured and vague before they are exposed to new concepts and skills training covering the problem (Bridges and Hallinger, 1992.). Whilst a broader delineation of the scope and
structure of problem-based learning is beyond the scope of this text (cf. Hmelo-Silver, 2004.), the given definition is useful for conceptual and instructional comparisons drawn on in this text. The popularity of the teaching method grew internationally (Savin-Baden and Major, 2004.; De Corte and Verschaffel, 2006.) over the
last
few decades, as it raises students motivation to learn because the outcome is no
longer a successful completion of a school task ("for the sake of school", Tarmizi et Sociologija i prostor, 51 (2013) 195 (1): 109-131
124
S o c i o l o g i j a i p r o s t o r
al., 2010.:4864) but the real life problems whose solution is meaningful outside the
school context. In that case the problem itself becomes the instrument of learning,
and through successful solution of the problem learning is inevitable (Culver, 2000.;
Kain, 2003.). This is opposed to the traditional mathematics instruction which is
focused on exercise, rules, concepts and mathematical relations to be learnt, but
which can easily turn out to be of limited use in unfamiliar real-life 'mathematical'
situations. Unlike in the problem-based learning situations, traditional instruction
does not provide much opportunity to develop one's own innate abilities and adapt
and change the methods applied to a task so as to fit new situations. Because of its
focus on group work and proving the successful solution of the problem, problembased learning fosters communication, graphical and visual presentation, modelling
and explicit group-reasoning.
Following Tarmizi et al. (2010.) we will take problem-based learning to consist of
the introduction of a real-life mathematics problem before being exposed to the
mathematical concept that was named as part of the learning outcome of the lesson.
Multiple paths to the problem solution are encouraged, and individual exploration
takes place. The students take to solving the problem through the group discussion
and the helpful notes from the teacher and examples from textbooks. This can also
include students' own mathematical formulation of the problem (as opposed to its
real-life description), predicting possible solutions, experimenting with different real-life situations and running their own student projects. Following the completion
of the task the students present their solution as a group, and the teacher in the end
summarises and reinforces the new concepts learnt.
The traditional teaching, on the other hand, is based on the teacher-centred instruction where students are led through introduction of new concepts and their use in
mathematical problem examples. The students most often copy this demonstration
from the blackboard. The students are then asked to practice similar questions as
the ones shown in examples by the teacher. They will also eventually be examined
on the questions similar to the ones practiced, through following tasks set in the
workbook or exercise book. Some of the practice can be done by individual students
on the blackboard, whilst others can follow and copy in their own notebooks. Part
of student learning may also be to complete the lesson by demonstrating ability to
publicly repeat definitions and formulas. The instruction itself is in this case seldom
interactive and most of the communication is one-way, with students as recipients.
In Croatia, recent research on the teaching methods, teaching materials and tools
shows (Baranović and Štibrić, 2011.) that the traditional approach to the mathematics teaching prevails in its many dimensions.
9
According to the teachers' own
responses, during mathematics lessons the Croatian students in compulsory edu-
9
We relate to the findings of the research described in the footnote 1. M. Domazet, B. Baranović, J. Matić: Mathematics competence and international...
125
S o c i o l o g i j a i p r o s t o r
cation most often solve standard mathematical tasks. For instance, most teachers
reported
10
that their students predominantly solve tasks they have demonstrated
(93.5% of responses), practice mathematical problems similar to those in the exam
(87.3% of responses), solve standard tasks individually at their desks (84.0% of responses), work on formal tasks from workbooks or textbooks (82.0% of responses).
On the other hand, the teachers reported that their students are least engaged in
independent exploration of mathematical concepts and patterns in the classroom
(5.9% of responses), application of mathematical concepts and patterns outside of
the classroom (10.9% of responses), explanation of their ideas and reasoning about
mathematics topics in written form (13.1% of responses), performing their own student projects (14.0% of responses), articulation of their own mathematical problems
(14.8% of responses), etc.
The use of teaching methods reflects this traditional approach as the teachers most
often use traditional teaching materials and tools while they rarely use contemporary
ICT and visualisation tools. More than 90% of teachers stated that they use geometric
demonstration equipment (97%) and students' textbooks (91%) often and very often.
A great number of them also use printed task-sheets and workbooks (90%) and so
called 'mathematical manipulatives' (84%). But only one third of the teachers use the
Internet, one fifth use mathematics software (e.g. Geogebra, Geometar - Skechpad)
and 16% of teachers use the mass media (e.g. newspaper, TV) as sources or aides.
With, for example investigative or problem-based, learning's connection to the
everyday application of mathematical knowledge and post-test retention of knowledge, Croatia's predominantly traditional teaching methods and tools seem out of sync
with requirements for development of mathematical competence. Despite teachers'
appropriation of the novel goals of application of mathematics to everyday life,
their teaching methods still reflect the deeper attachment to the traditional aim of
the transmission of abstract mathematical knowledge. On the other hand, traditional
instruction and focus on 'practice-makes-perfect' drilling instruction does not on its
own lead to increase in performance at international standardized testing for a broad
spectrum of students. Given the shift to competence-oriented aims of mathematics
instruction, a more arduous task of changing teaching practices remains (Halász and
Michel, 2011. above). As Julie (2006.) warns, mathematical literacy is more difficult
to teach than standard school mathematics.
In conclusion, having shown that traditionally framed concept of mathematics was
dominant in mathematics curricula and teachers' perception until very recently, as
well as the prevalence of traditional components in the mathematics instruction in
10
For the purpose of measuring the frequency of the students' activities during the mathematics lessons a scale consisting of 21 items (students activities) was developed. The items
were set on 5-grade Likert scale with possible answers "never" (1), very rarely (2), sometimes
(3), often (4) and "very often" (5). The percentages of teachers' responses: „often" and „very
often" are presented in the text.Sociologija i prostor, 51 (2013) 195 (1): 109-131
126
S o c i o l o g i j a i p r o s t o r
compulsory education in Croatia, we conclude that enacted/implemented mathematics curricula should be substantially changed if we want to improve mathematical
literacy or competence of Croatian students. In line with the international trends and
recent Croatian curricular changes it is laudable that teachers have largely adopted
the view of mathematics as applicable to students' everyday life and potential for
lifelong learning, but this remains to be developed through curricular concepts to
operational level.
Beyond the laudable aims, most teachers still see set-task completion and concept
adoption as the main forms of mathematical learning. Against the recent trends for,
and early calls in 1991. curricular description of mathematics, Croatian teachers still
largely employ teacher-centred traditional instructional methods. Though these can
lead to high testing scores, as exemplified by the East Asian economies, on their own they are insufficient to lead to the broader competence-framed outcomes
of learning. With PISA results unimpressive and the perceived difficulty of school
mathematics, changes to pre-service education and in-service teacher training are
recommended, so as to include detailed understanding of the new aims of mathematics instruction and the methods of achieving those.

Matematička kompetencija i međunarodna testiranja matematike: hrvatsko
polazište

Sažetak
Članak donosi pregled koncipiranja obveznog matematičkog obrazovanja kroz kompetencijske
ishode te prikladnih metoda poučavanja. Takav pregled daje se u svjetlu međunarodnih
utjecaja na koncipiranje matematičkog obrazovanja u Hrvatskoj kroz rangiranje matematičke
pismenosti 15-godišnjaka u PISA testiranju. Na početku se obrazlažu konceptualni konstrukti
u pozadini društvenih utjecaja na nad-državni razvoj pojma pismenosti/kompetentnosti u
obrazovanju i testiranju iz matematike. U tom svjetlu pregledavaju se prošla i sadašnja, te
predlažu moguća buduća, određenja i promjene školskog matematičkog obrazovanja i procesa
poučavanja matematike u hrvatskim osnovnim školama. Pregled empirijskih istraživanja
praksi i stavova o matematičkom obrazovanju u posljednjih nekoliko godina komplement je
pregledu teoretskih određenja. Cilj je istražiti i prikazati društvene i (komparativne) političke
utjecaje na sadržaj i poučavanje 'čvrstih' školskih predmeta kao što je matematika, obilježiti
trenutnu hrvatsku poziciju po međunarodnim testiranjima i empirijskim istraživanjima stavova
učenika i nastavnika, te preporučiti moguće neposredne korake u razvoju obrazovne politike
u području matematičkog obrazovanja.
Ključne riječi: PISA testiranje, kompetencije, pismenost, matematika, poučavanje, učenje kroz
rješavanje problema, obvezno obrazovanje u Hrvatskoj.

21. Design research in mathematics
education: The case of an ICT-rich
learning arrangement for the
concept of function
1
Michiel Doorman, Paul Drijvers, Koeno Gravemeijer, Peter Boon, & Helen Reed
Abstract
The concept of function is a central but difficult topic in secondary school mathematics curricula,
which encompasses a transition from an operational to a structural view. The question in this
paper is how to design and evaluate a technology-rich learning arrangement that may foster this
transition. With domain-specific pedagogical knowledge on the learning of function as a starting
point, and the notions of emergent modeling and instrumentation as design heuristics, such a
learning arrangement was designed for grade 8 students and field tested. The results suggest
that these design heuristics provide fruitful guidelines for the design of both a hypothetical
learning trajectory and concrete tasks, and can be generalized to other design processes.
1. Introduction
The function concept is a central but difficult topic in secondary school mathematics curricula
(Akkus, Hand, & Seymour, 2008; Ponce, 2007). Functions have different facets, and to make
students perceive these as facets of the same mathematical concept is a pedagogical and
didactical challenge. In lower secondary grades, functions mainly have an operational
character, and are calculation 'engines' that process input values into output values. In higher
grades, functions have the character of an object with various properties. The transition from
functions as calculation operations to functions as objects is fundamental for conceptual
understanding in mathematics.
Can computer tools help to foster this transition? Computer tools offer opportunities for
mediating the learning activities in which students engage (Sfard & McClain, 2002). The
availability of sophisticated computer tools for mathematics education, however, also raises
questions. Representations (e.g., formulas and graphs) and techniques (e.g., rewriting
equations) in such computer environments may signify mathematical concepts that are still to be
constructed by the students. As experts, we see the mathematics in the tool use, but does the
learner see this too? This inherent circularity is known as the learning paradox (Bereiter, 1985;
Gravemeijer, Lehrer, Van Oers, & Verschaffel, 2002; Van den Heuvel-Panhuizen, 2003).
To design a learning arrangement that avoids the learning paradox in using ICT-tools and
fosters the learning of the concept of function - and the transition from an operational to a
structural view in particular - is the central issue in this chapter. In a design research study we
1
This contribution is based on the following publication with permission of the editor: Doorman, M., Drijvers,
P., Gravemeijer, K., Boon, P., & Reed, H. (2012). Tool use and the development of the function concept:

from repeated calculations to functional thinking. International Journal of Science and Mathematics Education, 10(6), 1243-1267 428
investigate the question of how a learning arrangement with computer tools can foster the transition from an operational to a structural understanding of functions.
2. Theoretical framework
The theoretical framework that guides the design in this study includes (1) domain-specific knowledge on the concept of mathematical function; (2) the notion of emergent modeling; (3) theories on tool use and its instrumentation.
The concept of mathematical function
The teaching and learning of the concept of mathematical function is a widely researched topic (e.g., see; Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Ainley, Bills, & Wilson, 2005; Oehrtman, Carlson, & Thompson, 2008). A key issue in these studies is what Sfard calls the two sided nature of functions (Sfard, 1991, 1992). Her theory on the dual nature of mathematical conceptions identifies operational and structural concepts, the first concerning mathematical processes and the latter mathematical objects. In Sfard's view, the operational and structural conceptions are complementary. Historically, the operational aspect preceded the structural aspect, and the same might hold for individual learning processes, because the structural approach is more abstract than the operational. Dichotomies related to Sfard's operational and structural aspects have been brought afore by other researchers such as Dubinsky (1991) and Tall and Thomas (1991).
Based on an analysis of the available literature on this issue of operational conceptions preceding structural conceptions, the following sequence of three interrelated aspects of the function concept are distinguished:
1. The function as an input-output assignment
The function as an input-output assignment that guides the stepwise calculation of an output value for a given input value. For example, we can think of a function that converts an amount of dollars into an amount of euros, or a temperature in degrees Fahrenheit into degrees Celsius. Often, this view on function is seen as the starting point for students. An appropriate symbolic representation for this function view is an input-calculation-output chain. Figure 1 shows such a chain for calculation temperature in degrees Celsius from temperature in degrees Fahrenheit.
Figure 1: Input-output chain for temperature conversion
2. The function as a dynamic process of co-variation
The second aspect of the function concept concerns the notion that an independent variable, while running through its domain, causes the dependent variable to move through a set of possible outcome values. The dependent variable co-varies with the independent. Helpful representations for studying co-variation are tables and graphs, which can be scrolled through or traced. Figure 2 shows such a table for the temperature conversion example. 429
Figure 2: Table for temperature conversion
3. The function as a mathematical object
A function is a mathematical object which can be represented in different ways, such as arrow chains, tables, graphs, formulas, phrases, each of which providing a different view on the same object. The more structural view on functions includes families of functions, function comparison, and later on function differentiation or integration. For the object view on function, it is important to be able to see the connections between the different function representations. Figure 3 combines different representations for the temperature conversion example.
Figure 3: The different representations of the temperature conversion function
These three aspects of function reflect the operational- structural dimension as identified by Sfard (1991): the function as an input - output assignment reflects an operational conception and the function as a mathematical object involves a structural view, whereas the function as a dynamic co-variation process reflects an intermediate conception. 430
In line with this conceptual analysis, which is further elaborated in Doorman, Drijvers, Gravemeijer, Reed, and Boon (2012, see also Gravemeijer, Doorman & Drijvers, 2010), we want to design a learning arrangement for the topic of function that fosters the transition from an input-output conception to a more versatile view including a structural conception. This is the first design criterion. In the envisioned learning arrangement we implement computer tools with representations such as arrows, tables, formulas and graphs that initially may have hardly any meaning for students. The challenge for us - as designers - is to find ways in which these representations become useful models for the students. The notion of emergent modeling offers an orientation for addressing this challenge.
Emergent modeling
Emergent modeling is a design heuristic which originated in the framework of the theory of realistic mathematics education (RME) (Gravemeijer, 1999, 2007). RME builds on Freudenthal's (1991) image of mathematics as 'a human activity': while engaging in mathematics as an activity, students should be supported in re-creating or reinventing mathematics. The emergent modeling design heuristic is a means for organizing such a reinvention process. The starting point is an activity of modeling problems that are experientially real to the students. Models initially are context-specific and refer to realistic or paradigmatic situations. Then, while the students gather more experience with similar problems, attention shifts towards the mathematical relations involved. This enables students to use the model in a different manner: it derives its meaning from mathematical relations and becomes a base for more formal mathematical reasoning: a model ofinformal mathematical activity develops into a model for more formal mathematical reasoning (e.g., Gravemeijer, 1999; Cobb, 2002; Doorman & Gravemeijer, 2009). The learning paradox described in the introduction can be circumvented by designing a chain of activities that allow for a process of emergent modeling that fosters a thinking process in which symbolizations and meaning co-evolve (Cobb, 2002; Meira, 1995).
This approach is consistent with conceptual change literature, which argues that students must first explore a domain and recognize limitations or a need for more sophisticated tools, before they are ready to learn complex concepts (Lehrer & Schauble, 2002).
In this study, the notion of emergent modeling is an important design heuristic. It stresses the importance of starting with problems that offer opportunities to develop situation-specific reasoning and tentative representations for organizing repeated calculations and that have the potential to develop into more sophisticated - mathematical - tools and concepts (Gravemeijer, 2007). Taking this process of emerging models seriously asks for a design in which models for emerge in a natural way from models of, that are rooted in suitable contexts. This is a second design challenge for the learning arrangement.
Tools and instrumentation
Emergent modeling as a design heuristic does not particularly focus on the use of computer tools and the relationship between computer techniques, paper-and-pencil techniques, and conceptual understanding. Drawing upon Vygotsky's view on the dialectic relation between tool use and cultural practices, we consider it important to understand and carefully plan the role of tools in a learning process (Vygotsky, 1986; Wertsch, 1998). As Hoyles and Noss (2003) point out, tool characteristics do matter in the sense that their visualizations and the available techniques affect student learning.
Instrumentation theory was developed to address the problems that may arise when one starts to use a ready-made computer tool and explains the importance of aligning techniques that emerge in contextual problems with the techniques available in the computer tool. The theory focuses on the mediating role of tools by stressing the co-emergence of tool techniques and 431
meaning in a process of instrumental genesis (Artigue, 2002; Trouche, 2004; Drijvers & Trouche, 2008). Instrumental genesis comprises the development of cognitive schemes containing conceptual understanding and techniques for using a tool for a specific type of task. The resulting instrument integrates the tool and mental schemes. A bilateral relationship between the tool and the user exists: while the student's knowledge guides the way the tool is used and in a sense shapes the tool--the affordances and constraints of the tool influence the student's problem-solving strategies and the corresponding emergent conceptions.
In the case of functions, computer tools offer opportunities to dynamically and flexibly deal with different representations such as tables, graphs, and formulas. This may help students to overcome the difficulty of construing and integrating the operational and structural aspects of the function concept and its different representations. Computer tools can support students in exploring dependency relationships and investigating the dynamics of co-variation. The third design challenge, therefore, is to shape these opportunities, while ensuring that the techniques in the computer tool match with the targeted conceptual development.
3. Design
The study aims at designing and evaluating an ICT-rich learning arrangement for grade 8 students (age group 13-14 year) in the Netherlands,
1. which fosters the transition from an input-output conception to a structural conception
2. in which 'models for' emerge in a natural way from 'models of', that are rooted in suitable starting points
3. and which benefits from the opportunities ICT offers, while ensuring that the techniques in the computer tool match with the targeted conceptual development.
As a first design step, a hypothetical learning trajectory (Simon, 1995) was designed based on the theoretical framework and the literature review. In this trajectory description, problem situations, models, ICT techniques and targeted conceptual development were summarized and outlined.
Next, the design research was carried out in a cyclic process of three design cycles, one pilot and two full cycles, each lasting for about one year. The learning arrangement includes (a) a computer tool called AlgebraArrows, (b) a student textbook with both paper and pencil and computer tasks, (c) a teacher guide describing the various activities and their possible orchestrations, and (d) a computer- and written test
2
.
The computer tool is an applet called AlgebraArrows, which allows for the construction and use of chains of operations (so-called arrow chains) and provides options for creating tables, graphs and formulae and for scrolling and tracing. The applet is embedded in an electronic learning environment in which tasks are provided and through which the teacher can monitor students' responses (Boon, 2009). The AlgebraArrows window is embedded in the learning environment (see Figure 4). Figures 1, 2 and 3 were also made with this applet.
AlgebraArrows is meant to support the transition from operational understanding to structural understanding the concept of function in the following manner. First, students construct inputoutput chains of operations to carry out calculations. The chains can be applied to single numerical values as well as to variables. Gradually, the student activities focus on the investigation of dynamic input-output dependencies. The computer tool's slider bar and table
2
The trajectory description and the learning arrangement are available through http://www.fisme.science.uu.nl/tooluse/en/ . The digital part of it can be found at http://www.fisme.uu.nl/dwo/demo/en/ 432
scrolling options, in conjunction with the tasks, invite the students' development of a dynamic notion of a variable (see Figure 4). Finally, the students investigate families of functions, with their properties and representations, to develop a structural view of function. For instance, the table representation is initially understood as a tool for organizing corresponding input-output values in a contextual problem on mobile phone offers. Next, the applet's table option can be used as a tool for scrolling and zooming in on or out of these values, e.g., to analyze growth behavior or to find break-even points. This imagery of table and actions initially signifies repeated calculations and emerges into a model for a structural understanding of dependency relationships. In practice, these design considerations led to changes in the applet, such as the addition of zooming tools in the table option, similar to the zooming tools in graphs.
The tool techniques are meant to relate to paper-and-pencil techniques, and as such instrumental genesis should be natural and should contribute to the targeted cognitive development.
Figure 4: The computer tool AlgebraArrows embedded in the learning environment
The student textbook describes the activities for eight lessons. It starts with three preliminary paper-and-pencil group activities to create an exploratory orientation on the topic, to create the need for organizing series of calculations and to introduce the computer tool. In addition, these activities are designed to avoid discrepancies between tool techniques and conventional paperand-pencil techniques and to anticipate instrumental genesis through the use of representations and techniques that will be used in the computer tool. The three successive activities are:
• Calculating the area of a flexible quadrilateral, which students explore using a paper model, and which then leads to the introduction of a variable (the height of a parallelogram) and a calculation procedure or a formula for the area.
• Comparing two cell phone offers, with a focus on break-even points which creates the need for a function-concept (Ainley, Bills, & Wilson, 2005; Küchemann, 1981). 433
• Calculating the braking distance of a scooter for various speeds. It includes a tablerepresentation and is intended to create the need for graphing a trend for doing predictions.
During a classroom discussion of students' solutions orchestrated by the teacher (see below), an arrow chain is supposed to emerge as a useful way to investigate input-output relationships.
The arrangement continues with two computer lessons. During the computer activities, the focus shifts from solving specific situations towards the investigation of dependency relationships by means of break-even problems that ask for the generation and comparison of tables of input- and output values, and moving around in a space of possible values. According to the emergent modeling heuristic, a shift is expected to take place from sub-models that signify repeated input-output calculations to models signifying dependency-relationships, covariation and function object properties. The arrangement continues with a reflective lesson in which whole-class discussions and demonstrations align computer techniques with paper-andpencil techniques, a computer lesson with applications, and a closing lesson for summarizing results and creating consensus on representations and functional reasoning.
The teacher guide describes the different activities and their possible orchestrations (Drijvers, Doorman, Boon, Reed, & Gravemeijer, 2010). It suggests different classroom arrangements, such as small group work, poster presentations, computer activities in pairs, and whole class discussions on the results, supported by projections of computer work (Stein, Engle, Smith, & Hughes, 2008). This variety of classroom arrangements is expected to foster social interaction, to promote the articulation of tool use and to enhance reflection and generalization.
The final part of the learning arrangement consists of a computer test and a written test. This mixed media assessment reflects the arrangement as a whole. The written test captures transfer of learning from computer tool to conventional methods and contains questions about break-even points, and computer tasks where students could use the applet AlgebraArrows
3
.
Test items in the two tests are comparable in length and difficulty and have similar scoring instructions.
4. Research methods
To evaluate the design and to understand why the particular instructional setting potentially supports learning, design research was carried out (Gravemeijer & Cobb, 2006, 2013). The main hypothesis to be investigated is that the learning environment indeed fosters a transition from an operational view to a structural view, as reflected in the students' reasoning and in their way of using the computer tool. We briefly now describe the teaching experiments and data collection, and the data analysis.
Teaching experiments and data collection
After a first small-scale pilot study in one class, two successive teaching experiments were conducted in grade 8, with mid and high-achieving 13-14 year old students, for investigating their learning processes in relation to the learning arrangement. Each round of experiments took eight 50-minute lessons. The first was conducted with three classes from three different schools. The second was conducted on a larger scale. In this paper, we focus on screencast video data from pairs of students in the first teaching experiment. These students were selected by their teachers based upon criteria we provided: an average level of mathematical performance, a communicative attitude, i.e., willing to explain their reasoning and solution

strategies, and audible articulation. The qualitative findings are triangulated with quantitative
3
The full computer test and written test can be found at http://www.fisme.uu.nl/tooluse/en/ 434
posttest data from 155 students from five classes from two different schools in the second
experiment, for which the most complete data were available.
In both teaching experiments, whole class teaching sessions, group work and work in pairs
were videotaped in two of the participating classes and, in each of these classes, screencastaudio videos of two pairs of students working with the computer tool were collected. In addition,
students' answers and results to the written and the computer test administered at the end of
the experiment were collected.
Between the teaching experiments, the learning arrangement was improved. The overall outline
of the three different aspects of the function concept was not changed but fine-tuning the modelofto model-fordevelopment and the relationship between tool techniques, paper-and-pencil
work and mathematical thinking was needed. In order to better investigate the development of
the function concept, we placed a stronger emphasis on break-even points as a motivation for
investigating the dynamics of relationships. In addition, to establish to what extent the students'
final performance depended on the use of the available computer tool and to assess the
transfer of learning, both a written test and a computer test were added to the end of the
learning arrangement.
Analysis
The data analyses started with organization, annotation and description of the data with
software for qualitative data analysis (ATLAS.ti; see van Nes & Doorman, 2010). Initially, the
tasks in the learning arrangement served as the unit of analysis. Factual codes (task number,
student names, et cetera) were used to organize and document the data. Events in class videos
and screencast videos that were notable from the perspective of the research question were
transcribed and discussed in the research team.
In analyzing the first teaching experiment, we constructed a storyline as a reconstruction of the
students' learning process. The qualitative data sources were discussed with two external
experts to identify illuminating examples of the resultant learning process. This discussion
resulted in recognizing a shift in the students' reasoning with functions. Next, illuminating and
representative examples for important steps in the shift were identified. A code book was set up.
Next, we distinguished solution strategies used on two similar computer tasks on break-even
points that were designed for studying the development of students' reasoning with the
computer tool. One task was situated at the beginning of the computer lessons and the other at
the end. The strategies led to the construction of codes with respect to the use of
representations in the computer tool. These codes reflected the different aspects of the function
concepts, the types of tool use, and the position in the hypothetical learning trajectory. In a later
phase, these codes were also used for the quantitative analyses of students' answers to the
paper-and-pencil activity concerning the arrow chain (the booklets of 5 students were missing),
the screenshots of the answers to the two computer tasks, and the screenshots of students'
final work on the two computer tasks. A second researcher coded 55 out of 306 items (18%).
Good inter-rater-reliability was achieved (Cohen's Kappa = 0.79). A paired t-test was used to
compare the results on the written test and the computer test.
5. Results
The results of the study are presented in the form of a storyline of students' learning process in
relation with the learning environment, as reflected in their reasoning and in their way of using
the computer tool. This storyline offers opportunities to trace the development of our
interpretations and understanding of these learning processes. This approach is linked to
Smaling's (1987) view on 'trackability' and to Freudenthal's notion of 'justification' (Freudenthal, 435
1991). The storyline is illustrated with examples of student work and is also supported by the
quantitative findings.
The initial cell phone offer task: organizing calculations
The results of the initial open-ended group activities of the first teaching experiment show a
variety of solution strategies. In Figure 5 (top) the cell phone offer task is shown. The students'
posters below are illustrative for their attempts to organize the situations mathematically, i.e., to
organize repeated calculations, construct variables and use various representations. In the
poster on the left, students organize their repeated calculations by systematically writing them in
a list, which resembles an input-output relationship. This helped them to see the pattern in the
calculation, and to apply this pattern to a new input value. In the right poster, students use
formulae to describe their repeated calculations. Although not in conventional form, the
formulae show the identification of the two variables of the dependency relationship (m for
minutes and b for costs). The repeated calculations reflect how the operational aspects precede
the structural aspects of functions (Sfard, 1991). From an emergent modelling perspective, the
context apparently provides a suitable starting point.
Figure 5: Cell phone offer task and studentsíposter
Introducing arrow chains: visualize functions
In a whole-class discussion, the posters helped the teacher to evoke the need for determining
variables, dependency relationships and more efficient notations and tools for finding breakeven points. The teacher exploited the students' strategies by linking their initial ideas to the
intended tool use. A new mathematical goal emerged: repeated calculations are timeconsuming, what is the general pattern in the calculation procedures? How can this pattern be
described to calculate results 'automatically'? How could a 'calculator' help in comparing cell
phone offers? A calculation recipe comprising a fixed chain of operations emerged. This arrow
chain is the central representation of the computer tool. In the last activity before the computer
lessons, the students were asked to draw calculation chains for the two cell phone offers.
Figure 6 shows an illustrative answer to this task. 436
Figure 6: Written calculation chains for cell phone offers (called 'Soms' and 'Vaak').
The arrow chain as a model of repeated calculations appeared to be grounded in students'
previous activities and could begin to function as a mathematical model for (in terms of the
theory of emergent modeling) reasoning about dependency relationships. This assumption is
backed up with an analysis of the results of student booklets from the second experiment. The
analysis shows that 124 out of 150 students (83%) drew a similar chain while another 8 (5%)
drew this chain, but used it only for one specific calculation and did not label input and output
boxes. From an instrumental genesis perspective, the tool techniques were prepared for by
paper-and-pencil work.
Using the computer tool to create arrow chains
The third lesson - the first computer lesson - started with some introductory activities and then
continued with the cell phone problem (Figures 5 and 6). The task was to determine, with the
computer tool at hand, when it is advisable to change from one offer to the other. Two students,
Lily and Rosy, worked together on this task. After reading the problem on the computer screen,
they started to construct arrow chains with the computer tool.
[Rosy drags an input box into the drawing area. The box is connected to the operation - 80 and
that one is connected to x 0.15.]
Lily: And that added to the fixed costs.
[R agrees and connects the chain to + 22.5. Finally, they connect the chain to an output box.]
L: Well, when you phone for 100 minutes....
[enters 100 as input in both chains. TomSeldom (Soms) is cheaper than the other offer.].
R: .... Well, maybe 50.
[L enters 50 as input for both chains. They look at the results and are still not satisfied. They try
some more input values. Finally, they enter 200 in the input box of both chains. For the first time
TomOften (Vaak) is cheaper than the other offer. They are satisfied with this result and proceed
to the next task.]
The vignette illustrates how the arrow chain has become a means to organize the situation and
the calculation procedure. Lily and Rosy built the chain from the input box, adding operations
and finally connecting an output box. This construction signifies their previous calculations.
They focused on specific cases by entering respectively 100, 50 ... and finally 200 for
comparing the differences between the two offers. The arrow chain is used for repeated
calculations. The tool supports the construction of these chains, and the chain becomes a
means for analyzing and discussing relationships and successive operations, as a sequel to
merely solving repeated calculations. The tool technique clearly is linked to the students' paperand-pencil experience and supports their thinking. 437
Whole-class discussion capitalizing on hands-on experience
The start of the second computer lesson (the fourth in the learning arrangement), consisted of a
teacher-guided classroom discussion of students' computer work with the computer tool
connected to a data projector. Topics of discussion were the possibility to label input and output
boxes and to use tables. These tool techniques were already used by some of the students, and
now became 'institutionalized' through the whole class discussion. The teacher started the
discussion with an arrow chain for one of the cell phone companies:
Teacher: I heard different ways to find out how much I have to pay, how the amount changes,
how can you demonstrate that? [Silence] For example, if I call 10 minutes. How can I find out
how much I pay for 10 minutes?
Student 1: Put 10 in the input box.
Teacher enters 10 into the input box. This gives an odd result (first 30 free minutes are
subtracted). The result is discussed and the teacher varies the input by entering some more
values.
Teacher: Suppose I want to know the output from many input values, what more can I use?
Student 1: The table.
Teacher clicks the table tool and shows how you can scroll through the input and output values.
Teacher: Does anyone know another way to show how the output values change for different
input values?
Student 2: With a graph...
After this suggestion the teacher opened the graph tool. She demonstrated how to connect an
arrow chain to the graph window. Together with the students she investigated the options to
trace a graph and to zoom in and out. In this way, while demonstrating the tool techniques, the
teacher discussed the dependency relationships and the ways tables and graphs can be used
to analyze their dynamics. In the previous computer activities, Lily and Rosy did sometimes click
for a table or graph, but had not used it for scrolling or tracing values.
This observation shows how the teacher used the computer tool to create whole-class
consensus on how to use it for investigating dependency relationships. Both the techniques and
related concepts were part of the discussion. She did not show how to use these features for
finding break-even points. That was still a task for the students.
A different view on function
During the third computer lesson (the sixth lesson of the learning arrangement), we observed
that the strategy of Lily and Rosy for using the computer tool had changed while solving a task
on two offers by contractors called Pieters and Tweehoog (Figure 7).
Figure 7: Handyman task offers
The task in Figure 7 is quite similar to the cell phone activity (Figure 5). However, the way in
which these students analyzed the problem situation, phrased the structure of the solution
procedure and used the representations in the tool changed: AlgebraArrows was now used to
To get some jobs done in the house we can choose from two contractors:
Contractor "Pieters" charges 92 start costs and an hourly rate of 30.
Contractor "Tweehoog" charges 45 start costs and an hourly rate of 32,75.
You have a job of 9 hours. How much cheaper is Tweehoog than Pieters?
After how many hours of work is contractor Pieters cheaper than Tweehoog? 438
investigate the dynamics of relationships, rather than for case-by-case calculations. Figure 8
shows some subsequent phases in these students' work.
Figure 8: Different phases in students' work
First, the students identified the variables by creating labeled input- and output boxes for the
first arrow chain, with 'uurloon' meaning hourly rate and 'Kosten' for costs (Figure 8 top). Next,
they filled in the operations and completed the chain (Figure 8 middle). Then they constructed
the second chain for the Tweehoog company in similar way. Finally, they added tables, and
scrolled through them to find the break-even point for 18 hours (Figure 8 bottom part). This
behavior illustrates a different view on, and use of, the arrow chain compared to the initial
operational left-to-right construction of a chain for repeated calculations. More specifically, the
vignette illustrates how the arrow chain had become a tool for analyzing dependency
relationships. Lily and Rosy organized the dependency relationship by identifying, positioning
and labeling boxes for input and output variables and filling the gap between them with
operations. This construction signifies an understanding of the problem as a question about two
dependency relationships. For investigating the dynamics, they successfully operated the table
tool to zoom in and out for finding the break-even point. Corresponding to this new view on
function, the technique of constructing an arrow chain changed, now starting with labeled input
and output boxes rather than with input and then operations. This suggests a structural view on
function. 439
Triangulating case study findings with computer output
The second teaching experiment was used to quantitatively verify the hypothesis on the
transformation of the view on function during the computer activities. We found that for the initial
task 130 out of 155 students (84%) used the tool only for calculating successive input-output
values, while in the task at the end, 89 out of 152 students (58%) used the tool for structuring
and investigating the dynamics of the relationships.
Whereas the students' initial technique with the applet suggested an operational view on
functions, this more advanced technique reflects a transition towards a gradually developing
structural view. In other words, the shift in the use of the tool reflects the development from
viewing calculation recipes as tools for repeated calculations (as processes) towards reasoning
with structural characteristics of dependency relationships (as objects).
To investigate whether this transition also encompassed students' written work during the eight
lessons, we compared the scores of the computer test and the written final test. A paired t-test
showed no significant difference (p=0.20) between the final scores on the written test and the
computer test. The Pearson correlation coefficient of 0.38 between these scores was moderate
(p=0.001). This suggests that students who improved their reasoning through the described shift
evoked by the use of the computer tool were able to transfer learning to a more conventional
paper-and-pencil test.
6. Conclusion and discussion
Conclusion
In the introduction, we raised the question of how a learning arrangement with computer tools
can foster the transition from an operational understanding to a structural understanding of
functions. From the data analysis, we see the following characteristics of the learning
arrangement as decisive for fostering a transition from a calculation understanding to working
with correspondence and co-variation:
• The three initial open-ended problems and the poster activity helped students in coming to
see input-output structures in problems about dependency relationships and to use
representations to explore them.
• By enabling students to design and use arrow chains as a means of support for reasoning
about calculation procedure that bear meaning in everyday-life phenomena, the computer
tool supported the students in developing the notion of a chain of operations.
• By generating the results of a series of calculations for a variety of input values, the
computer tool strengthened the students' notion of a function as a calculation procedure
that transforms input values into output values.
• By generating output values for series of input values, by generating tables of input and
output values, and by enabling the students to move up and down the values in these
tables, the computer tool supported the students in developing a dynamic notion of a
variable that can move in a space of possible values, and the corresponding idea of covariation.
• By displaying arrow chains, tables and graphs the computer tool offers representations,
which the students could construe as affordances to start treating functions as objects
before they had become objects for them. In this way, the learning paradox may be
circumvented.
• By discussing students' work with the tool and showing specific features that some of the
students discovered, the teacher appeared successful in supporting most students in using

the table representation. 440
We conclude that the learning arrangement with a computer tool helped students to overcome the difficulty of integrating operational and structural aspects of the concept function and supported explorative activities for investigating the dynamics of co-variation, even though the students didn't reach the full level of "function as a mathematical object" but just began to make the transition towards this level of understanding. Further advances in this direction would encompass, for example, more different types of functions and operations on functions such as composition and multiplication.
Discussion
Before discussing the design heuristics of this study, we first address its limitations. The sequence of eight lessons fostered conceptual development in the domain of functions. However, the final test data do not give insight in whether all students made a similar step towards a dual conceptualization, with procedural and structural views, of functions. Students' work during the computer lessons revealed that the final screenshots of an activity sometimes are only approximate representations of the students' reasoning. Students can be close to a good answer and then delete everything as a result of a sudden doubt. Final screenshots don't capture this entire reasoning process. Additional process information is needed for a full understanding of students' conceptual development in relation to their tool techniques, although a balance must be found between the extensiveness and the manageability of the data collection.
As a final issue, we mention the generalizability from design-based case studies (Yin, 2003). We agree with Plomp and Nieveen (2009) that the results of design research have an analytical generalizability and a replication logic: the findings in this case may not be directly generalizable, but the design experiment may be treated as a paradigm case (Gravemeijer & Cobb, 2006, see also this volume), which offers domain-specific design heuristics that can be extrapolated to similar design studies. The extensive description of the interventions in Doorman, Drijvers, Gravemeijer, Boon, & Reed (2012) is intended to enable researchers to reenact the experiment in other settings as a way to evaluate our findings and to contribute to the development of a more comprehensive theory.
In retrospect, how do we view the three theoretically based design heuristics described in section 2? First, we used domain-specific theories on the acquisition of the concept of function, and on the transition from an operational to a structural conception in particular. This design heuristic was fruitful for outlining the learning arrangement. It had an important impact on setting up a hypothetical learning trajectory and on the design of the tasks. This particular design heuristic can be generalized into an overarching one, which is that - before engaging in design - a deep analysis of the topic is needed to be able to identify its learning obstacles and pedagogical challenges and to outline a learning trajectory.
A second design heuristic was the notion of emergent modeling, and its focus on the shift from model-ofto model-for. This heuristic not only guided the design of the learning arrangement, but the students' cognitive development, and their ways of using the tool initially as a tool for calculations and later as a tool for reasoning with function, reflects this shift. As such, this was a suitable design heuristic.
Third, instrumentation theory focuses on the interrelated development of techniques and concepts. As a design heuristic, it fostered a careful integration of computer activities and paper-and-pencil activities, which prevented discrepancies between tool techniques and conventional methods. The process of instrumental genesis was enhanced by the alternation between classroom discussion, small group activities and computer activities.
Altogether, while outlining the hypothetical learning trajectory and designing the tasks the three design heuristics provided important and concrete guidelines. Having a set of such design 441 heuristics is indispensable, but in the meanwhile does not guarantee a successful design: it is not just knowledge of appropriate design heuristics, but their application in different domainspecific situations that forms the heart of the 'art' of the designer.

Paul Drijvers (1958) is an associate professor at Utrecht University's Freudenthal Institute for Science and Mathematics Education, and a senior assessment expert at Cito, the Dutch testing and assessment company. His research interests include the use of digital technology in mathematics education, the professional development of mathematics teachers, algebra pedagogy, and curriculum development. After a career as teacher educator, he entered the field of research in 1990. His dissertation, in 2003, concerns grade 9 students' development of the notion of parameter using computer algebra tools. Besides his research, he is involved in the Dutch mathematics curriculum reform and national assessment projects. The following (co-)edited books reflect his orientation: Handbook mathematics didactics (in Dutch, 2012), and Secondary algebra education; Revisiting topics and themes and exploring the unknown.

Koeno Gravemeijer (1946) is professor emeritus in Science and Technology Education at Eindhoven University of Technology in the Netherlands. Earlier he was professor in Mathematics Education at Utrecht University (Utrecht, the Netherlands) and Vanderbilt University (Nashville, USA). His research interests concern design research as a research method, domain-specific instruction theories (such as the theory for realistic mathematics education, RME), and students' use of symbols and modeling. In relation to the latter he developed the so-called 'emergent modeling' design heuristic. Next to his research activities, he also has been involved in instructional design. He has been the leading author of an RME textbook series for Dutch primary schools, and he was involved in the development of the textbook series for the American Middle School, "Mathematics in Contexts"- a collaborative project of the Dutch Freudenthal Institute and the University of Wisconsin-Madison.

TOOL USE AND THE DEVELOPMENT OF THE FUNCTION
CONCEPT: FROM REPEATED CALCULATIONS TO FUNCTIONAL
THINKING
Received: 17 June 2011; Accepted: 30 January 2012
ABSTRACT. The concept of function is a central but difficult topic in secondary school
mathematics curricula, which encompasses a transition from an operational to a structural
view. The question in this paper is how the use of computer tools may foster this
transition. With domain-specific pedagogical knowledge on the learning of function as a
point of departure and the notions of emergent modeling and instrumentation as design
heuristics, a potentially rich technology-intensive learning arrangement for grade
8 students was designed and field-tested. The results suggest that the relationship
between tool use and conceptual development benefits from preliminary activities, from
tools offering representations that allow for progressively increasing levels of reasoning,
and from intertwinement with paper-and-pencil work.
KEY WORDS: emergent modeling, function concept, instrumentation, mathematics
education, technology
INTRODUCTION
The function concept is a central but difficult topic in secondary school
mathematics curricula (Akkus, Hand & Seymour, 2008; Ponce, 2007).
Functions have different faces, and to make students perceive these as
faces of the same mathematical concept is a pedagogical challenge. In
lower secondary grades, functions mainly have an operational character
and are seen as an input-output 'machine' that process input values into
output values. In higher grades, functions have a more structural character
with various properties (Sfard, 1991). They become mathematical objects
that are represented in different ways, are ordered into different types
according to their properties, and are submitted to higher-order processes
such as differentiation and integration. We argue that the transition from
functions as calculation operations to functions as objects is fundamental
for conceptual understanding in this domain.
Can computer tools help here? Computer tools offer opportunities for
thinking and learning as they can mediate the learning activities in which
students engage (Sfard & McClain, 2002). The availability of sophisticated tools for mathematics education, however, also raises questions.
International Journal of Science and Mathematics Education (2012) 10: 1243Y1267
The Author(s) 2012. This article is published with open access at Springerlink.comRepresentations and techniques in such computer environments often
signify mathematical concepts that are still to be constructed in students'
minds. This inherent circularity is known as the learning paradox
(Bereiter, 1985; Gravemeijer et al., 2002; Heuvel-Panhuizen, 2003). The
challenge, therefore, is to avoid these pitfalls and to integrate the use of
computer tools in such a way that it fosters the learning of the concept of
function.
The above is summarized in the research question of this study: How
can a learning arrangement with computer tools foster the transition
from a procedural calculation understanding to a structural correspondence and co-variation understanding offunctions?
The object of study in this report is a newly designed learning
arrangement in which the intertwinement of activities using both paperand-pencil and computer tools, in combination with the careful guidance
by the teacher, is meant to foster grade 8 students' conceptual
development of functions. We are particularly interested in activities
with computer tools that help students to construct mathematical
representations and actions, to explore these representations and to start
reasoning with them (Falcade, Laborde, & Mariotti, 2007).
THEORETICAL FRAMEWORK
What theoretical perspectives may help to design and use a learning
arrangement in which the use of computer tools is embedded and which
fosters the transition from an operational to a structural understanding of
function? First, we need domain-specific knowledge for analyzing the
character of this transition. Second, from the general background of a
constructivist view on learning, the notion ofemergent modeling may guide
the design. Third, theories on tool use and instrumentation may guide a
careful integration ofcomputer tools in the designed learning arrangement.
The Concept ofFunction
The teaching and learning of the concept of mathematical function is a
widely researched topic. Vinner & Dreyfuss (1989) show that students'
mental images of functions may be different from its mathematical
definition. Other studies confirm that students' function conceptions in
many cases are limited. For example, Bloch (2003) and Skaja (2003)
show that students cannot think ofdifferent functions that provide a graph
through the same pair of points. Based on the model by Pirie & Kieren
1244 MICHIEL DOORMAN ET AL.(1989), Meel (1998) shows that many ofthe participants in his study held
a rule-based interpretation of the function concept, which prevents them
from an object-view on the concept, which is needed, among others, for
the understanding of the notion of composite function. In their study on
the understanding of function, Oehrtman, Carlson & Thompson (2008)
stress the relevance of students' reasoning abilities and on a conceptual
orientation on the notion of function, which needs time:
We advocate for greater emphasis on enculturating students into using the language of
function in order to develop facility in speaking about functions as entities that accept
input and produce output, a more conceptual orientation to teaching function inverse and
composition, the inclusion of tasks requiring simultaneous judgements about entire
intervals of input or output values, and the development of student's ability to mentally
run through a continuum ofinput value while imagining the changes in the output values,
with explicit efforts to also promote, at developmentally appropriate time, the covariational reasoning abilities. (Oehrtman, Carlson & Thompson, 2008, p. 39).
In line with the previous research described above, we want to design a
learning arrangement for the topic of function that goes beyond the input-
output conception, that provides room for reasoning, and that helps to
overcome a too-limited concept image of function. In order to do so, Sfard's
theory on the dual nature ofmathematical conceptions plays a central role and
is exemplified by the transition from a calculation view to an object view on
function (Sfard, 1991). Sfard distinguishes operational and structural concepts,
the first concerning mathematical processes and the latter mathematical
objects. A function may operationally be seen as a computational process, as a
recipe to transform one number into another (or to link one number to
another), whereas, structurally, a function can be thought ofas a set ofordered
number pairs. The operational and structural conceptions are complementary.
Sfard observes that, historically, the operational aspect preceded the structural
aspect and argues that the same should be the case for the individual learning
process, because the structural approach is more abstract than the operational.
Similar dualities are described by Tall (1996) and Dubinsky (1991).
This dual nature of function appears difficult for students to
comprehend. Most remain entrenched in an operational-based conception
(Carlson, Jacobs, Coe, Larsen & Hsu, 2002; Breidenbach, Dubinsky,
Hawks & Nichols, 1992). Suggestions have been made to promote
operational and structural conceptualizations offunctions, for example, by
emphasizing the coordination of the dynamics of input-output dependency relationships (Oehrtman et al., 2008; Malle, 2000). Various viewpoints
can be chosen while analyzing the dynamics, like a correspondence view
and growth-oriented view (Slavit., 1997).
TOOL USE AND THE DEVELOPMENT OF THE FUNCTION CONCEPT 1245Different function representations afford different views on functions.
None of these, however, provides a complete description (Elia, Panaoura,
Eracleous & Gagatsis, 2007). Students will have to coordinate various
representations to come to get a handle at the phenomena they are
studying and to understand the relation between these phenomena and a
coherent conception of functions (Duval, 2006; Even, 1998; Janvier,
1987). To the most common representations, such as verbal descriptions,
tables, graphs, and formulas, Freudenthal (1983) adds the arrow chain
representation, in which subsequent operations are chained. He considers
the arrow chain as a didactically powerful representation for introducing
the operational input-output view.
These findings focused us on the transition from operational to
structural aspects of functional thinking and on the importance of using
various representations. Based on these findings, our design will be
guided by the following three interrelated aspects ofthe function concept:
Y The function as an input-output assignment
Y The function is an input-output assignment that helps to organize
and to carry out a calculation process. This initially somewhat vague
and operational notion gradually gets more nuances: How does the
output depend on the input; how does the input determine the output;
what patterns can be seen? The representation of an input-
calculation-output chain is appropriate for this view on function.
Y The function as a dynamic process ofco-variation
Y This aspect concerns the notion that the independent variable,
while running through the domain set, causes the dependent variable
to run through a range set. The dependent variable co-varies with the
independent. Initially, the linked change may be noticed in a
somewhat phenomenological way. Next, the question emerges of
how and why this process of joint dynamics takes place. Helpful
representations for studying co-variation are tables and graphs,
which can be scrolled through or traced.
Y The function as a mathematical object
Y A function is a mathematical object which can be represented in
different ways, such as arrow chains, tables, graphs, formulas, and
phrases, each providing a different view on the same object. The more
structural view on functions may be promoted by tasks focusing on a
global level, for example, on families of functions, on function
comparison, and later on function differentiation or integration.
In terms of Sfard's process-object duality, the input-output assignment
view stresses the operational character of functions: It is an action, which
1246 MICHIEL DOORMAN ET AL.takes the input and processes it until it becomes the output. The
mathematical object view clearly relates to the structural character of
the function: It is a 'thing', which can be member of a family, or be
submitted to higher-order processes such as differentiation.
Different function representations stress different aspects and uses of
the function concept. For example, one single arrow chain is suitable to
an operational, process view, while a family of graphs is more holistic in
nature and more suitable to a structural perspective.
Emergent Modeling
Emergent modeling is a design heuristic which originated in the frame ofthe
theory ofrealistic mathematics education (RME) (Gravemeijer 1999, 2007).
RME builds on Freudenthal's (1991) image of mathematics as 'a human
activity': While engaging in mathematics as an activity, students should be
supported in reinventing mathematics. The emergent modeling design
heuristic is a means for organizing such a reinventionprocess. The approach
takes its starting point in the activity ofmodeling contextual problems. In this
setup, models initially come to the fore as context-specific models that refer
to realistic or paradigmatic situations. Then, while the students gather more
experience with similar problems, attention may be shifted toward the
mathematical relations involved. This helps them to further develop those
mathematical relations, which enables them to use the model in a different
manner. The model starts to derive its meaning from these mathematical
relations and becomes a base for more formal mathematical reasoning. Or in
short: A model ofinformal mathematical activity develops into a modelfor
more formal mathematical reasoning (e.g. Gravemeijer, 1999; Cobb, 2002;
Rasmussen & Blumenfeld, 2007; Doorman & Gravemeijer, 2009). The
learning paradox, as described in the "Introduction," can be circumvented by
designing a chain of activities and a process of emergent modeling that
fosters a reflexive process in which representations and meaning co-evolve
(Cobb, 2002; Meira, 1995). This approach is consistent with conceptual
change literature, which argues that students must first explore a domain and
recognize limitations or a need for more sophisticated tools, before they are
ready to learn complex concepts (Lehrer & Schauble, 2002).
In this study, the notion of emergent modeling is used as an important
design heuristic. It stresses the importance of starting with contextual
problems that offer opportunities to develop situation-specific reasoning and
tentative representations for organizing repeated calculations and that have
the potential to evoke the need formore sophisticated—mathematical—tools
and concepts (Gravemeijer, 2007). For instance, the table representation is
TOOL USE AND THE DEVELOPMENT OF THE FUNCTION CONCEPT 1247initially understood as a tool for administrating values oftwo quantities (like
time and temperature). In a learning arrangement on functions, the table can
come to the fore as a tool for organizing corresponding input-output values
in contextual problems. Next, on the computer, this table can be used as a
tool for scrolling and zooming in or out these values for various purposes (e.
g. analyzing growth behavior or finding break-even points). This imagery—
table and actions—initially signifies repeated calculations and emerges into a
model for a structural understanding of dependency relationships. Taking
this process seriously asks for a design in which a table tool is not introduced
too quickly, but builds upon previous activities.
Tools and Instrumentation
Emergent modeling as a design heuristic does not particularly focus on
the use of computer tools and the relationship between computer
techniques, paper-and-pencil techniques, and conceptual understanding.
Drawing upon Vygotsky's views on the dialectic relation between tool
use and cultural practices, it is important to understand and carefully plan
the role of tools in a learning process (Vygotsky, 1986; Wertsch, 1998).

As a point of departure, we follow Hoyles & Noss (2003) in observing
that tool characteristics do affect student learning:
Tools matter: they stand between the user and the phenomenon to be modeled, and shape
activity structures. (Hoyles & Noss, 2003, p. 341)
Instrumentation theory focuses on the mediating role of tools by
stressing the co-emergence oftool techniques and meaning in a process of
instrumental genesis (Artigue, 2002; Trouche, 2004). Instrumental
genesis comprises the development of cognitive schemes containing
conceptual understanding and techniques for using a tool for a specific
type of task. The resulting instrument integrates the tool and mental
schemes. As a consequence, a bilateral relationship between the tool and
the user exists: While the student's knowledge guides the way the tool is
used and in a sense shapes the tool, the affordances and constraints ofthe
tool influence the student's problem-solving strategies and the
corresponding emergent conceptions.
Instrumentation theory reveals the problems that may arise when starting
to use a ready-made computer tool and explains the importance of aligning
techniques that emerge in the contextual problems with the techniques in the
learning arrangement with computer tools. Instrumental genesis can be
hindered by discrepancies between tool techniques and conventional paperand-pencil techniques (Drijvers et al., 2007). These insights help us to avoid
1248 MICHIEL DOORMAN ET AL.students carrying out computer tasks satisfactorily without mastery of the
underlying mathematical concepts and not knowing what to do in problem
situations without the tool at hand (Hennessy, Ruthven & Brindley, 2005).
For instance, we inserted preliminary paper-and-pencil activities as a
preparation on techniques with the computer tool and carefully sequenced
the use oftool options in the learning arrangement.
In general, computer tools are able to dynamically and flexibly deal with
different function representations such as tables, graphs, and formulas
(Ponte, 1992). This may help to overcome the difficulty of integrating the
operational and structural aspects of the function concept and its different
representations (Falcade et al., 2007). Computer tools can support
exploratory activities for coordinating dependency relationships and
investigating the dynamics of co-variation (Kaput & Schorr, 2007). In this
particular study, a computer applet called AlgebraArrows is used to support
the transition from a calculation understanding to an object understanding of
functions. The tool, together with the tasks that aim to exploit the tool's
affordances, will be presented in more detail in the "Methods" section.
METHODS
The design of, and teaching experiments with, the learning arrangement
not only aim at fostering students' functional thinking, but also at an
understanding of why the particular instructional setting potentially
supports learning. This requires cumulative cyclic, classroom-based
design research that allows for analyzing and improving learning
arrangements (Gravemeijer & Cobb, 2006). Design research involves
formulating, testing and refining conjectures, designing instructional
activities, and teaching experiments with these activities. The conjectures
provide for a connection between the teaching experiments and an
understanding of how students can be supported in the development of
functional thinking. Such a progression should take into account both the
cognitive development of the individual students, as well as the social
context in which the teaching experiments are to take place (Cobb &
Yackel, 1996; Gravemeijer & Cobb, 2006). We describe successively the
design phase, teaching experiments and analysis in this research.
Design Phase
An important part ofthe design phase involved both the literature study which
led to the theoretical framework described in section "Theoretical Framework,"
TOOL USE AND THE DEVELOPMENT OF THE FUNCTION CONCEPT 1249and the design of the learning arrangement. In this section, we report on the
design as it resulted from the sequence ofthree design cycles. As such, it is an
important result from the study.
The learning arrangement includes (a) a computer tool called
AlgebraArrows, (b) a student textbook with both paper-and-pencil and
computer tasks, (c) a teacher guide describing the various activities and
their possible orchestrations, and (d) a computer and written test.
1
The computer tool is an applet called AlgebraArrows, which allows for
the construction and use of chains of operations (so-called arrow chains)
and provides options for creating tables, graphs, and formulae and for
scrolling and tracing. Figure 1 shows an AlgebraArrows window, in
which students create and use their representations.
AlgebraArrows is meant to support the construction of input–output
chains of operations as a model of a dependency relationship. The applet
is embedded in an electronic learning environment, and the researchers, as
well as the teacher, can monitor and compare the students' responses with
class results. The activity of investigating this applet in pairs is expected
to foster a learning process of 'trial-and-improve' and 'negotiation-ofmeaning'. During these investigations, students can find patterns and
develop functional thinking while dealing with dynamic input–output
dependencies. As such, the computer tool is expected to provide students
Figure 1. The computer tool AlgebraArrows
1250 MICHIEL DOORMAN ET AL.with a means to structure inquiry about dependency relationships through
constructing and modifying arrow chains and through generating and
comparing argumentations.
The student textbook describes the activities for eight lessons. The
learning arrangement starts with three open-ended small-group activities
about different dependency relationships:
Y A first one on the area of a flexible quadrilateral, which students first
explore using a paper model and which then leads to choosing a
variable and finding a linear formula.
Y A second one on the comparison of two cell phone offers, with a
focus on break-even points, which have proved to be suitable
problem situations for addressing the concept of function (Ainley,
Bills & Wilson, 2005; Kalchman & Koedinger, 2005; Küchemann,
1981). As in the first activity, the functions involved are linear.
Y A third one on the braking distance ofa scooter for various speeds. It
includes a quadratic function.
These three activities are meant to create an exploratory stage that
reveals the students' current thinking, creates the need for organizing
series of calculations, and provides opportunities for the teacher to
introduce the computer tool. The students are asked to show their
reasoning on posters that are discussed with the whole class. This
discussion focuses on differences and similarities between the three
problem situations and their solutions for reaching consensus about a
model of a series of calculations (an arrow chain) as a sensible way to
proceed when investigating dependency relationships. This way, lessons
with paper-and-pencil in the regular classroom prepare for lessons in the
computer lab, which is meant to promote the integration of both
conventional and computer tool techniques.
After these three initial lessons, the arrangement continues with two
computer lessons. During the computer activities, students use the computer
tool to construct input–output chains of operations as representations of
calculation procedures. The chains can be applied to single numerical values
as well as to variables, and corresponding tables, formulas, and (dot) graphs
can be created (Boon, 2008; Drijvers et al., 2007). To shift focus towards the
inquiry of dependency relationships, students are confronted with breakeven problems that ask for the generation and comparison oftables ofinput
and output values, and moving around in a space of possible values. This
way, the computertool's sliderbar and table scrolling options, in conjunction
to the tasks, invite the students' development of a dynamic notion of a
variable (see Figure 1).
TOOL USE AND THE DEVELOPMENT OF THE FUNCTION CONCEPT 1251The computer activities are expected to offer students opportunities for
creating new mathematical goals that relate to co-variation and functions
as mathematical objects. The emergent modeling heuristic suggests a shift
from sub-models that signify repeated input–output calculations to
models for reasoning about dependency-relationships, co-variation, and
of function object properties.
After these five lessons, the arrangement continues with a reflective
lesson for aligning computer techniques with paper-and-pencil techniques, and finally a computer lesson with applications and a closing lesson
for summarizing results and creating consensus on representations and
functional reasoning. In total, the arrangement consisted of eight lessons.
The teacher guide describes the different activities and their possible
orchestrations. It suggests different classroom arrangements, such as smallgroup work, poster presentations, computer activities in pairs, and whole class
discussions on the results, supported by projections of computer work (Stein,
Engle, Smith & Hughes, 2008). The whole class discussions about students'
strategies and inventions are to provide a basis for focusing and converging
students' learning and helping them in developing their current thinking in
anticipation of future activities (Sherin, 2002). This variety of classroom
arrangements, in the intention ofthe designers, fosters social interaction, which
is expected to promote the articulation oftool use and exchange ofstrategies as
well as reflection, generalization, and preparation ofwhat is to come.
The final part of the learning arrangement consists of a computer test
and a written test. This mixed media assessment reflects the arrangement
as a whole and contains paper-and-pencil questions about break-even
points and computer tasks where students could use the applet
AlgebraArrows.
2
Test items in the two tests are comparable in length
and difficulty and have similar scoring instructions.
Teaching Experiments and Data Collection
After a first small-scale pilot study, the learning arrangement was tested
and improved in two successive teaching experiments in grade 8, with
mid- and high-achieving 13-14-year-old students. The experiments took
eight 50-min lessons. The first teaching experiment was conducted with
three classes at three different schools. The second teaching experiment
was conducted at a somewhat larger scale. In this paper's analysis, we
focus on qualitative screencast data from pairs of students in the first
teaching experiment, backed up with quantitative posttest data from 155
students from the second teaching experiment (five classes at two
different schools). The students were selected by their teachers based
1252 MICHIEL DOORMAN ET AL.upon following criteria we provided: average level of mathematical
performance, communicative attitude, and audible articulation.
In both teaching experiments, whole class teaching sessions, group work,
and work in pairs were videotaped in two ofthe participating classes, and, in
each of these classes, screencast-audio videos of two pairs of students
working with the computer tool were collected. These videos were used to
analyze the students' activities during group work and during computer
sessions. In addition, students' answers and results to the written and the
computer tests administered at the end ofthe experiment were collected.
Analysis
The data analyses started with organization, annotation, and description of
the data with software for qualitative data analysis (ATLAS.ti
3
; see van Nes
& Doorman, 2010). Initially, the tasks in the learning arrangement served as
the unit ofanalysis for clipping the videos. Codes were used to organize and
document the data. Remarkable events from the perspective ofthe research
question were transcribed and discussed in the research team.
In analyzing the first teaching experiment, we constructed a storyline as a
reconstruction ofthe students' learning process. The qualitative data sources
were discussed with two external experts to identify illuminating examples of
the resulted learning process. This discussion resulted in recognizing a shift in
the students' reasoning with functions. Next, illuminating and representative
examples for important steps in the shiftwere identified. In orderto investigate
this shift quantitatively, we revised the computer activities for the second
teaching experiment with a stronger emphasis on break-even points as a
motivation for investigating the dynamics of relationships. In addition, we
wanted to establish to what extent the students' final performance depended
on the use ofthe available computer tool. We therefore added both a written
test and a computer test to the end ofthe learning arrangement.
To allow for quantitative analyses of these hypotheses in the second
teaching experiment, we designed specific paper-and-pencil activities that
aimed at investigating these conjectures. We identified characteristics of
student answers to codify written student material.
Next, we distinguished solution strategies used on two similar
computer tasks that were designed for studying the development of
students' reasoning with the computer tool. One task was situated at the
beginning ofthe computer lessons and the other at the end. The strategies
led to the construction of codes with respect to the use of representations
in the computer tool. These codes could be used to codify screenshots of
students' final work on the two computer tasks.
TOOL USE AND THE DEVELOPMENT OF THE FUNCTION CONCEPT 1253For the quantitative analyses, we used data from 155 students in five
classes. These students concluded the experiment with both the computer test
and the written test. For 150 students, we coded their answers to the paperand-pencil activity concerning the arrow chain (the booklets of five students
were missing). We coded the screenshots ofthe answers to the two computer
tasks for all 155 students. A second researcher coded 55 out of 306 items
(18%). Good inter-rater-reliability was achieved (with a Cohen's Kappa of
0.79) on these items. For a comparison ofthe results on the written test and the
computer test at the end ofthe learning arrangement, we used a paired t test.
RESULTS
The results of the study are presented in the form of a storyline of
students' learning process. This storyline is illustrated with examples of
student work and is empirically supported by quantitative findings.
The Initial Cell Phone Offer Task: Organizing Calculations
The results of the initial open-ended group activities of the first teaching
experiment show a variety of solution strategies. Figure 2 (top) shows the

cell phone offer task. The students' posters that describe the two
cellphone offers are illustrative for their attempts to organize the
situations mathematically, i.e., to organize repeated calculations, construct
Figure 2. Cellphone offer task and students' posters
1254 MICHIEL DOORMAN ET AL.variables, and use various representations. Some students tried to organize
their repeated calculations by systematically writing them in a list (left
poster in Figure 2). This helped them to see the pattern in the calculation
and to apply this pattern to a new input value. In fact, the way in which
these students listed their calculations already resembles an input-output
relationship (the first number varying over the input values).
The right poster in Figure 2 illustrates attempts of students to use
formulas to describe their repeated calculations. Although their formulas
are not in conventional form, they show that these students identified the
two variables of the dependency relationship (m for minutes and b for
costs). The repeated calculations reflect how the operational aspects
precede the structural aspects of functions (Sfard, 1991). The operational
aspects were helpful for the teacher during the discussion ofthe posters in
evoking the need for determining variables, dependency relationships,
and more efficient notations and tools for finding break-even points.
Introducing Arrow Chains: Visualize Functions
These results provide support for the argument that rather open problems
in the beginning of a learning arrangement can result in various solutions
of students that (1) provide information about the students' current
thinking and that (2) create starting points for discussing the need for
more sophisticated tools.
These strategies were exploited by the teacher by linking the students'
initial ideas to the intended tool use during a classroom discussion. During
this discussion, new mathematical goals emerged: Repeated calculations are
time-consuming; what is the general pattern in the calculation procedures?
How can this pattern be described to calculate results "automatically"? How
could a "calculator" help in comparing cellphone offers?
A calculation recipe that exists of a fixed chain of operations emerged
from these activities. This arrow chain is the central representation of the
computer tool. In the next activity, the last one before the computer
lessons, the students had to draw calculation chains for the two cellphone
offers. Figure 3 shows an illustrative answer to the task to construct a
calculation chain.
The arrow chain as a model of repeated calculations appeared to be
grounded in students' previous activities and could begin to function as a
mathematical model for (in terms of the theory of emergent modeling)
reasoning about dependency relationships. This assumption is backed up
with an analysis of the results of student booklets from the second
experiment. The analysis shows that 124 out of 150 students (83%) drew
TOOL USE AND THE DEVELOPMENT OF THE FUNCTION CONCEPT 1255a similar chain while another eight (5%) drew this chain, but used it only
for one specific calculation and did not label input and output boxes.
Using the Computer Tool to Create Arrow Chains
The third lesson, the first computer lesson, started with some introductory
activities and then continued with the cellphone problem (see Figure 3).
The task was to determine, with the computer tool at hand, when it is
advisable to change from one offer to the other. Two students, Lily and
Rosy, worked together on this task. After reading the problem on the
computer screen, they started to construct arrow chains with the computer
tool.
[Rosy drags an input box into the drawing area. The box is connected to the operation –80
and that one is connected to x 0.15.]
Lily: And that added to the fixed costs.
[R agrees and connects the chain to+22.5. Finally, they connect the chain to an output
box.]
L: Well, when you call 100 min
[Enters 100 as input in both chains. TomSeldom (Soms) is cheaper than the other offer.].
R: .... Well, maybe 50.
[L enters 50 as input for both chains. They look at the results and are still not satisfied.
They try some more input values. Finally, they enter 200 in the input box ofboth chains.
For the first time TomOften (Vaak) is cheaper than the other offer. They are satisfied with
this result and proceed to the next task.]
The vignette illustrates how the arrow chain has become a means to
organize the situation and the calculation procedure. Lily and Rosy built
the chain from the input box, adding operations and finally connecting an
output box. This construction signifies their previous calculations. They
focused on specific cases by entering respectively 100, 50 ... and finally
200 for comparing the differences between the two offers. The arrow
chain is used for repeated calculations.
Figure 3. Written calculation chains for cellphone offers (called 'Soms' and 'Vaak')
1256 MICHIEL DOORMAN ET AL.Using the computer tool to create reverse chains
One ofthe following questions was to construct a reverse calculation chain for
calculating the number ofcalling minutes when you know the total costs. The
following vignette shows how three students (Ali, Bert, and Carl) discussed
their reverse arrow chain by using the dimensions ofthe involved variables.
A: You subtract that from that [points to total costs and the monthly fee] that results in an
amount.
B: Yes, say 10 euros.
A: And then you divide it by ... what do you get ... per minute or ...?
B: per minute.
A: Well, then you subtract 22,50 euro and divide it by 15 cent, and this results in minutes,
and then you add 80, that are the free minutes which you receive.
(...)
C: amount–amount and that is still an amount and you divide that by an amount, 15 cent
[the costs per calling minute]. The result is a number, not an amount, and that are calling
minutes.
The students had to stepwise analyze and unpack the function chain
and to reverse the operations with help of their contextual meaning. This
vignette illustrates how the contextual activity on the reverse arrow chain
afforded an understanding of the structure and the aim of the chain. The
tool technique to construct chains supports this, and the chain became a
means for analyzing and discussing relationships and successive
operations, as a sequel to merely solving repeated calculations.
Whole-class Discussion Capitalizing on Hands-on Experience
The start of the second computer lesson, the fourth in the learning
arrangement, consisted ofa teacher guided classroom discussion ofstudents'
computer work by using a beamer. Topics ofdiscussion were the possibility
to label input and output boxes and to use tables. These tool techniques were
already used by some of the students and now became "institutionalized"
through the whole class discussion. The teacher starts the discussion with an
arrow chain for one ofthe cell phone companies.
T: I heard different ways to find out how much I have to pay, how the amount changes,
how can you demonstrate that? [Silence] For example if I call 10 min. What ways do I
have to find out how much I pay for 10 min?
S1: Put 10 in the input box
T enters 10 into the input box. This gives an odd result (first 30 free minutes are subtracted).
The result is discussed and the teacher varies the input by entering some more values.
T: Suppose I want to know the output from many input values, what more can I use?
S1: The table.
TOOL USE AND THE DEVELOPMENT OF THE FUNCTION CONCEPT 1257T clicks for the table tool and shows how you can scroll through the input and output
values.
T: Does anyone know another way to show how the output values change for different
input values?
S2: With a graph ...
After this suggestion, the teacher clicks for the graph tool. She
demonstrates how to connect an arrow chain to the graph window.
Furthermore, together with the students, she investigates the possibilities to
trace a graph and to zoom in and out. In this way, togetherwith demonstrating
the tool techniques, the teacher discusses aspects ofdependency relationships
and how tables and graphs can be used to analyze their dynamics. In the
previous computer activities, Lily and Rosy did sometimes click for a table or
graph, but didn't use it for scrolling or tracing values.
This vignette shows how the teacher used the computer tool to create
whole class consensus on how to use it for investigating input-output
relationships. Both the techniques and related concepts were part of the
discussion. She did not show how to use these features for finding breakeven points. That was still a task for the students.
A Different View on Function
During the third computer lesson, the sixth lesson of the learning
arrangement, we observed that the strategy ofLily and Rosy for using the
computer tool had changed while solving a question about two handyman
offers by contractors called Pieters and Tweehoog (see Figure 4). The task
is quite similar to the cellphone activity. However, the way in which they
analyzed the problem situation, phrased the structure of the solution
procedure, and how they used the representations in the tool changed
from case-by-case calculations to investigating the dynamics of relationships with the tools at hand. In the following vignette, Lily starts the
discussion and operates the mouse and the keyboard.
L: Company Pieters charges start costs and an hour rate ... that is ...
R: Plus 92, times 30 ...
Figure 4. Handyman task
1258 MICHIEL DOORMAN ET AL.[L drags an input and an output box into the drawing area and creates a label for the in-box]
L: First company Pieters ... I write only Pieters here, eh?
R: Euro ... plus costs per hour Pieters ... and the total costs will come in here.
[The mouse moves from inbox to outbox and she creates a label and types the name ofthe
outbox. The variables are identified.]
L: Yes, here are the costs.
[The chain of operations is constructed and connected to the input and output boxes]
(...)
L: And the other is TweeHoog ...
[The inbox and outbox are positioned in the drawing area. Labels are created according to
the corresponding variables, with 'uurloon' for 'hourly rate' and interpreted as number of
hours.]
R: Strange costs per hour 32.75.
[The arrow chain of operations is constructed.]
R: Now you have to connect it to a table.
[They start to scroll in the table of the input values and quickly see that the break-even
point is at 18 h.]
(...)
L&R: From 18 h.
[They type in their answer: from 18 h.]
This vignette illustrates a different view on, and use of, the arrow chain
compared to the initial operational left-to-right construction of a chain for
TOOL USE AND THE DEVELOPMENT OF THE FUNCTION CONCEPT 1259repeated calculations. More specifically, the vignette illustrates how the arrow
chain had become a tool for analyzing dependency relationships. Lily and
Rosy organized the dependency relationship by identifying, positioning, and
labeling boxes for input and output variables and filling the gap between them
with operations. This construction signifies an understanding ofthe problem
as a question about two dependency relationships. For investigating the
dynamics, they successfully operated the table tool to zoom in and out for
finding the break-even point. The students' understanding ofthe problem and
phrasing ofthe related mathematical goals changed and new goals did emerge
(e.g. what are the involved variables?).
Backing Up Case Study Findings
The second teaching experiment was used to quantitatively verify this
conjecture concerning the shift in tool use during the computer activities.
We found that for the initial task 130 out of 155 students (84%) used the
tool for just calculating successive input-output values, while in the task
at the end, 89 out of 152 students (58%) used the tool for structuring and
investigating the dynamics of the relationships.
Whereas the students' initial technique with the applet suggested a
procedural view on functions, this more advanced technique reflects a
shift towards a structural view. In other words, the shift in the use of the
tool reflects the development from viewing calculation recipes as tools for
repeated calculations (as processes) to reasoning with structural characteristics of dependency relationships (as objects).
To investigate whether this shift also encompassed students' written work
during the eight lessons, we compared the scores ofthe computer test and the
written final test. In apaired ttest, we foundno significant difference (p = 0.20)
between the final scores on the written test and the computer test. The
correlation of 0.38 between these scores was moderate (p = 0.001). This
suggests that students who improved their reasoning through the described
shift were also shown to benefit from this during the paper-and-pencil test.
Overview ofthe Findings
To summarize, we found useful and illuminating pointers to what a
sequence on functions might help to achieve. The three preparatory openended group activities, in the beginning ofthe sequence, offer students an
opportunity to start from their own informal representations (see Figure 2).
The initial modeling processes resulted in tentative reasoning and
representations that the teacher could build on by introducing the arrow
chain as model of a calculation recipe. The arrow chain representation
1260 MICHIEL DOORMAN ET AL.might derive its meaning from the students' previous activities and might
support the emergence ofthe notion ofdependent and independent variables
and ofchains ofoperations during the subsequent activities (e.g. identifying,
positioning, connecting, and labeling input and output boxes). The notion of
arrow chains and varying input values preceded the scrolling through tables
and zooming in graphs for finding break-even points. This is a key element
of what is denoted 'imagery' in the emergent modeling approach: New
representations or sub-models signify earlier activities with earlier representations. Table 1 summarizes this envisioned development.
CONCLUSION AND DISCUSSION
Conclusion
The central question we formulated in the introduction ofthis paper is: How
can a learning arrangement with computer tools foster the transition from a

procedural calculation understanding to a structural correspondence and covariation understanding of functions? Although the arrangement had the potential to offer students opportunities to work with correspondence and covariation, in which functions representedby arrow chain and tables are starting to become mathematical objects for the students, we cannot claim that all students reached a structural understanding offunctions within the timeline of the teaching sequence. Nevertheless, we can identify the following characteristics ofa rich learning arrangement that foster a transition from a calculation understanding to working with correspondence and co-variation:

1. The three initial open-ended problems and the poster activity helped students in coming to see input-output structures in problems about dependency relationships and to use representations to explore them.

TABLE 1
Global outline of the intended learning outcomes

Start ofthe learning arrangement	End ofthe learning arrangement
Task perception	
Find value	Find relationship
Tool use	Construct chain (from left to right) and enter successive values
Construct chain (after identifying variables) and scroll table or trace graph	
Tool imagery	Repeated calculations
Dependency relationship	

TOOL USE AND THE DEVELOPMENT OF THE FUNCTION CONCEPT 12612. By enabling students to design and use arrow chains as a means of support for reasoning about calculation recipes that bear meaning in everyday-life phenomena, the computer tool supported the students in developing the notion of a chain of operations.

3. By generating the results of a series of calculations for a variety of input values, the computer tool strengthened the students' notion of a function as a calculation recipe that seizes on input values and produces output values.

4. By generating output values for series of input values, by generating tables ofinput and output values, and by enabling the students to move up and down along these tables, the computer tool supported the students in developing a dynamic notion of a variable that can move around in a space of possible values.

5. By displaying arrow chains, tables, and graphs, the computer tool offers representations, which the students could construe as affordances for treating functions as objects before they had become objects for them.

6. By discussing students' work with the tool and showing specific features that some of the students discovered, the teacher appeared successful in having most students start using the table representation.

In summary, we conclude that the learning arrangement with a computer tool helped students to overcome the difficulty of integrating operational and structural aspects of the concept function (Falcade et al., 2007; Sfard, 1991). In particular, the use ofthe tool supported explorative activities for coordinating and investigating the dynamics of co-variation (Kaput & Schorr, 2007).

Discussion

Before discussing the conclusions of this study from a theoretical perspective, we first address its limitations. The sequence of eight lessons fostered conceptual development in the domain of functions. However, the possibilities in the final tests were limited for assessing whether all students made a similar step towards a dual conceptualization, with procedural and structural views, of functions. Moreover, the validity of the strategy coding for underpinning the conjecture that emerged from analyzing the screencast-audio videos can be debated. The screen-audio videos and the observations during the computer lessons showed that the final screenshots ofan activity sometimes are only poor representations of

the students' reasoning. Students could be close to a good answer and then delete everything as a result of a sudden doubt. Final screenshots don't capture this entire reasoning process. Additional information is needed for a full understanding of students' conceptual development in relation to their tool techniques. However, the balance between a manageable data collection and as much information as possible will remain a problematic issue for this. A comparison with a control group is needed to better understand to what extent the improvement is the result of this learning arrangement and the computer tool.

Finally, the results cannot be generalized beyond this particular setting. The extensive description of the interventions is intended to enable researchers to implement the experiment in other settings as a way to evaluate our findings and to contribute to the development of a more encompassing theory. This study started from domain-specific theories on the acquisition of the concept of function and theoretical notions of emergent modeling, tool use, and instrumentation. How did the latter two perspectives work out? First, the notion of emergent modeling and its focus on the shift from "model-of" to "model-for," not only guided the design of the learning arrangement; indeed, the students' cognitive development, and their ways of using the tool initially as a tool for calculations and later as a tool for reasoning with function, reflect this shift.

Second, instrumentation theory focuses on the interrelated development of techniques and concepts. The careful integration of computer activities and paper-and-pencil activities prevented discrepancies between tool techniques and conventional paper-and-pencil techniques. The process of instrumental genesis was enhanced by this alternation between classroom discussion, small-group activities, and computer activities. The repertoire of applet techniques, however, was small and comprised rather simple technical skills. Even ifwe observed changes in how students built arrow chains, the main evolution concerned the reasoning attached to dependency relationships and was not a technical one.

Problem solving as a challenge for mathematics education
in The Netherlands
Michiel Doorman Æ Paul Drijvers Æ Truus Dekker Æ
Marja van den Heuvel-Panhuizen Æ Jan de Lange Æ

Accepted: 8 June 2007/Published online: 11 July 2007
FIZ Karlsruhe 2007
Abstract This paper deals with the challenge to establish
problem solving as a living domain in mathematics education in The Netherlands. While serious attempts are
made to implement a problem-oriented curriculum based
on principles of realistic mathematics education with room
for modelling and with integrated use of technology, the
PISA 2003 results suggest that this has been successful in
educational practice only to a limited extent. The main
difficulties encountered include institutional factors such as
national examinations and textbooks, and issues concerning design and training. One of the main challenges is the
design of good problem solving tasks that are original, nonroutine and new to the students. It is recommended to pay
attention to problem solving in primary education and in
textbook series, to exploit the benefits of technology for
problem solving activities and to use the schools' freedom
to organize school-based examinations for types of
assessment that are more appropriate for problem solving.
Keywords Mathematics education Problem solving
Realistic mathematics education Assessment
1 Introduction
The importance of problem solving in mathematical
thinking and thus in mathematics education is obvious to
many of us. Already in 1962, Polya described problem
solving as a characteristic of human activity:
Solving a problem means finding a way out of a
difficulty, a way around an obstacle, attaining an aim
which was not immediately attainable. Solving
problems is the specific achievement of intelligence,
and intelligence is the specific gift of mankind:
solving problems can be regarded as the most characteristically human activity. Polya 1962, p. v.
In line with the contribution by Schoenfeld (2007) in this
issue, we consider problem solving as the 'art' of dealing
with non-trivial problems which do not yet have a known,
routine solution strategy to the student, but which provide
opportunities for the student to develop new solution
strategies. This description distinguishes problem solving
from many activities with problems in mathematics courses, with or without context.
Realistic Mathematics Education is a leading view on the
learning of mathematics in The Netherlands. As a result,
problem solving in our country is often related to solving
real world problems. Still, we do want to stress that problem
solving is not at all restricted to real world problems; rather,
problems emerging from the 'world of mathematics' can be
very rich sources for problem solving activities.
The non-routine aspect of a problem is relative to the
history of the person who is confronted with it. A problem
can be a real problem-solving item for a student today,
while the same problem is part of a regular set of items
tomorrow. When a student has dealt with an item before,
the character of the activity will change.

DOI 10.1007/s11858-007-0043-2Now, having defined our topic, we will first focus on
recent developments in mathematics education in the
Netherlands.
2 Problem solving in The Netherlands: a brief history
As is the case in many countries, problem solving (in the
sense of the above definition) was not an explicit part of
the mathematics curriculum in The Netherlands until the
eighties. In primary education it still is not. For upper
secondary level, however, policy makers and math educators realized in the seventies that a serious problem
was emerging. The curriculum was well suited for the
students who were preparing for science, but not at all
for those pursuing an education (or profession) in other
domains such as social studies. It was decided that the
latter category of students, who struggled with the formal
and abstract approach, would be better served with a
more problem-oriented approach focusing on applications
and mathematical modelling. This also implied, of
course, a very different approach to what should be
learned and assessed. The science-oriented streams in
upper secondary education were not affected by this: no
realistic problem solving was included in the math and
science-oriented curriculum. The national examinations
remained straightforward and traditional, so these—high
level—students could be prepared for higher education
without any skills to invent new strategies for new types
of problems.
For the students who were preparing for the humanities,
a new curriculum was developed, the mathematics A curriculum (De Lange 1987), based upon realistic mathematics education (which will be discussed in the next section).
It was introduced as a new curriculum subject in pre-university education (vwo) in The Netherlands in 1989. Since
that year, in upper secondary school, two different types of
mathematics curriculum were being taught, mathematics A
and mathematics B. Mathematics B contained the mathematics needed for technical studies and studies in science
and mathematics at university level, its core component is
calculus. Mathematics A was meant for students who
prepare for academic studies in social or economical
sciences or other related subjects.
The purpose of developing the mathematics A curriculum was described as follows:
Mathematics A is intended for students who will have
little further education in mathematics in their academic studies, but who must be able to use mathematics as an instrument to a certain extent. In
particular, we have in mind those who have to prepare themselves for the fact that subjects outside the
traditional sciences are more frequently being approached with the use of mathematics.
This means that students must learn to be able to
assess the value of a mathematically tinted presentation in their education. To do this they must become
familiar with the current mathematical use of language, with formulations in formula language, and
with divergent forms of mathematical representation.
Furthermore, they must learn to work with mathematical models and be able to assess the relevance of
these models.
(Werkgroep van advies voor de herverkaveling eindexamenprogramma's Wiskunde I en Wiskunde II vwo 2005,
p. 19)
In mathematics A, the emphasis lay more on applications
of mathematics and on mathematical modelling than on
'pure' and abstract mathematics, and also more on the
processes needed to come to an answer than on the answer
itself (the product). In its initial years, modelling and
problem solving were at the heart of this subject. The research along the introduction of mathematics A (De Lange
1987) showed examples of real world problem solving, and
of the use of mathematics to solve real world problems. It
also revealed that problem solving lends itself excellently to
group work, which brought new problems and possibilities
to the fore, especially in the area of assessment. The research
hinted already at a fact that is now almost taken for granted,
as the outcomes of PISA 2003 prove: inter-subjective
scoring can be very reliable and fair (OECD 2005, p. 227).
Maybe because of the successful introduction of this
new type of mathematics, problem solving in The Netherlands since that time seems to be identified with solving
real world problems using mathematics. Even in the
'harder' and more scientifically oriented curricula, problem
solving was introduced 'in context'. Inside-mathematics
problem solving seems not to have caught on in The
Netherlands, at least not on a large scale.
In the ongoing discussion in The Netherlands, there is a
lot of confusion about the true meaning of problem solving
in relation to the theory of Realistic Mathematics Education. So let us now address this relationship.
2.1 Realistic mathematics education
and problem solving
In the aforementioned study (De Lange 1987), the real
world problems were used for problem solving in two
ways. First, according to the theory of Realistic Mathematics Education, the real world is a source or starting
point for the development of mathematical concepts
(Freudenthal 1991). Well chosen contextual problems offer
406 M. Doorman et al.
123opportunities for the students to develop informal, highly
context-specific solution strategies, and are used to support
mathematical concept building (Gravemeijer and Doorman
1999). In this phase, the criterion of potential for mathematical concept development dominates the criterion of
authenticity. In fact, the context may even be rather unrealistic or within mathematics, if concept development requires it. However, the contextual problem must be
experienced as a real problem by the students.
The second role of the real world is a little different. The
real world is used as the domain in which we can use our
mathematical concepts in the way we wish. The real world
now has to be truly authentic in order to let the highly
appreciated process of mathematization take full bloom.
The idea behind this application phase of the learning
process is twofold: to reinforce the concepts already
developed, and to engage in problem solving activities:
develop and deepen strategies.
If we reflect critically on the developments of the past
decades we distinguish three factors that made the implementation of problem solving only a limited success in

Dutch mathematics education. First, it became increasingly
difficult to make quality assessments for mathematics A.
The examinations became more and more predictable, so
part of the real problem-solving component was lost.
Second, many people translated the ideas behind mathematics A in a somewhat restricted way: the conceptual
mathematization part and the applied mathematization part
were confused, resulting in examination standards of long
stories in which students had to apply little mathematics.
Third, the level of authenticity went down with the increased use and popularity of 'applied problem solving'.
2.2 Today's problem solving practice
To summarize the state of the art in Dutch mathematics
education, we notice that students in upper secondary
education are not often confronted with inside-mathematical problems for which no known strategy is available.
This may be the reason for the modest scores of The
Netherlands in the mathematics Olympiads. Another matter
for concern is the lack of problem solving activities in
primary education. The focus here is on word problems and
eventually on solving real world problems. Solving insidemathematics problems is merely absent.
To assess the state of affairs concerning problem solving
in Dutch mathematics education, we will now first look at
the PISA-2003 results. Next, we will discuss a study on
problem solving in primary education. Then, a problem
solving competition for upper secondary education will be
presented. The paper continues with remarks on the
opportunities that the integration of technology offers for
problem solving, and ends with a conclusion.
3 Recent PISA-results
3.1 PISA-2003
In the 2003 version of the programme for international
student assessment (PISA) study, mathematics was the
main focus. Problem solving was an additional domain in
PISA-2003. The idea behind this domain, usually not
taught as a separate subject, was to test general problemsolving skills of students aged 15-16. Being able to apply
problem-solving skills in a variety of domains is an
important educational target in many countries and, as
indicated by the OECD (2003), these competencies are the
foundation of effective participation in society and development of talents in personal and professional life.
In order to solve these larger problem-solving tasks,
students must understand and interpret the available
information, recognize important elements that are represented and make connections to the real world situation.
They must be able to reason and communicate their arguments in writing. The solution is not obvious and the skills
needed usually do not belong to a single educational domain such as mathematics or science.
Within the domain of mathematics education, problem
solving is seen as solving problems for which standard
solution strategies are not yet available. In general, this
means the investigation of a larger problem. Often, these
problems in PISA-2003 are situated in a more or less
realistic situation. To solve these, the student first has to
'translate' the information and to create a (simplified)
mathematical model of the situation. After the problem is
solved within this mathematical model, the results are
compared to the real life problem situation. This might
result in rejecting (some of) the results, rounding the answers according to the situation or to adjusting the mathematical model (De Lange 2006).
There is a strong connection between mathematics as an
educational subject in The Netherlands and problem solving as defined by the PISA programme. Therefore, research
from the Dutch national test institute Cito and the Freudenthal Institute included the PISA problem-solving domain in a further analysis of the Dutch national
mathematics results of the PISA-2003 study (Dekker et al.
2006). We now present some of the findings of this study.
3.2 Problem solving and mathematical literacy
in the national study
Score points for both mathematical literacy and problem
solving literacy have a mean of 500 and a standard deviation of 100. This enables a comparison between the results
in both domains. In the 2003 study, the Dutch mean score
for mathematical literacy was 538 (place 4 on the interProblem solving as a challenge for mathematics education in The Netherlands 407
123national list) and the mean score for problem solving was
520 (place 12 on the international list). Figure 1 shows that
the difference between the two scores was the largest in
The Netherlands as compared to all other participating
countries; students in The Netherlands performed better in
the domain of mathematics than in problem solving (Gille
et al. 2004).
The international PISA report (OECD 2004a) claims
that the relatively high score of mathematical literacy as
compared to the problem solving results indicate that
mathematics education in The Netherlands, as measured by
PISA, is very effective. However, one could also argue that
problem-solving skills are lagging behind. Furthermore, the
researchers indicate that in no other country, apart from
The Netherlands, mathematics education is as aligned with
the competencies measured by the PISA study. Another
explanation is that the PISA problem solving tasks
emphasize general analytical argumentation skills without
building upon mathematical skills. Could Dutch students
be lacking these general skills? The research could neither
prove nor refute this.
When looking at student work on the mathematics
assignments, the researchers found that Dutch students,
when compared to their peers in neighbouring countries
(Belgium Flanders and Germany), were less persistent
when working at large tasks which took a lot of time and
energy to complete. This was not caused by a lack of
confidence; students in The Netherlands did not often skip
tasks, but almost always at least started the solution process. However, they gave up sooner, especially when
dealing with extensive and challenging tasks. The student
work on the problem-solving test was not analysed in this
study, but it may be expected that the same phenomenon
occurred there.
3.3 Are Dutch students mathematically literate?
As shown earlier, Dutch results were satisfactory when
compared to other OECD countries. But The Netherlands is
a highly developed industrial country and demands are
high for labourers in almost all professions. Which level of
mathematical literacy should this country strive for? The
Fig. 1 Differences between
mathematical literacy and
problem solving. Source: OECD
2004b, p. 54
408 M. Doorman et al.
123PISA study discerns six levels of mathematical literacy.
Level 1 starts at a score of 358 and ends with 420, level 2
has scores 420-482 and level 3, which contains the overall
mean score of 500, runs from 482-544. Level 4 scores are
within the range of 544-606, level 5 from 606-668 and at
level 6 scores are 668 and higher. Students working at
mathematical literacy level 4 can
....work effectively with explicit models for complex
concrete situations that may involve constraints or
call for making assumptions. They can select and
integrate different representations, including symbolic ones, linking them directly to aspects of realworld situations. Students at this level can utilize
well-developed skills and reason flexibly, with some
insight, in these contexts. They can construct and
communicate explanations and arguments based on
their interpretations, arguments and actions.
The mean score for Dutch students preparing for university
(vwo) was 639 in the PISA 2003 study. Students preparing
for vocational studies at a higher level (e.g. to become a
high school teacher or highly skilled laboratory assistant)
scored 594. However, about 60% of the Dutch students at
age 15 prepare for vocational education at a medium or low
level (vmbo) and most ofthem do not have scores at level 4
or higher as we would expect them to have. When looking
at the content of the PISA mathematical literacy problems,
these seem more suited for vmbo students and less for havo
or vwo students.
There are large differences between the countries taking
part in the study and this means that very weak students in
some countries must be able to answer at least some of the
questions. And so the Dutch results may seem satisfactory
as compared to other countries, by our own standards they
do not seem good enough and much is left to be desired.
Furthemore, the largest contribution to the relatively high
score in mathematical literacy in The Netherlands came
from the Reproduction cluster and not from the clusters
Connections and Reflection.
Providing sound arguments is a diffcult task for all
students, but Dutch students have been trained in doing so
during their school career. Moreover, for lower achieving
students the language aspect is an important issue, for both
passive and active use of language. The result of the Dutch
analysis of the PISA 2003 study led to some recommendations which are, not surprisingly, different for different
groups of Dutch students. For students at upper secondary
level, more emphasis should be placed on formal and
abstract mathematics.
For students in the lower ability groups (vmbo-level)
reading and interpreting skills need attention in order to be
better prepared for solving problems that are challenging to
them. This recommendation was made since we feel it is
unacceptable that so many students aged 15 are not
mathematically literate at the PISA scale of level 4.
To summarize this brief review of the Dutch PISA 2003
results on mathematical literacy and problem solving, the
most surprising result is that the problem-solving scores are
lagging behind. As learning to solve problems starts at an
early age, we now first consider a study on problem solving
in primary education.
4 Problem solving in primary education
Although the reform in mathematics towards Realistic
Mathematics Education resulted in a new generation of
primary school textbook series, problem solving, in the
meaning of solving non-routine mathematical problems,
was hardly given any attention in these textbooks. At
most the reform brought--to a certain degree-more
complex realistic problems in which the children had to
figure out, for instance, which of the several journal
subscriptions is cheaper and what it costs to organize a
birthday party. Puzzle-like problems, in which it is not
directly clear from the beginning how to start with solving
them, are scarcely found in the new textbooks. At best,
one can come across these problems in additional materials for high achievers.
As in the textbooks, non-routine problems are also not
included in the Cito test, taken by 90% of the sixth-graders
at the end of primary school (Cito is the national institute
for assessing educational progress). This test, through
which children get access to the higher levels of secondary
school, only consists of routine problems in a multiplechoice format.
The lack of non-routine problems in textbooks and the
Cito test make that not much attention is paid to problem
solving in primary school. Teachers do not offer children
an environment in which they can develop problem-solving
skills and the attitude that is necessary for coping with nonroutine problems. A mitigating circumstance that is often
mentioned is that problem solving is something that is only
attainable by the best students and that these bright students
can help themselves and do not need much help for
learning to solve non-routine problems. However, this
assumption is in contrast with the results that were found
when in 2004 high-achieving fourth-graders in twenty
schools were given a test on problem solving (see Van den
Heuvel-Panhuizen and Bodin-Baarends 2004).
For all of us who thought that we as mathematics
developers and researchers did our job quite well and
contributed to bringing our students into the higher ranks of
international mathematics achievement, the results of this
study came as a rude awakening. In the next section, we
will give more details about the study.
Problem solving as a challenge for mathematics education in The Netherlands 409
1234.1 A study on problem solving by high achievers
in grade 4
To begin with, it is quite telling that there was an external
reason for doing this study. The direct cause was a request
from Peter Pool and John Treffalt from the Assessment and
Evaluation Unit, School of Education, University of Leeds
to investigate how Dutch high-achieving fourth-graders

will perform problem-solving tasks that have been developed for the World Class Tests. In total, 15 problems were chosen which, for the number domain and the operations to be carried out, were more or less covered by the mathematics curriculum these Dutch students had dealt with in grade 4. However, the nature of the problems was somewhat special for the Dutch students. Most of the tasks were puzzle-like problems, such as number riddles. Students do not encounter this kind of problem that often in textbook series and tests in The Netherlands. The 15 problems were put in a test booklet with every problem presented on a separate page. The children were free to use the whole page as scrap paper. For some problems there was an explicit request to show how they solved them.
In total, 152 high achieving students in grade 4 (9-10 year olds) took the test. The students belonged to the top 20% ability range in mathematics. They were selected by their teachers on the basis of their mathematics score. In most cases this was the students' score on the Cito Student Monitoring Test.
4.1.1 Some revealing results
The analysis of the student responses in the test booklets showed that quite a number ofthe children did not make use of the work space when solving the problems. They did not have any other scrap paper available; this means that they worked on the problems without writing anything down.
This is remarkable, especially for problems that involve a lot of data or where you can find a solution by systematically trying out several options. For these problems, it is often practical to make notes and write down intermediate answers. Figure 2 shows an example of such a problem.
Table 1 shows the results on this item. Clearly, the problem was fairly difficult for the Dutch high-achieving fourth-graders involved in the study. Only 39 students, a quarter of the total group (25.7%), found the right number. The students in the United Kingdom did slightly better on this problem. Of the 184, year 4-5 students (8.5-9.5 years) who did this problem and who belonged to the 15-20% best students in mathematics, 34.2% came up with the correct answer (Peter Pool and John Trelfall, personal communication).
Furthermore, Table 1 reveals that 93 of the Dutch children, almost two-thirds of the total, did not make any use of the scrap paper. Even out of the 39 students who came up with the correct answer, 19 did not use the scrap paper. Since high achievers in mathematics were involved in this study, it is not really surprising that roughly half the children found the right answer mentally. Although this problem needs much calculation work, the difficulty does not lie so much in the knowledge of the tables of multiplication that is required. Bright students in grade 4 mostly know their tables. What it comes down to in this problem is the ability to take into account a number of different criteria at once. The result that gives more cause for concern is that 74 of the 113 children who did not find the right number did not write anything down.
The after-test interviews that were held with a selection of the students disclosed that the difficulties with this problem were not related to understanding the question. The children clearly understood the intention of the problem. Although the calculation itself did not always go as smoothly as one would expect in this group of students, that also was not the core of their problem. The study made it clear that the weakness of these good students lay in a different area, namely in not trying and not being able to keep up a particular approach. Moreover, this attitude might be strengthened by the fact that the children apparently were not used to writing something down to support their thought process.
In reviewing all the students' responses and the experiences from the interviews, three tendencies were found: many students did not write anything down, many students did even not start, and if they started quite a number showed lack of persistence.
Find the number
It is smaller than 100.
If you divide it by 7, there is no remainder.
If you divide it by 3, the remainder is 2.
If you divide it by 5, the remainder is 1.

123The tendency not to write anything down. This tendency raised many questions, but the study also revealed some ideas of how to explain this behaviour. For example, children (and teachers) might think that it is better not to use the paper, because they think that solving the problems mentally is a higher level of mathematics. The trend might also have to do with the fact that bright students hardly use (scrap) paper when they do their assignments in regular mathematics classes. A very different aspect that might play a part is that the children do not write anything down because they feel that you should not "make a mess" in a test. They learned from their teachers that it is important to work tidily.
The tendency not to start with the problem. The fact that the majority of the children who could not solve this problem did not try anything on paper either, is also significant. Except that the trend to not even start could result from the abovementioned refusal to write down anything in solving mathematics problems, another possible explanation could be that the children have not learned to use notes and organize data as a support for the solution process. In the case of this problem, one could think of listing the numbers that qualify according to a certain rule and then strike out the numbers that do not conform. Trying things out might break through the all or nothing atmosphere that now often prevails.
The tendency not to persist when attempting to solve the problem. A quite alarming experience in this study was that high-achieving students gave up after trying a few numbers. A possible explanation for this reaction may be that good students can find it difficult to persevere because they do not often come across problems that require profound mathematical inquiry. They usually do not have to think very long about the problems they normally encounter.
4.2 Some final remarks on problem solving in primary education
As was mentioned before, non-routine problem solving has a marginal place in the present Dutch mathematics curriculum in primary school. We believe that this should change and hope that the start that is given for this in the TAL learning-teaching trajectory for calculation with whole numbers in primary school will have an effect in teaching practice (Van den Heuvel-Panhuizen 2001). A complicating factor here is that up to now there has not been much support from textbooks series and the Cito test at the end of primary school. Both still stay far away from non-routine problem solving.
However, an interesting initiative to enhance problemsolving skills in primary education is the recently established Great Arithmetic Day. On this day, that is organized by the Freudenthal Institute, thousands of primary students (and their teachers) are engaged in problem solving. More research is necessary to see whether this extra-curricular activity can introduce more problem solving to the Dutch primary school curriculum.
After this short impression of the state of affairs concerning problem solving in Dutch primary education, we now turn to secondary education.
5 Problem solving at secondary level
As in primary education, problem solving in secondary mathematics education has only a marginal position. In the introduction to this paper, it has already been pointed out that even an application and modelling-oriented curriculum like the one for mathematics A tends to standardize problem-solving tasks into routine assignments. The national examination does not encourage paying much attention to problem solving skills. Textbooks usually do not address problem solving as a result of examination demands, designing teacher and student proof activities, and the time need for designing problem solving activities. An exception is the textbook series 'Wiskundelijn' (Bos et al. 1990), which contained so-called Systematic Problem Approach items. Such an 'SPA' explicitly aimed at the development of heuristics for dealing with open problems in the sense of Van Streun (1991).
Important initiatives for enhancing problem solving activities in upper secondary education are the Mathematics A-lympiad and the Mathematics B-day competitions. As we consider this to be types of competition which are exemplary to problem solving, an example of the first is discussed in more detail.
6 Mathematics A-lympiad: an experimental garden for problem solving
It seems obvious that problem solving should be an inherent part of the mathematics A curriculum. In the educational practice of mathematics A, however, less and less attention was given to really open ended problems that address higher order thinking goals, problem solving and modelling. This is mainly due to the fact that Mathematics A is assessed in a central, written, individual, final examination. The design of examination tasks that do justice to the purpose of the mathematics A curriculum turned out to be difficult. The examination questions, although presented in a seemingly realistic context, seldom asked for modelling or problem solving on a serious level. If these skills are not needed for the examinations, one cannot expect a great deal of attention to be paid to them during education. And so the circle is closed: 'poor' final exams bring about 'poor' education.
Problem solving as a challenge for mathematics education in The Netherlands 411
123To break this circle, the Mathematics A-lympiad was established outside the examination system. Its intentions were to design a 'task' that encompasses the original objectives of mathematics A and that asks for teamwork as well. As an extra motivating factor this task would be presented to students as a team competition.
In the announcement that is sent to all secondary schools with pre-university education, the competition is described as follows:
The competition is intended for students in grades 11 and 12 (age 16-18) who are taking mathematics A as a subject. It involves tackling a challenging problem as a team (three or four students). The competition consists of a qualifying preliminary round at the school and a final round at the weekend (Friday and Saturday) in a conference centre.
The open nature of the task implies that the teams have to forge the entire path from defining the problem, via strategy definition, solution and argumentation, through presenting the solution found. The result is a paper containing all of these aspects.
6.1 The competition and school examination
The Mathematics A-lympiad competition has been running since 1989. It consists of two sessions, a preliminary round in the schools and a final session in an external location. The competition has seen a growing number of participating schools in the first 10-12 years, though that number seems to have stabilized over the last couple of years with about 150 schools participating, with a total of about 1,500 teams. This means that every year about 6,000 Dutch pupils work in teams on an open ended authentic assignment for mathematics. An increasing number of foreign teams (from Denmark, Germany and the Dutch Antilles) participate in an international final round.
In the early years of the Mathematics A-lympiad, it was exceptional in mathematics education to call on skills such as problem solving, reading, writing, doing research, forming arguments, reasoning, critically reviewing mathematical models, mathematization, teamwork, planning: the full range of general and mathematical skills. With the Mathematics A-lympiad these skills have gained a set place in a large number of schools in The Netherlands.

This type of mathematics is precisely the mathematics
that many students will deal with later on in society:
solving more complex problems in teams where technical
tricks alone will not do. In the next paragraph we will
present an example of student work on one of the
assignments.
6.2 The diversity example—analysis of student work
An assignment in a final round was about bio-diversity.
Various species of plants and animals are disappearing
every day. The task for the student teams was to decide on
criteria for determining which plants and animals are most
important to save, if the goal is to keep species diversity
large enough.
In the first three problems the teams had to familiarize
themselves with the concept of bio-diversity. Then a
relative value scale had to be developed for the genetic
relationships of species. This value scale was to be used
for determining which species it would be better to
protect in order to keep diversity, from a genetic point of
view, as great as possible. In brief: the teams had to
develop a decision-making model. This model should
then be used for making decisions on the preservation of
species.
6.2.1 The plants in the photos
The assignment started as follows (see also Fig. 3).
'A number of photos of different combinations of plants
(A, B, C and D) was given to a number of scientists who
then ranked them according to decreasing diversity.'
Using this information the teams had to decide what
factors were clearly seen as important for diversity. Teams
were not asked to devise a function themselves that produces this ranking, but almost every team tried to do so.
This was probably done to compare their own ideas with
the assessment of the scientists. In general, there was little
difference for the factors found by the teams. As most
important criteria for determining the level of diversity
were mentioned:
- the total number of plants;
- the number of species;
- an even distribution of the numbers per species.
The standard deviation of the numbers was calculated as
a measure for this distribution. A smaller standard deviation was synonymous with better diversity. Some teams did
not think that this was altogether correct as a photo with a
few plants would be given a greater diversity than a photo
with many plants in the same ratios. One team replaced the
absolute numbers by percentages, as did a number of other
teams (Fig. 4).
One team did not think this was correct and explained
why, using a fictitious photo containing only one species.
The standard deviation would then be zero and that would
mean that it had the greatest diversity, even though in fact
it has the minimum diversity.
412 M. Doorman et al.
123Another team concluded that according to the above
method the diversity was greatest when all plants occurred
in equal quantities. However, nature is better served by
equilibrium than by equal quantities. And in equilibrium:
'... for example, very many more bacteria are needed
than elephants.'
A better factor for determining the level of diversity is how
much the number of each species in a photo differs from
the average number of this species (in all photos). The
thinking behind this was that the ecological equilibrium
will not be far from the average numbers. This method
meant that the photos with plants in the ratio of:
40:20:10:13.75:21.25 had the greatest diversity. When the
ratios were equal, a higher diversity would be allocated to
the photo with the greatest number of plants.
A different team compared the numbers of plants (see
Fig. 3) with the calculated averages. Checking this approach by using the plants on the photos meant that photo
3 had the greatest diversity, as it was the one that best
corresponded to the desired averages. Next is photo 2 as
one species was missing there. Then photo 4 because
species D had died out there and it was a species that
occurred more on average than species C, which was
absent in photo 2. Photo 1 was the last due to its large
differences from the averages, especially for species D
and E. This order corresponded to the order established by
the experts.
6.2.2 Genetic variation
In the second part of the assignment the teams were asked
to determine which species it would be best to protect from
the point of view of genetic diversity, by using a genealogical tree of genetic relationships.
The teams were asked to develop a value scale which,
together with the genealogical tree, could be used to
determine which species had to be protected and which
could be allowed to disappear if there was no alternative. In
the genealogical tree presented as an example in the
assignment (Fig. 5), it is specified for two combinations of
species which combination it would be better to protect
from the point of view of genetic variation.
Problems can arise here with regard to the term 'genetic
variation' as it can be defined in different ways. In general,
two approaches are recognized in the students' work. The
first approach uses the relationship between a species and
the original species. In this approach, the defined objective
is to preserve the original genetic material as much as
possible. Species that have branched off more often are
further away from the original species and will thus contain
less of the original material. With each division, the teams
assumed that a certain percentage of the material was
transferred into the new species. The teams that used this
approach conceded that these percentages were based on
their imagination. Generally the teams used a division in
equal parts, as is shown in Fig. 6.
Some teams who wanted to preserve the species that
were closest to the original species had rather strange
theories. The preservation of these species would have the
advantage that 'as many genes as possible' would be preserved. Species that were further away from this original
species contained 'fewer genes'. It was also believed that
by maintaining the original material the species that disappear could occur again more easily.
The second approach examines how the different species are mutually related. This can be done by counting the
nodes from one species to the next.
You go through the tree from one species to the next and
count along the way the number of places where new
species occur. This number is called the distance between
two species. These distances were set out by the teams in a
matrix and the columns were then summed. These totals
were then a measure of relatedness.
Fig. 3 Part of the diversity task
photo 1: 40 10 20 5 5
In percent that is:
photo 1: 50% 12.5% 25% 6.25% 6.25%
The standard deviation of these numbers is 16.49. If the diversity of the
other photos is calculated in this way, you get the following standard
deviations:
photo 1: 16.49
photo 2: 11.54
photo 3: 8.00
photo 4: 14.14.
These results also fit with the rankings of the experts.
Fig. 4 One team's result
Problem solving as a challenge for mathematics education in The Netherlands 413
123Figure 7 shows this matrix and the accompanying tree,
made by one of the teams. The species with the smallest
total distance is the one most related to the other species and
can, if necessary, be the one most easily dispensed with.
When this species is left out, a new tree can be made and the
process is repeated. If, as a result of selection, at a node only
one ofthe species had remained, almost all ofthe teams left
this node out as if it never existed. This move was never
justified but is indeed consistent when you consider all of
the species that have died out whose existence is unknown
to us. It is striking that none ofthe teams thought of looking
at the minimum and maximum distances instead of the sum
of the distances. After all, a minimum distance means a
close relationship between the two species and a maximum
distance means a distant relationship. With two species that
are closely related, it is less serious if one of them dies out,
at least according to the exercise.
The teams now had to adapt their value scale in such a
way that it was not possible that one species did obtain an
extreme score. In other words: the system had to give
somewhat 'flattened' results. A number of teams combined
the approaches mentioned before. The one group added up
the values from the value scale, another multiplied them.
For example, the distances were multiplied by the percentages. Logarithmic and exponential functions were also
used to bring the values closer together. None of the teams
examined this problem critically. One team stated that
flattening the system leads to a higher reliability. However,
they did not explain.
6.2.3 Comments
Some participating teams commented on the task in
interesting ways. For example, a number of teams criticized the approach in part 2 where genetic variation was
the central issue. According to these teams, there are more
important arguments for prioritizing the preservation of
certain species, i.e. ecological. As an example, take a
family of species that acts as prey, prey-predator, and
predator within an ecological system.
Some finalists thought it was more important for stable
species (with fewer divisions) to be preserved. On the other
hand it can be argued that it might be better to protect
quickly developing branches as new genetic variations will
occur more easily through them.
The task went on with a question on including a time
component to address the genetic evolution in time. For
reasons of space, this extension is not described here; we
refer to De Haan and Wijers (2000) for a more extensive
description of the assignment.
This genealogical tree is used for deciding, for example, that A and B are more
genetically related than A and D. Thus if only two species can be saved, then for
example saving the combination of B and D is better than saving the combination
of B and A. That is why D will be somewhat higher up the value scale than A. How
much higher depends on the whole set.
Fig. 5 Continuation of the task
Fig. 6 Tree with probabilities
Fig. 7 Matrix and tree
414 M. Doorman et al.
1236.2.4 Concluding the example
The search for an acceptable value scale by the teams was
often a wild search for appropriate formulae. Teams often
arbitrarily multiplied, divided, added and subtracted. The
underlying arguments were often forgotten in the process. It
was for instance stated that a certain parameter was important, but was not yet included in the scale, without saying
why they chose to include this specific parameter in this
specific way. This makes the allocation of values arbitrary.
This can be seen as a criticism ofthe assignment or ofthe
pupils, but it is more a criticism of the process of allocating
values. Furthermore, there was lack ofclarity with the terms.
Where for example is the separation between a breed and a
species within evolution theory? Is this part of the assignment about making a choice between different species of
finches or the choice between a dog, a cat and a squirrel?
The reader will notice that nowhere in the assignment it
was said that a formula had to be devised, but rather a
'system'. Why was it that almost all teams searched so
frenetically for a formula? Could it be caused by the use of
terms such as 'value scale' 'tree'? It is not easy and
often even impossible to convert non-mathematical considerations into formulae. It is often better to simply reason
them out. After all, one does not know how the different
considerations are linked together and how they have to be
included, and whether there are still unknown, more
important factors.
'Chance of survival' indeed seems to be a number, but

nobody knows how to calculate it. It is more a probability
derived from small talk than from theory or experiments.
That's why one of the teams stated:
We have to throw all the criteria into a large basket
and determine the value of each criterion. This presents a considerable problem. Every individual
weighs every criterion differently. You might think
that the economic aspect is important, but so also is
the social aspect. You can proceed purely rationally,
but also emotionally! In order to come to a reasonably objective opinion you must present your criteria
to a cross-section of society.
6.3 Influence of recent educational reform
Since 1998, upper secondary education in The Netherlands
has been restructured. A part of this reform is the growing
attention that is paid to general skills embedded in several
subjects. Larger, more complex open-ended tasks, which
focus on general skills as well as on subject-related skills
became a compulsory part of the school exam for every
subject. These skills are highly reminiscent of those mentioned as objectives for mathematics A in 1980. It is precisely because these skills will be assessed in the school
exams, that the interest in teaching and practicing higher
order skills has been revived. The assignments of the
Mathematics A-lympiad turned out to be perfect examples
of this kind of tasks and since 1998 its assignment is used
as part of the school examination in many schools. A
similar competition for Mathematics B, the Mathematics
B-day, is used in the same way and with equal enthusiasm.
The experiences with the B-day show that problem solving
tasks that are appropriate for team competitions can be
designed within the domains of pure mathematics and
mathematical applications in exact sciences as well.
From an organizational point of view, participating in
the Mathematics A-lympiad and B-day is very convenient
for the school: the assignment is provided by a committee
of experts; in one day, teams can produce a paper; students
are deprived of the possibility of obtaining 'expert
knowledge' from elsewhere, since everyone works for the
entire day on the same task.
There is, however, also a downside to this development.
As doing open-ended assignments, writing papers and essays
as well as working in teams became a regular aspect of the
mathematics lessons—and ofother curriculum subjects—the
initial motive for the Mathematics A-lympiad—to offer 'a
completely different type of assignment'—became less
important. This might have had a slightly negative effect on
the quality of the student work for the Mathematics Alympiad assignments. Nowadays, the mathematics is often
used on a more basic level, without the extra considerations
and argumentations that characterize real problem solving.
Other factors than getting used to this type of tasks play an
important role in the quality as well, the most obvious being
the recent reduction in math lessons ('teaching time') by
about 50% in The Netherlands. Nevertheless, the design of
the assignments and the evaluation of student work during
the finals remain an inspiring experimental garden for
investigating possibilities for problem solving in mathematics education.
7 New tools create new possibilities
As a final perspective on problem solving, we consider the
use of technological tools. New technological tools create
new possibilities for problem solving in mathematics.
These possibilities, as well as the difficulties, are now
illustrated for the case of the integration of the graphics
calculator.
As in many other countries, the graphics calculator was
introduced in the Dutch mathematics curriculum during the
nineties of the previous century. An important didactical
motivation for integration in the curriculum, as well as in
the national examination, is the way this tool supports
Problem solving as a challenge for mathematics education in The Netherlands 415
123explorative activities and problem solving abilities (Drijvers and Doorman 1996). Tools like the graphics calculator
provide a new and rich variety in possible problem solving
strategies. Even weaker students appear to be supported by
this (Streun et al. 2000).
The integration of the graphics calculator also fostered
new mathematical practices that would not be possible
without technological tools. We sum up some of the most
remarkable changes:
• Thanks to its direct feedback, the graphics calculator
offers opportunities for exploratory activities. Even
during the initial phase of familiarization, a problem
can often already be investigated graphically. Inventory
and classification activities can lead to discoveries
which then, through reflection and generalization, result
in interesting mathematical theorems. This contrasts
with the traditional method, in which definitions and
theorems are stated at the beginning of the learning
path in the expectation that insight will be acquired
through repeated application.
• One can quickly and effectively follow the results of
variation in the problem. The influence of a given
parameterin the formula can easily be visualizedby using
graphics. This enables users to continually alter their
frame of reference from global to local and vice versa.
• Due to the use of technological tools, the repertoire of
techniques and skills a student must master will
remarkably change. Freehand drawing of a graph based
on a strictly prescribed analysis of functions—a much
practiced skill in the past—will hardly matter. On the
other hand, skills such as estimating numerical values,
reading graphs, setting viewing windows and improving approximations increase in significance. A shift in
emphasis occurred away from traditional techniques
and towards a more flexible solution procedure, in
which a critical attitude is developed with respect to
numerical results.
The following example illustrates the ways in which
students made use of the graphics calculator's potential for
explorative activities. In Fig. 8, two coins lie next to one
another. The coin on the left is fixed. P is the point on the
edge of the coin on the right where it touches the coin on
the left. The coin on the right is now going to roll around
the edge of the coin on the left without sliding. The
problem is: what is the locus of point P?
The first questions in the task contained a concrete
orientation, the choice of an appropriate coordinate system
and the constructing of the motion equations. So far,
questions with straightforward solution strategies for these
students. Then the students draw the curve with their
graphics calculator, creating a cardioid-shaped image. The
distance of the moving point to the centre of the coin can
be changed. This can be generalized and the students can
investigate a variety of cases. This activity is new to them,
and they do not have standard solution strategies at hand.
They are free to classify the graphs they find as they
choose. The focus is on their investigational activities.
The graphics calculator immediately revealed any error
by drawing an 'impossible' curve. This led, on the whole,
to an improvement in the initial motion equations. For
instance, a number of students entered the following:
x0tP ¼ 2 cos t 1 þ cos 02tP
y0tP ¼ 2 sin t þ sin 02tP
The drawing in Fig. 9 revealed what was wrong.
This could now be improved! The students then entered:
x0tP ¼ 2 cos t 1 þ cos 02t þ pP
y0tP ¼ 2 sin t þ sin 02t þ pP
Ruthven (1992) uses the expression 'trial and improve'
for such problem solving skills with a graphics calculator at
hand. The matter of varying the distance between P and the
centre of the rolling coin could also be dealt with. Students
create graphs as shown in Fig. 10.
Interesting drawings result from these so-called Pascal
curves. During the last five minutes of the lesson, the results of classifications of the curves were listed on the
board.
Fig. 8 The problem situation with the rotating coin
Fig. 9 The cardioid on the screen of a graphics calculator
416 M. Doorman et al.
123a Shape
0 Circle
1 Cardioid
0 < a < 1 'dent'
a > 1 Loop
One student comments on the 'dent': ''When a is small,
the dent is also small, and when a gets bigger, the dent
grows too.''
Where the loop is concerned, the teacher asks: ''Does it
matter how much greater a is than 1?''
Student: ''When a is close to 1, it's small; if a is big, it's
big.''
Teacher: ''So does the small one ever catch up with the
big one?''
Student: ''No, they'll overlap, they'll get close together.''
The students watched the curves being created in a
dynamic manner. The graphs became a starting point for
further study, rather than the static end product of a vast
ritual of investigation into intersections of the axes, horizontal and vertical tangents, etc. The graphics calculator is
an excellent aid here. The students 'saw' the point on the
plane shift and the speed of the movement became visible.
The parametric equations that describe the movements on
the plane really came to life this way.
The user can see how a graph (or a curve or a group of
graphs) is created. When the picture is finished, TRACE
offers the opportunity to follow the graph point by point
and read the changing coordinates on the screen. The
graphics calculator's direct feedback encourages the students to reflect upon what they have done. This alternation
between experimentation and reflection is an important
aspect of problem solving and concept development.
As a consequence, the graphics calculator supports
exploratory activities. The students arrive at a classification
that they themselves have developed through their own
experience. The potential of the technological tool evidently
stimulates many students to engage in informative exploratory activities. The mathematical level of the result, however, tends to be rather varied. While such exploration can
lead to excellent discoveries and insights, the results are at
times disappointing. This has to do, on the one hand, with the
fact that drawing conclusions from investigative activities
places heavy demands on the students. Moreover, students
have to learn to deal with open problems, to appropriate new
tools and to develop an investigative attitude.
In addition to the aforementioned study on the opportunities that the graphics calculator offers to mathematics
education, recent research projects at the Freudenthal
Institute focus on tool-use in mathematics education and
concentrate on computer minitools (Bakker 2004, Doorman 2005, Drijvers et al. 2007) as well as on computer
algebra (Drijvers 2003).
To summarize the findings, we notice that the dynamics,
the direct feedback, and the possibilities to deal with complex
situations and to investigate many cases offer new opportunities for problem solving activities in mathematics education. The skills a student is expected to master are different
from those required in traditional situations. We conjectured
that the importance of mastering routine operations would
decline and the necessity for developing a flexible attitude for
working with tools would increase. Still, like the experiences
with problem solving in the mathematics A curriculum, the
difficulty for teachers and task designers is to avoid problemsolving tasks becoming routinized. If the students after their
work on the previous example on the cardioid would
encounter a task concerning the cycloid, their approach
would be much more standardized.
8 Conclusion
If we look back at recent developments in mathematics
education in The Netherlands, some remarkable observations can be made. While serious attempts have been made
to implement a problem oriented curriculum, based on
principles of realistic mathematics education with room for
modelling and with integrated use of technology, we notice
that this has been successful in educational practice only to
a limited extent. The main difficulties encountered first
involve the national examination, which strongly drives
educational practice, but by its structure does not allow for
real problem solving activities. A second obstacle is
formed by the textbook series, which are not very open to

problem solving and do not address its learning.
An important challenge is the design of good problem
solving tasks that are original, non-routine and new to the
students. Experiences with the Mathematics A-lympiad and
the Mathematics B-day suggest that such tasks best can be
developed in a team of educational designers and teachers.
This is a non-trivial process.
Fig. 10 Shamrock-shaped curve
Problem solving as a challenge for mathematics education in The Netherlands 417
123To overcome the difficulties, some measures should be
taken—and to a certain extent are already in progress. First,
we recommend textbook series to pay explicit attention to
problem solving skills and heuristics. Second, schools
should take the opportunity that school assessment provides
for problem solving activities. National initiatives such as
Mathematics A-lympiad and the Mathematics B-day offer
inspiring opportunities to do so. Teacher networks for
designing problem solving tasks can be fruitful, as might be
an exchange through a virtual community. Third, we recommend that teachers and textbook authors exploit the
benefits of technological tools for the purpose of problem
solving. Through technology, new mathematical horizons
can be opened that lend themselves for exploration and
problem solving activities. Fourth and finally, we recommend problem solving to be on the 'agenda' ofmathematics
research in primary education, so that students start to develop problem-solving skills at an early age.

Document body:

Interviewer: My study is about using technology, simple technology like cell phones, Whatsapp, Facebook, the interactive whiteboards, to help teachers to make the Maths more realistic for the learners. I want to work with a group of teachers, and where they have problem areas such as for example they have a problem teaching trigonometry or whatever the case may be. What I'm going to do is I'm going to design stuff using the cell phone, the Whatsapp, Facebook, interactive whiteboards to give it to the teachers and say here is an idea, try this in your classroom, see if that works, maybe this is a better approach. So that is roughly what my study is about. So I just want to ask these questions, and like I say answer what you know, you are welcome to feel free and relaxed as you answer. What sections of the curriculum are most problematic for you to teach?
Participant 1: Uhm, it's financial Maths, probability and what is it .... Geometry.
Interviewer: Geometry, okay because that's also new to the syllabus, the geometry.
Participant 1: But I was teaching geometry before.
Interviewer: Okay.
Participant 1: So, I'm learning again.
Interviewer: Ja.
Participant 1: Step by step now to teach geometry.
Interviewer: Okay, and probability? You don't really have an experience of probability either? Because that was also never in the syllabus before?
Participant 1: Ja, I'm also learning to teach probability. We have been to workshops of probability.
Interviewer: Okay.
Participant 1: Ja, but it takes time for one to master the curriculum.
Interviewer: Of course ja, and practice.
Participant 1: Ja, practice.
Interviewer: Ja, often the first year that you teach something, you don't know that content as well as the second year.
Participant 1: Exactly, the thing is, I started learning probability when I was teaching grade 12. After Papi left, then I took over. So I wanted to do it from grade 10.
Interviewer: I see, ja.
Participant 1: So this is how now I'm learning, right from grade 12. Because if you're teaching it at grade 12, there are some of the concepts that you don't know at the grade 11 and grade 10 level.
Interviewer: True, so that continuation is important?
Participant 1: It's important, ja.
Interviewer: That you start with the basics and then ...
Participant 1: Go up.
Interviewer: That an important aspect, good.
Participant 1: So this is now that I am learning that basics, I have taught last year grade 10 and grade 11, now in grade 12 I will know what to teach.
Interviewer: Good, now you have been exposed to the 3 levels.
Participant 1: Ja.
Interviewer: How often are you able to relate the content you are teaching to real-life situations? Is it possible or is it not really possible?
Participant 1: Ja, to some topics it is possible.
Interviewer: Okay, do you have the time to do it? Or is it not really realistic to expect one to relate the work to real-life?
Participant 1: Some of the topics, they come clear to real-life situations.
Interviewer: Okay, but others it's difficult to relate?
Participant 1: It's difficult to relate.
Interviewer: Ja, which sections of work do you think will be easiest to link to real-life situations?
Participant 1: Calculus, and also probability.
Interviewer: Good, ja.
Participant 1: And also financial Maths, because we are working with money everyday.
Interviewer: Good, ja, interest and stuff like that.
Participant 1: You see, most of our learners they are not, how can I say it, they are not familiar with the situations.
Interviewer: Hmm.
Participant 1: Like for instance you cannot just ask somebody from the farms about Kentucky, you see?
Interviewer: True, because they don't know what it is.
Participant 1: So if you're talking about the money in the bank, they have never been to a bank.
Interviewer: Hmm.
Participant 1: And how it operates, they don't have, what you call ....
Interviewer: An account.
Participant 1: Ja, an account. So it is difficult to relate this to somebody who doesn't know about the situation.
Interviewer: True.
Participant 1: That's my real problem.
Interviewer: So, it might link to real-life but the learners don't always know about those contexts.
Participant 1: Ja, those contexts.
Interviewer: Good. In which sections of the curriculum do you need help to link the content to real-life situations?
Participant 1: Like I said, in calculus, what is it .... ? When it has in calculus ...
Interviewer: The graphing? The application of calculus?
Participant 1: The application of calculus.
Interviewer: Okay, for example when they say the ball bounces, or determine the maximum speed or the minimum, okay the maximum, minimum.
Participant 1: Ja.
Interviewer: Do you think it is important to relate your teaching to real-life situations? Or is it not so important?
Participant 1: Definitely, it is more important to relate it to more real-life situations.
Interviewer: Hmm.
Participant 1: Like, I said, some of the learners they don't know, when you're playing football or any other sports, Maths is applicable everywhere.
Interviewer: True.
Participant 1: You see?
Interviewer: Hmm.
Participant 1: So they cannot relate what they are doing with Mathematics.
Interviewer: Ja.
Participant 1: When they are sleeping, when they get up, Maths is applicable to them, every way, they don't know that, so they take it as something that is very special, they put it aside.
Interviewer: And they think it's difficult, meantime is something that is part of their lives, and I think if they can see that as part of the lives, it will become less of an abstract subject.
Participant 1: They take it as an abstract subject.
Interviewer: Hmm.
Participant 1: Even their parents, they are worse than these learners.
Interviewer: True.
Participant 1: When we have a problem with a learner who does not do work, they always tell the learner, oh Maths, I've long done Mathematics in grade four, I don't know nothing about Mathematics, you see?
Interviewer: And they tell that to the children?
Participant 1: Ja, so it's difficult to teach Maths, very difficult.
Interviewer: It is. How do you feel about using technology in your teaching? Think of any form of technology, like I said interactive whiteboards, cell phone, computer, data projector?
Participant 1: Ja, last time when we were using the overhead projectors, but now the state of our school we cannot, we have so many projectors here, but they are not functioning.
Interviewer: Really?
Participant 1: It was easy to use them, rather than making use of the chalk.
Interviewer: Is it because you could prepare in advance?
Participant 1: Ja, we could prepare in advance. And then presently we've got only one projector in the school, so it is difficult to use the laptop when teaching. And some of the classes do not have electricity. That's another problem.
Interviewer: So, your facilities and your resources are a problem?
Participant 1: Ja, it's a problem.
Interviewer: If .... imagine it was a perfect world, and you could use technology, what would you like to use?
Participant 1: I like to use technology.
Interviewer: Do you?
Participant 1: Ja, if I'm given a chance everything is okay.
Interviewer: Any form of technology?
Participant 1: Ja, any form of technology.
Interviewer: Good. How do you feel about using mobile technology such as Whatsapp and SMS to discuss with me and other colleagues, possible ways of making the mathematics content more realistic for you learners? If you for example could send me an SMS is to say "I'm really battling to teach them the section, help me, give me some ideas", or perhaps to a colleague to say "how far are you with that section?" How do feel about that?
Participant 1: It's a good thing, it's a good thing.
Interviewer: Okay, and you would be willing to use something like that if it were available to you?
Participant 1: Ja.
Interviewer: Okay, what about a Whatsapp group? Would you be willing to join a Whatsapp group was colleagues, and with me? So that you can discuss maybe the same thing? Somebody could put on the group I've just taught the section of financial Maths and I had this good idea, try it in your class. Or I'm battling with that. How can you help me? Have you taught this already? A group? Is that okay? Would you be willing to be involved in something like that?
Participant 1: Yes.
Interviewer: Okay good. What experience do you have with Facebook, if any?
Participant 1: No, I don't use Facebook.
Interviewer: You don't use Facebook?
Participant 1: In fact I don't have time, ha ha.
Interviewer: Time is a problem.
Participant 1: Ha ha .... time as a problem.
Interviewer: True.
Participant 1: Time is a problem, because now I'm having extra classes with the grade 11's on Wednesdays and also on Saturdays.
Interviewer: So you don't have time for social media.
Participant 1: I don't have time for social media, I'm having a phone.

Interviewer: If one were to create a work group on Facebook, also to help with the Maths, do you think you would be interested? Or not actually?
Participant 1: I will be interested.
Interviewer: Okay.
Participant 1: Ja.
Interviewer: Good.
Participant 1: At least it will be for a good cause.
Interviewer: That's it, ja. Okay, so that question about how do you feel about using Facebook to discuss issues of making Maths more realistic for your learners? Rather than really social media? Then it's more like work on Facebook, you would be interested in using that?
Participant 1: Ja.
Interviewer: Good. What experience do you have regarding interactive whiteboards? You've got lots.
Participant 1: No, in fact I do not control it. Because that room is for CAT, and then the gentleman who showed you where I am, he is the one who is in charge, Mr Olifant.
Interviewer: Now, you've now noticed the learners sitting in the class at the interactive whiteboard sessions. What did you pick up there? You mention some of it in the classroom just now.
Participant 1: I always go and sit there doing my work. At least I can see there are two or three learners who are listening very attentively and follow what is going on and they ask questions. Some of them don't even bother to ask questions.
Interviewer: And maybe do they get bored? Some of them?
Participant 1: Ja, they are bored.
Interviewer: Because there is not somebody standing in front, it's like watching TV almost? And the show just carries on?
Participant 1: Ja, it carries on but it is very clear and loud. Everybody can see what is going on, even how it is worked.
Interviewer: But even then some of the learners don't take part? They sit quietly at the back?
Participant 1: At the back.
Interviewer: Okay.
Participant 1: Maybe it's those learners who are not interested in the subject.
Interviewer: Could be.
Participant 1: Hmm.
Interviewer: How do you feel about using the interactive whiteboard to discuss with me and with other colleagues issues about Maths, how to make it more realistic for your learners? How to deal with problem areas? Would you be willing to have a discussion on an interactive whiteboard?
Participant 1: In fact, I'm very happy when you are broadcasting because I said to my learners if it is somebody who is presenting, and then I am listening, so Maths is international because if I'm teaching this and somebody is teaching that, maybe you don't understand what I'm saying, but if you hear it from the second person, it comes nicely right.
Interviewer: True, sometimes they don't believe the own teacher. They want to hear it from somebody else.
Participant 1: Maybe they are ashamed to ask questions, and here they hear it for the second time, so somebody is going to ask questions about that, or maybe get clarity about that.
Interviewer: True, okay, that's interesting. What type of technology would you be most comfortable with in a project such as this one? Where you get involved with me and other colleagues to talk about Maths, to solve problems, to deal with issues? What kind of technology would suit you the best?
Participant 1: Laptop.
Interviewer: Laptop, okay.
Participant 1: I've got a laptop, but as I'm saying we only have one projector.
Interviewer: Ja.
Participant 1: I just wanted to buy myself one.
Interviewer: And for communicating with others? Email in other words? Or?
Participant 1: Ja, I could ...
Interviewer: Do you have access to email?
Participant 1: My email is not working, but I will try to fix it.
Interviewer: Okay. I'm just thinking of what can work for you, what would suit you the best?
Participant 1: Okay.
Interviewer: So, email can work for you?
Participant 1: Normally I'm using the email of the school.
Interviewer: Okay, thank you Mr Sindwa. Thank you for the valuable information.
Participant 1: It's my pleasure.

WHY TO TEACH MATHEMATICS
SO AS TO BE USEFUL
My
first task at this moment is to welcome you who have come here from
various countries to sacrifice one week of your holidays
for the benefit of
mathematical education all over the world. I trust this meeting will be as
useful as according
to the general
theme of this conference mathematical
education should be held to be. I trust we all will learn as much from each
other's experiences and arguments as we like to do and often have done at
such opportunities. With great satisfaction I remember the meeting of
December 1964 at Utrecht and I hope
the few among you who have partici-
pated
in that conference will share my feelings of gratitude. But whenever I
shall remember those pleasant days and evenings, and
lively discussions, I
will never
forget
the man whom I met first and last on that occasion, the
liveliest among all of us,
the much regretted Wittenberg,
this
fiery nature who
died much too early as
though he had burnt himself in his own fire. Though
I admit there was none among us who shared his opinions,
I am sure
everybody was
impressed by his honest search into the truth of our education-
al philosophy. To my mind, his definitive absence overclouds the bright
sky of this day.
The present colloquium
is an activity of the ICMI sponsored by
the
government of the Netherlands and by IMU. It is not the first in this new
period of ICMI and in this year. In January we met in Lausanne with the
physicists,
in a meeting sponsored by UNESCO, which was attended by
some among you.
In my opinion
the resolutions adopted at Lausanne are a
mile-stone in the philosophy of mathematical education.* If I substitute my
wishes and hopes
for my opinion,
I would say they should be so. It is
evident that the use of mathematics has been a key criterion in all arguments
on mathematics at that meeting.
In this
introductory address I feel I have to
justify
the general
theme of the
present conference rather than to tell you about
techniques of
teaching
useful mathematics. This means that I will not
speak about how to teach
mathematics so as to be useful but about why we should teach mathematics
so as to be useful, or rather about why we should teach mathematics so as
to be more useful.
Of course this is a question of educational philosophy, and as such it will
*

be answered in a different way according
to which philosophy we adhere to.
Yet educational philosophy
is not an abstract system. It depends on the real
educational system in which we live, and on our, positive or negative, attitude
with respect
to that system. Is the variety of national educational philoso-
phies really a drawback to international talks on mathematical education or
should I say that there is no better opportunity
to test them than to have
them bump against each other? Are not we too often and too readily
in-
clined, when reading or hearing about the educational experiences
in
another country, under another educational system,
to sigh:
it is just a pity,
but this does not apply
to our situation? I would say whenever this happens,
then something
is wrong either in the one system or in the other, or, most
likely,
in both.
It is generally admitted that there is a wide gap between the educational
philosophy of the U.S.A. and the Socialist European countries on one hand
and the continental Western European countries on the other hand, though
this gap has been narrowing
to a considerable extent. On the one side one has
for
long
times pursued
the ideal of one kind of education for all youth, on the
other side one has always overstressed that part of the educational system
which provides educational facilities for a small group of students selected
more on social than on intellectual grounds. I have to admit, and I do it
with shame and distress, that in the Western countries of continental Europe,
if we speak about mathematical education, we more often than not, mean the
gymnasiums and
lycees, and
tacitly forget
the about more than 90% who do
not attend this
type of schools. I agree
that a more balanced educational
system can be as bad if its highest
level is too low to do
justice
to the most
gifted students. But instead of discussing
the question which kind of in-
justice
is the least evil, I would rather try to do the most justice
to all people
and to the society they belong to.
I need not explain
to you why mathematics can be useful
though
the fact
itself is one of the most recent and most astonishing features of the history of
civilization. It would be more difficult to tell how mathematics can be useful
provided that we do not limit ourselves to counting up
instances of the
all-pervading
influence of mathematics in our culture, but ask what happens
in the individual if he applies mathematics or if he tries to. Much has been
done to
investigate

the
learning process, though
it is a fact that most of this
research has been rather
laboratory
than classroom-oriented. Very little,
if anything,
is known about how the individual manages
to apply what he
has
learned, though such a knowledge would be the key
to understanding
why most people never succeed in putting
their theoretical knowledge
to practical use.
Since mathematics has proved indispensable
for the understanding and
4

All use subject to JSTOR Terms and ConditionsWHY TO TEACH MATHEMATICS SO AS TO BE USEFUL
the
technological control not only of the physical world but also of the social
structure, we can no
longer keep silent about
teaching mathematics so as to
be useful. In educational philosophies of the past, mathematics often
figures
as the paragon of a disinterested science. No doubt it still is, but we can no
longer afford to stress this point
if this keeps our attention off the widespread
use of mathematics and the fact that mathematics is needed not by a few
people, but virtually by everybody.
Mathematics is distinguished
from other
teaching subjects by the fact
that, even in its actual totality,
it is a comparatively small body of know-
ledge, of such a generality
that it applies
to a richer variety of situations than
any other
teaching subject. Modern mathematics can be seen as an effort to
reduce this body of knowledge even more and to enhance the
flexibility of
what remains to be
taught. At the same time this fact about mathematics is
the source of the principal dilemma in
teaching mathematics so as to be
useful. In an objective sense the most abstract mathematics is without doubt
the most flexible. In an objective sense, but not subjectively, since it is
wasted on individuals who are not able to avail themselves of this flexibility.
On the other hand, teaching applied mathematics is as bad,
if it means
mathematics in a specialized context, which does not account for the
greatest virtue of mathematics, its flexibility.
Though
it might
look different, I am still busy with the question why
mathematics has to be
taught so as to be useful, after we had agreed
that it is
useful and that students are expected
to use it. There are two extreme at-
titudes: to teach mathematics with no other relation to its use than the hope
that students will be able to apply
it whenever they need to. If anything,
this
hope has proved
idle. The huge majority of students are not able to apply
their mathematical classroom experiences, neither in the physics or chem-
istry school
laboratory nor in the most trivial situations of daily
life. The
opposite attitude would be to teach useful mathematics. It has not been tried
too often, and you understand that this is not what I mean when speaking
about mathematics being taught
to be useful. The disadvantage of useful
mathematics is that it may prove useful as
long as the context does not
change, and not a bit
longer, and this is
just
the contrary of what true
mathematics should be. Indeed it is the marvellous power of mathematics to
eliminate the context, and to put
the remainder into a mathematical form in
which it can be used time and again.
Between two extreme attitudes one may be inclined to
try compromising.
If this means
teaching pure mathematics and afterwards to show how to
apply it, I am afraid we are no better off. I think this is just the wrong order.
I have always considered it a remarkbale fact that people are able to apply
simple arithmetic, but not quadratic equations or even linear functions. Do
5

All use subject to JSTOR Terms and ConditionsHANS FREUDENTHAL
not object
that arithmetic is so easy. It is not. Take such problems as:
If I have got ten marbles and I give three away, how many are left?
If I have got
ten marbles, and John has three
less, how many does he have?
If there are ten students in the room and three are girls, how many are boys?
If I am ten years old now, how old was I three years ago?
If B is between A and C, B is at a distance of 7 miles from A, and C is at a
distance of 10 miles from A, how far is B from C?
It is not so easy
to learn that in all these and a hundred other situations the
same arithmetical operation applies. It takes some time, but
finally everybody
succeeds in understanding
it. Why? I daresay, because arithmetic starts in a
concrete context and patiently returns to concrete contexts as often as
needed. The counterexample
is fractions. In its traditional
teaching
the
concrete context is no more than a ceremony which is hurried through
in a
jiffy.
If afterwards the abstract theory of fractions has to be applied,
its
comes too late, on too high a level, and is not connected to any previous
experience on a level where fractions should have been introduced. What is
the reason for this change of attitude of the teacher? Is the patience of the
schoolmaster exhausted when fractions turn up? I believe the answer is
rather that the schoolmaster himself does not know fractions in a concrete
context, and that for this reason he is not able to teach them in a more
responsible way
than he is used to do.
I am afraid this answer applies
to the greater part of our mathematics
teaching. Even the fact that a teacher applies mathematics himself, does not
necessarily imply
that he knows how he is able to do so and to use such a
knowledge
in his
teaching.
The problem, however,
is still much more serious. In the past, and mostly
even now, textbook writing has been dominated by quite other aims than
by
the goal of a mathematics that could be useful. Mathematics is a peculiar
subject. Arithmetic and geometry have sprung
from mathematizing part of
reality. But soon, at least from the Greek antiquity onwards, mathematics
itself has become the object of mathematizing. Arranging and rearranging
the subject matter, turning definitions into theorems and theorems into
definitions, looking
for more general approaches
from which all can be
derived by specialization, unifying several theories into one - this has been
a most fruitful activity of the mathematician, and no doubt our students
are entitled to enjoy
these fruits. No doubt modern mathematics is both
much more flexible and much
simpler
than the mathematics of
fifty years
ago. No doubt our students have to learn the most modern mathematics.
Teachers are more and more prepared and more and more inclined to bridge
the gap between school mathematics and grown-up mathematics which had
become wider from year to year.
6
This content downloaded from 143.160.38.146 on Fri, 10 May 2013 09:22:58 AM
All use subject to JSTOR Terms and ConditionsWHY TO TEACH MATHEMATICS SO AS TO BE USEFUL
However, this is not the whole story. The problem
is not what kind of
mathematics, but how mathematics has to be
taught. In its first principles
mathematics means mathematizing reality, and for most of its users this is
the final aspect of mathematics, too. For a few ones this activity extends to
mathematizing mathematics itself. The result can be a paper, a treatise, a
textbook. A systematic textbook is a
thing of beauty, a
joy
for its author,
who knows the secret of its architecture and who has the right
to be proud
of it. Look how such an author would
justify his construction: Why have
you defined addition on page 10 in such a circumstantial way?
- because
this more general definition will prove useful on p. 110. Why have you
proved
this geometrical
theorem in such an unnatural manner? - because
at this stage I restrict myself
to affine notions which have to precede metric
notions. Why do not you mention forces as an instance of vectors? - because
mechanics has to be based upon vector algebra and not the other way
round.
Systematization
is a great virtue of mathematics, and if possible,
the stu-
dent has to learn this virtue, too. But then I mean the activity of systema-
tizing, not its result. Its result is a system, a beautiful closed system, closed,
with no entrance and no exit. In its highest perfection
it can even be handled
by a machine. But for what can be performed by machines, we need no
humans. What humans have to learn is not mathematics as a closed system,
but rather as an activity,
the process of mathematizing reality and if possible
even that of mathematizing mathematics.
New mathematics has been met with criticism. People who apply mathe-
matics often feel uneasy when observing
that the mathematics
they have
been used to apply
is replaced by something they judge
less suited for appli-

cations. It is a fact that biologists, economists, sociologists are better pre-
pared
to apply modern mathematics than physicists who carry the burden
of a
longer tradition. In the universities the gap between the mathematics
of mathematicians and that of physicists has become
terrifying. It is a habit
of physicists
to treat any particular subject with that kind of mathematics
which prevailed at the time when that subject
turned up
in the history of
physics. For
instance, though physicists know eigenvalues of symmetric
matrices because Laplace
introduced them in a physical context, they still
deal with orthogonal matrices with such oddities as Eulerian angles, because
Euler was not yet acquainted with eigenvalues.
It would be a disaster if this
lag would become permanent, though I hope
it will not. Time ago I eavesdropped on a talk between a physics professor
and his assistants, criticizing his course and particularly such a subject as
Lagrange multipliers: this is not physics, one of them said, this is plain
linear algebra.
7
This content downloaded from 143.160.38.146 on Fri, 10 May 2013 09:22:58 AM
All use subject to JSTOR Terms and ConditionsHANS FREUDENTHAL
Probably we will have to wait for the next generation
to have physicists
reconciled with modern mathematics teaching.
It is a pity
that most of the criticism against modern mathematics is made
with no knowledge about what modern mathematics really
is. It is a pity,
because there is ample reason for such criticism as
long as mathematicians
care so little about how people can use mathematics. We are not entitled
to reproach physicists
for
identifying modern mathematics with a preposter-
ous educational philosophy, since this identification is of our own making.
I am convinced that, if we do not succeed in
teaching mathematics so as to
be useful, users of mathematics will decide that mathematics is too
important
a
teaching matter to be taught by the mathematics teacher. Of course this
would be the end of all mathematical education.

1995, Vol. 26, No.2, 114-145
RECONSTRUCTING MATHEMATICS PEDAGOGY
FROM A CONSTRUCTIVIST PERSPECTIVE
MARTIN A. SIMON, Pennsylvania State University
Constructivist theory has been prominent in recent research on mathematics learning and has
provided a basis for recent mathematics education refom1 efforts. Although constructivism has
the potential to inform changes in mathematics teaching, it offers no particular vision of how
mathematics should be taught; models of teaching based on constructivism are needed. Data are
presented from a whole-class, constructivist teaching experiment in which problems of teaching practice required the teacher/researcher to explore the pedagogical implications of his.theoretical (constructivist) perspectives. The analysis of the data led to the development of a model
of teacher decision making with respect to mathematical rasks. Central to this model is the creative tension between the teacher's goals with regard to studeot learning and his responsibility
to be sensitive ttnd responsive to the mathematical thinking of the studeots.
Constructivist perspectives on learning have been central to much of recent empirical and theoretical work in mathematics education (Steffe & Gale, 1995; von
Glasersfeld, 1991) and as a result, have contributed to shaping mathematics reform
efforts (National Council of Teachers of Mathematics, 1989, 1991). Although constructivism has provided mathematics educators with useful ways to understand learning and learners, the task of reconstructing mathematics pedagogy on the basis of a
constructivist view of learning is a considerable challenge, one that the mathematics
education community bas only begun to tackle. Although constructivism provides a
useful framework for thinking about mathematics learning in classrooms and therefore can contribute in important ways to the effort to reform classroom mathematics
teaching, it does not tell us how to teach mathematics; that is, it does not stipulate a
particular model.
The word "pedagogy," as used above, is meant to signify all contributions to the
mathematical education of students in mathematics classrooms. As such, it includes
not only the multi-faceted work of the teacher but also the contributions to classroom
learning of curriculum designers, educational materials developers, and educational researchers. Mathematics pedagogy might be operationally defmed using the
following thought experiment. Picrure 2Sleamers in an otherwise empty classroom.
This material is based on work supported by the National Science Foundation under

Ernst Von Glasersfeld, Terry Wood, and Ema Yackel, as weld as the contributions to this work
of the CEM Project team of Glen Blume, Sonja Brobeck, Billie Mazza, Betsy McNeal, and
Jaroie Myers. Martin A. Simon 115
The ingredient necessary in order to initiate mathematics learning is pedagogy.
This paper describes data from a classroom teaching experiment in which the
researcher served as mathematics teacher, the analysis of that data, and an emerging theoretical framework for mathematics pedagogy that derives from the analysis. The paper contributes to a dialogue on what teaching might be like ifir were
built on a consTructivist view of knowledge development. The specific focus of trus
paper is on decision making with respect to the mathematics content and mathematical
tasks for classroom learning.
This article begins with an articulation of the constructivist perspective that undergirds the research and teaching and then provides a review of the pedagogical theory development based on constructivism that preceded this study and contributed
to its theoretical foundation. The study reported here examines the pedagogical decisions that result from the accommodation of the researcher's theoretical perspectives to the problems of teaching.
A CONSTRUCTIVIST PERSPECTIVE
The widespread interest in constructivism among mathematics education theorists,
researchers, and practitioners has led to a plethora of different meanings for "constructivism." Although terms such as "radical constructivism" and "social constructivism"
provide some orientation, there is a diversity of epistemological perspectives even
within these categories (cf. Steffe & Gale, 1995). Therefore, it seems important to
describe briefly the constructivist perspective on which our research is based.
Constructivism derives from a philosophical position that we as human beings
have no access to an objective reality, that is, a reality independent of our way of
knowing it. Rather, we construct our knowledge of our world from our perceptions
and experiences, which are themselves mediated through our previous knowledge.
Learning is the process by which human beings adapt to their experiential world.
From a constructivist perspective, we have no way of knowing whether a concept matches an objective reality. Our concern is whether it works (fits with our
experiential world). Von Glasersfeld (1987, 1995) refers to this as "viability," in
keeping with the biological model of learning as adaptation developed by Piaget
(1970). To clarify, a concept works or is viable to the extent that it does what we
need it to do: to make sense of our perceptions or data, to make an accurate prediction, to solve a problem, or to accomplish a personal goal. Confrey (1995) points
out that a coroUary to the radical constructivist epistemology is its "recursive fidelityconstructivism is subject to its own claims about the limits of knowledge. Thus,
[constructivism] is only true to the extent that it is shown useful in allowing us to
make sense of our experience:' When what we experience differs from the
expected or intended, disequilibrium results and our adaptive (learning) process
is triggered. Reflection on successful adaptive operations (reflective abstraction)
leads to new or modified concepts.
Perhaps the most divisive issue in recent epistemological debates (Steffe & Gale,
I 995) is whether knowledge development (particularly relational knowledge) is 116 Reconstructing Mathematics Pedagogy
seen as fundamentally a social process or a cognitive process. The difference in the
two positions seems to depend on the focus of the observer. The radical constructivist
position focuses on the individual's construction, thus taking a cognitive or psychological perspective. AJthougb social interaction is seen as an important context for learning, the focus is on the resulting reorganization of individual cognition.
For Piaget, just as for the contemporary radical constructivist, the "others" with whom
social interaction takes place, are part of the environment, no more but also no less than
any of the relatively "permanent" objects the child constructs within the range of its lived
experience. (von Glasersfeld, 1995)
On the other hand, epistemologists with a sociocultural orientation see higher mental processes as socially determined. "Sociocultural processes are given anal]rtical
priority when understanding individual mental functioning rather than the other way
around." (Wertsch & Toma, 1995) From a social perspective, knowledge resides
in the culture, which is a system that is greater than the sum of its parts.
Our position eschews either extreme and builds on the theoretical work of Cobb,
Yackel, and Wood (Cobb, 1989; Cobb, Yackel, & Wood, 1993; Wood, Cobb, & Yaqkel,
1995) and Bauersfeld (1995), whose theories are grounded in both radical constructivism (von Glasersfeld, 1991) and symbolic interactionism (Blumer, 1969). Cobb
(1989) points out that the coordination of the two perspectives is necessary to understand learning in the classroom. The issue is not whether the social or cognitive dimension is primary, but rather what can be learned from combining analyses from these
two perspectives. I draw an analogy with physicists' theories of light. Neither a particle theory nor a wave theory of light is sufficient to characterize the physicist's data.
However, it has been useful to physicists to consider light to be a particle and to consider light to be a wave. Coordinating the findings that derive from each perspective
has led to advancements in the field. Likewise, it seems useful to coordinate analyses on the basis of psychological (cognitive) and sociological perspectives to order
to understand knowledge development in classrooms.
Psychological analysis of mathematics classroom learning focuses on individuals' knowledge of and about mathematics'. their understanding of the mathematics
of the others, and their sense of the functioning of the mathematics class. Sociological
analysis focuses on taken-as-shared knowledge and classroom social nonns (Cobb,
Yackel, & Wood, 1989). Taken-as-shared" (Cobb, Yackel, & Wood, 1992;
Streeck. 1979) indicates that members of the classroom community, having no direct
access to each other's understanding, achieve a sense that some aspects of knowledge are shared but have no way of knowing whether the ideas are in fact shared.
"Social norms" refer to that which is understood by the community as constituting
effective pruticipation in the mathematics classroom community. The social norms
'Ball (1991) defines knowledge of mathematics as conceptual and procedural knowledge of the subject and knowledge abom mathematics as "understandings about the nature of mathematical knowledge
and activity: what is entailed in doing mathematics and how truth is establ.ished in the domain. What
counts as a solution in mathematics? How are solutions justified and conjectures disproved? Which ideas
are arbitrary or conventional and which are necessary or logical?" (p. 7) Martin A. Simon 117
include the expectations that community members have of the teacher and students,
the conceptions of what it means to do mathematics in that community, and the ways
that mathematical validity is established.
Tt is useful to see mathematics as both cognitive activity constrained by social and cultural processes, and as a social and cultural phenomenon that is constituted by a community of actively cognizing individuals (Wood, Cobb, & Yackel, 1995).
We refer to this coordination of psychological and sociological analyses as
"social constructivism."
SOCIAL CONSTRUCTIVISM AND MATHEMATICS PEDAGOGY
Understanding learning as a process of individual and social constructiOn gives
teachers a conceptual framework with which to understand the learning of their students. Although the development of such understandings is extremely valuable, this
paper focuses on the question of how constructivism might contribute to a reconstruction of mathematics pedagogy. How might it inform the development of a framework for fostering and supporting learners' constructions of powerful ideas?
Wood, Cobb, and Yackel (1995) assert that
teachers must ... construct a form of practice that fits with their students- way of learning mathematics. Th.is is the fundamental challenge that faces mathematics teacher educators. We have to reconstruct what it means to know and do mathematics in school and
thus what it means to teach mathematics.
As I stated above, constructivism, as an epistemological theory, does not deftne
a particular way of teaching. It describes knowledge development whether or not
there is a teacher present or teaching is going on. Konold (1995) argues, "not that
a teacher's epistemology has no effect on how he or she teaches, rather that its effects
are neither straightforward nor deterministic." There is no simple function that maps
teaching methoddogy onto constructivist principles. A constructivist epistemology
does not determine the appropriateness or inappropriateness of teaching strategies.
Bauersfeld (1995) states,
The fundamentally constructive nature of human cognition and the processual emergence of themes, regularities, and norms for mathematizing across social interaction,
to bring the [psychological] and the social together, make it impossible to end up with
a simple prescriptive summary for teaching. There is no way towards an operationalization of the social constructivist perspective without destroying the perspective.
The commonJy used misnomer, "constructivist teaching," however. suggests to
the contrary that constructivism offers one set notion of how to teach. The question of whether teaching is "constructivist" is not a useful one and diverts anention
from the more important question of how effective it is. From a theoretical perspective,
the question that needs attention is, In what ways can constructivism contribute to
the development of useful theoretical frameworks for mathematics pedagogy?
It is overly simplistic and not useful to connect constructivism to teaching with
the romantic notion, "Leave students alone and they will construct mathematical I 18 Reconstructing Mathematics Pedagogy
understandings." Likewise, "Put students in groups and let them communicate as they
solve problems," is not much more helpful. History provides unsolicited empirical
evidence with respect to these approaches. Generations of outstanding mathematicians
who were engaged in mathematical problems, who communicated with their colleagues
about their work, required thousands of years to develop mathematics that we expect
our average elementary school students to construct (Richards, 1991). Thus, although
it is useful to have students work problems and communicate about their ideas, it does
not seem to be adequate as a prescription for mathematics teaching. The challenge
is, How can ma.lhematics teachers foster students' construction ofpoweiful mathematical
ideas that took the conunnity of mathematicians thousands of years to develop?
Richards asserts,
It is necessary [for the mathematics teacher] to provide a structure and a set of plans-
that support the development of informed exploration and reflective inquiry without taking initiative or control away from the student. The teacher must design tasks and projects that stimulate students to ask questions, pose problems, and set goals. Students will
not become active learners by accident, but by design, through the use of the plans that
we structure to guide exploration and inquiry? (p. 38 [Italics in the original])
Through empirical data and model building, this study attempts to examine the
process of constituting pedagogical designs.

RECENT THEORETICAL WORK ON PEDAGOGICAL FRAMEWORKS
Relatively little work in mathematics education has focused on the development
of theoretical frameworks for mathematics pedagogy consistent with constructivism.
This seems to be the result of several factors:
1. It is only recently that empirically based models for studying mathematics learning in classrooms have been articulated (cf. Wood, Cobb, Yackel, & Dillon,
1993). Earlier empirical work, which derived from, and contributed to, epistemological theory, focused on the cognitive development of individual learners (cf. Steffe,
von Glasersfeld, Richards, & Cobb, 1983).
2. Traditional views of mathematics, learning, and teaching have been so widespread that researchers studying teachers' thinking, beliefs, and decision making
have had little access to teachers who had well-developed constructivist perspectives and who understood and were implementing current reform ideas. As a
result there has been a Jack of connection between research on learning (which has
focused on constructivism) and research on teaching (which has focused for the most
part on traditional instruction).
3. The need for pedagogical frameworks is sometimes obscured by the tendency
to assume that constructivism defines an approach to teaching.
2
1 interpret Richards" s statement, "Students wiLJ not become active learners ... " as indicative of his interest in fostering more independent and reflective mathematical investigations and discussions among students. From a constructivist perspective. students are always active learners; however, the nature of what
is constructed in different classroom contexts may vary greatly. Martin A. Simon 119
Despite these factors, some important work has been done in recent years with
respect to rethinking mathematics teaching on the basis of a constructivist perspective
(in some cases without specific reference to constructivism). This work has focused
on identifying the roles of mathematics teachers and describing the nature of
"pedagogical deliberations" (Ball, 1993).
The Professional Standards for School Mathematics (National Council of
Teachers of Mathematics, 1991) envisions teachers' responsibilities in four key areas:
• Sening goals and selecting or creating mathematical tasks to help students achieve
these goals:
• Stimulating and managing classroom discourse so that both the students and
the teacher are clearer about what is being learned;
• Creating a classroom envirorunent to support teaching and learning mathematics;
• Analyzing student learning, the mathematical tasks, and the environment in
order to make ongoing instructional decisions. (p. 5)
Cobb, Wood, and Yackel (1993) elaborate the teacher's responsibilities in the
mathematics classroom. The teacher has the dual role of fostering the development
of conceptual knowledge among her or his students and of facilitating the constitution
of shared knowledge in the classroom community. Cobb et al. (1993) have
demonstrated that classroom conversations about mathematics, facilitated by the
teacher, result in taken-as-shared mathematical knowledge. They have also
described a second type of conversation that focuses on what constitutes appropriate and effective mathematical activity in the classroom. Such discussion contributes to the constitution and modification of social norms for mathematical acti vity, the contrat didactiqueJ (Brousseau, 1981).
Much of the teacher's responsibilities involve planning. However, the planning
of instruction based on a constructivist view of learning faces an inherent tension.
Brousseau emphasizes that students must have freedom to make a response to a situation on the basis of their past knowledge of the context and their developing mathematical understandings. If the situation leads the students to a particular response,
no real learning of the mathematical ideas underlying that response takes place. However,
" if the teacher has no intention, no plan, no problem or well-developed situation,
the child will not do and wiLJ not learn anything" (Brousseau, 1987, p. 8-my translation). Under these conditions, students learn other things, such as how to respond
appropriately to the teacher's leading questions.
Brousseau (1983). Douady (1985), Lampert (1990). and Ball (1993) have conducted
investigations into the nature of pedagogical thinking and decision making that
contribute to teacher planning. Brousseau (1987) asserts that part of the role of the
teacher is to take the noncontextualized mathematical ideas that are to be taught and
embed them in a context for student investigation. Such a context should be personally
meaningful to the students, allowing them to solve problems in that context. the solution of which might be a specific instantiation of the idea to be learned. (Ball's [1993)
l-y'he contrat didactique is also established by classroom routines that are not explicitly discussed. 120 Reconstructing Mathematics Pedagogy
notion of"representational context" seems consistent with Brous eau's siruarion.) The
teacher"s job is to propose a teaming situation within which students seek a response
to the milieu, not a response that is solely intended to please the teacher. For the problem to foster the learning of powerful mathematical ideas, the students must accept
the problem as their problem•: they must accept the responsibiHty for truth (Balacheff,
1990). Brousseau calls this the devolution of the problem.
The creation of appropriate problem contexts (situations a-didactiques) is not sufficient for learning. Brousseau points out that situations must be created for the decontexrualizing and depersonalizing of the ideas (simations didactiques). Learning involves
being able to use the ideas beyond the narrow context of the original problem situation. The teaching process should allow for this shift of pupils' interest from being
practitioners to becoming theoreticians" (Balacheff, 1990, p. 264).
Also necessary is what the French researchers call "situations for institutionalization" (Brousseau, 1987; Douady, 1985), in which ideas constructed or modified
during problem solving attain the status of knowledge in the classroom community.
This is consistent with the notion of mathematical knowledge as social knowledge,
as knowledge that is taken-as-shared by the classroom community. •
Lampert's (1990) useof"problems" corresponds with Brousseau's situations and
Ball's representational contexts. Lampert describes the pedagogical thinking in which
she engages to generate problems for her students.
At LhE beginning of a unit, when we were switching to a new topic, Lhe problem we started
with was chosen for its potential to expose a wide mnge of students' thinking about a
bit of mathematics, to make explicit and public what they could do and how they understand. Later problems were chosen based on an assessment of the results of the first and
subsequent discussions of a topic. moving the agenda along into new but related
mathematical territory. The most important criterion in pick.ing a problem was that it
be the sort of problem that would have the capacity to engage all of the students in the
class in mak.ing and testing mathematical hypotheses. These hypotheses are imbedded
in the answers srudenrs give to the problem, and so comparing answers engaged the class
in a discussion of the relative mathematical merits of various hypotheses, sening the
stage for the k.ind of zig-zag between inductive observation and deductive generalization that Lakatos and Polya see a characteristic of mathematical activity. (p. 39)
Such pedagogical thinking must be built on knowledge of mathematic and knowledge of students and how they team mathematics. Ball (1993) points out that teachers must have a "bifocal perspective-perceiving the mathematics through the mind
of the learner while perceiving the mind of the learner through the mathematics" (p.159).
Steffe (1991) stresses that the teachers' plans must be informed by the "mathematics
of students." The most basic responsibility of constructivist teachers is to team the
mathematical knowledge of their students and how to harmonjze their teaching methods with the nature of that mathematical knowledge" (Steffe & Wiegel, 1992. p. 17).
Decisions as to the nature and sequence of the mathematics to be taught are made,
according to Laborde (1989). on the basi of hypotheses about epistemology
'Although each problem solver may construct a somewhat different understanding of the problem, negotiation commonly takes place in the classroom to arrive at a raken-as-shared interpretation of the problem. MartinA. Simon 121
and learning. Ball (1993) further explicates the investigative narure of teaching: "Teaching
is essentially an ongoing inquiry into content and learners and into ways that contexts
can be structured to facilitate the development of learners' understandings" (p. 166).
Ball states that research is needed to further understand the pedagogical deliberations in reform-oriented mathematics teaching. Building on the worl< of the researchers
cited above and starting from a social constructivist perspective on knowledge development, my paper continues the discussion of pedagogical deliberations that lead
to the determination of problem contexts for student involvement. In particular, the
paper extends the notion of teaching as inquiry, examines the role of different aspects
of teachers' knowledge, and explores the ongoing and inherent challenge to integrate the teacher's goals and direction for learning with the trajectory of students '
mathematical thinking and learning.
THEORY MEETS PRACTICE IN THE CONTEXT
OF A TEACHING EXPERIMENT
This section focuses on data from a classroom teaching experiment, in order to
analyze situations in which a constructivist theoretical perspective came up against
the realities of real students in a real classroom. The nonroutine problems of
teaching require an elaboration and modification of theories of learning and teaching. When the researcher/theorist assumes the role of teacher in a research project,
he is uniquely positioned to study in a direct way the interaction of his theory and
practice. Particularly, this report focuses on the teacher/researcher's ongoing decision making with respect to the mathematical content of the course and the tasks
and questions that provided a context for the study of that content. This section begins
with some brief background on the teaching experiment.
Background
The teaching experiment was part of the Construction of Elementary Mathematics
(CEM) Project, a 3-year study of the mathematical and pedagogical development
of prospective elementary teachers. The project studied the prospective teachers in
the context of an experimental teacher preparation program designed to increase their
mathematical knowledge and to foster their development of views of mathematics,
learning, and teaching that were consistent with the views espoused in recent
reform documents (e.g., National Council of Teachers of Mathematics, 1989:
1991). Data collection with 26 prospective elementary teachers (20 of whom finished the program) proceeded throughout a mathematics course, a course on
mathematics learning and teaching. a 5-week pre-student-teaching practicum,
and a 15-week student-teaching practicum.
The research on the mathematics course and the course on mathematics learning and
teaching employed a constructivist teaching-experiment methodology, as described
by Cobb and Steffe (1983) for research with individual subjects. We adapted that methodology to research on classroom mathematics (in the manner of Cobb et al., 1993).
The author taught all classes. Classes were videotaped and field notes were taken 122 Reconsrmcting Mathematics Pedagogy
by project researchers. Videotapes of classes were transcribed for analysis. The
author kept a rctlective notebook in which he recorded his thinking immediately following teaching and planning sessions. Following each class the author met with a
second project researcher to discuss what he and his colleague inferred the conceptualizations of the students to be at that point and to plan for the next instructional
intervention. (In this section, "studems" refers to the prospective elementary teachers participating in the teaching experiment.) These meetings were audiotaped.
The teaching-experiment methodology involves "hypothesizing what the []earner]
might learn and finding ways of fostering this learning" (Steffe, 1991 , p. 177). This
research report represents an extension of the teaching-experiment methodology. Whereas
the teaching experiment was created to learn about students' developing conceptions
(our primary emphasis), analysis of the decision making of the teacher/researcher
in posing problems is potentially a rich source for learning about teaching (Cobb.
personal communication). This paper is based on such an analysis.
Class lessons generally consisted of small-group problem solving and teacherled whole-class discussions. No lectures were given. The primary mathematical goal
of the course was for students to learn to identify multiplicative relationships
(Simon & Blume, 1994a, 1994b). Previous research on a variety of populations (Hart,
198 1: Inhelder & Piaget, I 958; Karp lus, Karplus, Formisano, & Paulson, 1979) and
our pretest data with this population of students had shown that identifying ratio relationships tends to be difficult and that additive comparisons are often used where
multiplicative comparisons (ratios) are more appropriate. The mathematical content of the course began with exploration of the multiplicative relationship involved
in evaluating the area of rectangles.
Data and Analysis
The data presented focuses on three teaching situations, examining the relationship
among the teacher's decision making and the classroom activities. These data are
from the first 5 weeks of the 15-week mathematics course, the duration of the first
instructional unit. and are taken from class transcripts. the teacher/researcher's notes,
field notes from other researchers, and student journals. The ftrst unit (eight 90-minute
classes) focused on understanding the multiplicative relationship involved in evaluating the area of a rectangle. The three instructional situations described represent
the three subtopics of the instructional unit. For each situation, a description is
provided of the challenge that faced the teacher as construed by the teacher, the
decision that he made to respond to that challenge, and the subsequent classroom
interaction that was constituted by the students and teacher.
Note that fundamental to the teacher's understanding of the challenge was his contructivist perspective, whkh included the idea that students construct their understandings, they do not absorb the understandings of their teachers. Each of the three situations represents an attempt to promote and support powerful
constructions. Whereas
telling students what they should understand (a lecture approach) is relatively straightforward, developing situarioiiS a-didactiques or representational contexts is complex
and uncertain. In this latter approach, mathematics teaching is continually problematic. Martin A. Simon 123
The rectangles problem. As the instructor, r chose to begin the exploration of multiplicative relationships in the evaluation of area of rectangles. My purpo e was to
focus on the multiplicative relationships involved, not to teach about area. The
lesson I chose was one that I had used several times before with similar groups
of students. The lesson grew out of my observation that although many prospec-
tive elementary teachers respond to area-of-rectangle problems by multiplying,
their choice of multiplication is often the result of having learned a procedure or
formula rather than the result of a solid conceptual link between their understandings of multiplication and their understandings of measuring area. This lesson, which
was designed to foster the development of that I ink, was planned to be completed
in one day, although I anticipated that it might continue into the next class.
The lesson began with a smaU cardboard rectangle being given to each of the smaU
groups of students seated at the classroom's six rectangular tables. The groups were
challenged to solve the following problem.
Rectangles problem 1. Determine how many rectangles, of the size and shape
of the rectangle that you were given. could fit on the top surface of your table.
Rectangles cannot be overlapped, cannot be cut, nor can they overlap the edges
of the table. Be prepared to describe to the class how you solved this problem.
Each group of students used the given rectangle as a measure to count the number of rectangles along the length of the table and the number of rectangles along
the width of the table and then multiplied these two quantities. (For an extensive
analysis of the quantitative reasoning involved in this instructional unit, see Simon
& Blume, 1994b.
5
) However, a few of the groups raised the question of whether the
orientation of the rectangle should be maintained for the second measurement (see
Figure 1 a), or whether it should be rotated 90 degrees so that measuring is always
done using the same side of the rectangle (see Figure lb).
I

Figure la. Maintaining orientation of
the rectangle.
:
..... j

` . .
-- ----------, ---..... -..... ---.. ---
Figure lb. Rotating the rectangle to measure
the adjacent side.
During whole-class discussion, students described how they had solved the
problem. Then, to focus discussion on the multiplicative relationships. I asked them
5
Much of the data for this report was reported earlier in Simon and Blume (1994b). The earlier article focuses on the students' quantitative reasoning. This article revisits some of the data to unpack the
pedagogical issues. 124 Reconstr11cting Mathematics Pedagogy
why they had multiplied these numbers. Some responded by saying that "it seemed
like the easiest way," or "in previous math classes you learned the formula for areas"
(Simon & Blume, 1994b). Others said it works; the product is the same as the result
of counting up all the rectangles. I asked whether there was reason to expect that
it would always work. From my perspective, it is fundamental in mathematics to
consider whether a claim could be defended that the observed phenomenon would
always occur under a particular set of conditions. Most of the students seemed perplexed by this question. However, Molly explained:
Molly: Well, it would work because, um, multiplying and adding are related, in that multiplying is, is like adding groups, and so it would always work because you add them
up to see how many is in the square and to multiply the groups that go like that, that' LJ
always work. You would get the same number, I'm saying if you added them (Jr if
you multiplied that side times that side. Because you're adding, I mean, you-re multiplying the number of groups by the number in the groups, which is the same as adding
them all -P·
Molly clarified her explanation by demonstrating on the chalkboard how each row
of rectangles was a group (see Figure 2) and the number of rectangles in a row was
the number in each group. She showed that summing the rectangles in each row (rePeated
addition) was equivalent to multiplying the number in a row by the number of rows
(Simon & Blume, 1994b).
Figure 2. One group of four rectangles.
The other students' subsequent comments suggested that only a few of them perceived that Molly's explanation had advanced the discussion in any significant way.

Situation I. What instructional situation might afford other students the opportunity
to construct understandings similar to Molly's? It wasn't that the other students were
puzzled by Molly's explanation; they seemed unaffected by it. They continued to
respond to the question, "Why multiply?" in ways that indicated that the question
did not demand for them this type of justification. Responses included " ... 'cause that's
the way we 've been taught." and· · ... it's a mathematical law." Asking the students
for explanations and justifications was not sufficient. Our classroom community had
not established what counts for mathematical justification (Simon & Blume, in press).
It did not seem that convinuing this already lenghty discussion would be fruitful. Manin A. Simon 125
I had engaged them in a problem-solving activity using a hands-on activity and
fostered communication in small and large groups. Yet only a few of my students
showed evidence of learning the mathematics that I had intended them to learn. The
challenge that I faced was a product of both cognitive and social factors. Cognitively,
the majority of my students were employing a procedure that was well-practiced
but not well-examined conceptually. Socially, they did not have a view of mathematical activity in general and of appropriate activity for our classroom in panicular
that included the type of relational thinking and development of justification in which
I was attempting to engage them.
I realized that the development of norms for classroom mathematics activity would
take some time. Such norms would result from the activities in which we engaged
as a mathematical community and the discussions that we had about that activity.
Their competence in providing justification would grow as they engaged in discussions
in which the demand for justification was consistently present (Simon & Blume,
in press). Thus, from a social perspective, I needed to continue the process that I
had begun with them. However, this process could not happen in the abstract. Particular
content and tasks were needed as the context for the constituting of appropriate mathematical activity. Thus, I returned to my role of problem poser, but the question was,
"Which problems?" The traditional approach-assigning practice problems similar to the original one-seemed inappropriate. After all, the students were already
able to generate correct answers; the real problem was understanding why multiplication was appropriate. I needed to find problems that necessitated an understanding of the link between the solution strategy, counting the number of rectangles
along the length and the width and multiplying those quantities, and the goal of
determining the total number of rectangles that could be laid out on the table.
To generate such problems, I made use of conceptual difficulties that I had previously observed among students working on Rectangles Problem 1. For example:
Rectangles problem 2. Bill said, "If the table is 13 rectangles long and 9 rectangles wide, and ifi count 1, 2, 3 . . . , 13 and then again 1, 2, 3 ... , 9, and then
I multiply, 13 x 9, then I have counted the comer rectangle twice." Respond
to Bill's comment.
Problem 2 seemed to engage students in making a conceptual link between the
goal of counting all of the rectangles and the prevalent solution strategy of
counting rectangles along the two sides and multiplying. The following excerpts
from the class transcript show the development of these connections. (Note:
"Simon" refers to me, the teacher.)
Karen: When we're multiplying thirteen times nine we're trying to see ... how many nines
there are .... So if I'm looking at one nine, two nines, three nines, four nine· , I could
fmd out how much it would be with those numbers, but if I'm looking for thirteen
nines,} would want to see how many of tho e I would have if I would add them up
or if I would multiply them thirteen times. How many· how much would that be if
I had thirteen nines or nine thirteens? I'm looking for the amount-total amount that
that would be if I was multiplying how many groups of those or how many sets of
those would I have, if I would add each one of them up to get the total amount. 126 Reconstructing Mathematics Pedagogy
Karen has made some progress in justifying the use of multiplication. However,
Toni goes back ro how one use the formula appropriately. Her explanation is based
on her identification of the problem as an area problem and her knowledge of how
to measure length times width. Once again r attempt to refocus Toni (and,! suspect,
oLher students) on the underlying conceptual issue.
Toni: When we're trying to fmd how many rect.angles would fill that rectangle, we're looking for the area And when we find area we multiply length times width, and the columns
would probably represent the length and the rows would represent the width ....
Simon: Why does that work, that when we multiply the number of columns times the number of rows we get the area?
Molly: Well, r thought again it referred back to when you're using a row to represtlnt the
uniu. in a group. and the columns to represent the number of groups, and since multiplication is the same as repeated addition, that when you multiplied the number
of units in a group by the number of groups, you would get the total number of partS
in the whole.
Simon: And how is that connected to this issue about the comer?
Molly: Because it ... the comer not only represents a one, it's just one numbering of a grpup,
or it's also numbering a part of that unit-a unit io that group--so it's not, it's two
different things, just like when they were saying it's a row and a column, well, it's
two different things. It's a unit and also representing a group.
Candy: ... It makes it confusing to try to look at the length times the width .... You should
really treat it as so many sets or so many groups, like nine groups ... , thirteen groups
of nine. That way, you're not even going to deal with the comer and you won't even
have that problem.
Karen: Have we responded to Bill's problem about him thinking that he has doublecounted?
At this point, Karen brings us back to the original problem. For her, it is not enough
to decide whether one would be double-counting the comer rectangle; it is also important to understand BiLJ's thinking. which led to his confusion.
Karen: It appears to me that Bill's thinking about ... counting by ones .... one represents two
different things, but in his mind, at least from what he said, it appears that he only
sees one as representing one thing, and that is a counting number. He thinks he- s already
counted it.
Candy's and Karen's comments seem to demonstrate an understanding of how
the counting (vertically and horizontally) and the multiplication are related. I
push for further verbalization of the ideas involved to ascertain whether others in
the class have constructed similar meanings. Many now insist that we are really
counting rows and columns. I suspect that some of the students have latched onto
the notion of rows and columns in an unexamined way. The shi.ft from counting
boxes to counting rows and columns does not in itself lead to a connection
between counting the total number and the multiplicative approach. I refocus my
questions on this connection.
Simon:
Class:
Simon:
So I'm not counting boxes at all?
No.
OK. Isn't it a little mysterious that we're never counting boxes here and we wind
up with a number of boxes? Does that bother anybody? We didn't count boxes here. Martin A. Simon
127
we didn't count boxes there, and we wind up with boxes at the end. Tammy?
Tammy: If each box represents a portion of the row so we're really counting boxes but we're
just putting them in a set, instead of individuaUy.
Simon: OK, so which way are you thinking about the sets going? [Points at diagram on
the board] This way or that way? Choose one.
Tammy: VerticaUy?
Simon: So this is a set? OK. So you are saying this is nine what?
Tammy: Nine separate units inside of a set.
Simon: ... OK. So here 1 counted nine boxes in a set and then here I'm counting what?
Tammy: Thirteen.
Simon: Thirteen what?
Tammy: Boxes in a set.
[Ellen is shaldng her head]
Simon: Ellen, you don't like that.
Ellen: If you're going to do it that way, I think you have to say that you're going to take
the column as a set, nine boxes in one set ... then the thirteen in the row is the number of sets that you have. so it's not actually boxes, it's the number of that same
type of set that you have.
Ellen's final comment evoked many nods of agreement from her classmates. I considered, however, that for a student to follow an explanation might not require the same
level of understanding as would be needed to generate an explanation. Still, it
seemed clear to me from students' verbalizations that the number of students who were
seeing a connection between multiplication and counting the total number of rectangles
had increased. Perhaps Problem 2 shifted the discussion from my problem-justifying
the method that the students believed to be valid-to a community problem-how to
account for the "double- counting." Problem 2 seemed to provide a puzzlement, at least
initially for most of the students. We cannot assume, however, that aJl of the students
related to Problem 1 as my problem, nor that all of them owned Problem 2.
Situation 2. As we proceeded to explore the multiplicative relationship involved
in evaluiating the area of a rectangle, I came to believe that the context in which we
were working (area) was not well understood by many of the students. They
seemed to think about area as generated by multiplying length times width.
Although my primary focus was on multiplicative relationships, not on area, it seemed
clear that an understanding of area was necessary in order for students to think about
constituting the quantity (area) and evaluating that quantity. (See Simon & Blume,
1994b; and Thompson, 1994, for explications of the distinction between constitution and evaluation of quantities.) What action could I take as a teacher?
It seemed that, if indeed these students were unclear about what is meant by area,
the traditional response of "reviewing" the idea would be inadequate. Surely by this
time, their junior year of college, they had been present at many such reviews and
had some ideas that could be built on. I chose instead to pose a problem that would
push them to extend their understanding of area. I posed the following: 128 Reconstructing Mathematics Pedagogy
The blob problem: How can you find the area of this figure?
Students generated ideas in small groups. When we reconvened as a whole class,
they shared many ideas. Two methods stimulated a great deal of discussion. The
first was a suggestion that a string be put along the outline of the blob and then,
without changing the length of the string, reshape it into a rectangle, a figure whose
area we know how to determine. This method was based on an assumption,
eventually rejected by the class, that figures that have the same perimeter also have
the same area. The second method was to cut out cookie dough of a constant thickness so that it exactly covered the blob. Then, cut the cookie dough into squares
of a given size. Roll up the remaining dough and roll it out to the original thickness, again cutting out squares, repeating this procedure until there is not enough
dough remaining to make an additional square. This method was accepted by the
class as theoretically sound; however, they predicted that in practice it would be
difficult to carry out accurately.
The problem generated more than discussion on the validity of these methods.
I perceived that the contrast in the methods proposed by the students would enable
us to consider the issue of conservation of area, that is, under what changes in shape
the original amount of area is preserved. This was a challenging context for the students to think about the meaning of area. Considerable dialogue ensued in which
students seemed to be using the notion of area appropriately, comparing area
among different geometric shapes, and distinguishing it from the notion of perimeter that was brought up by the string strategy.
Situation 3. Following a discussion of why multiplication was used to determine
the total number of rectangles and after our work with the blob problem, I raised
again the issue that they had brought up in solving the original problem, whether
to tum the rectangle (Figure I b) or to maintain its orientation (Figure J a). I demontrated the former, rotating it 90 degrees to measure the second side (as in Figure
I b). (The quantitative reasoning brought to bear on this problem is analyzed in depth
in Simon & Blume, 1994b.)
Most of the students recognized that the method I demonstrated would not
determine the number of rectangles that could fit on the table. I then asked them whether
that method tells us anything about this particular table. (This question is referred Martin A. Simon 129
to as the Turned Rectangle [TR] Problem.) Consensus developed in the class that
the number generated was meaningless because the method generated a set of
"overlapping rectangles."
I was surprised by their response and concerned about what it indicated about their
understanding of the multiplicative (area) unjt. I had posed this extension to
encourage an understanding of the multiplicative relationship between linear measures of the rectangle and area measures. The measurement strategy in question and
subsequent computation was identical to what they previously had learned to do with
a ruler (procedurally). In prior courses, when I posed this question, several students
understood that the quantity resulting from multiplying the two linear measures represented the number of square units of area on the table. The square unit had sides
equal to the length of the rectangle used for measuring. (See Figure 3.) Generally,
the discussion that ensued led to a consensus with respect to tills point.
-·1·- · - ·-|· · ·+·· ·+· ·-·· ·-·-·-

to measure with. The sticks, however, are of different lengths. Louisa says, The
length is four of my sticks." Ruiz says, "The width is five of my sticks.-- What
have they found out about the area of the rectangular region?
Students worked the stick problem in groups of three. Some of the students were
able to see how the use of different size sticks could be thought of as determining
an array of nonsquare rectangles. Toni began the class discussion as time was running out. Ellen picked up the discussion in the following class.
Toni: It would pretty much be the same thing as a rectangle because ... the width of the
rectangle is smaller than the length of the rectangle. so it doesn't really matter,! mean.
the area ... would be 20 [of these small rectangles].
Elle11: I didn-t really understand until Tonj drew that diagram on the board, that I found Martin A. Simon 131
something out about area, and when she put that on the board, I realized that r had
started thinking that you were starting with the unit, and you had to start with the
unit to figure out the area. But ... in my mind she sort of went backwards, she ended
up with a unit of measurement by, urn, making the rectangle .
. . . Because the unit you're using is a rectangle that bas a length the size of the one
stick and the width the size of the other stick, so you're sort of going backwards and
ending up with a unit that means something .... (Simon & Blume, 1994b, p. 489).
Through the discussion of this problem and an extension question that asked them
to express the area ofRuiz and Louisa's rectangular area in terms of other units, I
was persuaded that most of the students understood the relationship between the
linear measures and the area measures in this context. The next step was to see if
they could use this understanding to revisit the problem involving turning the rectangle. Would the understandings that they had developed in the stick problem allow
them to question their assumption of the cardboard rectangle as the appropriate unit
of measure? The revised TR problem was an attempt to make the problem more concrete by having them actually measure out particular rectangular regions using the
method in question.
Revised TR problem. I used your [cardboard] rectangle and my method (rotating the rectangle) to measure two rectangular regions; one was 3 x 4 and the
other was 5 x 2. Draw these regions (real size). Record aU that you can determine about their areas.
Half of the small groups determined that squares were useful units for describing the areas of the rectangular regions and could explain their thinking.
Eve: First, when we started drawing it, we drew like all the rectangles, OK? So it
showed the overlapping up in the comer, but then we thought just take away the overlapping ... , and just think of it as a side, like this is a side and this is a side, like the
sticks that Louisa and Ruiz used, just to get this little edge right here as a stick and
this little edge right here as a stick, OK? ... So what it actually makes is squares, because
they're the same length ... you wouldn't talk about your rectangles, 'cause it has no
relevance. (Simon & Blume, 1994b, p. 490--491)
Some of the students who had not previously seen the usefulness of square units
in the revised TR problem did so in the course of the class discussion. However, anumber of students, who saw that measuring in squares worked for the problem, were unclear
how one would know "when to use rectangles and when to use squares."
DISCUSSION
The discussion of the teaching situations is divided into two parts. The first part
examines the teacher's role that emerges in terms of the decision making about content and task. This discussion, which focuses on the composite picture of teaching
seen across the three situations presented, leads to the articulation of a model of teacher
decision making called the Mathematics Teaching Cycle. The second part of the
discussion highlights particular aspects of each of the situations (considered separately), in an attempt to further elaborate the role of the teacher. 132 Reconstructing Mathematics Pedagogy
As teacher/researcher. I began the mathematics course with particular theoretical perspectives on teaching and learning, some of which were articulated earlier
in this paper. However. not surprisingly, these perspectives did not "tell" me what
to do as challenges arose. My responses to these challenges often were not the result
of well-articulated models. Rather, they were emerging patterns of operation in problem situations. It is only through a posteriori analysis that these patterns have been
characterized and used to enhance, modify, or develop theory. Thus, the reader should
keep in mind that the theoretical aspects of this section grew out of the data analysis and were not necessarily part of my explicit thinking as I was planning and teaching. Also. these patterns of operation were established over repeated encounters with
similar problem situations. 1 had taught essentially this way for many years. This
particular teaching experience led to further elaboration of my teaching; the teach--
ing-experiment design led to a new level of analysis of the teaching.
'In this section, I use the first person singular to refer to my actions and thinking
as the teacher. I use the third person, often referring to "the teacher" to designate
ideas that I am lifting from the particular .context in which I was the teacher. Because
I was the teacher in these epi odes, T use male pronouns in this section when referring to the teacher generically.
Unpacking the Teaching Episodes: Developing Theory
This section analyzes the teacher's role as decision maker as it emerges across
the three teaching situations.
The rectangles lesson was shaped by my understanding of the multiplicative relationship between the area of a rectangle and its linear measures. (The focus on my
personal knowledge does not discount that this knowledge can be viewed as
socially constituted and taken-as-shared in the mathematics education community.
Rather, it is expedient here to focus on my particular interpretation of these
socially accepted ideas.) My previous experience with prospective elementary teachers led me to hypothesize that my students would not share this knowledge.
Rather, I expected that their knowledge would be rule bound and that the concepts
underlying the fommla for the area of a rectangle would be unexplored. The disparity between my understanding, which I judged to be useful, and my sense of their
understanding defined my learning goal for the first segment.
Note that hypotheses of students' understandings may be based on information from
a variety of sources: experience with the students in the conceptual area, experience
with them in a related area. pretesting, experience with a similar group. and research
data. Initial hypotheses often lack data that are available as work with the students proceeds. Thus, the hypotheses are expected to improve (i.e., become more useful).
Having established my initial goal, that students would understand the relationship of multiplying length by width to the evaluation of the area of a rectangle, I
considered possible learning activities and the rypes of thinking and learning that
they might provoke. Following is a partial reconstruction of my thought process.
I suspect that for many of my students A = l x 111 is a formula that has no conceptual
roots. Concrete experience with area might be helpful, I need to keep in mind that they Martin A. Simon 133
come to the task already knowing the rote formula. A learning situation that does not
look like their previous experiences with area might preempt their resorting immediately to rote procedures.
Tiling a rectangular region would provide the concrete experience. If 1 can envision a
situation in which they form multiple units, sets of tiles, they may see the appropriateness
of multiplication, in essence "deriving" the formula. I will not mention area but just ask
them to find out bow many tiles. However, if they are to make connections with l x w,
they must do more than count each tile.
Ifl give them only one small tile, they will need to look for an efficient way of determining the number of tiles- which will encourage them to go beyond counting all of
the tiles. If I use rectangular tiles, they will not be able to measure mindlessly; they will
need to consider how their measuring relates to the placement of the tiles on the table.
Measuring with a nonsquare rectangle to determine the area encourages a level of visualization that is not required when one uses a ruler to determine square units, that is,
they will have to take into account what they are counting, the unit of measure, which
is based on how they are laying the tiles on the table.
The preceding thought process provides an example of the reflexive relationship
between the teacher's design of activities and consideration of the thinking that students might engage in as they participate in those activities. The consideration of
the learning goal, the learning activities, and the thinking and learning in which students might engage make up the hypothetical learning trajectory, a key part of the
Mathematical Learning Cycle described in the next section.
Besides the teacher's knowledge of mathematics and his hypotheses about the
students' understandings, several areas of teacher knowledge come into play,
including the teacher's theories about mathematics teaching and learning; knowledge of learning with respect to the particular mathematical content (deriving
from the research literature and/or the teacher's own experience with learners); and
knowledge of mathematical representations, materials, and activities. The
Mathematical Learning Cycle portrays the relationship of these areas of knowledge
to the design of instruction.
The only thing that 1s predictable in teaching is that classroom activities will not
go as predicted. Although the teacher creates an initial goal and plan for instruction,
it generally must be modified many times (perhaps continually) during the study of
a particular conceptual area. As students begin to engage in the planned activities,
the teacher communicates with and observes the students, which leads the teacher
to new understandings of the students' conceptions. The learning environment
evolves as a result of interaction among the teacher and students as they engage in
the mathematical content Steffe (1990) points out, "A particular modification of a mathematical concept cannot be caused by a teacher any more than nutriments can cause plants
to grow" (p. 392). A teacher may pose a task. However. it is what the students make
of that task and their experience with it that detennines the potential for learning.
Student responses to the rectangle problems led me to believe that students did
not adequately understand what is meant by area. As a result, I generated a new learning goal, understanding area. This goal temporarily superseded but did not replace
the original learning goal. Toward this end I posed the blob problem, anticipating
that the students would brainstorm some ways to frnd area, discuss those ways, and 134 Reconstructing Mathematics Pedagogy
in so doing strengthen their understanding of area. However, the specifics of what
happened resulted in additional, unanticipated learning. First, students proposed the
sLring strategy. On the basis of the understanding that I had developed of the students' conceptual ctiffculties in considering the string strategy, and on the basis of
the interesting contrast that I saw between the string strategy and the dough strategy (as a result of my own mathematical understandings), I revised my goal for instruction once again. I now saw as the (local) goal facilitating students' understanding
of conservation of area (not limited to Piaget' s assessment of the concept with children). I intended for my students to deal with the question, "Under what types of
change in shape does the area of a region remain invariant?"
My interest in their constructing answers to this question was based on three .factors: (a) I believed that it would further their understanding of area, my motivation
for posing the blob problem; (b) I saw an opportunity for learning based on the juxtaposition of the two strategies-an opportunity that I had neither planned for nor
anticipated; and (c) I believed that the concept of invariance, which Thad thought
about previously in relation to arithmet-c concepts but not area, was an important
one. The third factor also points out how my own understanding of the mathematical
connections involved is enhanced as I attend to the mathematical thinking of my
students. This evolution of the teacher's mathematical knowledge is also revealed
in the analysis of the third episode, the data involving measuring with only the long
side of the rectangle (TR problem).
My original goal that motivated the rectangles lesson was for my students to understand the evaluation of the area of a rectangle as a multiplicative relationship between
the linear measures of the sides. For me, as 1 began instruction. such an understanding
involved connecting an understanding of multiplication-as-repeated-addition with
the notion of identical rows of units of area and understanding the relationship between
linear units and area units. The latter concept was represented by the issue of turning the rectangle to measure- ! had not unpacked this understanding further.
The classroom discussion, however, pushed me to reexamine these understandings and to further elaborate my map of the conceptual terrain. (The use of the term
"map" in this context is meant to emphasize that the teacher's understandings serve
as a map as he engages in making sense of students' understandings and identifies
potential learnings.) The students' roisanticipation of the area unit (assumption that
the area would necessarily be measured in terms of cardboard rectangles) led me
to explore the importance of anticipating an appropriate unit. Anticipating the area
unit seemed to involve both an anticipation of the organization of the units, a rectangular array, and an understanding that the linear units define the size and shape
of the units within that array. (For a fuller discussion, see Simon & Blume, 1994b.)
The multiplicative relationship, therefore, involved the coordination of the linear units
to determine an area unit within an anticipated rectangular array. What I had
observed in my students had changed both my perspective on my students' knowledge and my perspective on the mathematical concepts involved (my internal
map). This reorganization of my perspectives led to a modification of my goals, my
plans for learning activities, and the students' learning and thinking that I anticipated. Martin A. Simon 135
The Mathematics Teaching Cycle
The analysis of these teaching episodes has led to the development of the
Mathematics Teaching Cycle (Figure 4) as a schematic model of the cyclical
interrelationship of aspects of teacher knowledge, thinking, decision making, and
activity that seems to be demonstrated by the data.
The three episodes create a picture of a teacher whose teaching is directed by his
conceptual goals for his students, goals that are constantly being modified. The original lesson involving the rectangles on the table was not a random choice, nor was
it Chapter 1 in someone' s textbook. The goal for and design of the lesson were based
on relating two factors: the teacher's mathematical understanding and the teacher's
hypotheses about the students' knowledge. I refer to "hypotheses" about students
knowledge to emphasize that the teacher has no direct access to students' knowl-
edge. He must infer the nature of the students' understandings from his interpretations of his students' behaviors, based on his own schemata with respect to
mathematics, learning. students, and so on. It is implied that the teacher can compare his understanding of a particular concept to his construction of the students'
understandings, not to the students' "actual" understandings.
As the teacher, my perception of students' mathematical w1derstandings is structured by my understandings ofd1e mailiematics in question. Conversely, what I observe
in the students' mathematical thinking affects my understanding of the mathematical ideas involved and their interconnections. These two factors are interactive spheres
of a teacher's thinking (Ball's, 1993, "bifocal perspective" discussed earlier).
Steffe (1990) states,
Using their own mathematical knowledge, mathematics teachers must interpret the language and actions of their students and then make decisions about possible mathematical
knowledge their students might learn. (p. 395)
The teacher's learning goal provides a direction for a hypothetical learning
trajectory.
6
I use the term "hypoilieticallearning trajectory" to refer to the teacher's
prediction as to the path by which learning might proceed. It is hypothetical
because ilie actual learning trajectory is not knowable in advance. It characterizes an
expected tendency. Individual students' learning proceeds along idiosyncratic,
although often similar, paths. This assumes iliat an individual's learning has some regularity to it (cf. Steffe, et al., J 983, p. 118), that ilie classroom community constrains
mathematical activity often in predictable ways, and iliat many of the students in ilie
same class can benefit from the same mathematical task. A hypoteticallearning trajectory provides ilie teacher with a rationale for choosing a particular instructional design;
thus, I make my design decisions based on my best guess of how learning might proceed. This can be seen in the thinking and planning that preceded my instructional interventions in each of the teaching situations described as well as the spontaneous decisions that 1 made in response to students' thinking.
6
1 choose to use "hypothetical learning trajectory." rather than traditional terminology, to emphasire
aspects of teacher thinking that are grounded in a constructivist perspective and that are common to both
advanced planning and spontaneous decision making. 136 Reconstructing Mathematics Pedagogy
The hypothetical learning trajectory is made up of three components: the learning goal that defines the direction, the learning activities, and the hypothetical learning process-a prediction of how the students' thinking and understanding will evolve
in the context of the learning activities. The creation and ongoing modification of
the hypothetical learning trajectory is the central piece of the model that is diagrammed
in Figure 4. The notion of a hypothetical learning trajectory is not meant to suggest
that the teacher always pursues one goal at a time or that only one trajectory is considered. Rather, it is meant to underscore the importance of having a goal and rationale for teaching decisions and the hypothetical nature of such thinking. Note that
the development of a hypothetical learning process and the development of the learning activities have a symbiotic relationship; the generation of ideas for learning activities is dependent on the teacher's hypotheses about the development of students'
thinking and learning; further generation of hypotheses of student conceptual
development depends on the nature of anticipated activities.

Figure 4. Mathematics teaching cycle (abbreviated).
The choice of the word "trajectory" is meant to refer to a path, the nature of which
can perhaps be clarified by the following analogy. Consider that you have decided
to sail around the world in order to visit places that you have never seen. One does
not do this randomly (e.g., go to France, then Hawaii, then England), but neither is
there one set itinerary to follow. Rather, you acquire as much knowledge relevant to
planning your journey as possible. You then make a plan. You may initially plan the
whole trip or only part of it. You set out sailing according to your plan. However, you

must constantly adjust because of the conditions that you encounter. You continue Martin A. Simon 137
to acquire knowledge about sailing, about the current conditions, and about the areas
that you wish to visit. You change your plans with respect to the order of your destinations. You modify the length and nature of your visits as a result of interactions
with people along the way. You add destinations that prior to your trip were
unknown to you. The path that you travel is your "trajectory." The path that you
anticipate at any point in time is your "hypothetical trajectory."
The generation of a hypothetical learning trajectory prior to classroom instruction
is the process by which (according to this model) the teacher develops a plan for classroom activity. However, as the teacher interacts with and observes the students, the
teacher and students collectively constitute an experience. This experience by the nature
of its social constitution is different from the one anticipated by the teacher.
Simultaneous with and in interaction with the social constitution of classroom activity is a modification in the teacher's ideas and knowledge as he makes sense of what
is happening and what has happened in the classroom. The diagram in Figure 4 indicates that the assessment of student thinking (which goes on continually in the
teaching model presented) can bring about adaptations in the teacher's knowledge that,
in turn, lead to a new or moctified hypothetical learning trajectory.
Figure 5 describes the relationship among various domains of teacher knowledge, the hypothetical learning trajectory, and the interactions with students.

of students' knowledge" directly. However, because this was not the emphasis of the model, and in order
to simplify the diagram, those arrows are not included,) 138 Reconstructing Mathematics Pedagogy
Beginnjng at the top of the diagram, the teacher's knowledge of mathematics in interaction with the teacher's hypotheses about the students' mathematical knowledge
contribute to the identification of a learning goal. These domains of knowledge, the
learning goal, and the teacher's knowledge of mathematical activities and representation,
his knowledge of students' learning of particular content, as weU as the teacher's conceptions of learning and teaching (both within mathematics and in general) contribute
to the development of learning activities and a hypothetical learning process.
The modification of the hypothetical learning trajectory is not something that only
occurs during planning between classes. The teacher is continuaUy engaged in adjusting the learning trajectory that he has hypothesized to bener reflect his enhanced
knowledge. Sometimes fine tuning is in order, while at other times the whole thrust
of the lesson must be discarded in favor of a more appropriate one. Regardless of
the extent of modification, changes may be made at any or all of the three components
of the hypothetical learning trajectory: the goal, the activities, or the hypothetical
learning process.
Other Aspects of the Teacher's Role
Each of the three teaching situations portrays particular aspects of what teaching. which embodies reform principles. might be like. I discuss a few of these in
this section.
The original rectangles problem was planned for one or two class periods;
instead, eight periods were spent on the mathematics that was generated. Experienced
teachers might affirm that it is difficult to determine in advance exactly how long
it will take to teach a particular concept However, the discrepancy between the amount
of time anticipated and the amount of time spent in this case is well beyond the imprecision of planning. This discrepancy points at the experimental nature of mathematics
teaching. "Experimental" denotes the ongoing cycle of hypothesis generation (or
modification) and data collection that characterizes the teaching portrayed.
In the first situation, involving the tiling of the tables. I, as the teacher. perceived
a lack of understanding among a majority of the students of the relationship between
length-times-width and the counting of all the rectangles on the table. My response
was to pose additional problems based on students' conceptual difficulties that I had
witnessed in the past. r selected thought processes that I thought students could determine as not viable, but that would likely be problematic initially for them to
invalidate. (Rectangles problem 2 is an example.) My rationale was that previous
student 'conceptual difficulties (from the teacher/researcher's perspective) are potential difficulties for roy current students and represent useful hurdles for them to encounter
in the development of more powerful ideas.
This approach represents a sharp contrast to the approach to instruction characteristic of traditional mathematics instruction and represented by mathematics textbooks. Traditional instruction tends to focus on one skill or idea at a time and then
provide considerable routine practice to "reinforce" that learning. The mathematics
is subdivided into small segments for instruction so that students can experience success on a regular basis. In contrast, Situation L demonstrates a view of learning as Martin A. Simon 139
one involving a complex network of connections. Learning is likely to be fostered
by challenging the learner's conceptions using a variety of contexts. The teacher
can be compared to an athletic coach who employs a variety of practice activities
that challenge the athletes' strength and skill, often beyond what is required of the
athlete in competition (dribbling two basketballs while blindfolded, playing a
soccer game where each player may not touch the ball two consecutive times, per-
forming a figure skating program three times in a row with only a 2-minute rest in
between). These activities are not aimed at constant success, but rather at increased
competence. Growth is a result of challenge to body and mind. Conceptual difficulties that I have previously observed in students are not to be avoided; rather. they
provide particular challenges, which if surmounted by the students, result in conceptual growth. This fits with French researchers- notion of "obstacles epistemologiques"
(Bachelard, 1938, cited in Brousseau, 1983), that overcoming certain obstacles is
a natural and essential part of conceptual development. These obstacles are a
result of prior concepts that, although adaptive in earlier contexts, are maladaptive
given the demands of the current problem situation.
A second feature of the approach seen in Situation 1 is subtler. As a teacher, I often
do not have a well-developed map of the mathematical conceptual area in which
I am engaging my students; that is, I may not have fuJy articulated for myself (or
found in the literature) the specific connections that constitute understanding or the
nature of development of understanding in that area. Rather, as was the case when
I started the rectangles instructional unit, my knowledge of what it means to
understand the particular concept may be carried in part by particular problem sit-
uations. The kinds of difficulties that students encounter provide me with key pieces
of what it means to understand. Thus, in such cases, my operational definition of
understanding is the ability to overcome these particular difficulties; I may not
have unpacked the difficulties in order to understand the conceptual issues that
are implicated. Thus, even if I do not have a thorough knowledge of what constitutes mathematical understanding in a particular domain, having a rich set of
problem situations that challenge students and having knowledge of conceptual
difficulties that they typically encounter provide me with an approximation that lets
me be reasonably effective in promoting learning in the absence of more elaborated
knowledge. (This is not to suggest that the more elaborated understanding would not
be more powerful.) Indeed, engaging students in these problem situations and with
these conceptual difficulties gives me an opportunity to learn more about what it means
to understand the concepts involved.
Underlying Situation 2 is an idea that highlights a difference between teaching
based on a traditional view of learning and teaching based on a constructivist perspective. Rather than "review" what is meant by area or assign "practice problems,"
my approach was to challenge the students in a way that might push them to extend
their conceptions of area. The review-and-practice approach is based on learning
as improving storage and retrieval. of received information. (Although I am not negating the importance of memory, I contend that it is not what is most important, most
interesting, and most problematic for educators in the domain of mathematics.) My 140 Reconsrructing Mathematics Pedagogy
approach in Situation 2 reflected a view of understanding as a network of connected
ideas that is further elaborated as the understanding is used to solve novel problems.
Situation 3 was the most difficult to analyze. I brought to the teaching situations
a view that learning is triggered by disequilibrium. When the students were convinced that the rotated rectangle method of measuring and calculating provided no
useful information about the table, I 'lied in every way I could to provoke disequilibriwn,
but to no avail. In-depth analysis of the data suggests that my interpretations of the
students' thinking that led to their conclusion was not adequate. Whereas I had thought
that they saw my method as counting the number of overlapping rectangles, I now
beJieve that they were saying that the method involving turning the rectangle
counted nothing because in the process I was overlapping the rectangles. This subtle difference in thinking may account for my inability to foster disequilibrium.
Having failed to promote disequilibrium, I embarked intuitively on another strategy. I backed away from the particular problem to try to focus on a part of the understanding demanded by the problem. A posteriori analysis suggests that what I was doing
was fostering the development of know-edge that, when the students returned to that
problem, might contribute to the students' experiencing cognitive conflict In this case,
if I could help students build an understanding of the relationship between linear and
area measures of a rectangle, they would then experience a conflict between those understandings and the expectation that measuring with the cardboard rectangle resulted
in a measurement where that rectangle was the unit of area. This teaching episode seems
to emphasize that disequilibrium is nor created by the teacher. He can try to promote
disequilibrium. However, the success of such efforts is in part determined by the adequacy of his model of students' understanding. It also seems to support the notion that
learning does not proceed linearly. Rather, there seem to be multiple sites in one's web
of understandings on which learning can build.
IN SUMMARY
Constructivist views of learning have provided a theoretical foundation for mathematics education research and a framework within which teachers can understand their
students. However, constructivism also poses a challenge to the mathematics education
community to develop models of teaching that build on, and are consistent with, this
theoretical perspective. Small-group interaction, nonroutine problem solving, and manipulative materials can be valuable tools in the hands of mathematics teachers. Yet the
ability to use these tools is not sufficient to allow teachers to be the architects of productive learning situations resulting in conceptual growth. Theoretically based
frameworks for teaching bave the potential to guide the use of these tools.
By what means can a teacher help students to develop new, more powerful
mathematical concepts? Novice teachers. who want their students to "construct" a
particular idea, often ask for the idea from their students, consciously or unconsciously
hoping that at least one student will be able to explain it to the others (Simon, 1991).
Such an approach does not deal with a key question: If a group of students do not
have a particular concept, how does a teacher work with them to foster their development of that concept? Marrin A. Simon
141
The principal currencies of the mathematics teacher (iflecturing is rejected as an
effective means of promoting concept development) are the posing of problems or
tasks and the encouragement of reflection. The data analysis described in this paper
and the resulting Mathematics Teaching Cycle address the issue of the process by
which a teacher can make decisions as to the content, design, and sequence of mathematical tasks. The model emphasizes the important interplay between the teacher's
plans and the teacher and students' collective constitution of classroom activities.
The former involves creation of instructional goals and hypotheses about how students might move towards those goals as a result of their collective engagement in
particular mathematical tasks. However, the teacher's goals, hypotheses about learning, and design of activities change continually as the teacher's own knowledge changes
as a result of being involved in the culture of the mathematics classroom.
A goal structure for mathematics education such as the one elaborated by Treffers (1987)
is needed in specifying possible learning environments by teachers. But this element
of possible learning environments is just as dependent on the experiential fields that constitute learning environments as the latter are dependent on the former. Mathematics
educators should not take their goals for mathematics education as fixed ideals that stand
uninfluenced by their teaching experiences. Goal structures that are establjshed prior
to experience are only starting points and must undergo experiential transformation in
actual learning and teaching episodes. (Steffe, 1991, p. 192)
Steffe's comments seem to underscore the cyclical nature of this teaching process.
The Mathematics Teaching Cycle portrays a view of teacher decision making with
respect to content and tasks that has been shaped by the meeting of a social constructivist perspective with the challenges of the mathematics classroom. Several
themes are particularly important in the approach to decision making represented
by this model.
1. Students' thinking and understanding is taken seriously and given a central place
in the design and implementation of instruction (consistent with Steffe, 1991).
Understanding students' thinking is a continual process of data collection and
hypothesis generation.
2. The teacher's knowledge evolves simultaneously with the growth in the students'
knowledge. As the students are learning mathematics, the teacher is learning about
mathematics, learning, teaching, and about the mathematical thinking of his students.
3. Planning for instruction is seen as including the generation of a hypothetical
learning trajectory. This view acknowledges and values the goals of the teacher for
instruction and the importance of hypotheses about students' learning processes (ideas
that I hope I have demonstrated are not in conflJct with constructivism).
4. The continually changing knowledge of the teacher (see #2) creates continual
change in the teacher's hypothetical learning trajectory.
These last two points address directly the question raised earlier in the paper of
balance between direction (some may call this "structure") and responsiveness to
students, a creative tension that shapes mathematics teaching. The model suggests
that, as mathematics teachers, we strive to be purposeful in our planning and
actions, yet flexible in our goals and expectations. 142 Reconstructing Mathematics Pedagogy
The mathematics education literature is strong on the importance of Jistening to
students and assessing their understanding. However, the emphasis on anticipating
students' learning processes is not developed by most current descriptions of
reform in mathematics teaching. Research on how students develop particular mathematical knowledge (cf. Steffe, et al., 1983, see pp. 118 & 135; Thompson, 1994)
informs such anticipation. Perhaps one explanation for the success of Cognitively
Guided Instruction (Carpenter, Fennema, Peterson, & Carey, 1988), in which
teachers learned about research on children' s thinking (Carpenter & Moser, 1983),
is that it increased reachers' ability to anticipate children's learning processes. BaU J
(1993) articulates a similar position emphasizing the role of teachers • hypotheses
about student learrung. "Selection of representational contexts involves conjectures
abom teaching and learning, founded on the evolving insights about the children's
thinking and [the teacher's] deepening understanding of the mathematics" (p. 166).
The data from this study must be seen in its particular context The teaching practice was embedded in a teacher education program; the mathematics students
were prospective elementary students. As the teacher. I felt no pressure to teach from
a preset curriculum nor to cover particular mathematical content, a condition that
is probably the exception rather than the rule for mathematics teachers. Mathematics
teaching with other populations involves a set of different constraints. Research in other
contexts wi ll inform us about the degree of context dependence of the ideas generated.
A possible contribution that can be made by the analysis of data and the resulting model reported on in this paper is to encourage other researchers to examine
teachers' "theorems in action" and to make teachers' assumptions, beliefs, and emerging theories about teaching explicit At the minimum, the paper should serve to emphasize the need for models of mathematics teaching that are consistent with. and built
on, emerging theories of learning. Much research remains to be done to understand
the implications for practice of teachers holding constructivist perspectives. It is the
recognition that constructivism does not tell us how to teach that will motivate increased
work in this area.
A well-developed conception of mathematics teaching is as vital to mathematics

teacher educators as well-developed conceptions of mathematics are to mathematics
teachers. Informed decisions in each case are dependent on a clear sense of the
nature of the content being taught. Considering the Mathematics Teaching Cycle
as a way to think about mathematics teaching means that teachers would need to
develop abilities beyond those already currently focused on in mathematics education reform, particularly the ability to generate hypotheses about students'
understandings (which goes beyond soliciting and attending to students- thinking),
the ability to generate hypothetical Learning trajectories, and the ability to engage
in conceptual analysis related to the mathematics that they teach. This last point supports proposed reforms of mathematics for teachers (cf. Cipra, 1992; Committee
on the Mathematical Education of Teachers, 1991) and supports arguments that the
mathematical preparation of teachers is far from adequate if teachers are to engage
in pedagogical deliberations as characterized in this paper.
FinaJly. it should be noted that the role of the mathematics teacher as portrayed
in this paper is a very demanding one. Teachers will need access to relevant Martin A. Simon
143
research on children's mathematical thinking, innovative curriculum materials, and
ongoing professional support in order to meet the demands of this role.

WISKOBAS AND FREUDENTHAL
REALISTIC MATHEMATICS EDUCATION
ABSTRACr. Freudenthal was the founder of so-called realistic mathematics education. In it reality
does not only serve as application area but also as the source for learning. We take a newspaper article
as an example of a rich context problem. It contains elements from all of the important areas of leaming
for mathematics education in primary school (grades I through 6). In the following these topics of
learning are discussed. Historical comments will be indicated each time, in particular relating to the
influence of Freudenthal. Freudenthal laid the foundation for this didactical realism and determined the
development of various learning strands, but more indirectly than directly because he himself did not
design or outline themes and learning strands. Attention is devoted briefly to the integral educational
development of Wiskobas and Freudenthal's contribution to it, especially in terms of developmental
research. The summary, in conclusion, is given by way of a problem that was posed by Freudenthal -
his last one.
INTRODUCTION
Freudenthal is strongly associated with Wiskobas2. This is rightfully and wrong-
fully so. Wrongfully so because Wiskobas originated in 1968 without the involve-
ment of Freudenthal and continued after 1981 without his direct participation.
Rightfully so because of the lasting influence of his range of ideas on the work of
Wiskobas. And not only on Wiskobas, and therefore on primary education, but
equally through Wiskivon on secondary education (grades 7-12), which will not
be described in this presentation3.
It was Freudenthal who in 1971 - upon the founding of the IOWO - put
Wiskobas on the track of realistic mathematics education, away from the trodden
path of traditional arithmetic, and away from the up and coming New Math. New
in Freudenthal's views was not only that he wanted to incorporate everyday reality
emphatically in mathematics education, but especially also his fundamental idea
to let that rich context of reality serve as a source for learning mathematics.
In the initial period it was predominately the rich contexts in the form of
topics, projects, locations, stories and clippings which determined the appearance
of Wiskobas. Later it was more the new learning strands which drew the attention.
In the following there is first an example of one of those themes for the
teacher, together with some historical comments about the place of such problem-
situations in realistic mathematics education in primary school (grades 1-6) in the
period 1970-1990, and Freudenthal's contribution towards the development of
these themes. Thereafter the latter is done for the learning strands of the Wiskobas
Educational Studies in Mathematics 25: 89-108, 1993.

program and in conclusion for educational development as a whole. We start by
accentuating the description of the content of the Wiskobas program. Later it
is especially Freudenthal's influence as a member of the Wiskobas team which
receives attention.
1. RICH 'THEME: VAN GOGH IN THE FIELD
1.1. Van Gogh Problem
From the outset of the Wiskobas project at the IOWO Freudenthal stimulated
'mathematics fraught with relations', or as it was later called 'mathematics in rich
contexts' - to which the influence of Decroly was not foreign (Freudenthal, 1973).
From the available categories of rich themes a newspaper clipping
is chosen here,
intended for the (initial) teacher training. To be precise the example consists of
two newspaper clippings, both about a rather unusual reproduction of one of Van
Gogh's 'Vase with Sunflowers' (see Figure 1).

All use subject to JSTOR Terms and ConditionsWISKOBAS AND FREUDENTHAL: REALISTIC MATHEMATICS EDUCATION 91
It took Andrew Scott, a horticulturist in Scotland, ten days to make a repro-

duction of Vincent van Gogh's 'Sunflowers'. With the assistance of twenty volunteers he copied the painting in a Scottish wheat field, using 250,000 colourful garden plants. The botanical 'canvas' is 14 square kilometres in size and 'very beautiful', Scott concludes after having inspected the scene from a helicopter. (Trouw 17-8-'91).
In another newspaper one could read:
Scott used various kinds of plants and shrubs to portray a picture of over 10.000 square meters. (Volkskrant 17-8-'9 1).
On the basis of these clippings we asked the teachers the following question:
> Which report is the most accurate, Trouw or Volkskrant? Explain your answer as convincingly as possibly.
When this problem had been solved and discussed the next question was raised:
> How do you suppose this discrepancy in sizes occurred?
It was added that the newspapers were given the area in square yards: 12820 square yards (De Moor and Streefland, 1991). More explicitly:
> Could the area of 'over 1 0,000 square meters' be correct?
> How do you explain the error of the 14 square kilometres?
1.2. Brief Comment
In determining which area seems the most plausible, there are first of all the arguments of geometry which the teachers raise. In making estimations of length and width tractor tracks and the height of the trees were considered: how wide is a track and how high a tree, roughly speaking! These sizes as such are the first topic of discussion and reflection. All kinds of reference points are brought up. One teacher follows up with an interesting method: the 'projection' of the side-lines of the painting to the road with trees showing at the top of the photo (Figure 2). It is obvious from looking at the trees, that this 'canvas' cannot be 3 or 4 kilometres wide, but some one hundred meters at most.
Then there is also the computational argument in answering the first question with regard to the density of the plants in the painting: 250,000 plants on 14 square kilometres or on 10,000 square meters? In the latter case there would then be 25 plants on 1 square meter - that would seem reasonable, after some sizing up. But 250,000 plants on 14,000,000 square meters is 25 plants on 1400 square meters or 1 on 56 square meters, so 1 plant on a rectangle of 7 by 8 meters, the floor of our classroom, and of course that is too far apart.
Moments of discussion are introduced when making an inventory of the various solutions. But the result of one and other is clear: 10,000 square meters seems by far the most realistic size. It could also very well concern a rectangle of 60 by 70 meters, as reported on the news on television the day before! (Length and width do not differ that much, but the area does. How is that possible?)
Then the correct area is given - 12,820 square yards. We take another look at those 10,000 square meters and 14 square kilometres and do so in that order.

Fig. 2.
When converted does 12,820 square yards correspond with somewhere close to 10,000 square meters? One yard is 91.44 cm, let us say 0.9 meters.
There is disagreement: one group feels that the answer should have been well over 1 1,000 square meters (0.9 x 12820 = 115380) or even 1 1,500 square meters; someone else prefers close to 12,000 square meters, and there are those who can agree to the figure of some 10,000 square meters (0.8 x 12820).
Of course the issue of rounding off is discussed at length. But particularly the main issue of whether to multiply by 0.9 or by 0.8 (or divide).
A square of 10 by 10 yards can serve as a model.
This is then converted to a square of 9 by 9 meters. Therefore 100 square yards corresponds with 81, let us say 80 square meters.

All use subject to JSTOR Terms and ConditionsWISKOBAS AND FREUDENTHAL: REALISTIC MATHEMATICS EDUCATION 93
If 100 becomes 80 than 12820 therefore becomes ... The double number line is used:
100 12820
80
Or perhaps better the ratio table, because of the possible confusion of 'square' with 'length' on the number line:
100 10.000 12820
80 800 ?
Different methods of calculation are possible; for example via 10,000 and correspondingly 8,000, or abbreviated via 130 times as much at the top, therefore also 130 times 80 at the bottom, or via 8/10 times 12820 - some 10,000 square meters does appear to be correct!
Actually this problem is best posed separately and the solutions inventoried and discussed one by one. But even more important is to relate the conversion of square yards to square meters to the earlier conversion of square kilometres to square meters, and to draw attention to the matter of the zeros and the linear connection between kilometres and meters, and the conversion of measures of volume.
In conclusion the unravelling of the matter of the 14 square kilometre.
The teachers are helped on their way: the first mistake also occurred here in the conversion of square yards to square meters via the factor 0.9. Who remembers what else went wrong? We latch on to a smart suggestion from one teacher: indeed 12820 was not multiplied by 0.9 but divided by it. Perhaps an understandable error, just like the first one, because the idea was that the result in square meters would have to be smaller than 12820, and becoming smaller means that you must divide, right?!
Next, the result of 12820: 0.9144 will probably be worked out on the calculator: 14020.122. The decimal point is easily overlooked. Now move the decimal point six positions to the left and we have 14.020122 square kilometres, rounded off to 14 square kilometres.
That is how it might have gone, but more likely the decimal point was placed three positions to the left (from meters to kilometres as it were) from 14020.122. Whatever the case, the error has taught us that division does not always give a smaller result. And the most important thing that was learned is perhaps, that in cases like these you must always examine the answer to see if it is plausible.
By the way, one question remains unanswered: how did the Scottish arrive at 12820yd. 22 5 641?
At any rate it has become clear that many aspects of mathematics can be raised here in an integrated fashion. In the early days of Wiskobas, but also thereafter, theme-oriented examples like this, but also at the level of primary education, had an important informative and stimulating influence.

1.3. Historical Comments
Before the founding of the IOWO, Freudenthal wrote the following about mathematising:
'The globally structuring force, as we called it, should be lived through reality. Only this way can we teach mathematics fraught with relations, can we be sure that the student integrates the mathematics he has learned, and can we guarantee the applicability of mathematics'. (Freudenthal, published in 1973, p. 132).
It is evident that the introduction of rich themes corresponds with this basic idea, i.e. was strongly stimulated by it. The IOWO snapshots, published in Educational Studies in Mathematics on the occasion of 'H. Freudenthal's Retirement from the Directorship of IOWO' (1976) attest to this: 'An Island of Geometry', 'Ship Ahoy', 'Our Earth', 'Building a Bungalow', 'Gulliver', etc. Many themes were developed in the course of time. In his farewell speech Freudenthal even went so far as to predict that the integrative aspect of mathematics was dominant to such a degree that mathematics as a separate subject would cease to exist in time:
'What will mathematics education look like in 2000? The answer is simple. There will be no more mathematics education in 2000, it will have disappeared. There will be no more subject called mathematics, no math program, no math textbook to teach from' ... 'It is there to be lived and enjoyed, just as reading, writing, handicrafts, art, music, breathing, in integrated education'. (Freudenthal, 1977, p. 294).
After 1976 mathematising was distinguished in a horizontal and vertical component (Treffers, 1987) and also in the functions which rich context can accomplish in mathematising (de Lange, 1979, 1987). The integrative themes have a specific horizontal mathematising purpose, i.e.: they are primarily directed at the application, practice and relating of learned knowledge and skills in context situations. The model-type contexts on the other hand have primarily a vertical mathematising purpose, i.e. that they are in particular directed at the progression within the subject structure, therefore on the practising of knowledge, skills and concepts within learning strands (Gravemeijer et al., 1990). By this distinction in horizontal and vertical mathematising, about which Freudenthal said 'For a long time I have hesitated to accept this distinction' (1991), the importance of the integrative themes was brought back to realistic proportions: they are important, but overemphasis leads to empiristic mathematics education with too little attention for vertical mathematising. In an evaluation discussion about the Wiskobas project4 in the IOWO period (1971-1981) Freudenthal himself came to the conclusion that Wiskobas spent too much energy in those days on the design of themes ('domains of reality disclosed to the learner in order to be 'horizontally' mathematised') and too little on model contexts (to be 'vertically mathematised') on which in the eighties the emphasis came to lie much more. Also the form and content of the theme changed in the eighties to some degree. Besides themes, projects, locations and stories there appeared the clippings. Their value was recognized by Freudenthal:

Here is not a domain but a small piece that is cut out, although its paradigmatical value for mathematising and for acquiring a mathematical altitude may be enormous in comparison. (Freudenthal, 1991).
See 'Van Gogh in the field', we might add.
2. WITH A VIEW TO LEARNING STRANDS
In the Van Gogh problem there were elements from the main learning strands of the Wiskobas program:
- basic skills and column arithmetic
- ratio and fractions
- measurement and geometry.
In the following these learning strands will be regarded from the points touched on in 'Van Gogh' to acquire some insight into the specific characteristics of each. For each main learning strand some historical comments are made about their development in the period 1970-1990. In each instance there will be a short reference to the involvement of Freudenthal.
2. 1. Basic Skills and Column Arithmetic
Mental arithmetic is efficient calculation for which both memorized knowledge as well as insight in arithmetic rules is necessary, with furthermore the particular 'faces' of numbers and the relations between them. The Van Gogh problem offers various possibilities for mental arithmetic in combination with estimated calculation, forexampleof 1% x 12500 = 8 x 1250 = 4 x 2500 = 2 x 5000 = 10,000-
the strategy of halving and doubling. The Wiskobas program leaves much room for mental arithmetic. Column arithmetic is not introduced until the beginning of grade 4. Until that time mental arithmetic has received every opportunity to develop. In the traditional math program column arithmetic (with adding and subtracting) started one year earlier, at the beginning of grade 3, and in consequence snowed mental arithmetic under completely. There are even countries (among them the USA) where column arithmetic to one hundred often already starts in grade 2. In consequence pupils have almost no opportunity to consider numbers on their value, something which is also expressed in the achievements (for a comparison see Treffers, 1991 a). Estimation arithmetic has meaning when it concerns the rough determination of the result, the general assessment of the result in terms of magnitude, and if one must handle not precisely determined information. And that is exactly what was done in the Van Gogh problem, where experience information was used (misused), approximation, rounding off and (in)accuracies in determining the height of trees by roughly converting yards to meters and square yards to square meters and examining whether about 10,000 square meters is close... Although the Wiskobas program does devote much attention to estimation - it is both a goal and a means - this is not yet sufficiently

evident in educational practice in Holland, contrary to mental arithmetic that is practised sufficiently.
In conclusion, column arithmetic that in 'Van Gogh' could remain in the back-

ground by using the calculator. But this also applies in general: the importance
of learning the number algorithms has been strongly reduced by the introduction
of the calculator. In the Wiskobas program this is expressed in a special manner,
namely in the connection between mental arithmetic and column arithmetic. Col-
umn arithmetic procedures are developed from stylized mental arithmetic. This
occurs according to a gradual process of schematising and abbreviation. And the
end level can differ (per group or per pupil). An example of how this works for
division. The following transportation problem can for instance serve as point of
departure for long division: 1128 fans must be transported in buses that seat 36.
How many buses will be needed?
This problem is solved at different levels in the course of the learning strand
(Figure 3).
And these solutions illustrate the abc of the entire learning strand.
Something similar happens for multiplication. For example in a context prob-
This content downloaded from 143.160.38.146 on Wed, 3 Jul 2013 05:07:28 AM
All use subject to JSTOR Terms and ConditionsWISKOBAS AND FREUDENTHAL: REALISTIC MATHEMATICS EDUCATION 97
lem in which 7 x 24 occurs: (1) via repeated counting, (2) abbreviated to the
front-end method 7 x 24 = 140 + 28 = 168, and (3) the end-front standard
algorithm that starts with the units.
Historical Comments
One might even go so far as to elevate the stylized front-end methods of mental
arithmetic to (new) standard algorithm. The Wiskobas program, which serves as
informal National Curriculum (Treffers, De Moor, 1990), emphatically points out
this possibility. Currently it is not clear to what degree textbooks and teaching
practice are prepared to go with this. There is clarity about the modest importance
of column arithmetic: currently there is an obvious trend in The Netherlands to
delay it (let us say until grade 4, as proposed by Wiskobas) and to restrict it in
favour of mental arithmetic and estimation arithmetic. This shift did not take
place until in the eighties however. During the IOWO-period (1971-1980) the
mentioned parts of basic skills and arithmetic were still fairly unrelated: there was
a separate algorithm program. And column arithmetic was introduced in grade 3
in those days.
No special didactics had been developed for the learning of the tables of
multiplication or elementary mental arithmetic. That did not occur until the
eighties for addition and subtraction (Treffers, 1991b), for multiplication and
division (ter Heege, 1985), for elementary mental arithmetic with the aid of
the empty number line on the basis of an idea by Whitney (1988), and for the
combination method mental arithmetic-column arithmetic (Treffers and De Moor,
1990). Programs were developed for mental arithmetic for instance, and the writers
of math methods also gave an important impulse. In short, too many people to
mention together brought about a small revolution in the program development
for basic skills and arithmetic.
In conclusion, a few remarks about Freudenthal's influence on the outlined
development of basic skills and column arithmetic. Contrary to what one might
expect, Freudenthal was hardly involved at all with this area of development.
And as far as the above mentioned issue about the relation and shift in position
of mental arithmetic and column arithmetic is concerned, one will find nothing
on the subject in his last book (Freudenthal, 1991). He was not keen, so it
became evident in the early stages of Wiskobas, on the fundamental importance
of memorized knowledge of addition and multiplication tables. This did change
somewhat under the influence of the Wiskobas group, but the fact remains that
this area certainly did not have his special interest. It lay much more with the
other major areas, which we will now review from the Van Gogh problem.
2.2. Ratio and Fractions
The first of the 'Van Gogh' problems concerns visual ratios. Numbers barely play
a role in determining that 14 square kilometres cannot be correct: the practised
eye sees immediately that this cannot be a rectangle of 3 - by 4 kilometres,
considering the trees, the tracks, the whole scene. Ratios also appear in the
This content downloaded from 143.160.38.146 on Wed, 3 Jul 2013 05:07:28 AM
All use subject to JSTOR Terms and Conditions98 A. TREFFERS
Wiskobas program in similar fashion, therefore at first only as visual ratios from
the observation world of drawings, maps, models and illustrations, whereby it
must be determined whether the ratios are correct or have to be adjusted. Later in
the program a number element is added. At issue then is estimation or determining
the exact ratio relationship, whether ratios are equivalent, or else to compare ratio
relationships, or determine the fourth proportional. In the 'Van Gogh' item for
instance, visual ratios were concerned, to determine the plant density for the two
given measurements and the conversion of (square) yards to (square) meters.
But of course there are many more forms in which ratios can appear: mixing,
borrowing, conversion, fair distribution, and the linear relating of measures such
as unit-price, price-weight, road-time and so on, to which the mentioned questions
about ratios can be applied. The dominant think and calculation models employed
are the (empty) double number line and the ratio table (also consider the (estimated)
conversion of 12820 square yards to square meters) which can both serve on many
levels of schematising and abbreviation - of course also for the special ratios which
are called percentages. Wiskobas has from the very start devoted much attention
to this rich area.
Fractions do not play an important role in the Van Gogh problem. Only in the
relationship between yards and meters do they appear, and then only in the form of
decimal numbers. And working with them can even be avoided by size reduction
or by working with squares of ten by ten. This immediately indicates one of the
strategies with which to approach and explain the multiplication and division of
decimal numbers, namely by changing measurement units with the help of the
rectangular model or else trying to get rid of the decimal point. But fractions can
also be used to solve ratio problems: ratios and fractions can be related to each
other. Ratio (fair) division for example of pizzas, chocolate bars etc. can lead
to breaking up and hence to fractions. Sharing of objects can achieve the same.
Accurate measurement with a prescribed measure also. And thus there are many
inroads to fractions which are used by Wiskobas in the first concept-forming phase.
At issue is not so much operating with fractions in the more formal sense, but fair
sharing, distributing and measuring and then the description of these activities and
their results - the development of comprehension and language. The relationship
with ratios is expressly maintained at this stage, partly to compare fractions and
to determine the (in)equality thereof through ratios (Streefland, 1991 a). In a next
phase when operating with fractions is brought more to the fore, it is especially
the measurement aspect that is employed. Keywords here are: mediating unit,
named fractions, the rectangle model and the strip or the (empty) double number
line (Streefland 1991a, b, and Treffers, 1991b). An example from the last in
conclusion:
|
i i year
(3) (12) months
This content downloaded from 143.160.38.146 on Wed, 3 Jul 2013 05:07:28 AM

Problems such as -y + 4y; 4y - 4y;
↑
x ly; y : ly can be solved via the
3 2 3 2 3 2 3 2
mediating unit of month, therefore the underside of the double number line, but of
course also directly with fractions on the upper side of the number line. Note the
difference in notation between adding and multiplying: -y x -y is not possible
but l x ly is right, i.e. that
|
serves as operator. In the abstract notation 3 +
and 4 x 4 one cannot read the different status of 4 in these notations, as one can in
the notations with letters. Later on in the course pupils must themselves try to find
the right divisor to be able to work away the fractions by imagining a chocolate
bar with a varied number of pieces, or a strip, or a double number line. So much
for details concerning fractions, otherwise we will digress too far from the 'Vase
with Sunflowers'.
Historical Comments
In describing Freudenthal's influence on the development of education for fractions
and ratios one must immediately list his monumental 'Didactical Phenomenology
of Mathematical Structures' (1983) of which parts were already published as
early as 1973. And it is notably the phenomenological reflections about ratios and
fractions which have had great influence on the development of learning strands
in this area. And yet there was no evidence of direct extraction of education from
this analysis. Even stronger, upon first introduction one sooner had the feeling
that one was being distracted from it. Take fractions for instance: the enormous
variety and complexity of appearances, as described by Freudenthal, had an almost
paralysing effect on anyone doing developmental work on this subject. Add to this
the emphasis that Freudenthal placed on unicity of individual learning processes
- thereto in part inspired by the 'walks with Bastiaan' his grandson - and one can
imagine what an enormous burden developmental research in this area was faced
with. The result of these efforts is visible in the fundamental work of Streefland
(1991a) which in turn adds new elements to the phenomenology, such as fair
sharing via ratios and the working with a mediated unit for named fractions. And
the notation thereof with letters, plus the (empty) double number line as master
model for operating with fractions by Treffers (1991b). In short, Freudenthal
indicated where to look and how to look (observation of learning processes) but
even he did often not know in advance what would be discovered. His influence
was and is fundamental, but also difficult to pinpoint concretely because he was
not directly involved in the design of learning courses and did not really have
clear cut suggestions for the total education structure for these complex learning
courses.
A typical and intriguing remark in this regard was the following: "Why don't
we approach fractions in the same way as initial arithmetic, namely depart from
elementary context problems and from there try to arrive at formal arithmetic?" A
remark that has remained with me until today and a major principle of Wiskobas
for the development of ideas about calculating with fractions - leading to ratios,
to mediated measures, to named fractions, to explicit notation thereof, to the
(double) number line... Therefore indeed comparable to initial arithmetic where
also initially one works with named numbers, and the empty number line plays
This content downloaded from 143.160.38.146 on Wed, 3 Jul 2013 05:07:28 AM
All use subject to JSTOR Terms and Conditions100 A. TREFFERS
an important role. But it took ten to fifteen years for this encouragement to
take concrete shape, one which Freudenthal himself had not anticipated either,
but could ultimately appreciate. And still the developers had the feeling that it
was what Freudenthal had intended all along. 'Wiskobas and Freudenthal', a
complicated relationship - difficult to separate, and certainly in terms of ideas
because Freudenthal was a member of the Wiskobas team.
2.3. Measurement and Geometry
'Van Gogh' is mainly about measuring - the measuring of area. Listed below are
six aspects of measuring in the Wiskobas program. These apply generally, but we
will illustrate them briefly using the example of area.
1. Comprehension of measurement is not automatic. What does it mean to
measure area in square meters, kilometres, yards? What is area? The
number of plants, for example, says something about the size of a field or
else the area. And through this relation to another, more concrete magnitude,
area can be made visible, and thus the development of comprehension of
measure be promoted.
2. Secondly, 'everyday' measurements must be related to the realm of experi-
ence and imagination of the children. What is a square meter, how big is
that? Can a non-square also have an area of 1 square meter? How big is a
square kilometre, imagine this in your surroundings. How big is 14 square
kilometres in that regard? What is the area of the floor of our classroom?
Pupils must allow a host of reference points about measure to sink in: how
tall are you, how fast is the car going, how many people live in a large
city, what is the temperature today... and so very many more. Items like
'Van Gogh' pertain to this. The Wiskobas program places strong emphasis
on it. Numbers of measurement can establish arithmetic in the reality of
children.
3. Development of strategies of measuring is inherent to measurement. Notably
estimation is of crucial importance, especially estimation on the basis of
personal reference points. See the trees, the tracks in 'Van Gogh', we already
mentioned them in respect to estimation. Estimating and measuring are
closely related.
4. The relationships between measures and magnitudes must be examined.
Metrics is one of these aspects - see 'Van Gogh'. But also relations between
circumference and area, between distance, time and speed, and so forth.
5. Calculating with numbers of measure sets special demands, notably when
dealing with rounded off or inaccurate numbers. Compare the indications of
250,000 and 12,820 in the Van Gogh problem, for instance. And the matter
of the rounding off of yards and meters - is that allowed? Errors can be
blown up when multiplying or dividing (compare 60 x 70 m - not such a
poor estimate but the area is quite far off). Matters to which attention must
be devoted in relation to measuring, estimating and calculating.
This content downloaded from 143.160.38.146 on Wed, 3 Jul 2013 05:07:28 AM
All use subject to JSTOR Terms and ConditionsWISKOBAS AND FREUDENTHAL: REALISTIC MATHEMATICS EDUCATION 101
6. And finally, the collection and processing of numerical data in graphs, tables,
diagrams and so forth, something not found in the 'Van Gogh' item. Drawing
graphs, interpreting them, all of this is also part of measuring.
All in all measuring offers a natural access to arithmetic, it provides models
and context problems which cover a wide area. Various skills and fields are related
through measurement - see 'Van Gogh'. The Wiskobas program reflects the great
importance of measurement.
There is very little geometry in Van Gogh... Although...? There is an element of
spatial orientation in the first problem and certainly in the perspective-problem (De
Moor, 1991). The Wiskobas program contains problems concerning projecting
and visualizing (1), orienting and localising (2), and shapes and pictures (3). The
children are encouraged to construct, calculate and reason.
In the first phase of geometrical instruction the structuring of spatial experi-

ences are mainly visual and implicit: the insights are in fact not expressed in words other than 'I see it this way'. Later intuitive notions must be more considered and better argued by means of language symbols, pictures, reasoning. Then explicit concepts are developed such as angle, perpendicular, direction etc., which possess a certain relation and which can be built up on in secondary education.
In the category of projecting and visualizing, to be somewhat more explicit, problems fit such as:
- Why do shadows become longer when you walk away from a street light and not when you walk away from the sun?
- Why does the moon walk along with you?
- Why does the thumb when held near the eyes change position if you close first one eye and then the other?
- Why do railway tracks converge in the distance?
No easy questions. They especially give an impression of the continuing line of geometry from primary to secondary education. The Wiskivon team (Goddijn, Kindt, Schoemaker and others) produced a great variety of ideas in this field on which Wiskobas also took advantage. Mathematical world orientation requires investigation, explanations of the self-evident, of own experience. There is a great deal of geometry in the Wiskobas program. And that is visible in the publication 'Five years IOWO' (Freudenthal, Janssen and Sweers, 1976) - you can tell at a glance.
Why? Because there is not another part in the program that can be as motivating, that can promote the forming of a mathematical attitude so much, that appeals so strongly to general objectives, as does geometry.
Historical Comments
Freudenthal, the great promoter of geometry education wrote:
The deductive system of geometry - the ideal for an elite school, was a farce, even for the elite pupils, and for the schools for the masses even less than that. At the end of the sixties I succeeded in formulating what I considered to be the solution: deduction yes, but then local, something the pupils can oversee, not global, as a system thought up by hobby horse riders. (Freudenthal, 1987)
This content downloaded from 143.160.38.146 on Wed, 3 Jul 2013 05:07:28 AM
All use subject to JSTOR Terms and Conditions102 A. TREFFERS
The Wiskobas group and certainly also Wiskivon, the group responsible for secondary education within the IOWO, needed only little urging in this direction: geometry was manifesting itself from reality on every side - geometry as mathematical world orientation which required no extensive didactical phenomenological analysis to develop quickly. The major part of 'Five years IOWO' is about measurement and geometry, for a part integrated with ratios. Freudenthal was also the great promoter behind measuring. He devoted a didactical phenomenological reflection to measuring (1984), to measuring length (1983) and area (1978).
Generally it can be said that the result of Freudenthal's strong fixation on phenomenological diversity of the appearance forms of mathematical structures and on the great individual variety of learning processes was that he was extremely reluctant to dictate learning paths in the steering of education.
In the earlier mentioned evaluation talks about Freudenthal's own estimate of his role in the development of mathematics education in the period 1970- 1980, also regarded against the background of recent developments in the eighties, he was very frank in putting forward that his contribution had probably lacked enough of a steering element. Steering both in regard to those giving instruction and the alignment of the instruction material. Seen in that light it is no coincidence that the keyword 'reinvention' from this first major work (1973) is called 'guided reinvention' in his last book (1991).
Summary
Realistic learning strands start with the informal context bound working methods of children, in their personal reality. From there models, schemes, symbolisations are developed which serve as intermediaries to gradually bridge the gap between these start situations and the level of the formal, more general subject related operations. The learning of the tables for instance starts with the item about the number of days in so many weeks. Visualising via the time line and the calendar leads directly to the (empty one sided and double) number line and the rectangle. Two master models which are of essential importance for insight in multiplication, also in the areas of ratios, fractions and measuring. And for learning long division a dynamic context problem about the transportation of passengers with buses serves as model context or paradigm that provides a concrete basis for formal operation. The same occurs for fractions with problems about fair sharing and measuring, whereby the language of fractions is developed and where comparing and operating are given a concrete basis of orientation.
With this specific vertical mathematising combination of the starting situation from personal reality and the subsequent model forming, schematising and symbolising, and added to the horizontal theme-approach, all of this together distinguishes the realistic approach from the mechanistic, structuralistic and empiristic domain theories and practices. (See Treffers, 1987, 1991b). Freudenthal laid the foundation for this didactical realism and determined the development of concrete education for various main learning strands, but more indirectly than directly because he himself did not design or outline themes and learning strands.

3. INTEGRAL EDUCATION DEVELOPMENT
3.1. Historical Comments
As mentioned before, Wiskobas already existed before the founding of the IOWO in 1971. And the idea of integral education development already existed before Wiskobas became a department of the IOWO. Wiskobas pioneers Wijdeveld and Goffree more or less brought it along when they joined the IOWO, or really, acted as co-founders. The idea to approach innovation of mathematics education on a wide front - via training institutions of future teachers, via in-service training, training of counselors and instructors, research, development, via textbooks, and curriculum development - this was an idea that Freudenthal was most keen on. The more so when he established in 1970 that the Wiskobas movement was not only viable, but that is was also well organized in one national and several regional working groups. When the IOWO was founded he wholeheartedly gave his best efforts towards coordinating and realizing the integral approach of education development in the best possible manner. And it is predominantly due to Freudenthal's authority, status and influence that this integral approach did indeed bear fruits. Even though his critical attitude with regard to educational research, curriculum and test development did guarantee that the discussions were always lively - to put it mildly. The consequence of the broad approach was in any case that at the end of the eighties the development of textbooks, tests and curricula were well attuned to the national final standards and to the (informal) national curriculum (de Jong, 1986). While in many other countries (Ernest, 1991) any such attunement is lacking and the textbooks, the national curriculum and the tests explicitly lack the concrete views of progressive educators. For a description of this process of integral education development and the construction of an adequate infrastructure it would lead too far a field to go into this very complex process at this time. Freudenthal does dwell on the matter rather extensively in his last book (1991) in his outline of 'The Landscape of Mathematics Education', in which he concentrates on theory forming, research and dissemination. These three aspects become visible most explicitly in developmental research. And what Freudenthal writes about it is so important that I would briefly call attention to it here.
3.2. Developmental Research
Developmental research denotes a comprehensive program that is directed at innovation and improvement of education. It is research with an important development component: it is not merely established how things 'are' in existing education (especially research on errors is very popular in this respect) but much more how things should be, and one develops education that suits these findings (in a theoretical and practical sense). Development and research take place in an integrated cyclistic process. And the developer must report on that process: the own learning process therein, and the rational and empiric justification of the developed product must be made clear, so that others can also benefit from it in their development, research and teaching (also see Gravemeijer, 1989). Developmental
This content downloaded from 143.160.38.146 on Wed, 3 Jul 2013 05:07:28 AM
All use subject to JSTOR Terms and Conditions104 AT TREFFERS
research comprises much more therefore than empiric testing, but rather all sorts of aspects of innovation, among them that of dissemination - this as opposed to the more common research. Freudenthal observed that developmental research of this kind does not fit well in the current RD and D model, and therefore also not in regular educational research.
4. CONCLUSION
In July 1990 Freudenthal pointed 'his' associates of the OW & OC (currently the Freudenthal Institute) to the following article in a national newspaper:
THE POLISH KNOWN AS HARD WORKERS
Every year tens of thousands of Poles come to The Netherlands to work in the flower bulb industry for a few months. (...) This is the fourth time for Zygmunt. He has worked both in the fields and in greenhouses. Currently he is working in the transportation department of a company at the flower auction. "I load up the trucks, that is heavy work. On average I work 220 hours per week. That's no problem, because that's the way to make money" says Zygmunt (NRCIHandelsblad, July 1990)
> The question is: Is that possible, to work 220 hours per week?
Children of 9 and 10 (start of grade 4) appear to answer this question in many different ways:
- "I have no idea, I guessed 'yes'."
- "No, because my mother already works 180 hours per week. If he worked even more hours than he already does she would be busy all day."
Interesting answers because it proves that children do not automatically mathematise the problem, for example by coming up with the given that a day has 24 hours and a week 7 days. Children of 5 and 6 do not yet have this knowledge. And apparently neither do some nine year olds. In any case they do not already use reference numbers of this kind.
Even if they do have that knowledge, the reasonings and calculations differ substantially. Take the reasoning which departs from an 'exhausting' work week, therefore of '7 x 24' to refute the result of 220 hours. The calculations of '7 x 24' vary greatly: repeated counting 24 + 24 + 24 + 24 + 24 + 24 + 24 by various calculation methods; front-end method of stylised mental arithmetic 7 x 24 = 7 x 20 + 7 x 4, and the end-front method of the standard algorithm.
Characteristic for realistic mathematics education is that it puts such diversity to good use. For instance the front-end method can be presented as an abbreviation of repeated addition and also as basis for column arithmetic.
This does not exhaust the source of instruction possibilities: efficient arithmetic and estimation can also be used as examples:
- A day has 24 hours, so I take 7 x 25 = 175; minus 7 hours = 168 hours, the answer is 'no' (Figure 4).
- No, because 10 workdays is already 240 hours, so 220 hours would be more than 9 (Figure 5).

All use subject to JSTOR Terms and ConditionsWISKOBAS AND FREUDENTHAL: REALISTIC MATHEMATICS EDUCATION 105
Fig. 4.
"xx t0
wa
Fig. 5.
- No, because 220 7 = 31 2, but a day only has 24 hours (Figure 6).
The example shows how many learning possibilities there are in that one context problem. Not that all of these opportunities must indeed be employed, but one or several should be used, such as the discussion and analysing of the relations between the various solution methods of (stylised) mental arithmetic, estimation and column arithmetic.
Mathematics can be developed from (personal) reality in natural manner: the formal rules and procedures can be derived from the informal working methods of the pupils - that is the heart of didactic realism.
In the first part of 'Revisiting Mathematics Education' (1991) Freudenthal gives an in-depth analysis of the specific 'common sense' character of mathematics. 'Specific' because according to Freudenthal the mathematical activity distinguishes itself there from natural sciences. Elementary mathematics was invented many times over in the world in an independent manner, but there was only one Newton, Mathematics develops according to a gradual ongoing process. But primitive mathematical notions retain their original value as knowledge, skill and insight increase, while the natural science intuitions often prove not to hold after a time. In short, mathematics is excellently suited for gradual rediscovery, accord-

ing to Freudenthal (also see Goffree, 1992). In the second part of his last book the didactical principles of 'guided reinvention' are described, and in the third part Freudenthal concentrates on theory forming, research and dissemination. A few elements from these two parts about didactics and innovation are brought forward in this article about realistic mathematics education:
to bear witness for the product to make it plausible and transferable, which demands an attitude of self-examination on the part of the developmental researcher: a state of permanent reflection. (Freudenthal, 1991).
Much about Freudenthal and his relationship with Wiskobas has not been highlighted: his ideas about levels in the learning process, his views on the issue of assessment, didactical classification methods, the educational-theoretical framework of realistic mathematics education and so on. But most of all his personableness, his intriguing off-hand remarks, his elaborations on seemingly futile observations of learning processes, his passion, his ability to use simple examples to show that mathematics is everywhere, his attention for both 'simple' and 'complex' forms of mathematics, his respect for practitioners of teaching, his admiration for a point well argued, his style of writing, his undisguised disapproval of developers and researchers who do not do justice to mathematics nor to the child, do no justice to mathematics as a human activity, to 'mathematics as an educational task' ...

One of the children answered the Zygmunt-item as follows: 'Yes, 220 hours
per week is possible, because you can load trucks and let the tulip fields grow at
the same time'.
Indeed, that is possible. Because that is also how Freudenthal worked... And
at the same time he let grow the tulip fields of realistic mathematics education. It
was a privilege working together with him in the Wiskobas team.
NOTES
I would like to thank Aad Goddijn, Fred Goffree, Rob de Jong, Edu Wijdeveld and other colleagues
for their useful comments on the first draft of this article.
2 Wiskobas is an acronym for the Dutch translation of 'mathematics in primary school. The Wiskobas
project started in 1968 and was later adopted by the IOWO (Institute for the Development of Math-
ematics Education). When this article mentions Wiskobas it refers to the project team that operated
within the IOWO and after its termination continued its work at other institutes, and in the course
of time was even expanded somewhat. When the text refers to the Wiskobas program, this refers to
the informal National Curculum for arithmetic in primary school that was compiled at the end of
the eighties at the initiative of Wiskobas staff, by a wide group of progressive educators to whom,
for this occasion, we will refer as the Wiskobas movement. Wiskobas spearheaded this movement.
Freudenthal was the most prominent member of this innovative group.
3 The department for secondary education within the IOWO was called Wiskivon. It originated
somewhat later than Wiskobas. Freudenthal's direct involvement with this group was initially less
intensive than it was with Wiskobas. But his ideas also found their way into secondary education via
Wiskivon, both through the SLO (Curriculum Development Foundation) and the research group OW
& OC (currently the Freudenthal Institute).
4 This conversation was held on 11 August 1989, between H. Freudenthal and the author.

(HF. in: Editorial letter 5 July 1978)
In the case at hand however, these so-called heuristics are dependent in a more awkward manner. I
mean, dependent on the specific problem to be solved, and therefore I call them clues - a clue for
every problem and a problem for every clue. It reminds me of teaching techniques such as: '3+2 are
...? No answer. 'Think'. No answer. "F..". "Four". "No". "Five". "Very good'. Of course this is
This content downloaded from 143.160.38.146 on Wed, 3 Jul 2013 05:07:28 AM

an exaggeration but you will understand what I mean. I am not at all surprised that the experimental
group is superior to the control groups.
Then for the subject of 'integration'. Of course, if you train students in a subject like this you
should do it methodically. Unfortunately the first question is whether students should be trained in
a subject like this, or whether there are not more important subjects in mathematics to be taught,
regardless the career the student has in mind. Do not forget that the whole teaching subject of
calculating indefinite integrals was invented to be tested out. I wonder whether it still exists at most
universities.
As a matter of fact almost all efforts to develop diagnostic tools in teaching arithmetic show
the same features as the project you have sent me. One of the most outstanding and worst among
them is the Swedish project. Any physician who would make such a superficial diagnosis, from mere
symptoms, would rightly be labelled a quack. I have never seen any benefit in ascertaining whether
a child is not able to perform this or that partial arithmetical operation even though all of them might
have been carefully selected. It is not important to know which problems a child cannot solve if
no effort is made to ascertain why it cannot. In order to know why children fail, one must observe
them. In medicine it is called aetiology if one tries to find the causes for failure. I am sure this is the
right way to make a diagnosis because in the course of the years I have had some experience with
remedial work, and during the last few years I have cooperated with a group of psychologists, who in
fact have singled out a few important causes of failure, which in a sense are still symptoms, though
more profound than those one discovers through armchair analysis of arithmetical problems rather
than by observing the leaming processes. The tests proposed in your project do not even apply to low
achievement computers, let alone to human low achievers. I suppose that serious work on diagnosing
low achievement in arithmetics has been done and is still being done at quite a few places in the world,
but unfortunately it is lost in the flood of irresponsible work. I call it irresponsible because it seduces
good teachers, who try to understand why certain children fail, to believe that superficial testing may
supersede careful observations, and because it teaches average teachers and student teachers to suffice
by looking for mere symptoms instead of looking for more profound reasons for failure. In the research
I alluded to, it appears that more than 50% of serious cases of low achievement are due to the lack of
any decent instruction, which for that matter is the consequence of poor teacher training. Those poor
teachers, rather than learning to look for possible causes of failure, were educated to believe in blind
tests.

GEOMETRY BETWEEN THE DEVIL AND THE DEEP SEA
PHILOSOPHIES
For many years New Mathematics has meant new subject matter, and this is
what it still means in many cases. Where people tried to teach it, it became
meaning new teaching techniques. There are few people to which it means a
conscious philosophy.
Of course, there is no educator without a teaching philosophy, or should
I say, without two teaching philosophies, an explicit philosophy he professes,
and an implicit one he acts out. The latter is the more interesting and the
more important. I do not like explicit philosophies but I cannot understand
educators unless I make their implicit philosophies explicit. This is why I
start with philosophy. It is too bad, but I cannot help it.
I will try first to answer three philosophical questions. Since they are
questions of a philosophy, that is of human attitudes, they admit a gamma of
answers, and among these answers there are a few which I like better than the
remainder.
My first question is: what is mathematics? I mean not how mathematics is
defined but what is it to the human mind? Les us ask another question: what
is language? There are two answers: language as a stock of words, prefixes,
suffixes, flections, grammar and syntactical rules, and language as an activity
of speaking, reading, writing, and expressing oneself. Linguists consider it as
a great discovery of de Saussure's distinguish these two aspects of language,
ready made and acted out language. Both aspects are operational in language
teaching. As long as children are small they will be taught a language as an
activity, whether it is their mother tongue or a foreign - this does not make
too much difference. As they mature into rational beings, the teaching philo-
sophy shifts from the activity to the ready made subject matter interpretation
of language. You know that it does not work too well. Why not? Because it
is a wrong philosophy? No, there are no wrong philosophies. Both the
stock and the activity interpretation of language are correct but they apply to
different people. The one is good for linguists who take a language as a
subject matter and the other for the users of the language, who in fact, are
the majority.
What is mathematics? Of course you know that mathematics is an activity
because you are active mathematicians. It is an activity of solving problems,

of looking for problems, but it is also an activity of organizing a subject
matter. This can be a matter from reality which has to be organized accord-
ing to mathematical patterns if problems from reality have to be solved. It
can also be a mathematical matter, new or old results, of your own or of
others, which have to be organized according to new ideas, to be better
understood, in a broader context, or by an axiomatic approach.
A great part of mathematical activity today is organizing. We like to
offer the results of our mathematical activity in a well organized form where
no traces betray the activity by which they were created. This objectivation
is a habit of mathematicians from the oldest times. It is a good habit, and it
is a bad one. We freeze up the result of our activity into a rigid system, be-
cause this is objective, because it is rational, and because it is beautiful, and
this we teach.
Few people know that mathematics is an activity. Little children are
taught mathematics as an activity, but as they mature into rational beings,
we are prone to teach them a well organized prefabricated deductive system
of mathematics, because rational beings may be supposed to understand
deductive systems. You know that it does not work very well.
My second question is: what is education? It is good luck that the first
piece of education in history we know about, is a lesson of geometry, the
socratic lesson Menon's slave was taught on doubling the square. Socrates
taught the slave not the solution of the problem nor solving the problem, but
finding the solution by trial and error. He did not teach a ready made solu-
tion but the way of reinventing the solution. Two millenia later Comenius
said: "The best way to teach an activity is to show it." This is a socratic idea,
though it involves more than a socratic lesson. While Socrates taught his
lesson, the slave listened, whereas Comenius will show the student an activi-
ty to explain afterwards what it means and finally to have it imitated by the
student.

Modern educators are likely to subscribe to a variation of Comenius'
device. Not
"The best way to teach an activity, is to show it" but rather
"The best way to learn an activity, is to perform it."
It is a mere shift of stress though it is an important one.
The traditional answer to the question "what is education?" is "transfer of
culture". I think it still prevails. Recently I discussed the task of the univer-
sity (or rather the Task of the University) with a bunch of students, mostly
from the humanities. Its task is, they said, to provide information, and if they
challenged the university, then they did so because the university provided
not enough information, or wrong information, or biassed information, or
because it suppressed information. The university should offer its disciples

All use subject to http://about.jstor.org/terms GEOMETRY BETWEEN THE DEVIL AND THE DEEP SEA 415
an encyclopedia of all available information, and from this they would
choose what they liked. Maybe this was just the look of the disciplines they
studied (if they studied at all and did not refer to information about the
study). Anyhow they seriously believed that elsewhere studies were conduct-
ed according to such medieval didactics; that the future physician was told
by his professors how to cure illness, the engineer how to build bridges, the
mathematician how to calculate. In fact this was once the practice of teaching.
Today, I told them, scientific aptitudes are taught in hospital wards, labo-
ratories, and practice rooms, and for the advanced student participation in
research is a chapter of his curriculum. They agreed that cycling, swimming,
skiing cannot be learned from a textbook, but I could not convince them that
science was as well an activity that could be learned, not in lectures and from
books, but by acting it out.
No astrologuer is needed to read the writings on the wall. The students
I told of who could understand the learning process only as an information
flow, are the same who reproach the university that it provides wrong infor-
mation and who would use the information channels of the university to
funnel what they consider as true information. If this were the point, they
would even be right. The only answer they should be given is that learning is
a different thing but receiving information.
From Comenius onwards learning has been becoming more and more an
activity. This has been a consequence of the changes in science and society.
For this reason I may dismiss the question whether people learn better by
active building up the subject than by passive reception of a ready made
matter. In fact much depends on the kind of subject matter what is better. It
does not matter whether the authoritarian method of cultural transfer is bad
or wrong or inappropriate in the learning process. It is much worse: this
method is simply impossible, it does not agree with the character of modern
society. The authority of the older cannot be maintained in the learning pro-
cesses of emancipating youth. Our cultural assets are too dangerous to be
offered the youth as ready made material. The instruction we provide should
create the opportunity for youth to acquire the cultural heritage by their own
activity. They should learn that the selfreliance they claim elsewhere extends
to their own role in the learning process.
My third question is about mathematical education. Should mathematics
be taught according to a deductive system? Most mathematicians are prone
to answer in the affirmative. Maybe it is not always possible, but in principle
it should. In any case they will try.
How can you teach logarithms before a theory of real number? How can
you teach probability without an axiomatic definition of the fundamental
concepts? How can you teach angles before analytic functions? How can
This content downloaded from 143.160.38.146 on Tue, 24 May 2016 06:16:52 UTC
All use subject to http://about.jstor.org/terms 416 HANS FREUDENTHAL
you compute the area of cylinder, cone, and sphere before superficies of
curved surfaces has been defined?
How can it be done? It can. It happened in history and didactically it is
the correct way. Logarithms were invented when the ancient theory of real
number was eclipsed by more naive approaches. Probabilities were computed
for centuries without axiomatic principles. Angles are as old as mathematics
itself. Fortunately Archimedes has never been bothered by H. A. Schwarz'
paradox on the area of curved surfaces.
Actually students can learn to work with the slide rule without any
axiomatic or any creative definition of real numbers and can discover the
logarithmic property of the area of the graphic for $y = 1/x$ before they know
integrals. They can work with probabilities as soon as they know fractions.
They can understand and work with angles in mathematics and reality.
They can find out areas and volumes by rational means with no general
theory on areas and volumes.
Of course, mathematics involves deductivity. Working with the slide rule
and the protractor is no mathematics, measuring areas and volumes is no
mathematics. But accepting a deduction is no mathematics either, unless you
adhere to the interpretation of mathematics as a ready made subject.
In which order, if not in a deductive one, should mathematics be taught?
The answer is simple: in that one in which it can be learned, which means,
the order in which it could be invented by the student. This is not at all a
revolutionary idea. It is the socratic lesson. In a thought experiment the
teacher has been reinventing the subject matter as though he himself were
the student, and this is what he teaches. Modern didacticians would require
that rather than teaching the reinvention, the teacher should have the stu-
dent reinventing himself the subject matter. This is a modern reenforcement
of the socratic idea.
Let us take the example of teaching Peano's axioms on natural numbers
to a boy who knows quite a bit of school algebra. The deductive approach
would be formulating the axiom system to derive a series of theorems from
it. The thought experiment, on the other hand, guided by historical expe-
riences, shows that nobody can invent Peano's axioms unless he has first
formulated the priciple of complete induction. Further, nobody can formu-
late complete induction unless he knows what it is, and there is no knowl-
edge about complete induction, unless it has been experienced as a proving
activity. So the student should be brought into one or more situations where
he can reinvent the trick of inductive reasoning. There are quite a lot of them,
Pascal's trinagle, number of permutations, fundamental arithmetical laws,
and so on. With virtually no help students learn to find and so use the prin-
ciple of complete induction, though it is a hard thing to formulate it. From
This content downloaded from 143.160.38.146 on Tue, 24 May 2016 06:16:52 UTC
All use subject to http://about.jstor.org/terms GEOMETRY BETWEEN THE DEVIL AND THE DEEP SEA 417
complete induction one could proceed to Peano's axioms if the thought ex-
periment shows a way to do it. Of course, the student cannot hit on the idea
of framing complete induction into an axiomatic system, unless he has
already acquired a certain experience of axiomatic systems, that is of axio-
matizing. If he has not, Peano's axioms is certainly not the best example to
start axiomatics with.
The previous example shows a remarkable structure of the learning pro-
cess which completely differs from the deductive structure of mathematics.
The van Hieles called it the levels in the learning process. The student applies
certain new rules unconsciously until at a certain moment he becomes con-
scious about them. From analyzing the structure of the subject matter he
switches to analyzing his own mathematical activity. He grasps the laws and
regularities of his activity, which enables him to apply them more conscious-
ly. Maybe he even succeeds in formulating their principles in general terms.
The van Hiele levels of the learning process are often characterized by a
logical feature: the activity on one level is subjected to analysis on the next,
the operational matter on one level becomes a subject matter on the next
level.
Mathematics on the lowest level used to be allowed to start as an activity.
Experiments, in particular by Dienes, have shown that children can per-
form rather involved mathematics on this level, that is to say they can
develop an activity which on a higher level would be interpreted as mathe-
matics. This bottom level is an indispensable precondition of mathematics.
This should be stressed against people who rightly object that it is no mathe-
matics at all. It is bottom-level, it is indispensable premathematics.
Adding numbers represented by counters is no mathematics. As soon as to
add 5 to 8 the child physically or mentally divides the 5 into 2 and 3, it per-
forms an act which on a higher level can be interpreted as mathematics. As
soon as the child grasps this principle and tries to formulate it, it reaches
the first level of mathematics.
WHAT IS GEOMETRY?
For long times mathematics has been synonymous with geometry. In fact,
there existed other branches, too, algebra, trigonometry, calculus, which,
however, were not much more than collections of haphazard, badly founded
rules, whereas geometry was a perfect logical system, where everything
rigorously followed from definitions and axioms. You know that things have
changed; today mathematicians are prone to reject traditional geometry,
because it is not a rigorously deductive system.
The deductive structure of traditional geometry has never been a convincThis content downloaded from 143.160.38.146 on Tue, 24 May 2016 06:16:52 UTC
All use subject to http://about.jstor.org/terms 418 HANS FREUDENTHAL
ing didactical success. People today believe that geometry failed because it
was not deductive enough; to my opinion it failed because its deductivity
could not be reinvented by the learner but only imposed.
There have been many efforts to reform teaching geometry. In my coun-
try Tatiana Ehrenfest-Afanassjewa, the wife and collaborator of the famous
physicist Paul Ehrenfest, was much influential. Her "Ybungensammlung" of
1931 is still a treasure of geometrical exercises. Tatiana Ehrenfest did not
reject deductivity. On the contrary, some deductive system, influenced by
Helmholtz' axiomatics, was the goal of her method. But her geometry
started as a science of physical space, of the space in which the child lives and
moves, as an organization of the learner's spatial experiences.
It sounds oldfashioned to claim that geometry should be related to physical
space. In fact, Tatiana Ehrenfest knew mathematical axiomatics and culti-
vated it, but she was also a physicist who knew about the profound physical
implications of space theories. Many didacticians today would reject physi-
cal space as a field to be organized by mathematics. We are mathematicians,
or are we not? We are builders of mathematical structures, and if physicists
and other people can use them, they may take them, but no deductive
system can be built on the quicksand of reality, and mathematics may not be
contaminated by elements which are foreign to deductivity. If for instance
the system commands us to start geometry with the affine plane, then physi-
cal space with geometry with its solid bodies, its distances, deplacements and
fittings is only in obstacle to good mathematics.
This is one philosophy, and I think it is a good philosophy. As long as
people are building a deductive system they are often obliged to close their
eyes for the seductions of reality. But there are other activities, and there
are people who will never build deductive systems of their own or even
rebuild those of others though they need mathematics. We cannot expect
them to espouse this philosophy.
Finally nobody can deny that we live in space, that we move in space, that
we analyze space, to be better adapted to it. In fact, we are so much used to
space that we easily forget about its importance for ourselves and for those
we are educating. Let us ask a few haphazard questions:
Why does a piece of paper fold along a straight line?
Why does a rolled piece of paper become rigid?
Why does a tied paper ribbon show a regular pentagon?
How do shadows originate?
What is the intersection of a plane and a sphere, of two spheres?
What kind of curve is the terminator on the moon?
Why can the radius of a circle be transferred six times around periphery?
This content downloaded from 143.160.38.146 on Tue, 24 May 2016 06:16:52 UTC
All use subject to http://about.jstor.org/terms GEOMETRY BETWEEN THE DEVIL AND THE DEEP SEA 419
How come a beautiful star arises by this construction?
Why is the straight line the shortest?
Why do congruent triangles fit to cover the plane and why do congruent
pentagons in general fail to do so?
How can people measure big distances on the earth, the diameter of the
earth, and distances of celestial bodies?
What does a cube look like if viewed along a spatial diagonal?
What is larger, the superficies of a sphere cap, or that of the cylinder around
it?
What is the shortest path for a light ray to travel from one point to another
while touching a mirror?
How does a kaleidoscope work?
What is the biggest sphere in a tetrahedron?
Which kind of closed curves are equally as wide in all directions?
How does the liquid level in some vessel change if a certain quantity of
liquid is added?
What is the relation between real and apparent size of a body?
If a cube is split into six square pyramids with their vertices in the center and
these pyramids are turned outside upon the corresponding faces, why
does a rhombododecahedron arise?
How can you measure the inclination of a line and a plane, or of two planes?
Is there a horizontal (a vertical) line in every plane?
What is the difference between a right and a left screw and why are not they
equivalent under rigid motions?
What is a rigid motion on the sphere?
Why is a convex polyhedron rigid?
Why can a table with four legs wobble, and what is the difference with a
table with three legs?
Why does a door need two hinges, and how can we add a third?
And finally the old question: why does a mirror interchange right and left

though not above and below?
Notice that I did not ask any questions of practical use. My task would have been much simpler if I had done so. Notice, too, that there were no "puzzles" in the list, but only questions of principal importance and which nevertheless can be answered with little ingenuity.
Many mathematicians will consider my questions as irrelevant in teaching mathematics. With no regret they would leave them to physicists or other kind of people if need be that students get acquainted with space. Indeed, almost none of those questions can be fitted into a preconceived system of mathematics. To be sure, this is not only true for such questions of geometry,
This content downloaded from 143.160.38.146 on Tue, 24 May 2016 06:16:52 UTC
All use subject to http://about.jstor.org/terms
but for almost all questions which arise in reality. In particular, probability is an instructive case. All real problems of probability are irrelevant for an axiomatic probability fitted into a preconceived system of mathematics, and axiomatic probability in turn is irrelevant for solving real problems in probability.
I espouse the philosophy of teaching mathematics related to reality. Mathematics is important for many people because it admits of multifarious applications. I do not trust teachers of other disciplines to be able to tie the bonds of mathematics with reality which have been cut by the mathematics teacher. Moreover, I do not believe that mathematics, not tied to lived reality with strong bonds, can have a lasting influence in most individuals. We mathematicians retain the mathematics we learned, because it is our business. People usually forget what is not related to the world in which they live. For most people mathematics cannot be an aim in itself; if they have learned it in an unrelated way, they will never be able to use it.
CONCRETE MATERIAL THE CHILD CAN HANDLE
Tatiana Ehrenfest developed an introductory geometry course of exercises in space. Meanwhile many others designed concrete material, in our country for instance the van Hieles and van Albada, to stimulate a geometric activity of folding, cutting, glueing, drawing, painting, measuring, fitting, paving. People generally call it experimental geometry. I do not like this word. If the word means that the student is expected to experiment, then the greater part of his mathematical activity should be experimental, as is ours as far as we are creative mathematicians. If the term is chosen to remind of experimental physics, it is wholly mistaken. "Experimental geometry" suggests procedures like determining X by measuring a string laid around a circle periphery, a silly exercise you will never meet in such collections. In former times they called it mensuration, an activity which leads nowhere. The introductory geometry exercises by Ehrenfest and others, however, are zero level activities in that they prepare for the higher levels. The attitude of the children who work with this material greatly differs from the realism of the physical laboratory. To illustrate this I will give you a few examples.
Children in Dina van Hiele's class (12 year olds) got the task to design a sidewalk pavement with square flagstones. One of the children drew stones with cracks and sandgrains in the groves between the stones. One hint was sufficient to convince the child that these were inessentials in geometry.
Dina van Hiele gave the children bags with congruent cardboard triangles, quadrangles, pentagons, hexagons, which should be used as tiles to pave the plane. The pieces were not congruent enough to give a good fitting, but
This content downloaded from 143.160.38.146 on Tue, 24 May 2016 06:16:52 UTC
All use subject to http://about.jstor.org/terms
the children never complained; they built the patterns as though they were regular and understood them as regular. In general from the beginning of geometry they accept bad fittings and imperfect congruencies and symmetries as though it were perfect ones.
As the children get the task to draw a triangular pavement, they will first use the cardboard material but as soon as they have grasped the pattern, they will finish building and start drawing. None of them will add the drawn triangles piecewise but all of them will first draw long horizontal lines between which the triangles are to be fitted. Some of them use a second set of parallel lines; it is very rare that a child starts with drawing immediately three sets of parallel lines.
DINA VAN HIELE'S EXPERIMENTS
Before Tatiana Ehrenfest it was an axiom that geometrical instruction started in the plane. More precisely it started with points, continued with lines, and since the plane were the place to locate these objects, all happened in the plane. Tatiana Ehrenfest once told when she taught classes, parents complained that she discussed spheres with children before they had learned defining straight lines. In many countries plane geometry started in the 7th grade, geometry in space in the 10th or 11th grades. Children who were good in plane geometry, often failed in space geometry. Their spatial imagination had been killed by too much and too exclusive plane geometry. In our country the usual start in geometry is now in space. To give an example, I sketch Dina van Hiele's first course, with 7th graders.
She started geometry with the cube, but of course with no definitions. Cubes of different material were shown, cardboard, wooden, meccano cubes. The discussion led to constructing cardboard cubes. In this process the children became acquainted with the geometrical instruments and with fundamental notions such as right angles (defined by folding). In the meccano cube two kinds of diagonals were identified. After face diagonals had been drawn on the selfmade cube, the question arose how to find exactly the spatial diagonals. The teacher showed a cube with its upper face open to allow a look inside. There was a cardboard diagonal partition wall in it. The wall could be removed. It was a rectangle. The children understood this hint to construct the spatial diagonals. The children made a cardboard partition rectangle and noticed that it could be fitted in several ways into the cube. In how many? Other examples of double counting were dealt with. The children made more regular bodies.
The class then proceeded to studying symmetries first in space, then with plane figures. One half of a symmetric figure was completed to a whole. A

All use subject to http://about.jstor.org/terms
mirror was used to check the result; the discussion led to an analysis of the concept of symmetry. A host of symmetric figures were considered and constructed. The discussion then focussed on the rhomb as a starting point for many constructions. This trimester of geometry finished with angles. Of course no definition of angles was given. Angles were made, estimated, measured. The principle of this first stage of geometry was, as Dina van Hiele put it: Rationally guided operations with concrete material.
A detailed report on a second trimester's course has been the main subject of Dina van Hiele's thesis. It is the wealthiest treasure of didactic observation and analysis in mathematics I ever saw.
The subject of this course was "tiles". After the children had become acquainted with congruency and regular polygons, they were given bags containing congruent regular polygons as a first concrete material to study the covering of the plane by congruent shapes. The children discovered by reasoning that the angles of a triangle sum up to 1800, the analogous facts for other polygons, and the interrelation between these facts. They discovered why certain shapes of tiles did not fit to cover the plane. (Not all pentagons, but are there pentagons that fit!) Logical relations were put into arrow patterns. In the triangular pavement the children discovered parallelograms, "saws", "stairs", equality of angles, "enlargements", symmetries and regularities; areas were compared by decomposition. Logical arrow patterns were combined into logical "trees".
The third trimester subject was again congruency, mainly in space. Solids were made, and volumes were compared by decomposition. The final piece of work and the acme of the course was the construction of the rhombododecahedron.
FITTING
I could only sketch the subject matter of Dina van Hiele's first course. The method and its analysis is more relevant. Though the plane provides easier opportunities of logical analysis in geometry, space with its solids is more concrete. It better meets the children's creative wishes. Figures are drawn, solids are made.
There is one exception in plane: paving a floor with congruent tiles. Here the leading psychological idea, I mean fitting, is the same as in space and it is realized as concretely. Fitting is a motor sensation. Psychologists can tell you how strongly the motor component of the personality is marked at a young age, how important motor apprehension and memory may be.
Things fit. Do children ask why? Apart from a rare exception young children do not. All these miracles of our space do not seem to make any impression. But they grind as millstones. The highest pedagogic virtue is
This content downloaded from 143.160.38.146 on Tue, 24 May 2016 06:16:52 UTC
All use subject to http://about.jstor.org/terms
patience. One day the child will ask why, and there is no use starting systematic geometry before that day has come. Even worse: it can really do harm. The clue of geometry is the word "why". Only joy-killers will deliver the clue previously. The miracles of fitting are to prepare maturity for systematic geometry. But even if this has been reached, they will not become redundant. They are raw material for geometrical thinking. The child should recall and reconsider the treasure of old problems at every new stage.
Of course fitting as a leading idea requires that space is acknowledged as the home of solid bodies. There are no fitting problems in affine geometry. Affine geometry is a sophistication that needs a lot of deductive experiences to be invented. It can never be the start of geometry.
DEDUCTIONS
There are many ways of organizing the child's exploration of space. I quoted Dina van Hiele's because it has most profoundly been analyzed. The period covered by Dina van Hiele's course shows a steady though discontinuous growth of the child's ability to logically organize his own activity. On level 0 the child is thinking as it were with his hands, his eyes, his kinesthesis. To the viewer who knows mathematics the child's activity looks like mathematics. When the teacher shows the partition wall of the cube, the child succeeds in constructing its spatial diagonal, and this activity can be interpreted by the viewer as the same reasoning that leads himself to construct the spatial diagonal. In geometry the child can for a long time continue this 0-level activity until it starts reconsidering it consciously - there are quite a few who excellently perform on this level and never reach a higher one, but the reason that they fail often is that they are pressed too early and helped by algorithms to simulate acting on a level they did not reach.
Several times I stressed that in this approach no definitions are provided for geometrical objects when they are introduced. If the antididactical inversion is applied, a deductive exposition starts with definitions. (Traditional geometry texts even define what is a definition, which is still a higher level of learning.) In socratic didactics such an approach would be impossible since nobody can define a thing unless he knows what he should define. It is even worse in mathematics, where "definition" has a very special meaning. A definition in mathematics does not just tell people what a certain word is supposed to mean, but definitions become links in a deductive chain, and you cannot forge the link unless you know where it should fit.
If Dina van Hiele showed their students a cube, a rhomb, a parallelogram, or if she gave examples of congruent figures, the students never failed to understand which shape she meant, as well as they recognize what is a chair,
This content downloaded from 143.160.38.146 on Tue, 24 May 2016 06:16:52 UTC
All use subject to http://about.jstor.org/terms
or a bottle, or a doll though this has never been defined nor have they been confronted with all objects of these sorts. Of course there may be some uncertainties, for instance whether a square should be counted among the rhombs, and a rhomb among the parallelograms. Though the teacher can impose definitions that settle the questions, this means degrading mathematics to something like spelling, ruled by arbitrary prescriptions.
If the child knows what a rhomb or a parallelogramme is, it may visually discover properties of these shapes. There are a lot of them, and in the class discussion children will recite them. A parallelogramme has its opposite sides equal and parallel, its diagonals bisect each other, opposite angles are equal, adjacent angles are supplementary, the parallelogramme has a centre of symmetry, it can be split into congruent triangles, congruent parallelogrammes will cover the plane. There are a host of visual properties which ask for organization. Here starts deductivity; rather than being imposed it unfolds from local germs. The properties of the parallelogramme become deductively interrelated, and finally one emerges (maybe different ones for different children) from which the others can be deducted. This property can be taken as a definition, and now it can be understood why a square and a rhomb should be considered as parallelogrammes. By this activity, the child learns defining, too, and it experiences that in mathematics a definition is more than a description, that it is a means of organizing properties of a thing deductively. However, on this level the child would not yet be able to analyze the process of defining and to tell what is a definition. Indeed, this is again a higher level of the learning process.
To those who believe in a system, this method is a horror. A deduction needs a firm ground, and you cannot reason rigorously about things you have not rigorously defined before. This is a sound philosophy though it is not that of a creative mathematician. Definitions are not preconceived to derive something from them, but more often they are just the last element of the analysis, the finishing touch of organizing a subject. Children should be granted the same opportunities as the grown-up mathematician claims for himself. Telling a kid a secret he can find out himself is not only bad teaching, it is a crime. Have you ever observed how keen six year olds are to discover and reinvent things and how you can disappoint them if you betray some secret too early? Twelve year olds are different; they got used to imposed

solutions, they ask for solutions without trying. Good geometry instruction would be a means to teach them a lot of things, to teach them organizing a subject matter, and what is organization, to teach them conceptualizing, and what is a concept, to teach them deducing, and what is a deduction, to teach them defining, and what is a definition, to have them to distinguish why some organization, deduction, definition is better than others. Traditional inThis content downloaded from 143.160.38.146 on Tue, 24 May 2016 06:16:52 UTC
All use subject to http://about.jstor.org/terms GEOMETRY BETWEEN THE DEVIL AND THE DEEP SEA 425
struction is different. Rather than giving the child the opportunity of organizing spatial experiences, the subject matter is offered as a preorganized structure, with all concepts, definitions, deductions preconceived by the teacher who knows of every detail which aim it serves - or rather by the textbook author who has carefully built in all his secrets.

THE SYSTEM

Traditional geometry was taught as a deductive system. It was a fake system but by teaching it teachers used to indoctrinate themselves to believe in the system. In that time geometry was the only part of mathematics that was taught according to a system, while other parts were simply collections of thumb rules. Things have changed. There have been rare attempts to save the character of geometry by means of some Hilbert style axiomatics. The other extreme is, rather than mathematics, to teach a system of mathematics and to fit geometry into this system. Which pieces of geometry are really fitted into the system and on which places, does not depend on geometry but on the system. The usual frame is to begin with affine vector space on which later on an inner product is imposed. The most conspicuous aspect of space, I mean fitting, is disregarded and ignored by affine geometry. But it is still worse. In such a rigid approach no opportunity is left for children to explore space and the bodies in it, to organize the subject matter, to invent definitions and deductions. Among all the problems I quoted when I asked 'what is geometry?' there is none that can meaningfully fit into such a system. Maybe you can compute the intersection of a sphere and a plane or of two spheres by linear algebra but to discover that the result is a circle you have to know what is a real sphere in real space. Of course you can figure out that the radius of a circle is the side of the inscribed regular hexagon by means of an analytic proof if you like proofs that obscure all essentials. To discover that congruent triangles can cover the plane, while pentagons can in general not, linear algebra is entirely unfit, but is even no appropriate means to prove such facts. I would be able to continue this way with all examples I gave earlier. The geometry allowed by linear algebra is an utterly dreary product. Its highlights are to prove that two different straight lines can have none or one intersection, that for circles these numbers are 0, 1, or 2. Maybe vector algebra still provides a tasteless proof for the three bisectors of the sides of a triangle passing through one point. The only geometrical subject that could adequately be tackled by vector space, I mean barycenter and convex bodies, is generally disregarded because it does not fit into the system of mathematics. Usually such a system of mathematics is not less ramshackle than old geometry was, but today the authors learned how to make more successful
This content downloaded from 143.160.38.146 on Tue, 24 May 2016 06:16:52 UTC
All use subject to http://about.jstor.org/terms 426 HANS FREUDENTHAL
attempts to hide its deficiencies. This, however, is not the feature for which I blame system builders. It is rather the dogmatism of the system, and the didactical inversion. Systembuildingcould be one of the aims of mathematical education and maybe even a realistic one provided that organizing a subject matter has been exercised on a lower level. An imposed system, however, prevents the student from learning organizing a subject matter on any level.

GEOMETRICAL AXIOMATICS

Some people have been anxious to save genuine geometry from denaturation by linear algebra. To do so, they tried geometrical axiomatics. In fact, it is another way to kill geometry. It is more or less Hilbert-style axiomatics, with a long list of axioms, most of them seemingly trivial, though there may be a few quite complicated ones among them. The deductional structure usually is quite sketchy; the greater part of argumentations consists of such formulas as "it is easily seen that ...", and "we omit the proof which would be lengthy though it would not offer any new insight". It is a frank confession and it is true; reasoning within such system is, indeed, a dreary occupation. What is interesting in an axiomatic system is constructing it and verifying whether it is complete, that is, checking whether its geometry can be coordinatized in the usual way. If somebody needs geometry in algebra or analysis, he never reasons within an axiomatic system, which would be much too complicated.

It is not because of its complexity that I blame such an axiomatic system. It is the way in which it is offered to the students. They should use it to perform mechanical deductions in it, an activity which the author honestly dismisses as irrelevant. The essential activities around such an axiomatic system are reserved to its author: first, organizing globally the geometric subject matter to get the axiomatic system, cutting the bonds with the organized subject matter, to afterwards restore them by checking the completeness of the system. Geometrical axiomatics cannot be meaningful as a teaching subject unless the student is allowed to perform these activities himself. Usually he is not allowed to do so. Either the author judges that axiomatizing is a business of grown up mathematicians rather than of learners, or he knows from his own axiomatizing activity or a thought experiment that it would be much too difficult for the student. Indeed, a student who never exercized organizing a subject matter on local levels will not succeed on the global one. Prefabricated axiom systems have merits of their own. They are an acceptable subject matter for people who are experienced in axiomatizing. If a student has learned axiomatizing with easier material, he will recognize in a complicated axiomatic system the same features he
This content downloaded from 143.160.38.146 on Tue, 24 May 2016 06:16:52 UTC
All use subject to http://about.jstor.org/terms GEOMETRY BETWEEN THE DEVIL AND THE DEEP SEA 427
knows from his former experiences, and he will be able to disentangle this system and to understand it as though he built it himself. But if axiomatizing has never been exercized, such an axiomatic system of geometry is only one more piece of indigestible mathematics.

The method by which the axiomatician attempts to save geometry from the claws of linear algebrists, is: competing with the mathematical rigor of linear algebra. It is a mistaken idea.

RIGOR

System builders know one level of mathematical rigor and often they manage to stick to this one during a course of many years. All below this level, which is their own, they consider as fake, and all above as highbrow. Active mathematics, however, knows many levels of rigor, and good teaching should respect them. It should also respect the fact that rather than being imposed each of these kinds of rigor should naturally develop in the learning process. On a low level it can be rigorous figuring out 8 +5 by counting five more steps from eight. On the next level the learner is required to split it into (8 + 2) + 3 and to use mental addition tables up to 10. Still later it is rigorous to know 8 + 5 = 13 by heart and to use it as a technique of addition tables up to 20. On a certain level it may be rigorous to read 5-8 from the number line, on a higher level rigor would mean to prove it by a kind of induction, on a still higher level rigor should require that it is understood as a definition, and finally it can be rigorous as a deductive consequence from an axiomatic system.

Every subject matter knows, on the level on which it is tackled, its own criteria of rigor. In the learning process they arise as tacit conventions between the learner and his surroundings, which are dropped or modified as the learning process continues. Reaching a certain level implies knowing by which rules of rigor it is governed, the main deficiency of an algorithmic activity on a level which has not actually been reached is that the learner does not master the rigor of that level.

This level theory of rigor is not to excuse sloppiness. Verbalistic definitions and arguments that in fact neither define nor argue anything, are as bad on every level. Circularity of arguments shows the same features on any level, though the criteria of circularity may vary. In a highly formalized system non-circularity can be checked by a computer, but you have to educate your mathematical sensitivity to feel on any level what is a circular argument. Axiomatics is not at all the highest level of rigor. Most axiomatics are poorly formalized, in particular those of geometry. This is no blame if the degree of formalizing corresponds to the level on which the axiomatic system is presented.

AXIOMATICS AND TRADITIONAL DEDUCTIVITY

Often the objection is raised: Traditional deductive geometry is also axiomatics though it is the bad one of the juggler who is hiding his axioms in his tophat and sleeves. Is not honesty a better policy?

The assertion that traditional deductivity and axiomatics proper are not essentially different is both right and wrong. Axiomatics from Pasch and Hilbert onwards up to our days, presupposes the syntax and semantics of of every day language. One defines "lines are parallel..." and continues speaking of "parallel lines", "parallel projection", "parallelism", and so on, one defines "intersecting lines" and continues with "lines that meet each other". Of course this is entirely justified on this level. But there are other levels. One can take offense of this linguistic unformality and try to formalize axioms and other statements. Formalizing, too, knows levels: on a very high level even deduction is being formalized. It is not true that axiomatics is the summit of honesty and rigor. Every level knows its own honesty and rigor, which cannot be enforced in teaching, if the student has not reached this level. It is again and again attempted, though with sham success. Geometrical axiomatics is particularly dangerous. High level tricks are so easy and captious to be built in. The author hopes that thanks to the automatism of the axiomatic method these built-in features would function automatically, that is, without the students' understanding of the trick. I know such policy is not unusual in teaching though conscientious educators fight it. I fear axiomatics may lead us deeper into this swamp.

If didactically viewed, axiomatics and traditional deductivity are much different. The difference can be characterized as that between global and local organization of a subject matter. Everybody knows how long it lasts to have an average student view a proof as a whole. It lasts still longer to have him oversee the connections with other propositions. If, with much trouble, he has reached this level, he is pressed upon the next, the global organization. There is still another important factor. In the course of his instruction the student has become acquainted with two kinds of defining, the descriptive definition which fixes a familiar subject by reading characteristic properties from it, and the algorithmically constructive, creative definition which produces new subjects out of old ones. Axiomatics shows another feature by which it is distinguished formally and didactically from traditional deductivity: the implicit definition, which through descriptive, is creative but not in an algorithmic way.

LOCAL ORGANIZATION

How to save geometry if axiomatics cannot do it? Nobody would ask how to
This content downloaded from 143.160.38.146 on Tue, 24 May 2016 06:16:52 UTC
All use subject to http://about.jstor.org/terms GEOMETRY BETWEEN THE DEVIL AND THE DEEP SEA 429
save physics or zoology, which have never been axiomatized. Students learn to figure out the price of 3 pounds of sugar if that of one pound is given, and the area of a rectangle if the sides are known, though the greater part of the notions involved have never been fitted into an axiomatic system. In applying mathematics you never move within an axiomatic system, and if by chance somebody would ask how to save applications, he probably would mean how to protect them against the axiomatic dogmatism. Probability is a most beautiful application which is gravely endangered in teaching to be killed by axiomatics.

Geometry can be saved if it is presented as a field in which the student can be active. As a prefabricated subject it is due to die by suffocation.

I already explained how in introductory geometry the student can learn to invent organizing the shapes and phenomena in space, by means of geometrical concepts and their properties. On the next level he would organize these concepts and properties by means of relations of a logical nature. On a still higher level this relational system may be a subject of investigation.

Let us take one example. The crucial mathematical childhood experience of quite a few mathematicians who wrote autobiographies, was the perpendicular bisectors of a triangle passing through one point. It is, indeed, a beautiful theorem. Children can easily find it, provided it is formulated in a less symmetric way: "Draw the bisectors of AB and BC, which intersect at M; look where the bisector of AC passes." Let us analyze the proof in the same way as the learner should do after he found it.

The proof rests on the property of the bisector of XY being the set of all points equidistant from X and Y, which may have been recognized by symmetry arguments. M is on the bisector of AB whence

MA = MB;

M is on the bisector of BC whence

MB = MC.

From both follows

MA = MCI,

whence Mis on the bisector of AC.

The proof is a combination of a few surprises. The first and second equalities are found by applying the bisector property one way, the third is a consequence of applying it the other way, the third is a consequence of applying it the other way. First and second, M is on the bisector, thus M is equidistant, third, M is equidistant, thus M is on the bisector. I think this is the first psychologically convincing occurrence of the logical complex
This content downloaded from 143.160.38.146 on Tue, 24 May 2016 06:16:52 UTC
All use subject to http://about.jstor.org/terms 430 HANS FREUDENTHAL

characterized by such concepts as inversion, necessary and sufficient, if and only if.
The next surprise is the transitivity of the equality of line segments. The seemingly trivial property of transitivity should be made explicit to understand the proof. Again I think it is the first possible approach to the transitivity property and the first example of its productivity.
The third surprise is that such a symmetric statement as that about the three perpendicular bisectors must be tackled in an asymmetric way to prove it. It is an important step to learn that "three lines pass through the same point" means the same as "one line passes through the intersection of the two others". It is the first example of a methodological paradigm which serves up to the highest levels of mathematics.
The fourth and maybe the greatest surprise is that an incidence theorem (three lines passing through one point) is proved by metric arguments. It requires a not so easy analysis to understand the profound reason of this feature.
Finally it may be mentioned that the theorem leads to the fascinating construction of the circumcircle.
The proof of the theorem on the perpendicular bisectors is not only a marvelous piece of geometry, and a rich source of didactical ideas, it is a good example in geometry for what I have called, local organization. It can be dealt with as soon as children have understood the perpendicular bisector as a locus of equidistance. They need not be able to prove this crucial property of the perpendicular bisector. A proof of the locus property of the bisector cannot contribute anything to the understanding of the circumcircle theorem. I even doubt whether a proof of such an obvious fact as the locus property of the bisector can be recommended at an early stage. At a more advanced stage, it would make more sense to ask why the perpendicular bisector of XY is the locus of points equidistant of X and Y; then one may even ask why equality is transitive, which comes down on understanding what equality means. One can ask why the bisectors of different sides of the triangle intersect, why straight lines have at most one intersection. Of course such an arrangement contradicts the philosophy of mathematics as a prefabricated system. It is the way of exploration, in mathematics and in any science whatsoever, the way to understand and explain phenomena.
The question why the bisectors are concurrent is much alike that why the electric bell rings or why it does not, why the stomach does digest food and why it does not digest itself; why comets have a tail, and who committed the murder. It is questions "why?" asking for a reason or for a cause. And they have also in common that no answer is definitive. You can continue asking "but why is the bisector a locus of equidistance?" "why is equality
This content downloaded from 143.160.38.146 on Tue, 24 May 2016 06:16:52 UTC
All use subject to http://about.jstor.org/terms
transitive?", "why does the current activate the electromagnet?", and so on.
The answer to any question contains the germs of fresh ones. It is an apparently infinite chain, although Aristoteles believed it could be suspended on the principles as the first reason and on God as the first cause. But does it really matter whether the chain is infinite or not, if at least I am able to avoid circularities? The practice of every day knowledge as well as of science, indeed, is, at a certain moment, to stop asking why. To repair the bell, I do not need Maxwell's theory, and if I study Maxwell's theory, I can dismiss field quantization.
I admit from this point onwards mathematics is a bit different. Mathematicians invented the axiomatic trick, that is accepting the vice of circularity as a virtue. You stop asking what are points and lines; instead of an explicit definition you tell what you are allowed to do with them. Actually every science behaves so, every science is based on implicit definition, but mathematics is the only one in which this is cultivated as the summum of deductivity, and even more, after a system has been axiomatized, its bonds with reality can be cut; by anontologization it becomes a self contained field.
We are again back at axiomatics, but I think we can now more clearly distinguish what axiomatics means. A mathematical text may start with axioms because it is ready made mathematics. Mathematics as an activity never does so. In general, what we do if we create and if we apply mathematics, is an activity of local organization. Beginners in mathematics cannot do even more than that. Every teacher knows that most students can produce and understand only short deduction chains. They cannot grasp long proofs as a whole, and still less can they view substantial part of mathematics as a deductive system. We are lucky if they can learn organizing locally a mathematizable field of reality or a piece of mathematics itself, because this is just what they will need in every day life and in their profession.
Organizing locally is not a deficient or illicit or dishonest activity in mathematics. It is a generally accepted attitude of the grown up mathematician in pure and applied mathematics even if he would never publish such exercises. None of the various axiom systems of geometry has ever been used to find or to prove geometrical statements if they are needed in algebra or analysis. It is much too complicated and the road from the axioms to important theorems is much too long. The proof is superseded by the firm conviction that it can be done but that it is hardly worthwhile. One is satisfied with the local organization up to a changing horizon of evidence. Coxeter's Introduction to Geometry is a marvellous demonstration of this attitude. The author knows in any case exactly where this horizon is lying, and which kind of rigor is adapted to the subject matter, for instance, that no recourse to the axioms is needed for Morley's theorem on the trisectrices, whereas a theoThis content downloaded from 143.160.38.146 on Tue, 24 May 2016 06:16:52 UTC
All use subject to http://about.jstor.org/terms
rem like Sylvester's on collinear points which essentially depends on order properties, needs an axiomatic background.
OTHER VIRTUES OF AXIOMATICS
None of the axiomatic systems of geometry are such that they can be taught high school students as an experience, but maybe some could be offered to otherwise axiomatically experienced students (I mean students experienced in axiomatizing) as a subject to be analyzed. What would be the educational context of such an attempt?
We know that axiomatics is important, and if possible, the student should learn what axiomatics is. There are, however, so much easier subjects to be axiomatized than geometry, such as groups, measure, linear order, cyclic order, angles, and so on. I have already rejected geometric axiomatics as an expression of rigor. What is rigor, depends on the context. To justify axiomatizing geometry by arguments of rigor, one has to show a context in which local organization is not adequate. There are such contexts but usual axiomatics does not apply to them.
Another benefice of axiomatics is cutting ontological bonds. In the usual abstracting axiomatics it is too easy a business. In geometrical axiomatics, which is describing rather than abstracting, it is much more difficult. Linear algebra on the other hand, contains too little geometry to make the cut of ontological bonds effective. It would be worthwhile to show the student how geometry can be made independent of physical space but it is not easy. Of course, you can tell it with formulae like "it is easily shown", and "we omit the proof", but this is not more than verbalism.
Axiomatics is also an organizational form of foundational investigations. The axiomatical structure allows to investigate the scope of such and such an axiom by omitting or replacing it. This, too, can more easily be done with simpler axiomatic systems though it shows special aspects and charming features in geometry.
I would mention here an approach which is foundational though it has not been worked out to full fledged axiomatics. It is P. J. van Albada's:
Within spatial euclidean geometry one turns to geometry on the sphere, which by identification of the antipodes may be even transformed into the elliptic plane. Theorems known from euclidean plane geometry are investigated in elliptic geometry. Some remain valid, others cannot be transferred. To become familiar with elliptic geometry one tries to derive theorems of elliptic geometry from each other. Theorems that hold in both geometries ask for proofs that are valid in both of them. This leads to a problem which the student should have met in abstracting axiomatics: a common fundament

of euclidean and elliptic geometry. I have not yet studied this problem sufficiently to tell you how it can be solved on high school level: I suppose the best way would be to try something like the approach of the Helmholtz-Lie space problem.
(In this proposal the elliptic geometry could not possibly be replaced by the hyperbolic one. The model of the hyperbolic plane is artificial and hardly accessible to a synthetic approach, and without a model, that is, as Bolyai and Lobacevski did it, it is hardly recommendable.)
GROUPS IN GEOMETRY
Transformations in geometry were long ago advocated by F. Klein as a consequence of his so-called Erlanger Programm. The breakthrough of transformations in geometry is of a rather recent date. How to explain this delay, even in Germany, where Klein had been the venerated master of a generation of teachers?
It is a complicated story. Foundations of geometry in the 19th century originally meant the Helmholtz-Lie foundational approach of defining a geometry by group axioms. Klein was never a foundationalist; he was even a complete stranger to the axiomatic idea. The Erlanger Programm is classifying given geometries by their groups. The slogan "geometry is the invariance theory of a group" is only intelligible within the restricted frame of a few classical geometries which may be derived from projective geometry by distinguishing certain subgroups of the projective group. Not before E. Cartan's homogeneous spaces has the Erlanger Programm been interpreted in a foundationalist sense. As to the technique Klein's geometry has always been algebraic rather than synthetic. On the other hand Pasch and Hilbert turned away from the Helmholtz-Lie group theory interpretation of foundations of geometry. Without doubt Hilbert's Grundlagen der Geometrie have contributed to lengthen the life of Euclid's methods for half a century, whereas Klein's algebraic approach was too little geometry to be interpretable in school mathematics. At their best Hilbert's and Klein's approaches were teacher's background knowledge which hardly influenced school instruction.
In a 1956 report I stated that though transformations were progressing in school geometry, the exposition was classical and there was not any textbook based on the transformation idea. Even the problem how to introduce and to teach transformations had not received due attention. Though meanwhile many textbooks have been going to teach transformations, rather than being solved, the problem has been aggravated. Wrong concretizations to visualize transformations have become quite usual in experiments and textbooks. It is an old misapprehension in textbooks, and it is continuously made in

Piaget's work, to visualize a transformation as picking up a figure and laying it down elsewhere without changing its shape or after having applied some similarity or affinity. With the free mobility of figures no group can be formed. To get a group one has to pick up the whole plane (or space) and put it down elsewhere. Free mobility of figures is much more intuitive than geometrical transformations. The less intuitive is very likely to be blocked by the more intuitive one, especially if moving models are used.
A more recent, and even more mistaken concretization of transformations, say of the plane, is putting pawns or persons on selected spots of the plane and interpreting a transformation as a command to these figures to change their places. Of course, all is due to end up in nonsense.
Good teaching of geometrical transformation is not easy, indeed. Maybe this has been one more reason why transformations progressed so slowly in school education. In the 1956 ICMI report I stated there is still some hope left. There is one transformation that is immediately seen as a transformation of the whole plane, rather than as the movement of a figure in the plane or as a march of selected pawns. It is axial symmetry. Central symmetries and rotations are much more difficult; translations is the most difficult case. If the teacher starts with axial symmetry and if rotations and translations are introduced as products of axial symmetries, there is a real chance that the child will grasp the concept of transformation even in the introductory phase. There is another approach to geometrical transformations. It is by means of the square lattice, which is the most natural, or even the only natural infinite figure. Free mobility of the square lattice can, indeed, suggest translations and rotations of the whole plane.
There are, however, more reasons, why to start with symmetries. They are more interesting than translations and rotations. To a young child congruent figures are the same. It will not hit upon the idea that something has happened if a figure has only been carried to another place. To an unsophisticated mind translating is no transformation. In this regard rotation is somewhat better than translation. If a cube is translated, nothing has happened; if it is turned and put on a corner, something has changed. But mirror reflection gives the strongest feeling of an important event. Symmetry as a transformation is more attractive, more abundant, and more problematic than translation and rotation. In almost all national ICMI reports of 1956 its usefulness in teaching was stressed. Meanwhile symmetry has vastly penetrated into textbooks as far as they teach geometry.
There is one Dutch course of modern geometry by transformations for 12 year olds, by Kuipers, Siepelinga, Troelstra and Tromp. They start with symmetries and introduce translations and rotations as products of symmetries; equiformities and affine transformations appear later. The books are

written in a group theory spirit though groups are not explicitely mentioned. Deductive bonds are loose in the beginning to grow gradually stronger.

TEST PAPERS
Such new methods are more readily accepted by the students than by the teachers. Traditional geometry was difficult to teach, but its level of rigor was firmly ruled by a common opinion. Teachers complain that with deductively looser methods grading of testpapers becomes more problematic. "We cannot any more tell wrong from right", is a frequent complaint. They overlook that with old geometry it was easier only within a complex of mouldy and rusty conventions.
Old style geometry will not survive for more than a few years, but if teachers, indeed, choose the easy way to tell right from wrong when grading testpapers, geometry will be lost. Problems on sets and linear algebra are more reliable provided they are dull enough.
Geometry is endangered by dogmatic ideas on mathematical rigor. They express themselves in two different ways: absorbing geometry in a system of mathematics as linear algebra, or strangulating it by rigid axiomatics. So it is not one devil menacing geometry as I suggested in the title of my paper. There are two. The escape that is left, is the deep sea. It is a safe escape if you have learned swimming. In fact, that is the way geometry should be taught, just like swimming.

199 PREFACE

This book is a product of love and respect. If that sounds rather odd I initially apologise, but let me explain why I use those words. The original manuscript was of course Freudenthal's, but his colleagues have carried the project through to its conclusion with love for the man, and his ideas, and with a respect developed over years of communal effort. Their invitation to me to write this Preface enables me to pay my respects to the great man, although I am probably incurring his wrath for writing a Preface for his book without his permission! I just hope he understands the feelings of all colleagues engaged in this particular project.

Hans Freudenthal died on October 13th, 1990 when this book project was well in hand. In fact he wrote to me in April 1988, saying "I am thinking about a new book. I have got the sub-title (China Lectures) though I still lack a title". I was astonished. He had retired in 1975, but of course he kept working. Then in 1985 we had been helping him celebrate his 80th birthday, and although I said in an Editorial 'State1'ment in Educational Studies in Mathematics (ESM) at the time "we look forward to him enjoying many more years of non-retirement" I did not expect to see another lengthy manuscript. Most people in their 80s do not aspire to write yet another book (particularly if they have already written nearly 200previous publications in mathematics education -- see the list at the end of this book). But of course Freudenthal was not like most people, and that is one reason why this book is so important. Although it wasn't his last piece of academic writing, it was his last major contribution to our field and it offers the reader a kind of synopsis of his perspectives. It is the definitive Freudenthal.

Not that there is anything final about the book nor about its messages. As Leen Streefland said in his tribute in ESM 21/6 "he himself already prepared the first milestone of the post-Freudenthal era", namely this book. In particular the book poses the kinds of questions and issues which Freudenthal himself enjoyed grappling with, and which in another way show the love and respect he had for children. He rarely spoke overdy about this, but shines through all his writing as a beacon to all of us in mathematics education, and in education generally. His writing focuses as always on the essential concerns of mathematics education, as he saw them, and children are our principal concern.

The book is sprinkled with anecdotes and stories, with references to colleagues in the pursuit ofunderstanding and wisdom, both adult and children, with respect to the predecessors on whose shoulders he stood, and with criticisms of those whose ideas he did not approve of. The language is "Freudenthal-English" and I do not say this in any unkind way. He enjoyed languages so much, and he was so aware of the dangers of words controlling his thoughts, that he tried to be creative

craftsman with his languages. He said in his letter of May 1989, when he sent me his draft manuscript "I did it by text processor -- a time-consuming activity because the easiness of correcting makes it difficult to stop correcting".

If you have read Freudenthal before, you will know something of what to expect -- the insights, the reflections, the charming and apposite examples, the scathing criticisms, the amusing asides, the wisdom -- they are all here. I f you haven't read any of his writings before, then I have only one piece of advice -- don't try to skim-read, or to read too quickly. You need to engage with his words, in order to relate to his ideas. I f you can manage to do that, I am sure that you, like everyone else who has engaged with them, will never be quite the same person again. That is, I believe, what he would have wanted.

Alan J. Bishop

APOLOGY AND EXPLICATION

This is neither preface nor introduction but rather an apology .and a .warning: -e present book adds nothing but itself to work that I have p.ubished m the past m various places. I have renounced originality, I have reframed from offering the reader any new experiences, aspects, or ideas he might feel entitled to expect -- reason to apologise. Resuming old ideas, my aim is now one of comprehensiveness, not by compiling but by selecting and streamlining, by includin- essentials and eliminating contradictions. Views, even when supported by evidence, _are susceptible to change. *My* present viewpoint is "here -nd now", th-t of rev1-w rather than of overview. I felt prompted by two expenences. Negauve: readmg dated quotations from my own work where I did not recognise myself. Positive: a visit to China, where in lectures, seminars, and discussions I tried to display and illustrate my view on mathematics education in all its aspects. The present ?-rk somehow reflects these talks, albeit in no way textually. Therefore the subtitle, meant as an homage to my listeners who, by their critical curiosity, induced me to improve on clarity and concreteness.

Hans Freudenthal

MATHEMATICS PHENOMENOLOGICALLY

1.1 WHAT IS MATHEMATICS?

I . I.1 Sure and certain

What is mathematics? A thorny question. Don't look it up in a dictionary! Whenever I did the answer was wrong.

"Mathematics' looks like a plural as it still is in French "Les Mathimatiques".

Indeed, long ago it meant a plural: four arts (liberal ones worth being pursued by free men). Mathematics was the quadrivium, the sum of arithmetic, geometry, astronomy, and music, held in higher esteem than the (more trivial) trivium: grammar, rhetoric, and dialectic. Only when this plural was no longer understood, was its final 's' usurped by sciences, like physics and economics, that historically did not deserve it.

On closer inspection it appears that I have answered the question "What was mathematics?" , to wit in Greek-Roman era, in the Middle Ages, and even somewhat thereafter.

As far as I am familiar with languages, Dutch is the only one in which the term for mathematics is neither derived from nor resembles the internationally sanctioned Mathematica. The Dutch term was virtually coined by Simon Slevin (1548-1620): Wiskunde, the science of what is certain. Wis en zeker, sure and certain, is that which does not yield to any doubt; and kunde means knowledge, science, theory. Indeed, since Stevin, and even before, mathematicians have behaved as though this were the proper defmition of mathematics; but since it seemed to be pretentious rather than a definition it could not find favour in the eyes of dictionary authors.

Even though it does seem to be pretentious it was a lucky strike of Stevin's to name a science (and quite a few others) after what he grasped to be its most characteristic property, rather than after its subject. The most characteristic property of mathematics was certainty, or so he believed. But how certain is "certain"? Isn' t common sense the first, the nearest certainty, and is there anything as remote from common sense as mathematics? Common sense takes things for granted, for good reasons or for bad ones. Mathematics asks for good reasons, as does any science, maybe even for better ones than any other. The need for certainty in science is not satisfied by taking things for granted; certainty has to be pursued, and in mathematics this is done by a quite peculiar mental activity. It is this mental activity rather than its subject matter that characterises mathematics as the field

where this a-tI':ity -an be exercised most adequately and most efficiently. We shall keep this m mmd m order to deal with it more specifically in due course:

that ts, mathematical method as a mental activity which, for some mysterious reason, creates certainty and does so, it would seem, beyond compare.

".1athemal1cs as the field of the most adequate and efficient use of the mathematical method? So there are fields outside mathematics where mathematical method does apply, maybe less adequately and efficiently. Or are these really outside mathematics? How far does mathematics as a field extend? Let us turn back to Stevin! He did not, in fact, use the word wiskunde but wisconst, or as we would spell it nowadays, wiskunst. Kunde means science while kunst means art. At our medical schools they teach geneeskunde, the science of curing, while the medical doctor's practice is geneeskunsl, the art of curing. As a name-giver for domains ?f ;-search Stevin pref-rred the noun kunst above kunde, art above science. "Art" m . Arts and Sciences sounds different from "art" in "Arts and Crafts". With which second noun did Stevin combine "art"? Slevin was an engineer but I am sure he understood it both ways, as many before and after him had 'done and would do.

Mathematics as an -- a mental art to be sure, which for most people will be closer to crafts than to sciences, a tool rather than an aim in itself, *more* relevant beca_use it works than because it is certain. But why does it work? Because it is certam? Although many people trust mathematics more than it deserves it works only w_hen it.is rightly applied. But what is right or wrong? Is there a-y way to ve-fy 1t and if so, 1sn 't such an verification again mathematics and -- if it is -- to which degree? Once one has admitted that mathematics is an art one cannot shirk the responsi?ility of judging_ whether, in particular cases, it is being properly used or rather ?:mg abused_; whlle trying to decide, one behaves once again like a mathemat1c1an. Let us illustrate this with a well-known historical example:

In spite of precursors, probability began with the discusion of two problems. The second was the probl1me des partis. Let me present it in a simplified version:

Two _persons A and B have agreed on a series of games (with equal chance of wmning for either); the first to earn five points will collect all the stakes. It so happens that the series must be broken off with the score standing at

A:4 B: 3.

How should th- stakes be divided? People could not agree. Some said: in the ratio 4_: 3; others said: (5 - 3): (5 - 4). Indeed, there is something to be said for each view. But what does mathematics say? Or rather, what did the mathematician Pascal say when he ":"as asked his opinion? Nowadays we would say: Let us auc-11-n the state of affars! How much would A' and B' pay in order to continue? If B evens the score the stake must be divided fifty-fifty but the chance that he would do so is in fact 50%. Therefore he can claim just one-fourth of the stake and so the fair ratio of sharing is 3 : 1.

Behold -e -athe-atidan called to decide upon the right or wrong way to apply

t-J--c; :-:.J t' C.I-- fl.Tl -.'~.::nr-:.:-.! 1 -...,i:,- .. , A 11. "7 "::: -: .:-: _co 1-.1<?;? ·:::;------ · .. ;- ·:'..ff-':'- ;-_t-::s' ·•1- ..,t "-.,._, ,.-"--- --

was again one of arithmetic, that is of mathematics; and a mathematician was sorely needed to reveal this perspective.

As a useful tool, mathematics has conquered a rich variety of fast expanding areas of science and society, and as a tool it has proved indispensable for a rapidly growing host of people, who use mathematics because they cannot do without it.

Yet again: how sure and certain is this mathematics?

Voyager 2 arrived one second late at its meeting with Neptune -- after having travelled for 12 years, it is true. So sure and certain is mathematics. Or is it? Astronomers count by millions of years, and on the scale of millions of years the one second would be one day -- at least if one admits proportionality. But sure and certain? When they predicted the moment of closest approach, they added some '±' to account for the "mean error". Mathematics knows precise numbers only -

- I once heard a purist affirm. And what about error calculus? -- I asked him. That is physics, geodesy, astronomy -- he retorted; contrived, indeed, by mathematicians involved with mathematics "outside" mathematics. Judging how sure and certain some applied mathematics may be is again mathematics -- formal mathematics in error calculus; as such it is sure and certain as long as it is rightly used, that is, with insight rather than as a recipe, which unfortunately happens more often than not in its educational version. Nowadays, streamlined error theory no longer suffices for judging how sure and certain mathematics is "outside" mathematics. How about the numerous "mathematical models"? Mathematics is sure and certain to the extent that one faces the question how sure and certain it is.

Yet let us not forget mathematics as an aim in itself, which allured adepts as early as Babylonian Antiquity, and which historically has proved indispensable as a forceful motor for its own long-term development. It is an important aspect, although ofless concern to us here, since our subject of mathematics education embraces a much larger group than only future professionals of whom once again only a small minority choose mathematics as an aim in itself.

Even if the "inside" certainty of mathematics is taken for granted, there still remains something to be said about its "outside" certainty. The answer to this is predesigned: it depends on the mathematical behaviour of the one who ventures out -- a point for further discussion. Anyway, Simon Stevin may have had good reasons to characterise mathematics as what is sure and certain, and his predecessors and successors had to behave accordingly, even if they failed to reflect on it.

But what about the great majority? Are we too bold in assuming that, even to the

man in the street certainty is mathematics' most significant feature, far beyond
the limits of his ability to handle it? If this assumption is correct, one may ask
how this confidence in the certainty of mathematics has come about. The answer
is determined by the extent to which and the way in which people have become
acquainted with mathematics.
Most people have been taught mathematics as a set of rules of processing or, as
we call it in mathematics, of algorithms -- an agreeable experience where they
have learned to master them, and a disagreeable one if they have failed. One reason why teachers teach it this way is tradition: it is the way they learned it them-4 CHAPTER I
selves, while they have forgotten that it was not the way they really understood
mathematics if ever they did. The other reason is the structure of mathematics
which, unlike any other art or science, can be mounted in rules and algorithms. It
is an astonishing fact that these rules never fail or -- if they do fail -- that it is the
user who feels guilty, looks for errors of his own and tries to repair them. But to
whom is this fact astonishing? Or is it simply an unfounded belief -- subjectively
unfounded? Let me close this subsection by telling a little story:
A 75 year-old woman whose help is regularly invoked by children and students
s-uck in their ho-ewo-k, met -- perhaps for the first time in her life -- a profesmna- mathema!c-an, JUSI when she had taught a college student the (Euclidean)
algorithm for finding the greatest common divisor of two whole numbers. She
asked the mathematician why this works or rather, whether there were any reason
'.^hy. The ma1'e-atician helped her to answer the question on her own. Maybe it
is worth mentl!oming how he did this. He gave a mere hint: I f a and bare two numbers and a >b (in fact he chose a pair of such numbers), compare the greatest common divisor of a and b with that of a and a-bf
The next time she asked him a question it was about an old-fashioned algorithm
for finding the square root, in which she had believed all her life. Now the mathematician refused and instead taught her a more efficient algorithm, which she
accepted comprehendingly.
-till another time she asked him why under addition, subtraction, and multiplicallon of two numbers the sum of digits behaved in correspondence with the original numbers -- a phenomenon that was easily explained.
Never did she ask the mathematician why, performing arithmetic, the inverse operation "proves the sum", why the algorithms of the various arithmetical operations ".ork, why operations are commutative, why prime factorisation is unique.
Why did she doubt some rules (or did she?) and accepted others? Later on we will
try to answer this question.
I.I.2 Mathematics as common sense
Earlier on I aske- whether common sense isn't the primordial certainty, the most
abundant and reli-ble source of certainty. In a sense it is, although from olden
limes onwards philosophers and explorers have sounded warning notes against
that -ery common sense, which is easily deceived by cunning Nature.
Iron is colder than wood -- this is common sense, at least as long as one uses the
common sense thermometer of one's fingers. Unfortunately, sometimes this
statement ceases to be true; for instance, when exposed to the blazing sun, iron
feels hotter than wood. "Conduction of heat" helps us out of this dilemma. This
is "uncommon" sense, yet common to physicists and to people who learned and
didn't forget their physics lessons. It is the weakness of school lessons to be forgotten, and physics is not exempt from this rule. Whenever this haooens, ii is
- - - ' - r ---. -
MATHEMATICS PHENOMENOLOGICALLY 5
worthwhile. In due course we shall reconsider and discuss the poor permeability
of the membrane separating classroom and school experience from life experience and we will ask for measures on how to improve it.
My example confronted the physicist's "uncommon" sense with the "commoner's" common sense. But is it really that simple? Whether something is common
sense is witnessed by how it is verbalised in common language. According to
common sense the sun rises and sets. On authority it has been accepted that this
statement is amended, if necessary, by the adverb "apparently". Moreover, the arguments substantiating why reality is different are accepted on authority, as is apparent from the almost verbal way in which they are repeated. I wonder how
many people would be able to tell which phenomena and arguments in this particular case moved astronomers to distinguish between appearance and reality.
But many distinctions between appearances and realities have likewise moved to
the state of common sense and are verbalised in common, even daily language.
However, sunrise and sunset occur in this context of appearance and reality only
as far as astronomy is concerned, and even astronomers aren't astronomers all the
time.
According to common sense the Earth used to be flat. This common sense statement differs essentially from the preceding one beCause in (what mathematicians
call) a first approximation the Earth is indeed locally flat and allows us even now
to behave as though it were so. However, not only as astronomers are we engaged
by its roundness, but also as travellers, and as early as we are shown globes and
maps. Nevertheless, even adults sometimes wonder why the sun is the hottest at
noon rather than in the morning and evening when it is "closer to earth". Yet this
common sense conflict is nothing but a low level example of a behaviour which
is not unusual even on higher cognitive levels; in fact, it is an example, and at that
a striking one, of applying simplistic rather than readily available sophisticated
models.
If things have not changed in the mean time, it is the didactical principle in phys-
ics and chemistry to fight common sense by exorcising it: common sense ideas
obstruct scientific ones. Researchers wonder why people -- even those who had
been taught physics at school -- still adhere to common sense ideas, which should
long ago have been expelled. Take the following example:
Again and again subjects are given tests of the following kind: A cyclist. two opposite
arrows on the ground, and the question of whether the forward force is stronger than
the backward one (that of friction). Or the parabolic path of a ball tossed up, and the
question of at which point it experiences the maximum force. Researchers search
again and again for new explanations of why most people fail these tests. They forget
that more often than not force- is associated with velocity (rather than with acceleration). Descartes and Leibniz mathematised force as a function of speed (though they
disagreed about the kind of function) and even in the past century conservation of
force meant conservation of energy. Even today (and even in technical language) the
Newtonian definition of force has not at all displaced other uses. Although the physicist on the meny-go-rolllld feels the centrifugal force, the physicist outside calls it apparent. Would it not be wise to recognise this fact in instruction and to deal compara-6 CHAPTER 1
lively with various concepts of force and appreciate them according to their merits?
In. general I believe that in instruction it would be more recommendable to start
with common s::nse -d-s rather than to reject them as outdated and better being
suppressed. Tius belief is supported in any case by the fact of the more or less
spontaneous development of mathematics.
Among mathematics rooted in common sense the most striking example is, of
course, whole number. (-imilarity is another, though superficially less striking,
-xample.) <'.hlldren acquire number in the stream of their physical and mental acllvihes, which U:a_k-s it difficult for researchers to fmd out how this happens in
detail. The acqu1511tion of number is strongly supported (if not made possible) by
the corre-ponding numerals in spoken language, the acquisition of which can be
mor- easily traced through observational research. As the child acquires the syntacnal structural means to build new sentences so it occurs with the morphological structural mean- to build spoken numerals, beyond necessity and need, and
far beyond -e physical 3.'d (at least initial) mental grasp of number. Going on
-d on m this. se-uence is the first verbalised expression of the mathematical
mmd, an astomshm.g feature which can hardly be overestimated, though it has not
drawn much atten-on'. due 10 being simply a matter of fact, and experienced as
con:mon sense, which is not to be questioned. The morphology of spoken numerals is, moreover, the first algorithm of mathematical character the child acquires:
a common sense algorithm acquired by means of common language.
My stat-ent that researchers have paid little attention to children's first and spontaneous arithmetical activities would seem to be contradicted by the title of p- ag t'
work (wTh S . k) 'La ,, ' e s
. I ze- a . ge:-se d- nombre chez l'enfanl" (1941). The contradicllon, how-ver, hes only m the btle, since the work itself is not at all concerned with
the g-ne-is of -umber. In fact, the genesis of mind had been thoroughly studied by Pi-
aget - his earh-r work. This genetic approach should be sharply distinguished from
the_ ep-temolog1cal one h.e chose in his later work. In order to make clear what this
-witch mvolved, let me bnefly sketch the history of the number concept and its teachmg.
In contrast to his geometry, Euclid's arithmetic is rooted in the whole number of common -ense and, up the middle of the 19th century, the scientific approach to number
remamed common sense. As soon as infmities are to be dealt with arithmetically this
-mmon sense _approach becomes blemished by paradox. Cantor removed this b1em-
15h by abandorung the then common sense approach in favour of a more sophisticated
on-, later on extended by Frege-Russell in an even more refined way from infinities to
fimte natural number and its foundation.
-Piaget'- epistemology, epistemo means a state of knowledge as advanced as accessible to himself, which in the case of number happened to be the Frege-Russell approach, at le-- such as he interpreted it (and at a later stage, for mathematics in general, Bo-baki 'i system-. This_highl- sophisticated number concept is
Piaget's touchstone, his tool for asse-sm- children s understanding of number at various ages, in far
from common sense s1!uallons, and using an artificial language both created for the
-ake of assessment Obviously, this - -o way to trace the genesis' of number. It proved
instead to be the source of such oddities as non-conservation never observed in the
i.mfnrtrunfitely -nre -ex.:unples :f genetic lo\'..Se.1:'.T--. It is a pity th-t Pil.1,1l)'.e-s 1f".".'.,,.Dl1Ment?_!
MATHEMATICS PHENOMENOLOGICALLY
genesiology to epistemology has ever been noticed.
Later on I will return to this question.
7
Let me add the remark that the common sense roots of number extend further (or
are extended) alongside learning language, which proceeds from speaking to
reading and writing. Isn't it noteworthy that in written and printed language the
mathematical symbols for natural numbers precede their phonetically constructed alphabetical equivalents of spoken numerals ("3" precedes "three", "100" precedes "one hundred")? Anyway the mathematical symbols for nahlfal numbers
are integrated into written language. Literacy and numeracy overlap in this region, and even beyond. The place value principle, though deviating from the seriation principle prevailing in common written language, participates in the integration as do -- to a higher or lower degree in various languages -- the basic operations
on natural numbers.
I have adduced these striking examples of the overlapping and integration of
mathematical and common language as witnesses of the common sense origin of
early arithmetic. The tree of knowledge, rooted in common sense, has, as it were,
sprouted arithmetic as a branch in its own right -- historically as well as in individual life histories. In the course of life, common sense generates common habits, in particular, where arithmetic is concerned, algorithms and patterns of actions and thoughts, initially supported by paradigms, which in the long run are
superseded by abstractions. These products of common sense acquire in turn the
behavioural status of common sense, while their common sense ancestry may
have even been forgotten. Historically viewed, there have been stages, or even
levels of common sense, and the same holds for individual development what is
common sense may depend on the community that shares it.
Is common sense then something like the greatest common di visor of insight,
shared by the members of a certain community? Indeed, but it is then a quite large
common divisor with relatively small mutual divergences, at least as long as
emotion is checked by cognition. In the case of the probleme des partis the parties
quarrelled about how to divide the stakes until a judge resolved the quarrel, albeit
not on the strength of common law but by common sense. This was a sounder
common sense than that of the quarrelling parties, which was spoiled by badly
understood law-like algorithms. The judge's decision created a new paradigm of
common sense.
Whereas historians are able to trace the cognitive development of mankind as a
development of common sense, it is difficult to attempt the same with individuals, whether by observation or reflection; wrong application of rules, however,
and wrong transfer of patterns may provide indications. At any developmental
stage of common sense it may be significant how much the learner has contributed to this progress. One extreme is learning without being intentionally taught,
and the other is learning what has been bluntly imposed; and since the first is
more deeply rooted in previous common sense, it may matter some time in the
future how the development took place in the past It matters whether, for instance, an arithmetic algorithm was acquired as an abridged and streamlined ver-8 CHAPTER I
sion of former common sense activities, or whether abridging and streamlining
(or even the algorithm itself) were imposed. Sure, some, algorithmically gifted
people, learn to apply even imposed algorithms adequately; others -- perhaps the
majority -- fail 10 identify the new algorithmic procedures with the common-sensical ones from which they should have originated through abridging and streamlining. They fail because some time in the past they were asked to take mental
leaps which exceeded their mental powers. Even though they flawlessly learned
the algorithm, they will fail to use it in true life situations where common sense
counts; they will instead depend on less efficient lower level operations.
The following is a well-known example: We are taking a trip of 215 km; how
much do we still have to drive after 88 km?
Children reason: 88 + 12 = 100, +100 = 200, +15= 215. The subtraction is not
recognised (or not ventured); to such pupils the minus key on the calculator is of
no use.
Researchers have signalled this "relapse" and marvelled on it. Rarely, however,
has it been diagnosed as a consequence of instruction, since no alternative instruction was envisaged alongside the imposition of the new algorithm (which
was sometimes embroidered with explanations for conscience's sake). The new
algorithm, however, never did have the opportunity to reach the state of common
sense; afraid of applying a wrong algorithm or the right algorithm wrongly, the
learner instead relies on what has remained common sense to his mind.
Let us now answer the question posed at the end of the story of the 75 year-old
algorithmic performer! The fact that after more than half a century she still masters the various algorithms well enough to teach them, characterises her as an algorithmically gifted person. Why did she worry about one kind of rule but take
others for granted? Well, common sense is taken for granted. Rules learned by
imposition will be taught the same way, at least if the learner who became a
teacher is able to teach. But having been imposed they never had a real chance to
develop into common sense ofa higherorder. Is it a privilege of old and wise people to doubt what looks like common sense, or can you not teach this behaviour
to the young?
Why "sure and certain", I asked earlier on, and I announced that this might be a
question of behaviour. Of common sense? Yes, but also--I would add now -- of
a tendency to doubt common sense.
Where common sense as the root of mathematics is concerned, up until now I
kept silent about geometry (except for one clause in parentheses). Yet I am convinced that geometry even precedes arithmetic in individual development. One
of the earliest symptoms -- I believe -- is awareness of similarity of figures; this
is found so early that it looks like innate (or might it even be so?)
"Similarity" is even characteristic for what happens with geometry by the token
that every day language has no word for it. (This was already the case in Greek,
and Greek mathematicians had to think up a word for it, which they did by reMATHEMATICS PHENOMENOLOGICALLY 9
wards mathematics: Until the higher grades a term for the striking feature of similarity is withheld from the pupils -- obviously because on- does not dare- speak
about geometric similarity until one feels able to define it formally. THiS parsimony with regard to geometrical language, which is more difficult, indeed, heavily contrasts with the way in arithmetical instruction, where the number sequence
is handed to the learner, as it were, on a plate.
Geometry is doomed to fall behind arithmetic in the development of verbal expression. Geometrical arguing is kept on -e level of"I can- it", and when an
attempt is made to raise it to a higher one, it may be loo late m most cases. Common sense does not get the opportunity to develop into more common sense -- a
consequence of lacking instruction.
1.1.3 Why mathematics is different
Let us be clear about one thing: to the view and mind of most people, mathematics, though deeply rooted in common sense, is more remote from. it than anyth;ng
else. What made it move so far away? The deeper the root the higher the top
Mathematics is different, indeed, and we will take notice of this fact when we will
turn to education. From the very beginning it has been different It is the oldest
among the sciences, even preceding astronomy by more than two millennia.
Mathematics was more easily invented, as it was simply a question of common
sense -- only better organised. And it developed in this way, becoming more and
more organised, according to a pattern I am going to describe.
You know that 3•2=5 and the area of a rectangle by common sense. But as soon
as Nature gets involved common sense becomes misleading 3-': everybod- knows.
For common sense is even more urgently in need of expressmn and ennchment
by transfer of knowledge than is mathematics -- and ever more urgently the -ar
ther removed a science from mathematics; and even where common sense is a
nuisance it may persist alongside more educated views. Unlike the law of inertia
or Newton's theory of gravity, the elements of mathematics have been invented
independently of one another at various places in the world. While sciences underwent revolutions mathematics evolved, even during these revolutions and under their influence. How to explain this difference, what dynamic granted mathematics this apparent continuity of development?
Common sense in order to become genuine mathematics and in order to
progress, had to
0
be systematised and organised. Common sense experiences, as
it were coalescez into rules (such as the commutativity of addition), and these
rules a-ain became common sense, say of a higher order, as a basis of even h.igher

order mathematics -- a tremendous hierarchy, built thanks to a remarkable mterplay of forces. . .
I have stressed earlier and I stress again that our first verbalised mathematics --
that of number -- distinguishes itself from any other verbalised knowledge by the
fact that its mere form, detached from its contents, foreshadows [ifnot radiates) 10 CHAPTER I
its mature form and contents. Its tremendous structure -- strictly regular after a
short archaic start -stands unrivalled by any ol.her linguistic phenomenon; and in
I.his respect I.he phenomenon is interlinguistic as far as languages have been created in need of number. By I.he same token, number is even more common sense
I.han any ol.her human idea. Moreover, I.his fact itself is common sense to such a
degree I.hat it is hardly noticed and rarely made explicit, all.hough it has greatly
influenced mathematical thought as well as I.hinking about mathematics. The formal isomorphism between the mental object "number" and its numeral expression, which looks like substantial identity, has been I.he source of thinking about
the relationship between mathematics and language, of identifying mathematical
language with the language of mathematics, and of viewing mathematics as a
mere language.
Properly said, it has not been as simple as that: what is considered to be true
mathematics started by impoverishing that primordial structure of whole number,
depriving it of the positional strait-jacket (the primordial fall as it were) by which
mathematics escaped and outgrew common language. It was New Math's historical fault not to notice the depth of this fall, which eventually became a jump,
from the positionally structured numeral to the more abstract free whole number.
Number is the first realm where symbolism acquires a reality of its own, a reality
apparently independent of its creator, who in turn tries to reorganise his creation,
and by means of it his environment. But even this organisation would seem to
have existed for eternity, at least as long as the view is restricted to whole
number, which Kronecker believed to have been created by God, only to be
spoiled by human efforts to transcend it.
Structuring, whether applied to products or to processes, means emphasising
form. The first non-trivial structure as such, i.e. whole number as I.he product of
the process of counting, begot rich process and product content which, organised
by ever new structures, in tum begot new contents -- a never ending cyclic process.
Through reflecting on his own activity man discovers paradigms, which are abstracted into patterns of mental action, and made conscious as schemes by which
thought is organised on behalf of new progress -- adaptable schemes, that is,
which allow for varieties of use, as well as, in the same right, rigid single-purpose
schemes which, thanks to their rigidity, can lead a life of their own, called algorithms. These forms in tum can become subject matter, a nucleus, as it were, of
higher order contents -- again a repeating process, an interplay of form and content, which characterises mathematical thought. This interplay includes the linguistic expression by means of which mathematics is communicated as a product
and a process. New content and form require new terminology which, in order to
be efficient, has to be streamlined, both symbolically and notationally. Symbols
and notations, in the course of reflection, again become subject matter handled as
such.

Historically, discoverers incessantly switched duties. fa fact, each discoverer behaves as an organiser as soon as he sets out to _make his discov_enes known, although this is not a specific feature of n_iathemat1cs. In mathemaucs, h.owever, o'.·
ganising and reorganising is a consunumg affair, and the newly acquired organisation forms may become content in the sense of subject matter to .be exammed
as such. As far as longevity is concerned, no system of mathematics can equal
Euclid's, which came near to suffocating its subject Yet only a bnefbreathing
space was allowed to Bourbaki's: it became outmoded almost at the same pace
as it was developed; outmoded as a system, that is, while giving birth to new content. .
This is why mathematics is different and why it looks even more different to
more people. Schemes of thought can be imposed, algorithms can be taught as
rigidly as computers are programmed, and, to be sure, such -fro?' ."e not l?-t on
algorithmically gifted people; concepts can be taught by lmgmsuc defm1uons,
and this again works very well with people who are good verbalisers themselves.
Last but not least, the interplay between form and content includes what is commonly called applied mathematics, provided the environment to which mal.hematics is applied is already being seen through the spectacles of mathemau-s.
"Mathematical model" is the fashionable term for form, abstracted from parad1gmatical application, and again models and their use become the subject matter of
mathematical reflection, as though they were part of the environment. Modelling
too can be taught by impoiition -- successfully or to no avail -- depending on the
preparedness of the learner.
All in all, this explains why mathematics is different, both objectlvely and subjectively, and it also explains why people do not grasp the reason why it is different. Content must be assimilated, while form can be imitated for the purpose of
reproduction. It seems to be easier to teach and learn structured form than structureless content. It is as easy to yield to this temptation as it is difficult to resist
it This, then, is I.he familiar image of mathematics: a set of algorl.hms, as worthless as it is strict if one does not understand how and why it works. It is a misleading view, which is given the lie as soon as less strict schemes are to be applied.
We will recall the reason why mathematics is different when we discuss education. There we will explain why mathematics is learned differently and therefore
should be taught differently, that is, neither as form nor as content but while
maintaining respect for lhe interplay between them, acted out in the teaching/
learning process! Learning is progress in knowledge and ability. Their interplay
does not sound like that of instruments and voices in a concerto. It is rather a
change of viewpoint from content to form, and conversely, leading to ever higher
levels, by jumps as high as the learner can perform, and guided but not lifted by
the teacher. 12 CHAPTER I
1.1.3.I Examples
Let us dwell upon the interplay between form and content! As stressed above the
origin of the number sequence is form, even linguistic form. While used for
counting it acquires content - - a rich variety of content. When in turn abstracted
from this variety of counted phenomena, it acquires the status of lhe mental object_ th_at is: more or less formal whole number, though still laced in the formal
str.ut-J-cket of _lhe d-irnal system, and still attached by short strings to counting
something, w-ch a:ms at content. Addition and subtraction are meaningful as
c:nntent operauons m preparation for their formal practice, which for a certain
ll-e r-mams supported by models which arose as content. Commutativity of add1uo- is s--ested by what addition meant as content before it acquired the -- at
least1mphc1t-- state of a formal rule; it can then, on a higher level, become a matter of mathematical content, when studied, for instance, with its consequences, in
the context of operauve laws. The relation between addition and subtraction arises as a matter of content before it is formally applied, in order to become once
again subject matter and content in the context of algebraic structures.
Let us skip multiplication, whi-h shows similar features, and turn to divisibility.
This -ses m -he c_ontext. of distri-uting, which is content, but more rapidly than
any!hmg else m anth?euc 1t acqurres a most surprising formal status, only to recover that of content m number theory. There it becomes a matter of arithmetic
scrutiny, in particular s-mulated by the phenomenon of prime number, which
means, as far as content 1s concerned, number resisting any arrangement in rectangular patterns. The search for prime numbers and research on prime numbers
is largely one of mathematical content Yet the convention not to admit the
number 1 as a pri_me number, is formally motivated, namely by the preference for
an -3;5Y formulal:IOn of the theorem on unique prime factorisation. Extending divmb1hty to other domams. (such as polynomial rings) is a formal procedure,
where the part played by 1 1s taken over by lhe inversible elements.
"I'e swn of digits (in decimal number notation) provides a formal criterion for
d1v'.s1b1hty by 9, although its proof, at least at a low level, requires content reasonmg, for _mstance, by displacing balls on the bows of the abacus. The clock dial
s_uggests anthm-llc modnlo 12. Operating modulo a whole number is a formal actlVity, from :-'h1ch such mathematical objects arise as finite rings and fields,
:h1ch m th-1r tum become ?,1athen:iatical contents. Manipulating formally .f1.,
as th_ough its square were 2 , acqmres mathematical content in the polynomial
domam modulo !·- 2.
Positive n-mber owes its existence to the geometric context of distances. Positive
and ne?auve --umbers (together with 0) form what is called real number, beyond
which is 1magmary or complex number. In brief, historically (for more of it, see
[146], Chap. XV) as early as Babylonian Antiquity there were methods -- one
might even say, formulas - -to solve linear and quadratic equations arising in geOfffff·-_T'f Qr U1 irl!Y".1'-0.<:' W•" ,.. -01.... ·,_.., • • 1 . .
. -·-· ·_ ---- ----- ... ,_.. ..:, ·:·- ._ .an7.,.i--f-17.:!1.11c-,a-·-v1e'c:..--:-:-:-c•J1, ·"_:.i·.-z-cr:'f,.I-:c?<:

them had to be rejected as being "false", and then merely because one only knew
positive numbers? Eventually, around 1500, courageous mathematicians took the
plunge. In spite of their being "false", one conld marvellously reckon with these
numbers by preserving and extending lhe old arithmetical laws. And lo and behold, one century later, the "negative" numbers were assigned a -- geometrical -
- place, left of O on the number arrav pointing at the right Formal number acquired a content, thanks to which the whole plane could be co-ordinatised. The
formal requirement that all algebraic equations can be solved brought forth a content-rich geometric-algebraic activity on the entire plane. We hardly need to add
that soon this content again turned formal -- a new link in the long chain of form
and content. Thanks to Gauss' geometric representation complex numbers
(which had come into being as formally required solutions of algebraic equations
and had long been repudiated as ontological monsters) acquired respectability
and content status.
Common formal properties of certain algebraic structures led to define lhe field
concept through formal requirements, with the obvious preconception of adding
a new object -- the field -- to mathematical contents. Efforts to lend content to
formal divisions by O, and to formal (divergent) series such as 1-1+1-l+ . . . are
other examples of the dramatic historical interplay between form and content In
ancient history formal patterns for solving quadratic equations geometrically by
the so-called application of areas led to the discovery of curves, afterwards recognised as conic sections and redefined as such by Apollonios, only to be redefined anew by means of formal equations in Cartesian geometry.
The term "variable", as it is used today, embodies the symbiosis of form and content in the most striking way. Originally letters, whether indicating arbitrary
points as in Greek geometry or arbitrary numbers as in Vieta's algebra, were
nothing but easy generic names for these kinds of objects; yet, in the kinetic imagination of the inventors of Calcnlus and their followers, as well as in analytical
mechanics, letters became symbols for mathematical and physical objects which
varied time-dependently or due to mutual dependence. Initially the law ofthis dependence was not made explicit but implicitly given by the surrounding mathematical or physical context, which could be a curve or a mechanical event, involving these mathematical or mechanical objects. When the first literal function
symbols appeared, that is, for solving lhe differential equation of the vibrating
taut string, they were again no more than generic names of mathematical objects;
as soon as necessity required it, they then became variable objects themselves. In
the course of history as well as in mathematics acted out day by day, we may notice this incessant switch back and forth between letters as symbols for "empty
places" (indeterminates or unknowns) and as symbols for variable mathematical
objects.
As flout of necessity our exposition led us to the role oflanguage in the interplay
of content and form. Linguistic form should be well distinguished from abstract
(mental) form. Language serves to express both (abstract) form and content. Historically, addition, subtraction, and equality were formal mental objects, present-14 CHAPTER I
ed in clumsy colloquial language, long before shorthand use of the plus, minus,
and equality symbols appeared (which later even crossed the frontiers of mathematics and penetrated into colloquial language); and this is the way it still happens nowadays in individual histories. On the other hand, reasoning about such
symbols, for instance about meaning and use of the equality sign, involves dealing with them as subject matter, that is, lending them the slatus of content. The
same holds lrue for brackets as tools for slructuring formal expressions and formulas. The need to linguistically express x
2
as a function of x requires the creation of linguistic tools, which resemble content It may be a matter of content
whether in a group structure the group operation itself is called addition or multiplication; but this very choice formally decides whether the neutral element is
then called 0 or l . Interpreting (in highbrow style) a group as a quadruple, consisting of (I) a setG, (2) a mapping ofG x G on G (multiplication), (3) a (neutral)
element of G, (4) a mapping of G on G (inverse), and thereby fulfilling certain
(group axiom) conditions, means that mathematical language is being dealt with
as if it were content.
1.1.4 Mathematics as an activity
When we distinguished slages or levels of common sense we noticed that attaining them depends on the individual's own contribution, on his activity. Common
sense lakes things for granted, as I mentioned, while mathematics asks for good
reasons. Certainty has lo be pursued, and the way this is done, characterises mathematics as an activity, leading to ever improved versions of common sense.
Most of the Dutch names Simon Stevin proposed for the various sciences involve
activities rather than objects and instruments. Mathematics is a quite peculiar activity. Thinking logically? It depends on what "logic" is intended to mean. Logic
as an established science or as common sense? Let us postpone tackling this question!
Mathematics as an activity is a point of view quite distinct from mathematics as
printed in books and imprinted in minds. To be sure, mathematics is a precious
treasure-chest of tools, precious that is for those who can put them to good use.
This is true for any instrument, many of which can be handled by an inexperienced child: a switch to light a room, a key to open a door, a bell to ring; and
many more, which require more sophisticated, yet narrowly streamlined programs in order to be handled, such as algorithms in mathematics.
Every researcher, every producer of mathematics will readily admit that mathematics is an activity -- his private activity, the product of which may or may not
be published. Indeed, any author is entitled to have his privacy respected. Moreover, why should he annoy the public with the !ale of the production process as
it took place? Indeed, the author should not lead the reader of his work along all
the wrong trails and into the blind •lleys explored by him and eventually aban-
. ·.

lowed to watch the process leading to the result as it would have laken place if
the author had somehow suspected all along what he finally came to know for
sure? In the past some textbooks and even research papers were -tten in this
way, but the fraction of mathematicians who prefer this style of editmg has been
declining steadily.
Let us avoid any source of misunderstanding! If I speak about products of mathematical activity, I do not do it in the narrow sense of new propos11:1ons and th-
orems. I include proofs, even definitions and notations, as well as the layou- m
print and thought. Reading mathematics and listening to it is also mathei:iauca,
the mathematical activity of reproducing what is being offered, as though it were
the receiver's own production. Reproducing should be an easier laSk than producing. Unfortunately, the ever more common style of presenla-on frustrates ra-er
than favours this opportunity. The style of modern presenlal:lon creates the lli-
sion that what is sure and cerlain, has been so from eternity rather than smce its
discovery was completed and its presentation polished. Yet our cerlainties are incessantly menaced, if not by confulation -- which has become r- -- th-n by a
longing for more certainty, deeper insight and broader -nderstanding which .has
become quite common. In this respect at any rate there is no reasonable cerlamty
about what will be considered sure and certain in-the future.
Mathematicians, even when reproducers rather than producers, tend to restrict the
right to practic<>mathematics as a menial activity to an elite -- to those who ennch
mathematics as a subject matter by new discoveries. Those who do not belong to
this elite are required to purchase a stock of knowledge and abilities fro'. ' -e
shelves of the mathematics supermarket. If some choice is indeed granted, is this
at least left to the consumer, or does somebody else even do the shopping for
him?
Does this profusion of metaphoric language bother you? Mathematicians -e or-
ganisers albeit in other fields and with other aims than those who are active m
industry: trade, traffic and administration. A similar, if not identic- .men?11
make-up is characteristic of all of them. But in no other field does organising display itself in such purity, impose itself with such force and infil-te so profou?d-
1 y as it does in mathematics. Mathematics grows, as it were, by its self-orgamsmg
momentum.
No wonder mathematicians like to present their subject in a well-organised slate,
and textbooks are frequently judged according to their degree of organisation.
But for the great majority neither mathematics nor its organisatio- is an aim in
itself. As a useful tool mathematics has conquered and covered a rich - variety of
fast expanding fields of science and society, and as a tool it has become ndispensable to a quickly growing crowd of people. People increasingly use mathematics
more often than they are aware of. They use mathematics because they cannot do
without it.
That is mathematics as an activity of discovering and organising in an interplay
of content and form; later on we will have to ask the question of whether mathematics teaching has really caught up with this development. 16 CHAPTER 1
1.1.5 Mathematics and reality
If I were to continue in the same way, that is, by focusing on the mathematical
process, I would imprudently be neglecting the medium in which this process
takes place, which provokes this process and which is affected by it. Let us have
a closer look at it!
Common sense reveals itself in those actions -- physical and mental -- which are
common to people who share common realities. There is no reason, were it even
possible, to restrict "reality' to the mere experience of sensual impressions. Even
at the lowest level, reality is an inextricable mix-up of interpretation and of what
a purist would call sensual experience. If somebody says
when I heard the doorbell ring, I looked out the window and saw Alice and smelled
her perfume

one may believe him and take for granted that this is the report on something that,
in the reporter's eye, really happened. There is no reason why one should listen
to vulgar positivists who object that "in reality" the ear of the person calling himself " I " was struck by noise ofa certain pitch, interpreted as that of a doorbell, his
eye by a flood of light waves, interpreted as issued by some source called Alice,
and his nostrils were invaded by a stream of molecules, interpreted as Alice's
scent In fact, the " I " could have been a dog, and the above sentence could have
been part ofa story on the animal's behaviour, told in the first person's style. The
doorbell's ring, and Alice's look and scent are primitives, hardly suitable for further analysis. Questions like "how do you know that it was the doorbell's ring and
Alice's look and scent?" may or may not elicit reflection. "It is windy" may be a
primitive indoor observation, which only afterwards is justified by references IO
moving branches and clouds. "A bang" and "a short-circuit" may be descriptions
of the same event on various cognitive and linguistic levels. A number of atomic
events read by a Geiger counter, a passing K-meson, and a supernova burst are
primitives to the physicist or astronomer who observed and reported these events,
although to be reduced to more pedestrian ones, they need profound theories.
"Cheerful" and "sad" may be irreducible predications (whether pronounced with
regard to other people or oneselfi), and reducible only by reflection. To some
readers, Homer's characters may be real persons, and their adventures real facts,
as real as the world on the stage may be to the spectator. There can be little doubt
that, as early as the lowest cognitive level, the species canis is as real as any particular dog, with whom it even shares a common name. I once told the story of a
little boy to whom at an early stage "Utrecht" meant any place he spotted which
resembled the neighbourhood of his home; a few years later this became a vague
territory, later on he was able to localise it on a map, and after a few more years
it became an administrative-political entity, which finally acquired a new, and to
him even more vigorous dimension -- that of history. This all happened within an
ever expanding reality, which included such institutions as The University, The -- ;, - ,' ,-c - cMATHEMATICS PHENOMENOLOGICALLY 17
alities let us ask what a micro-computer means to various people: -commodity
with a certain price to the seller, a weight in i-ilogran;is '.'.J -e deliverer'. unexplored land to the novice, and to the exi:ert a part of his bfe s world, which has
long since been abstracted from the tangible mstrument. . .
How real concepts are depends on the conceiver, and under given crrcums_tances
cognitive grasps can be more vigorous than man- and --sual ones, which are
in fact always mixed up with cognition. Mathemaucal n:al1ues --early p-enom
ena in individual development, that is, not only geometncal realities but -th'.'et
ical ones as well. Numbers which are represented by observed and imagined
quantities, named by spoken and written numerals, and mutually_ connected by
actual, imagined and symbolised relations, belong to a real'." which can ex'.'nd
from the nucleus of everyday life experience to the far frontiers of mathemaucal
research, depending on the involvement of who is con-e:ned. In sp11: of hundreds
of years of resistance -- even on the part of mathemaucrans -- nega-v_e and complex numbers and their operations have become as real to ma-ema_11c1ans as positive ones had been for centuries, and whole numbers for millenma, and at -ey
now belong to the reality of most people who have learned some math_em-ucs.
Reality is historically, culturally, environmentally,_individually, and subiec:u-ely
determined. Lawler's "micro-worlds" are less- obiecuve and Bauersfeld s domains of subjective experience" less subjective th- these_ te-- may suggest.
Solipsism is :is artificial a construct as is all-embracmg obiecuv1sm. I pre-er to
apply the term "reality" to that which at a certain stage common sense experiences as real.
"Real" is not intended here to be understood ontologically (whatever ontology
may mean), therefore neither metaphysically (Plato) nor physically <A2stotle);
not even, I would even say, psychologically, but instead commonsens1-ly as
when one uses is meant by the one who uses the term unreflectingly. It_ 1- ?ot
bound to the space-time world. It includes mental objects a-d mental acuv111es.
What I called "expanding reality" is accounted for on ever h1g-er levels 7f common sense and witnessed by levels of everyday language or various techmcal languages.
The farther one's reality extends, the more often and more sharply one -eeds to
zero in on more or less manifest fragments, isolated by aspects of real11? .. Th-s
may tum out to be an advantage or a disadvantage_. Transfer of electnclly -s
served by insulation, yet transfer of ideas by short-crrcmts. In -twee- there is
the cellular structure of biological life, defined by membranes with a highly_ selective and effective permeability, which is the amazing result oflong evo1uuon.
The permeability of the membranes dividing individual realities may de-nd on
the active or passive origin of these fragments: whether they are due to mtemal
evolution or imposition from outside. . . .
This is the key, in my opinion, to understanding the poor permeability 7f the
membrane separating classroom and school experience from life _expenen-,
which I alluded to and promised to analyse in due cour- when I wil_ deal :-"1th
mathematics education; in spite of the fact that mathematics, as well as its various 18 CHAPTER I
domains and aspects, is already a striking example of the poor, or even the lack
of, permeability of membranes. The specific relation between content and form -
- the emphasis on form, reinforced by the existence of a particularly efficient language -- favours the growth of watertight membranes between mathematical and
"outside" contents, between mathematical language and everyday life or more
technical languages. And this takes place in spite of the fact that mathematics
could be an outstanding example of bruad-minded integration into reality. Indeed, as pointed out earlier, mathematics, unlike any other science, arises at an
early stage of development in the then "common sense reality" and its language
in the common language of everyday life. Why does it not continue in this way?
How can one strengthen this integrated existence in order to resist the temptations
of separation and isolation? "Mathematics starting and staying in reality" was the
title of a lecture I once gave on several occasions to answer these questions. In
due course I will repeat these answers, which are of an educational character.
1.1.6 Concepts or mental objects?
What is the difference between number and number concept, between ratio and
the concept of ratio, between triangle and the concept of triangle, between similarity and the concept of similarity, between X (an object) and the concept of X?
This is a meaningful question for non-mathematical objects X as well, as are:
force, mass, heat, evolution, content, form, science, government, race, humanity,
poetry, pop art. The above sequence looks like one of increasing distance between "X" and "concept of X". There is at any rate a difference between both of
them. "Concept ofX" seems to mean how one conceives of an object X in acertain perspective, say, by inspection, reflection, analysis, scrutiny, or whichever
you wish.
There would be no cause to ask that question were there not a tendency to decorate tenns for objects, for dignity's sake, with the prefix "concept of"; even this
would hardly matter if one could disregard the consequences, in particular for
teaching where cognitive learning is concerned. Unfortunately teaching concepts
looks more dignified than mere teaching. Teaching concepts is likely to create the
illusion of adding more understanding to what is learned.
There have been various number concepts -- Euclid's, Canlor's, Dedekind's,
Peano 's, Frege' s, Russell-Whiteehead's, Kleene' s -- which differ formally as well
as substantially from each other. This difference, however, is a matter of expert
sophistication, and of more concern to researchers in Foundations of Mathematics than to the great majority, even among mathematicians. There have been various concepts offorce --Aristotle's, Descartes', Leibniz's, Newton's. Physicists
decided in favour of Newton, but they have so far failed to prevent people from
nourishing less educated ideas on force.
Cognition does not ,-tart with concepts, but rather the other v;ay around: conce11ts
MATHEMATICS PHENOMENOLOGICALLY 19
an earlier stage than any other field of knowledge. Forinstance, :.'odd" and "ev-n"
can be defined on the basis of "whole number". Indeed, the first mathematical
science, that of the Pythagoreans, was about Odd and Even. But what about
"whole number"? It is generated by a process, that of counting, rather than by an
explicit definition, only to become a matter of common sense rather than a -on
cept. At least since Euclid, mathematicians have searched for deeper foundauons,
and they have succeeded. New Math adherents believed that children should not
be denied this benefit. They fought common sense number, without success.
Back to Basics eventually meant back to common sense.
Specimens of circles suffice to explain what are common sense circles, and nobody who is shown a circle doubts that it has a centre (whic? may be fou-d by
trial and error or in a more sophisticated way). But at least smce Euchd, crrcles
were defined -s locuses, and in Cartesian geometry by algebraic equations. New
Math adherents fought the common sense approach, and in a s-nse they s3cceeded, at the price of expelling geometry entirely from mathemaucs mstrucuon.
Jn the mean time it has become clear to increasingly more people that, where n_onmathematicians are concerned, teaching the concept of X is not the appropnate
way to teach X. Cautious researchers now admit that concepts are pre-eded _by
something less fonnal, by initiations, preconcepts, or whatever they call it, which
in the long run means that the proper goal is still that of teaching concepts. In my
view, the primordial and -- in most cases for most people -- the final goal of
teaching and learning is mental objects. I particularly like this tenn because 11 can
be extrapolated to a term that describes how these objects are handled, namely,
by mental operations. .
Whole number, the number line (even if drawn on the blackboard), geometncal
shapes (even if materialised); all are mental objects, so far:" It is understood_(and
it is understood) that visual images are rough representabons of mental objects.
How do mental objects develop to become concepts, and what criteria reveal
whether this has indeed happened? In the case of whole number, shedding _the
strait-jacket of the positional system may be the sym-tom. -ost often verball_sation and formalisation may indicate concept formauon. It is worth menuonmg
that historically the mental object of group preceded the group concept by about
half a century. Leibniz and John Bernoulli used the word "function" for something that was no more than a mental object, and only upon the first appearance
of a letter symbol for a function in papers of d' Alembert and Euler was the road
paved for the function concept. .
The distance between ment:lil object and concept will depend on the subject matter, but even more on the individual and his particular situation. This is the reason
why it must be respected in instruction. When we deal with the teaching/learnmg
process the question "Concepts or mental obje-ts?" will be para?elled by the d1-
dactical one: "Concept attainment or constituuon of mental objects (by mental
operations)?" 20
CHAPTER I
1.2 STRUCTURE AND STRUCTURES
Structure is form abstracted from its linguistic expression. We will focus on
structure with regard ID mathematics, although much of what we have ID say applies ID a broader context In mathematics the relationship between form and content is reflected by that between something having or being a structure. Structuring is a means of organising phenomena, physical and mathematical, and even
mathematics as a whole.
1.2.1 Structures --poor and rich
A few examples will give us a clearer view of what structure means in mathematics.
A tetrahedron may be taken as a siructure consisting of four vertices, six edges,
and four faces in their mutual relation of "this vertex lying on that edge and in
that face, this edge containing that vertex and being contained in that face, this
face containing that vertex and that edge"; it is what one calls a combinalDric
structure, which in this particular example entails restricting oneself to the relations of containing and being contained in, and forgetting about what points, edges, and faces actually are, i.e. that edges are straight and faces are flat. What is
the use of so poor a structure? Well, with sets of such combinatoric tetrahedra one
can build absiractpolyhedra by identifying faces of different telrahedra with each
other -- sticking them IDgether as it were. Tetrahedra can thus be used as building
blocks for larger structures, which may become the subject of profound research
known as combinatoric topology.
We need not, however, content ourselves with the combinatoric stucture of the
telrahedron. It is more natural IO consider it as a solid in space, with true points,
edges, and faces. This is again a structure, a geometric structure. As a geometric
structure a tetrahedron is a richer structure than combinatorically. There is more
one can say about it; within this structure one can, for instance, measure distances, edges, angles, surfaces and volume.
A tetrahedron is also called a triangular pyramid. Or is it the other way round, is
the triangular pyramid a tetrahedron? No. I f this were ttue, how could it happen
that a regular triangular pyramid need not be a regular telrahedron? Well, triangular pyramids and tetrahedra are different structures. By definition, a pyramid
has a bottDm and a top (even though one is allowed ID turn the pyramid upside
down). A telrahedron can be converted into a triangular pyramid in four different
ways, as a matter of fact, by appointing one of its vertices to its top, and the opposite face to its bottom. The triangular pyramid is a richer structure than the tetrahedron.
Let us now knead the solid tetrahedron as though it were clay or dough, let us
press and deform it but refrain from tearing apart what is connected, and connect-
• :- - `Cl • • -)' .. ,_,_. I c 1_ c.
MATHEMATICS PHENOMENOLOGICALLY 21
dumb-bell. The vertices, edges, faces have disappeared. The thing is still connected and is so in a very special manner, spherelike (and certainly not like a
ring). it is a topological structure, poorer than the previous one of the geometrical
tetrahedron: no role has been assigned to distances, angles, rectilinearity, and so
forth.
1.2.2 Structures defined by relations
So far we could have contented ourselves with calling our objects figures rather
than structures. In order to become structures they must be described structurally.
Figures can be constructed out of their parts. Something that is finished can be
described structurally. One focuses on certain relations between the elements of
the figure, and chooses among them a set that characterises the figure in mind.
The easiest case is the combinatoric tetrahedron: four arbiirary objects are called
vertices, each pair of them is assigned to be an edge, and each trio to be a face,
with the mutual relations of containing and being contained. The geometric tetrahedron, on the other hand, can be described as a metric structure, by assigning
a mutual "distance" to each pair of its points (ofvertices only). It is less easy to
explain how a to polo gica/ siructure is described: by telling what is near to each
other, with no ap,lJeal to quantitative distance, that is, in a qualitative way; indeed,
topology forbids tearing and glueing, which would affect qualitative distance. As
a topological structure the border of a disk is the same as a whimsical closed
curve, but it is different from a siraight or curved line segment, which on their
part are IDpologically both the same.
More -- as well as more stringent -- relations increase the wealth of a slructure.
Dropping relations impoverishes and appending relations enriches sttuctures in
the same medium.
1.2.3 Algebraic structures
The system of whole numbers 1,2,3,. . . can be interpreted as a slructure in various
ways. While postponing the cardinal aspect, I start with the ordinal one, the
counting sequence, which is an order structure of the kind "somehow it starts and
each has its successor", while the names of the particular things do not matter. An
addition can be derived from the order in such a structure: to each pair of things
it assigns a third, its sum. Now imagine you have forgotten how this addition has
arisen! Then all that is left is an infinite system of things, distinguished by symbols, and a table with two entries which, for every pair of these things, tells what
you want ID be their sum. The relations in this system are of the form a + b = c.
It is what one calls an addition structure. The present one has some remarkable
properties, for instance, that a+ bis always the same as b +a. Maybe, next ID this
table you allow for a second one (which may or may not be dependent upon the
first) which of every pair of things tells what you want to be its product. This en-
" /"Jtc..S [::2fi/
b 1'7'1'11 - 33 22 CHAPTER I
riches the structure with relations of the kind u .v.=w.
Such systems are called algebraic structures. There are plenty of them with two
or even more operations, which may satisfy widely different condition-.
I.2.4 Structures --from smaller to larger
The best known among the algebraic structures are the number structures
• Ill, of the natural numbers 0,1, 2, . . .
• 21, of the integers . . . -2,-1, 0, I, 2, . . .
• <I;I, of the rational numbers, represented by fractions of integers such as 1 _i
5.33 • 3. 3.
•JR, of the real numbers, among which, for instance, ..fi., e, it
• CC, of the complex numbers a + b i where i = J:j

It is a sequenc_e of structures of increasing size, although not primarily -- and not
even necessarily -- of mcreasing richness.
The operations of addi-on and multiplication are the same in all these examples,
as are structunng relations of the kind
a+b::c, u. v::w,
whereas some of their properties may change. The equation
a+x:: c
is in general solvable for x only if negative numbers are admitted, the equation
u. x= v (u ,oQ)
only if rational numbers are involved, the equation
x.x=k (k>O)
only in the domain of non-negative real numbers. For instance, the solution of
x2=2 cannot be obtained as a fraction of integers, although it can be approximated
-y such frac-on-; --, H, -, : . are increasingly better approximations of ..fi..
Approowatmg is a topological concept. Beside with the algebraic structure,
the_domam ofreal (as _well as -t of complex numbers) is provided with a topological structure. In this sense 11 is not only larger but also richer than that of the
mtegers. In another _se_nse_ N, -e structure of natural numbers, is richer than <Q,
-'_and C. Indeed, div151bTIIIy JS a rich concept in JN, but a poor one in <Icl, JR, and
MATHEMATICS PHENOMENOLOGICALLY 23
I.2.5 Generating the number system
The system of real numbers is geometrically represented by the number line,
where each point, by its distance from the point 0, represents a number, positive
at one side and negative at the other. In this model the algebraic operations are
visualised by simple geometric mappings.
In the Greek tradition this was the common sense approach to (positive) real
number, which was inundated by the "arithmetisation" wave in the past century.
Arithmetisation meant disavowing the traditional geometrical foundation, and
founding conversely geometry on number. The real numbers were to be defined
by sequences of (approximating) rational numbers, the rationals as fractions of
integers, and the integers as natural numbers preceded by a plus or minus sign.
One long step backwards was taken when inatural number in turn was founded
on nude sets, deprived of any structure (and ultimately all sets on the empty set).
Sets were to be compared with each other by mapping, that is, by laying them
mentally elementwise along each other. If the sets A and B fitted each other they
were said to have the same cardinal; if they did not, even though A could be fitted
to a part of B, then A was said to have a smaller cardinal than B.
The common sense.counting number, and the common sense measuring number,
as visualised on the numberline ruler, were derived from one common root by
this profound analysis: the structureless set. Lack of structure may be an advantage in Foundations of Mathematics, which is high level mathematics, but much
too high to start with. Indeed, the proper beginning is or should be common sense.
At present most people will agree that New Math's contempt for common sense
has been a historical mistake. But has everybody really learned this lesson?
1.2.6 Geometric structures
The geometric structure most familiar to us from early childhood onward is the
space we live in -- euclidean geometty as it is called. Solid bodies allow us to
compare, or rather to define, distances, and according to this system of distances
the straight vision lines are experienced to be the shortest. From early childhood
onwards we are familiar with faithful pictures of objects, obtained by shrinking
and enlarging, called similar in mathematics. No doubt similarity even precedes
number in cognitive development.
During the 19th century poorer geometric structures than the euclidean one began
drawing the attention of geometers. Impoverishing a structure -- provided this
means removing what under certain conditions look like scrolls and curls -- can
lead to greater profundity. It is an art creative mathematicians have learned to
practise and master during the past century.
In euclidean space we are dealing with distances, angles, straight lines, circles,
planes, spheres. A first step towards impoverishing this structure is to forget
about the general comparability of distances and angles, while preserving recti-24 CHAPTER I
linearity and parallelism. This leads to affine geometry. In affine geometry all
parallelograms are the same: rectangles and squares cannot be distinguished from
other parallelograms, nor can circles be distinguished from ellipses.
A next step is to forget about parallelism, while preserving rec ti linearity. This
produces projective geometry, where all quadrilaterals are the same and all conics are the same.
One more step, and then even rectilinearity disappears as a structuring property.
Space is being impoverished to become what we formerly called a topological
structure, where we can still distinguish open curves from closed ones, the interior of a closed surface from its exterior, see whether or not a closed curve in
space is knotted, and whether or not a pair of closed curves is linked.
More than a century ago this kind of classification was introduced into geometry
by Felix Klein, when proclaiming his Erlanger program. This was the first modern attempt at structuring mathematics itself, or rather a part of it: geometry.
1.2.7 Structure of mathematics
It is one thing to interpret a small or large object as a structure, and quite another
one to attempt this with an entire area of scientific cognition. When compared
with creating, organising scientific cognition seems to be an inferior activity. Yet,
as stressed before, in no science are these two activities so densely interwoven as
they are in mathematics. A century ago such an organisation was attempted in geometry and for half a century the much broader task of organising the whole of
mathematics remained dormant. After the second World War this task was undertaken by the French group Bourbaki. Although their work required a large
amount of creativity, its eventual result could not in principle be anything but a
deductive codification of existing mathematics. To be sure, Bourbaki's work is a
monumental system of mathematics, which -- although now out of date on essential points -- has contributed enormously to the growth of mathematics. Even so,
it has in the mean time been overtaken by mathematics itself. I doubt whether a
fresh attempt can or will be tried in the future.
Bourbaki's hierarchy is primarily oriented from poorer to richer structures and -
- accidentally, and certainly not as a matter of principle -- from smaller to larger
ones. As a matter of fact this is indeed the most natural strategy for a systematic
build-up: from poorer to richer. It starts, as it were, with a tabula rasa, with that
which lacks any structure, i.e. the clean set. But after all, how can rich structures
be created from this poor start?
If A is a se- one may consider the set P(A) of its subsets, which in fact has a remarkable structure, effected by the structuring relation of containing and being
contained in.
Or, starting with two sets A and B, one gets their product, the set of pairs; it is
obtained by steadfastly taking one element of A together with one of B -- a con-
-.-.-;-.---:- I

--.i -f .-j --
Fig. 1
25
This product set is heavily structured, both horizontally and vertically. Similarly,
the whole plane can'be structured as the product of two s-aight line-, where --ch
of its points is represented by a number pair -- the way this 1s done m coordinate
geometry. .
These are mere examples of how to impose structures on given or ad hoc constructed sets -- order structures, algebraic structures, topological structures, and
combinations of structures. They can be built into a hierarchy, in order to impose
a hierarchy upon mathematics as such -- one hierarchy among many conceivable
possibilities. There is not, and never will be anything like the -erarchy of mathematics. This fact is evident from the variety of textbooks, which differremarkably from another. There is certainly an inclination, at university .level, in particular to teach mathematics as a hierarchy, although one teacher will put more water
i-to the hierarchic wine than the other, depending on the degree of immediate
utility of the mathematics taught. .
Even so consumers of mathematics should be introduced to mathemattcal structures wherever it matters, and maybe even be made aware of their structural aspects to a certain degree. This does not, however, mean 1!13t mathemati-- as such
should be presented to them as a structure, either accordmg to Bourbaki s or any
other conception. It would be a futile attempt, to be sure. .
Moreover, a system like Bourbaki's, or any variant whatsoever, d-s not do JUStice to mathematics as a servant rather than a master. The most striking shortcoming of any system of mathematics may be its treatment of natural number: most
often a disregard for the numeration structure, i.e. the decimal system.' From the
most pedestrian to the most sophisticated practice of numbers, the decimal structure is its dominating feature. From the (merely linguistic) learning of numerals
to operating efficiently with numbers, this structure is indispensable. Ye- m no
system of mathematics is it ever mentioned. Indeed, high level mathe-attcs has
been objectified and stripped of such human rudiments like the dec!mality of our 26 CHAI'IER I
fingers and toes. True mathematics behaves universally rather than anthropomorphically.
This, then, is the most striking feature of the epistemological and practical inadequacy of Bourbaki-like systems. There are more misfits. Visual geometry has
no place in them. Similarity, which in cognitive development even precedes
number, is far remote in this hierarchy, and even then is detached from its visual
origin. No place is assigned to computers, which are functional slruct!ures. Mathematical modelling of slructures for the benefit of even the simplest applications
is incompatible with the hierarchic rigidity of such systems. No attempts have
ever been made to structure mathematics as seen from reality as epistemological
source and domain of applying mathematics, although such attempts would be
extremely desirable -- psychologically, pedagogically, educationally and didactically. By their mere existence the deductive systems prevent these attempts
from being undertaken.
1.2.8 Structures as viewed from reality
This is not to belittle mathematical structures. By discovering structures within
mathematics we have learned to better understand the inherent organisation of
our knowledge. Many psychologists and educationalists still perceive cognitive
development as concept attainment. Superficially this is evident from the numerous titles of research papers which contain the word "concept", and in a more profound way from innumerable experiments where the possession or development
of concepts is said to be tested.
Knowledge as a hierarchy of concepts is a prominent feature of the Aristotelian
theory of science and epistemology. Its methodological inadequacy has become
m-nifest, mainly under the influence of mathematics. Aristotelian hierarchy is
oriented from the general to the particular, the general embracing the particular.
It is most perfectly realised in biological taxonomies, where one descends along
the lines of groups, divisions, classes, subclasses, families, species, varieties. Yet
outside botany and zoology concept formation by classification has proved unsatisfactory. Knowledge is not just more than but quite a different category from
a reference !fora or fauna, as is slructuring, when compared with classifying.
Classes contam each other, or are contained within each other; in this way generality and particularity are expressed by mere size. If, in the case of slructures, one
speaks of general versus particular -- which I do not -- the poorer struc:ture would
be the more general, and particularity would develop by enrichment.
By slructuring rather than forming concepts we get a grip on reality. We do this
with rich or with poor structures according to our needs. Impoverishing may
mean generalisation in the sense of wider applicability. Among the poorest scientific slructures, those of mathematics are distinguished by their large measure
of applicability as exemplified by numbers and geometrical objects. MathematiMATHEMATICS PHENOMENOLOGICALLY 27
As I stressed before, the identiFication of learning with concept attainment is a
superficial view, even though it is not unusual with psychologists and educationalists. It is to Piaget's merit that he stressed slructure, at least in theory, though
not as consequentially in practice.
1.2 .8.1 Structure of science, and development
I wish to stress once more the distinction between slructures within a science --
in particular mathematics -- and the s1ructure of a science. It is an old adage that
cognitive development proceeds from the particular to the general, and this direction is therefore considered compulsory for the educational process. Yet it lacks
sophistication as an adage, mainly because of the multifarious interpretation of
"general versus particular". It may be taken for granted that, for a child, being acquainted with a particular dog (or with a few of them) precedes acquaintance with
the species "dog", but classbuilding is only one aspect of cognitive development
and, for that matter, quite a modest one. Generalisation starts with situations rather than with objects and the function of a particular situ-tion is paradigmatic rather than classbuilding.
Piaget's view is more ;;ophisticated than the traditional adage, if not its direct
converse. According \o Piaget, development takes place along epistemological
lines, where epistemo is not individual cognition but, with regard to its contents,
independent of the developing individual. As a consequence, the structure that is
manifest in the present state of science is at the same time the pattern of the individual's cognitive development Experiments serve to corroborate this parallelism, and they were designed with this purpose in mind, or at least this was their
intention.
Piaget nourished this conviction before Bourbaki built his system, or at least before he could have become aware of it. He fully practised it in his work on geometry'. He chose the structure of geometry familiar to him as the canvas on which
the child's development must be recorded. This structure was Felix Klein's, although geometry had by that time already outgrown it, if ever it had fitted at all.
According to Piaget development progresses from the poorer to the richer slructures as he found them in Felix Klein's hierarchy; it goes from topology via projective and affine to euclidean geometry and, according to him, this is true as well
for the perceptive, the representative, and the cognitive aspects of development.
Piaget's view betrays a high degree of confidence in -- or should I say, obedience
to -- mathematics' hierarchies, although this has been belied by his own experiments as well as by those of others. At an early stage a child who is unable to
draw neat squares and circles, can easily distinguish neat copies of squares and
circles from bad ones.
When Piaget was confronted with Bourbaki's system of mathematics, he accepted it as an epistemology which can be interpreted genetically, or so it would
seem. In fact, I believe this to be a misinterpretation of Piaget's reaction. I rather 28 CHAPTER 1
tllink that Piaget's own conception of cognitive structure had been entirely completed by tl!at time. His acknowledgment of Bourbaki's structure of mathematics', rather than being a recognition, was an attempt to adapt the Bourbaki system
to his own conception. This has, however, often been interpreted as a support lent
by psychology to the enterprise of teaching mathematics according to the structure of this science, an enterprise which became famous under the name of New
Math and eventually proved to be a failure.
Piaget can hardly be blamed for this. Even though he believed in the genetic-epistemological value of a structure of science, tllere is no proof that he advocated
teaching according to curricula patterned on the structure of a science.
This brings us to the next point, which will anticipate later discussion.
1.2.8.2 Structure of science, and instruction
In spite of their failure in mathematics, curricula patterned on the structure of a
science, are becoming fashionable in other areas. As a pure mathematician I am
able to view more clearly the relativity of what is offered as a structure of mathematics. If I place mathematics within the larger context of knowledge and abilities, I am struck by the large gaps in what is often propagated as structure of
mathematics; for example, the lack of the numeration structure and the disdain
for visual geometry and for even the simplest applications. As a mathematician I
also feel obliged to tum against the structure of science as a means to structure
education, because my personal experience has shown me how easily mathematicians yield to this temptation.
Piaget's work supplied me with no argument from developmental psychology in
favour of a science structure curriculum, nor can this be justified by educational
theory. A science structure codifies systematically (and in the case of mathematics this means deductively) the state of that science at a given moment and, for
that matter, of a science tl!at is not even the subject of the instruction envisaged.
Moreover, there are serious arguments against science structure curricula. Systems of mathematics reveal a hierarchy oriented from poorer to richer structures
which the curriculum designer tries to imitate. "From poor to rich" is, viewed
mathematically-didactically, a questionable principle. Poor structures are utterly
abstract as is evident from the poorest of all, the structureless set. Didactically
one cannot come to grips with it, or it should be by concretising, by filling out the
abstract form, and in practice this is done by creating artificial, and often even
false concretisations. In genuine mathematics, sets as well as all of these structures serve goals; they are because they are operational. At the level where science structure curricula start, however, there is nothing mathematical one can do
with sets. So, as a curriculum designer, one arbitrarily invents things to do with
sets, which have nothing to do with the need for sets in mathematics -- false concretisation and operationalisation; nor do these have anything to do with the need
'-- .•.-.-.
MATHEMATICS PHENOMENOLOGICALLY 29
other poor structures in elementary instruction are introduced with no otller aim
than to pay lipservice to the science structure.
If these are but unfortunate slips, there are also more profound arguments against

the precedence of poor over rich structures, even from the viewpoint of developmental psychology. What is usually called abstracting, is most often nothing but impoverishing a structure. Mathematical structures have arisen in richer contexts and be created in order to be applied where they have arisen and beyond. The orientation from poor to rich has been suggested by ready to hand mathematics. In due course we will deal with learning "mathematics in action", which is re-creating mathematics, not aimlessly of course, but under guidance. If this is agreed upon, the didactically recommendable direction will be the same as that in which mathematics arises, that is, from rich to poor.
1.2 .8.3 Structuring rich context mathematically
Didactically I have opposed rich to poor mathematical structure. This, however, is not enough. One should not be satisfied by staying within mathematics. The rich structures to be offered should also be sought for olf(side mathematics, albeit with a mathematical-didactical afterthought. After the failure of science structure curricula, teams of developers chose another way: that of offering non-mathematical rich structures in order to familiarise the learner with discovering structure, structuring, impoverishing structures and mathematising. By this means he may discover the powerful poor structures in the context of the rich ones in the hope that, by this approach, they will also function in other (mathematical as well as non-mathematical) contexts. Starting with poor mathematical structures may mean that one will never reach the rich non-mathematical ones, which are in fact the proper goal.
Let us illustrate this by an example!
Who is not familiar with the so-called logical blocks, 24 in number, available in a rich variety of models, for instance, red/blue, circle/square/ triangle, big/small, thick/thin? They are a paragon of an entirely prestructured world: one piece for each combination of the four criteria. Abstract operations on sets can be concretised marvellously by means of such a model. I have opposed to this system another one which I have called a liUle world, although I have never insisted on teaching it: it is, as it were, a toy shop containing cars, animals, dolls, buildings, and so on, of various sizes, kinds of material, colours, grades of mobility, and so on. The criteria of classification are not imposed a priori but are discovered and developed by the learner himself -- characteristics of colour, size and so on, which need not be sharply determined but may be susceptible to shades. lu this little world, combinations of characteristics may be represented by many objects as well as by none, for instance, no big black wooden house but many little red tin cars. In brief, it is not a prestructured world but rather a world to be structured.
In this case, structuring is performed by classifying. I chose this example not be-30 CHAPTER 1
cause I may believe in classifying as an important cognitive activity, but rather as an example that, thanks to its simplicity, sharply features the difference between poor and structured on the one hand, and rich and to be structured on the other. Logical blocks are a striking example of the implementation succeses which can be reaped with sharply structured material -- cheap successes obtained thanks to love of ease. Rich material, open to structuring, which provides for more didactical opportunities, is more demanding and therefore less easy to implement.
Let us finish here! A large number of rich contexts for mathematics instruction is now available, more than anybody can imagine. The main problem is that of implementation, which requires a fundamental change in teaching attitudes before it can be solved.
1.3 MATHEMATISING
1.3.1 The term
After this discussion on the context and the internal and external structure of mathematics, we tum again to mathematics as an activity and look at one of its main characteristics: mathematising. Who was the first to use this term which describes the process by which reality is trimmed to the mathematician-- needs and preferences? Such terms usually emerge during informal talk and discussion before they ent-r.the _literature, and nobody can tell who invented them. In any case, m-themausmg 1s _a process that continues as long as reality is changing, broadening and deepemng under a variety of influences, including that of mathematics, which in tum is absorbed by that changing reality.
Mathematising as a term was very likely preceded and suggested by terms such as axiomatising, formalising, schematising, among which axiomatising may have been the very first to occur in mathematical contexts. Axioms and formulas are an old heritage, although the meaning of"axiom" (or "postulate"), and the form of formulas has changed in the course of time. Euclid's Elements are no paragon of flawless deductivity, as people believed for centuries, nor were they ever intended as such, as some people still seem to believe. Axiomatics, as we now use this term, is a modem idea, and ascribing it to the ancient Greeks is, in spite of precursors, an anachronism. Nevertheless, reshuffling an area of knowledge so that end_s,are chosen as starting points, and conversely, using proven properties as defm1uons to prove what was a definition originally -- this structuring 'upside down" is a mathematical activity of long standing. It is as old as Greek mathematics, or perhaps even older, although never until modem times has it as con-
-:i:---- ,-r- 1--'-o,,.•.-.'----•---i--, -_IC.'-.-,.-';'::'"•+---:.·:·---.'.-'1·-·); (2_

rooming axiomatic systems are the result of attempts to reorganise fields of mathematical research. This technique is called axiomatising, and is well understood and mastered by modem mathematicians. Its first striking example was groups.
From the tum of the 18th century onwards, mathematicians were confronted with mappings of sets upon themselves, often singled out by invariance properties, and were led to compose such mappings. In this way they became acquainted with sets of transformations which, under composition, automatically satisfied the well-known postulates, required later on for groups. Cayley, in 1854, took the unifying step to define, by means of these postulates, the (finite) object he called a group; yet not before 1870 did this new conception become whole-heartedly accepted by leading creative mathematicians, and then also in infinite substrates.
Formulas, in everyday life as well as in symbolic language, are as old a feature as axioms, or even older. Improving the linguistic expression by increasingly effective symbols and symbolisms has been a long process, which first concerned mathematical subject matter and only later also affected the language in which this subject matter was expressed. This process of trimming, adjusting, and transforming language is called formalising.
To be sure, as popular as axioms and axiomatising might be in modem mathematics, they are only the highlights and the finishing touches in the course of an activity where the -tress is on form rather than on content. The same holds true with regard to forlnulas and formalising. Axioms arise from paradigms or sets of paradigms, and axiomatising means generalising experienced paradigms. It is an old human habit to make one's experiences and actions paradigmatical, to generalise them by abstracting them into laws and rules, to create schemes to fit reality. This last activity is called schematising, which is the counterpart to axiomatising and formalising insofar as contents rather than abstract form and language are concerned.
The preceding exposition serves to explain the origin of the term mathematising as an analogue to axiomatising, formalising, schematising. I pay so much attention to it since it is not unusual, in particular in education, to restrict the term to one of its components. I myself insist on including in this one term the entire organising activity of the mathematician, whether it affects mathematical content and expression, or more naive, intuitive, say lived experience, expressed in everyday language. But let us not forget about the individual and the environmental dependence of "lived" and "everyday life" on expanding reality and progressing linguistic sophistication!
1.3.2 Some aspects
Modelling
Moreover, with regard to schematising there is a tendency to identify schemas with such things as solving formulas and procedures within formalised mathematics. Nowadays the term "schema", in the broad sense, seems to have been su-32 CHAPTER 1
perseded by more topical "model" -- a valuable term, but unfortunately devaluated by thoughtless use and misuse. I have castigated this practice often enough, or so it seems to me. [87]
Mathematics has always been applied in nature and society, but for a long time it was too tightly entangled with its applications for it to stimulate thinking on the way it is applied and the reason why this works. Counting was indeed, common sense; surveyors acted as though their pegs and rods were geometrical points and lines, and money changers, merchants, and ointment mixers behaved as though proportionality were a self-evident feature of nature and society. Even the astronomers in Babylonian Antiquity stuck as long as feasible, or even longer, to linear inter- and extrapolations in their attempts to describe celestial phenomena numerically; which meant, by means of piecewise linear and by zigzag functions, which their Greek heiresses eventually changed into goniometric ones. But goniometric functions did not drop from the sky they were studying. The underlying theory was that celestial movements ought to be circular. Efforts to save both this postulate and the contradicting phenomena gave birth to what we now would call a model describing the celestial movements -- a contraption of circles, epicycles and excenters which, geometrically and numerically processed, required goniometric functions. This model survived for almost two millennia. Kepler, rather than offering a new model, formulated three general mathematical laws of planetary motion, derived afterwards by Newton as consequences of his theory of gravitation. Newton himself refused to contrive primitive mechanic models for explaining gravitation. So, as time went on, physicists had to accept, quite often grudgingly, attraction by the force of gravitation as a model in its own right which, second only to Huygens' wave theory ofllight, was the first model in modem times to transcend common sense experience. History repeats itself: When elastic models of light propagation, suggested by 19th century's common sense mechanics, to refine Huygens' wave theory failed, physicists had to accept Maxwell's electro-magnetic light model.
Modelling is a modem feature. Until modem times the application of rigorous mathematics to fuzzy nature and environment boiled down to more or less consciously ignoring all of what appeared to be inessential perturbations spoiling the ideal case. For a long period, simple geometry and arithmetic had sufficed to strip such ideals of their disguises. But what is ideal and what perturbation? The first example of a non-commonsensical split between ideal and perturbation was delivered by Galileo: uniform motion as the ideal, perturbed by resistance or, as Newton put it, by force in general. In a way this methodology has survived up to the present day. Even ifa "rigorous" theory is available, it is almost never applied as -uch but instead simplified in order to be accessible to actual processing, which afterwards may be refined by better approximations, or immediately by feedback models. The first great example of non-trivial idealisation of this kind is d' Alembert's vibrating taut string: by neglecting, as it were, the string curvatL1 .,1\;\ 1.-'.'". ;;'.'--'G-;;'.-..ds ---- fl:'.f--'";T-O:-f--'-1-Q! >"I'.'SJ';.<f.\'\1 ,,.<--.1_-c;;;, ", .. .__-_ -c; ":-:'--f-t:-_: -I'l\f':' .-._t

become a standard tool in applied mathematics.
In natural sciences the first use of the word "model" is probably related to the well-known orrery models of the solar system, where the interplay of planetary and lunar movements caused by gravitation is rendered (coarsely simplified) by means of a mechanical device; being merely a model, justice is done to the kinematics though not to the dynamics of the celestial motions, while for practical reasons the radii of the spheres representing the celestial bodies are disproportionate to each other as well as when compared with the sizes of the orbits. Familiar as the Rutherford-Bohr atom model may be, it describes the atom and its manifestations as a little solar system, with strange restrictions imposed on the possible orbits; its model character stems from the ad hoc conditions to which the orbits are subjected, and the ad hoc assumptions regarding jumps from one orbit to another which are incompatible with the laws of classical physics. A more recent model is the drop model of the nucleus, in which protons and neutrons are smeared out as a fluid -- an idea typical of a simplifying model. A particularly revealing example is the cosmological model of the expanding universe. It was originally contrived as a purely kinetic explanation of the all-sided flight of the galaxies yet, as time went on, it became enriched by numerous features of dynamics and of elementary !'article physics, although it was still understood as a grossly simplified model of the evolution of the cosmos.
All these are idealising models, which introduce mathematical precision into a coarser physical reality or simplify a reality that is tacitly agreed to be more complex than its so-called model. Strangely enough the first use of the term "model" in mathematics aims at just the contrary: concrete models of abstract geometrical shapes, in plaster or wire and cardboard. The same mathematician who had a large collection of such geometrical models made -- Felix Klein -- was also, if I am not mistaken, the frrst to apply the term "model" within mathematics itself. I mean here the image of non-Euclidean within projective geometry--Cayley's invention which was interpreted as a model by Klein in order to concretise abstract looking non-Euclidean geometry within the frame of the more concrete looking projective geometry. Although not as palpable as gypsum models, this model is indeed more easily accessible to visualisation than its pre-image. Klein's example was the root of the present model concept with regard to axiomatic systems: what is implicitly given by formal axioms is made explicit by means of a suitable mathematical object which, as it were, fills the axiomatic form with what looks like substantial content. For instance, a particular group or transformation groups in general function as models of the general, axiomatically defined, group concept Or euclidean, in particular three-dimensional space may serve as a model of axiomatically defined linear or metric spaces. On the scale of concreteness, however, one can progress even further, by stepping out of pure mathematics, and consider physical, or merely experienced space as a model of its axiomatically defined pre-image.
Only for the sake of completeness did I mention this use of the term "model", which is actually the inverse of the term we started with. As a matter of fact, in 34 CHAPTER 1
the. present context we are not concerned with models of axiomatic systems, wiech are. lav1sh.ly used in foundational research, but rather with modelling in the sen.se of 1deahsmg. By this means we are able to simplify complex situations which are dommated by mathematical theories of too great a complexity to be pracucal, or which are only accessible by ad hoc mathematical theories.
Since onr -ubject is modelling as an aspect of mathematising, I would like to stress that m the present context I should readily include tangibly concrete models such as wind-tunnels where aeroplane models arc tested and laboratory simulauons of hydrodynamic theories. In other words, models that are evaluated by observauon rather than by mathematics, even though their mere construction may require more mathematics than the processing of many less tangible models. I would not even -xclude computer simulations of such tangible models, where the factual evaluauon requrres less mathematics than does the simulating activity. On the other hand I strongly oppose the fashion of slapping the label "model" on any -ystem of algebraic, differential or integral equations (related to or arising in applied r-earch) -- "math- -ical model", as they like to call it. According to my. term mo logy, a m?-tel 1s JUSt the -- often indispensable -- intermediary by which .a complex reality or theory is idealised or simplified in order to become accessible to more formal mathematical treatment. I therefore do not like the term "-athematical mod-l" in a context where it wrongly suggests that mathematics drrectly o- almost directly applies to the environment. As a matter of fact, this only remamed true as long as mathematics was tightly entangled with the environment. I lay so much stress on the role of the model as an intermediary because peo-le are all too often unaware of its indispensability. Much too often mathemaucal. formulas are applied like recipes in a complex reality that lacks any intermediate model to justify their use.
Probabil.ty and statistics are particularly striking examples. In probability the um from which -ots are drawn is, along with other random devices, the model by means of w-1ch one attempts to mathematise everything in the world that seems to be. condluoned by c-nce: pollination of plant by another of the same species, m-ages and deaths m a populauon, which are viewed -- rightly or not -- as if maung and dymg were decided by casting lots. This model suffices for simple -pphcauon- o.f probability in statistics. As far as I know, however, no models exist for mediaung the conventional -- or should I say, ritual -- use of correlation a_nd regression. coefficients and factor analysis in a certain kind of social, in parucolar, educat10nal research: these tools have simply been copied from other sciences. where they are reasonably justified by intermediate models.
Looking back I realise that I have dwelt more on models than on modelling, and m rather general terms at that. Maybe suspicion that this might happen was the proper reason why I hesitated so long to tackle the subject. Of course, I could have overwhelmed the reader with a catalogue of streamlined models such as harm-nic oscillator-, electric networks, transition matrices, diffusion p-ocesses, ?0:f'f) "-'-.. d-V_'(:::'--.. . ,,.,.:·.·.•.-.·.·.·

within a formulation and across formulations
within a symbolisation and across symbolisations,
within an axiomatic system and across axiomatic systems.
Why this multiplicity of "and across"? Because discovering common features,
similarities, analogies, isomorphisms is the way towards
generalising
as a subconscious habit or as a more or less conscious activity. More often than
one tends to believe, generality is achieved by the aha experience of one single
• paradigm
only to be reinforced by a few (albeit not necessarily many) more of them. Now,
generalising paradigms
is the inverse of
• exemplifying general ideas
which, if imposed, is an instance of what I have tend to call the "antididactical
inversion", which I will deal with later on. However,
approaching problematic generality paradigmatically
is a valuable
• heuristic activity
to be distinguished from fashionable heuristics, which is understood as a kit of
prefabricated tools.
When stressing the efficiency of the unique paradigm, I had in mind the sudden
emergence of fresh mental objects and operations. Yet objects and operations can
become routine through daily practice, and eventually tiring enough to provoke
streamlining and short-cutting,
which may lead to
progressive
organising
schematising 36 CHAPTER 1
structuring
and, in particular, as far as clumsy language and symbolics are concerned, to
progressive
formalising
algorithmising
symbolising.
A particularly important aspect of malhematising is !hat of
" reflecting on one own's activities,
which may instigate a
• change of perspective
with the possible local result of
• turning ihings upside down
and the global one of
axiomatising
which again, if imposed, are instances of antididactical inversion.
1.3.3 Examples
(to be continued in 1.3.5)
1. Find the middle between 16 and 72 on lhe number line! Children I observed
shifted the two points uniformly towards each oilher, first by units, and then
by larger steps, in particular by steps of 10. Short-cuts led to halving the difference, lhe half being added to the smaller number. In general terms !his
means the expression
a+ 1 (b - a).
which by algebra equals the more usual one
1 (a+ b).
After I suggested that shifting away from each other lhe two numbers would
as well keep the middle, the children eventually shifted the smaller one to 0,
and consequentially lhe larger to a+ b which, as it were, proves the usual expression for the middle.
Rather than imposing a method of finding the middle between two numbers,
it is allowed to gradually develop through progressive schematising. To
achieve generality of this scheme, one paradigm seems to suffice, even beyond the domain of whole numbers. If verbalised, the general solution " I add
the two given numbers and divide by 2" may be reformulated via the stage
"half the sum of the two given numbers" in algebraic idiom and thereby contribute to motivating the creation and the use of algebraic language.
Another generalising streak may be by asking the original question with regard to more than two numbers, with the aim of establishing the mental object
of average and the scheme of averaging. Only if one is satisfied by formal
generalisations this can be done by "the sum of the given numbers dIYide<l by
MATHEMATICS PHENOMENOLOGICALLY
37
soon as contents are aimed at, one should look for situations where the envisaged addition imposes itself in a natural way or is even implicit to the situation. I.e: not the adding of ages, sizes, prices, and so on, but rather daily consumptions of a certain food, working hours, one person's receipts or expenses
during a week or a month; or, given the total consumption of some food or
other commodity by some population, ask for the consumption per capita, or
as for speed per second, as derived from speed per hour.
It would be too much to go into more detail in dealing with the concept of average only on behalf of schematising and formalising. I will, however, mention one more generalisation of the concept of "middle", namely, the "middle" of a plane figure or a solid body. Many aspects of mathematising are required for answering the
questions which may be asked in this context.
2. If one tap fills a basin in one hour and the other takes two hours, how long
will it take both of them together to fill it?
This problem of venerable age (together with venerable ones such as two labourers working together, two people surviving together on a certain quantity
of food, and so on) looks ridiculous only as long as it is not integrated into a
broader context of mathematising and is expected to .be solved according to
imposed traditional schemes. Children to whom I posed the problem divided
lhe filled basin into two parts, each of which was assumed to be filled separately by one of the taps; two-thirds of the basin by the "larger" and one-lhird
by the "smaller" one, so both of them were filled in two-lhirds of an hour.
Even when larger numbers were given children stuck to this visualised proportionality reasoning, supported, for instance, by the substitution of a
number of "slow" taps for a "fast" tap. This strongly diverges from the traditionally sanctioned scheme of reduction to one hour: If the two taps fill the
basin in a and b hours, respectively, then in one hour the first fills - and the
second i of the basin; therefore both of !hem together manage ! + ! of it, and
the whole basin in
hours. The children's reasoning, however, corresponds to dividing the whole
basin in the ratio
b: a
to be separately filled by the two taps, thus ah of the basin by the first, which
is then the factor by which the original a hours have to be reduced.
Surprisingly, as soon as this kind of problem takes the guise of two people
walking towards each other with different speeds, adults familiar with this
type of problem usually do not notice its isomorphism with the other ones but
solve it by linear path-time graphs. It seems that distances to be distributed
among two persons are more likely to elicit geometrical strategies than are
quantities, such as tap water, work and food. :!i
38 CHAPTER I
Mental objects such as "speed" are basically schematised and formalised in
two -- opposite -- ways:
path per time and time per path;
the latter is particularly preferred when comparing sport achievements. Gasoline consumption is another example of the twin schematisation: the driver
figures out how far a full tank can take him, in order to know whether he can
cover a certain distance with one tank.
If one is aware of the manifold phenomena relaled to this twin schematisation
and the important interrelatedness of its components, the basin and taps problem and its companions begin to look less ridiculous. Harmonic adding and
averaging (that is, affer transformation into reciprocals) is indeed a precious
scheme which, to be acquired, requires carefully guided schematising.
3. The criterion for divisibility by 9, as learned at school, is hardly mathematics,
but challenging its validity-. The positional system, m<;>delled by the abacus,
can be a source of schematising: If the given number is represenled by balls
on the bows of the abacus, than transferring a ball from one bow to another
means changing the number by a multiple of 9; so if all of them are transferred
to the units bow, it appears that modulo 9 the number itself equals its sum of
digits. This reasoning extends by generalising to other positional systems.
4. With regard to schematising, percentages is too far-reaching an instrument to
be dealt with at length here. We will only indicale one feature as it is of paramount importance: the restructuring switch
from p percent more or less
to (l+ ff;) or (1 - -r(lo) times.
5. When do the two dial-hands of the clock cover one another? Infinite series,
simple algebra, or linear graphs can answer the question but, once answered,
a short-cut produces the very scheme: during one full turn of the short hand
the long hand turns 12 times, thus overtaking the short hand 11 times within
12 hours, at equal intervals. This is a far-reaching scheme, applying among
others to explain a few astronomic phenomena.
6. Ten children are at a birthday party; there are two more boys than girls.
A milk-can with milk weighs 10 kg. The milk left in it weighs 2 kg more than
the empty can.
Chickens and rabbits on a farm: 13 heads and 36 feet.
Starting by trial and error, which becomes less efficient with larger numbers,
children begin to use a rich variety of preferably visual schemes to answer the
related questions. Reasonings starting with If: If each girl takes a boy, . . . If
each rabbit was a chicken, . . . Again the end of generalising is reached in algebra.
7. In case you are not yet familiar with it, stop to think about the following problem: In a crowd of people among any five people there are always two of the
':::'JI'.i.c- .-, . .'.€. Sh :;-.,.:r -rW--1 t_ ':'.TIC-C:: G - 7 .::;--'r tr :'"I --- -'-" .' ---': -- \\' ---:-; _-. r- :' -:'I'- -, . - 1.A _,.:., .:.,, '>-1
MATHEMATICS PHENOMENOLOGICALLY
39
change the perspective: In fact there are no more than four year-classes.
8. Two players, and a pile of !(ij)matches, from which they shall in turn remove
at least one and at most ten. The player who takes the last matches, wins the
game. Since the winner cannot butreveal the trick to the loser, almost all people know it. So let the couple play another game:
A pile of matches, from which each may in turn remove a power of 2. Again
the player who takes the last matches, wins the game.
If the pile is 1or2, the player whose turn it is wins; if it is 3, he loses; if 4 he
wins, and so he does with 5 by removing 2 and thus putting the other in the
losing position 3. I f 6, however, whether he removes l, 2 or 4 he cannot but
yield the other a winning position, and therefore loses himself. 7 and 8 are
saved by removing l or2 respectively, but 9 is again on the wrong side. Going
on one would guess that multiples of 3, and no others are losing positions for
the player whose turn it is. How can you prove it? The result suggests arithmetic modulo 3. Powers of 2 modulo 3 equal l or 2. So all those high-brow
powers of 2 do not matter at all but instead it all comes down to removing one
match or two - a slight variant of our old game.
Another variant: only prime numbers (1 included) are allowed to be removed.
Again we draw up a list of winning and losing positions for the player whose
turn it is: e '
Clearly
1, 2, 3, 5, 6, 7, 9, 10, 11, . . . are winning positions
4, 8, 12, . . . are losing positions.
Indeed, whichever prime you subtract from 12, for instance, you grant the
other a winning position; however, subtracting 1, 2, or 3 from a number on
the upper line puts the other player into the lower line. This suggests arithmetic modulo 4, which degrades the game to the old one with simply replacing
10 by 3.
Still another version: The numbers you may remove are 1 and 4. Then the positions
1, 3, 4, 6, 8, 9, 11, . . . are winning positions,
2, 5, 7, 10, 12, . . . are losing positions.
Modulo 5,
1, 3, 4 are winning,
and 0, 2 are losing.
Indeed, the player whose turn it is in the first kind of state can answer any
move -1 by -4 and conversely, and thus preserve his stale.
The games proposed here show similar features to each other. What is the
deeper nature of their similarity? Are they mere paradigms of a more general
one and, if so, how to formulate this?
Rather than starting paradigmatically in each case as we did, the usual way of
presentation is to start with the final result in order to prove it -- the antididactical inversion. We presented an open end rather than a final result.
9. A sequence of disks 1, 2, 3, . . ., one side black, the other side white. To start 40 CHAPTER 1
with, all have the black side up. All even numbered disks are turned upside
down, then all divisible by 3, then all divisible by 4, and so on. Which ones
will in lhe long run again be black side up? People start experimentally, then
look for prime divisors and suchlike, only to finish with the short-cut that any
non-trivial divisor k of n has its counterpart divisor -,both of which coincide
only in the case where n is a square. A neat expositi-n would start just at this
point
10. Schematising experiences like the following leads to the idea of multiple
counting: three edges meeting at each of the eight corners of the cube would
seem to result in eight times three edges, whereas in fact there are no more
lhan twelve of them.
11. Draw one broken line throngh the five points (fig.2) of the Five of
• •
•
• • Fig. 2
the die, touching each point once and only once! How many different figures
can be obtained?
First, the idea of "different figures" must be schematised, which is done by
what is called congruence. Then the counting procedure must be structured
by classifying suitably, for instance, with respect to the midpoint of the Five:
take it as the start, as first stop, as second stop, and continue this way with a
comer.
12. Quite another aspect of malhematising but that of the preceding problems is
exemplified by the famous "grains on the chessboard": In order to estimate
264 , one replaces 2
10
by 10
3
• It is an example of numerical schematising.
13. So far I have neglected the linguistic features of mathematising. So in order
to make a choice, I consulted [87, IV,15]. Choosing means losing, which I do
not like. So please, do as I did!
14. I also didn't pay enough attention to change of perspective. This is a particularly rich subject as appears from the examples in [87, IV, 16]. Meanwhile, I
could add many more but I won!t. The subject deserves a more systematic
treatment, which I do not dare to undertake.
15. A barrel, closed on the upper side, except for four holes, which are arranged
in a square (fig.3). Right beneath the holes there are four disks, one side
MATHEMATICS PHENOMENOLOGICALLY

41
Fig. 3
black and the other side white, although their colour is invisible. The player is allowed to choose one or two holes and tum the corresponding disks upside down.
After this operation the barrel is rotated at random around its vertical axis into a
new position, yet in a way that the player cannot identify the holes he chose before. The operation is repeated ad libitum. As soon as all the disks show the same
colour on heir upper side, a bell rings and the game is finished.
Look for a strategy which guarantees that eventually all the disks will show the
same colour!
This problem is a rich mine of mathematising features. Since I should not like to
disappoint readers who would enjoy solving the problem by themselves, I have
relegated the solution to '111 Appendix.
I.3.4 Mathematising -- lwirzontally and vertically
Treffers, in his thesis3 of 1978, distinguished lwrizontal and vertical mathematising -- not sharply but with due reservations: Horizontal mathematising, which
makes a problem field accessible to mathematical treatment (mathematical in the
narrow formal sense) versus vertical mathematising, which effects the more or
less sophisticated mathematical processing. For a long time I have hesitated to
accept this distinction. I was concerned about the theoretical equivalence of both
kind of activities and, as a consequence, their equal status in practice, which I was
afraid would be endangered by this distinction. How often haven't I been disappointed by mathematicians interested in education who narrowed mathematising
to its vertical component, as well as by educationalists turning to mathematics instruction who restricted it to the horizontal one (to use Treffers' terminology)!
Eventually I have reconciled myself with the idea of this distinction, even to the
point of appreciating it positively; I do add certain nuances to its formulation, but
in a way that still respects Treffers' intentions, I believe. I have accepted the distinction because of its consequences for mathematics education, and in particular,
for characterising educational styles. I will explain this in detail when I will deal
with theoretic frameworks of mathematics education (3.1.2).
Let us characterise the distinction as follows: Horizontal mathematisation leads
from the world of life to the world of symbols. In the world oflife one lives, acts
(and suffers); in the other one symbols are shaped, reshaped, and manipulated, 42 CHAPTER 1
mechanically, comprehendingly, reflectingly; this is vertical mathematisation.
The world of life is what is experienced as reality (in the sense I used the word
before), as is symbol world with regard to its abstraction. To be sore, the frontiers
of these worlds are rather vaguely marked. The worlds can expand and shrink --
also at one another's expense. Something may belong in one instance to the world
oflife and in another to the world of symbols (road-systems, geographical maps,
geometrical figures, bills, tables, forms to be filled out, and so on). Natural
number can already belong to the world of life, while abstract addition still requires symbolic schemes. Abstract addition may have been incorporated into the
world oflife, while the cognition of its commutativity (or multiplication based on
it) still needs models which are processed and the equivalence of which is understood in the world of symbols. For the expert mathematician, mathematical objects can be part of his life in quite a different way but for the novice. The distinction between horizontal and vertical mathematising depends on the specific
situation, the person involved and his environment. Apart from these generalities,
examples on various levels are the best way to explain the difference between
horizontal and vertical mathematising.
1.3 .5 Examples
I . Counting: In order to be counted an unstructured set ofobjects or events must
be structored -- manually, visually, acoustically or mentally -- while in a more
or less structured set the available structure must be uncovered or reinforced.
This requires horizontal mathematising. Applying the counting sequence to
this (created or uncovered) structore, on the other hand, is vertical mathematisation, which, depending on the structure, can take place in a more or les sophisticated way: by using multiplication, for instance, to count a set presented
or interpreted in a rectangular structure.
2. More or less: Structoring two given sets simultaneously may be horizontal
mathematisation, while finding out which is part of which may be vertical.
Or, at another level, counting both of them may be horizontal mathematising,
while in this case reciting the number sequence, and listening to which
number precedes which, vertical.
3. Adding: A problem requiring the addition of five and three imagined marbles
to be added to each other may be mathematised horizontally by the "fingers
schema", while counting the fingers may still be vertical mathematisation. Or,
at another level, the preceding problem is mathematised horizontally by the
arithmetical sum 5+3, which is solved vertically by counting forth, or by the
replacement 4-M, or by memory.
4. Adding: If the number realm up to 10 belongs to the world oflife, then solving
8+5 by way of (10-2)+(5+2)=10+5 may be vertical mathematisation, while
dle structures of both S1lmmands have been obtained horizontally.
MATHEMATICS PHENOMENOLOGICALLY
43
ing if 2 and 9 are visually or mentally combined as linearly .structured sets and
their combination is read backwards. It may be vertically interpreted as soon
as the law of commutativity is generally applied.
6
. Addition: It is a sign of vertical mathematisation when additiondisfusedBin
1
slCtuations like the following: After the distances from A to B an ro- o
have been paced off, the distance from A via B to C, rather than bemg paced
off anew, is obtained by adding.
7. Multiplication: Five times eight (things) may be mathematised ho-zo-tally
by the rectangular scheme of 5 rows of 8 each. In vertical mathemattsatton it
is for instance read as the sequence 8, 16, 24, 32, 40.
8. Multiplication; In the long run, addition of equal summands is recog-ised anlld
dealt with as an operation in its own right -- a process that starts homonta Y
and finishes vertically.
9. Division: When dividing a number of objects among a number of persons
(dealing playing-cards to players around a table, for instance), one can start
by distributing the objects one by one, or by distributing an equal number of
objects to each person, continuing until the objects are exhausted; this is horizontal mathematisation of the distribution problem. Vertical mathemattsmg
can be seen in the search for increasingly larger shares (eventually as large as
is convenient) in order to shorten the process. This Pr,ocess is a conspicuous
example of progressive schematising (in the present case, progressive al?-
rithmising, eventually directed towards the standard algonthm of long division).
10. Combinatorics: If A and B are joined by 3 roads and B and C by 4 roads, then
how many ways lead from A via B to C? Horizontal mathematisation is -ec
ognising the structure of the problem, which may start with clever countmg,
in order to finish with vertical mathematisation by means of the product Applying this "roads scheme" in other situations may":" either horizontal or vertical mathematising, depending on the case. Replacing 3 and 4 by letter symbols is vertical mathematisation.
11.Ratio: Mathematising of visual similarity geometrically and arithmetically
may take place along a path where horizontal and v-rtical tra-ks alternate
with each other, starting with statements like: what 1s double m size here,
must also be double in size there.
12.Ratio: Putting the football scores 2 to 1, and 3 to 2 on a par with eac- other
may be refuted by comparing them with 4 to 3, 5 w4, and so on, wh1ch.'s a
trick of vertical mathematisation. Trying to find a farr method of companson
may require the use of horizontally introduced and vertically processed geometric schemes or proportionality tables.
13. Linearity: Ratio can be further mathematised vertically by the sch-me .and the
straight line graph of the linear function, as can many everyday s1tuattons involving ratio be mathematised horizontally. The rela-on bet-een cons-t ratio and straightness is a feat of vertical mathemattsatton, as is the relatton between the value of ratio and the steepness of a graph. The homontal mathe-i !
44 CHAPTER I
matisation of commercial transactions involving both a fixed and a
proportionally detennined rate is followed by a vertical one of relating features of the transaction to features of the graph.
14.Figurate numbers: Sizes and relations between figurate numbers may be a
matter of h-rizontal mathematisation as long as they are geometrically represented. For mstance (fig. 4): the sum of the first n odd numbers equals thenth square. Or (fig. 5): the sum of the (n -1)-th and then-th triangular number
equals then-th square. As soon as such expressions and relations are put into
fonnulas to be processed, vertical mathematisation takes over which, in the
-ong run, is e-perienced horizontally. The inductional steps required for provmg suc.h relatmns '.'"e again of- vertical character, even though in the long run
they will be expenenced as bemg horizontal. Verbalising complete induction
such as what is used in the proof is again an occurrence of vertical mathematisation.

• • • • • • • • • •
• • • • • • • • • •
• • • • • • • • • •
• • • • • • • • • •
Fig. 4 Fig. 5
15.P-scal t-iangle: This situation is similar to the preceding one. As long as the
tnangle ts given as such, then numerous relations between its elements are obtained .by horizo-tal mathe-atisation. The usual algebraic expression of the
bmom1al coefficients reqmres vertical mathematisation, as do well-known
combinatorial problems related to the Pascal triangle.
16.A-ea: Areas delimited by rubber strings on the geoboard are numerically obtam-d by honzontal -athematisation. In this vein the discovery that triangles
havmg the sru:ne honzon- basis and equal heights also have equal areas appears .to surpnse e-en qmte a few adults who had learned geometry at school.
Relating this expenence to the fonnula for the triangular area requires vertical
mathematising.
CHAPTER2
DIDACTICAL PRINCIPLES
Rather than being a didactical phenomenology of mathematical structures [146]
the first chapter was one of mathematics itself, although I left "didactical" out of
the title. Here it reappears. As far as the relation between teaching and learning
is concerned I like "didactics" better than "education" -- influenced as I am by
continental tenninology. I therefore chose it also for the title of the second chapter, together with "principles", which means trying to avoid details, certainly with
respect to subject matter. The principles I will deal with are my choice. In fact I
was led by one particular principle: doing didactical justice to the results of the
phenomenological analysis .
Didactics of a subject area means the organisation of the teaching/learning processes relevant to this area. Didacticians are organisers: educational developers,
textbook authors, teachers of any sort, maybe even students, who organise their
individual or group learning processes. The present work is not primarily concerned with didactics, and npt at all with ready-made didactics as opposed to didactics as an activity. Our'view on didactics will reflect the one on mathematics
presented in the first chapter: mathematics arising by mathematising is mirrored
by didactics arising from didactising. Notice that the intended parallelism even
extends to distinguishing horizontal and vertical didactising: from the didactical
reality to becoming conscious of it on the one hand and to paradigmatising it on
the other.
Yet there is a difference: the view on mathematics was the result of a phenomenological analysis, while mathematical didactics viewed as an activity is a postulate, inspired by the character of the subject area. When we discuss the practice
of mathematics education will be discussed (3.3), this parallelism will be elaborated in more detail; meanwhile it will remain implicit to the exposition of ideas,
which were conceived and are to be reborn by didactising. So, by didactising, justice shall be done to the results of the first chapter in the broader sense of this parallelism.
2. I GUIDED REINVENTION
"Problem Solving" and "Discovery Learning" have become catchwords. I never
liked them as mere slogans, and I like them even less since I first time saw them
exemplified. Problem solving: solving the teacher's or the textbook author's or
the researcher's problems according to methods they had in mind, rather than the
45 46 CHAPTER2
learner himself grasping something as a problem. Discovery learning: i.e. uncovering what was covered up by somebody else -- hidden Easter eggs.
I shall not start an idle discussion on whether mathematics arises by discovery or
invention, or to what degree it does so as a science or as an art. With regard to the
subject matter to be organised I preferred the term "discovery"; in the context of
teaching, however, my choice oflong ago was "invention", which embraces both
content and form, fresh discovery and organisation. Inventions, as understood
here, are steps in learning processes, which is accounted for by the "re" in reinvention, while the instructional environment of the learning process is pointed to
by the adjective "guided". In the first chapter I analyzed mathematics as an activity. Indeed, mathematics in individual lives starts in this way. But is the learner
allowed to continue like this? Curious children will not ask for permission; indifferent and lazy ones prefer to be guided. So in order to explain how I imagined
mathematics would be learned I long ago' chose the term 'guided reinvention".
It didn't catch. Should I have done otherwise? Fortunately I did not
Why not "heuristic", for instance? Old Pol ya, in his marvellous books, guided
young Polya, according to the heuristic method, to reinvent mathematics. Heureka -- I found it -- is what Archimedes exclaimed after an unexpected discovery.
Some time ago, upon consulting English dictionaries, I could not locate the adjective
"heuristic" between "hetman" and "hew"; only in a Dutch-English dictionary did I
find it as the translation of its Dutch counterpart. So I went to a larger library. Neither
the adjective nor the noun "heuristic" were recorded in any English encyclopedia,
whereas they occurred in the oldest Dutch, French and German ones I consulted. With
the dictionaries I fared a little better but I had to resort to the biggest ones to encounter
at least the adjective "heuristic"; not until the nineteen-fifties and sixties of this century did either "heuristic" or "heuristics" emerge as a noun. Needless to say, in the continental vocabularies the corresponding adjectives and nouns have long been terms in
good standing. Of course, the lack of terms does not at all imply the lack of the concepts they cover. Believe it or not, up to a quarter of a century ago the geometric term
.. congruent" did not exist in standard English, although we may take it for granted that
British teachers and students knew as much about congruent triangles as did their continental peers.
No doubt "heuristic" entered the English vocabulary via mathematics education.
Unfortunately, it did so in the form "heuristics" where the additional "s" did not
reflect that of physics and economics but was indeed meant as a plural. Unfamiliar with the continental tradition, the anglophone authors did not mean by heuristics a didactical method but rather a set of tricks and wrinkles, helpful for solving
mathematical problems. When I made my choice, I could not possibly have foreseen this development. So it was mere good luck that I chose "reinvention" rather
than "heuristic method". I would not have liked to see ideas on learning mathematics which I tried to convey by "reinvention", drowned by what is now fashionably known as "heuristics". -
I also failed to choose another term of good standing -- the term "genetic method"
-- because it does not allu-i.e to any activity of the kamer; moreover, althou-h it
.

DIDACTICAL PRINCIPLES 47
Leaming as a genesis, as opposed to teaching as implementation would be a good
metaphor, were it not for the biological associations of the adjective "genetic" as
opposed to "societal".
On the other hand it can hardly be denied that the first appearance of mathematics
in cognitive development does look like an almost biological genesis -- I mean
here the emergence of similarity and of whole number. Al the same time, the unfolding of number is driven by the learner's dynamics, which manifests itself (as
I pointed out earlier) in a constructive linguistic activity. The learner reinvents
the number sequence more or less consciously and this reinventing activity may
even extend to arithmetical operations. It is well-known that some children reinvent arithmetic on their own, to various degrees indeed which depends on the
children's individual characteristics as well as on their environment. Is it therefore too far-fetched to assume that, with some support, every normal child might
be able to reinvent as much mathematics as needed in one's future daily life? This
does not in fact happen and it is difficult to ascertain whether it would be possible
or not, because in general, after a promising start, the child is not given the opportunity to reinvent anything whatsoever, at least in institutionalised learning.
Instead, knowledge and action patterns are more or less imposed, as is most of
the knowledge the child acquires by instruction. This is not the place to ask to
what degree this is justifiable in general, since we are concerned here with mathematics which, as I explained earlier on, is different. One.of the reasons why it is
different is history. Can the historical learning process of mankind somehow be
repeated by individual learners? A clever youth can reinvent quite a lot of mathematics on his own, I said. So why should less clever ones not be able to do so
with the help and under the guidance of others -- adults as well as their peers?
Why should they not be able to continue the way they began?
Not all the way, to be sure. No individual needs to run through the whole historical pedigree and conceptual hierarchy of knowledge and abilities which grew
and were built through the incessant interplay of form and content. But why
should people not get the chance to aspire, to climb and to dive to heights and
depths as steep and as deep as they can reach and afford? Aside from this there
must be, in whatever direction, some level within everybody's reach. I confess
that the horizon of these levels is the one thing in mathematics education that,
over the years, I have become ever more interested in -- its natural extension and
the opportunities and possibilities to extend it as far as feasible.

This is a view at variance with that of prescribing to people a priori the mathematics they should learn. Learners should be allowed to find their own levels and explore the paths leading there with as much and as little guidance as each particular case requires. There are sound pedagogical arguments in favour of this policy. First knowledge and ability, when acquired by one's own activity, stick better and are more readily available than when imposed by others. Second discovery can be enjoyable and so learning by reinvention may be motivating. Third it fosters the attitude of experiencing mathematics as a human activity.
Traditionally, mathematics is taught as a ready made subject. Students are given 48 CHAPTER2
definitions, rules and. alg?rithms, according to which they are expected to proceed. Only a small mmonty learn mathematics in this way. If you ask mathema-
11c1ans how they "'.'cl papers, most of them will answer that they try to reinvent
tllerr co-tents. I believe the young learner may claim the same priviliege.
To do JUSlice to the phenomenological analysis I include definitions into the
realm of -ings students are entitled to reinvent. A fonnal theory of ready-made
mathematics starts with definitions and notations. Once upon a time each of tllem
was coined. Gradually and in connection with each other tlley have been improve- ul.Jn. Indeed, knowl-ge (however acquired) must be organised and systemalised m order to be efficient and effective, and fit to be communicated to otllers and to oneself (that is.' to remember it). If the student is granted the same opportumty `:_e may trust hrrn to better grasp the need of definitions and notations.
But definitions and notations are only llle start of ready-made mathematics. I
chose these as particularly striking examples, but all ! said about them holds for
the entire course of the more or less deductive ready-made system.
History teaches us how mathematics was invented. I asked the question of whether the learner should repeat the learning process of mankind. Of course not.
Throughout the ages history has, as it were, corrected itself, by avoiding blind al-
-eys, by cutlling short numer?us circuitous paths, by rearranging the road-system
itself. We know nearly nothing about how thinking develops in individuals, but
we can learn a great deal from the development of mankind. Children should re-
7'3t the learning process of mankind, not as it factually took place but rather as
11 would have done if people in the past had known a bit more of what we know
now.
New generations continue what their forbears wrought but they do not step in at
the same. level reached by their elders. They are consigned to much lower levels
from which they resume the learning process of mankind, albeit in a modified
way. Ed-cators are ch-ged with the ?ask of helping them, not by prescribing but
by allowmg the-m- to rem vent the mathematics they should learn. I agree this is far
from easy, yet it 'is even -or- difficult to properly understand how far and why.
The first and for-most thmg 1s to become aware of this challenge and to prepare
on-self to meet •.t as well as prepanng those one wants to guide on the way of
grndng therr gmded ones: "Teacher training" will give us the opportunity to
resu-e this questlo- (albeit entangled with the problem ofreinventing didactics
by didacusmg) but m the mean time I can say that common sense and guided remvenllon of mathematics will again pave the road to the answer.
It will not be a simple answer since guiding reinvention means striking a subtle
bal-ce between the freedom of inventing and the force of guiding, between allowmg the learner to please himself and asking him to please the teacher. Moreover, the learner's .free choice is already restricted by the "re" of "reinvention".
The learner shall invent something that is new to him but well-known to the
gm de.
DIDACTICAL PRINCIPLES
49
2.1.l Guiding -- where to?
Governments, who consider themselves responsible for assessment, want educational objectives to be formulated in tenns of subject matter and neatly tailored abilities, the mastery of which can be tested "objectively" (as they call it) -- that is, by computers. It is for the teachers' own good, our objectivists stress; teachers should be free to arrange their teaching at will, as long as their students are deemed likely to attain the prescribed goals. Educational authorities are supported by educators who promise to shape these kinds of instruments of assessment, and opposed by others who doubt their validity in advance. A justifiable doubt, it seems to me, but this doubt does not discharge them of their responsibility to look for better tools of assessment. This is a serious problem, which we must tackle in due course.
Meanwhile we cannot evade the question of where to guide the reinventor. Not surprisingly, I shall not answer this question with catalogues of subject matter and neatly tailored abilities. To be sure, they are indispensable, that is, as indispensable as is the table of contents in works like the present one. But table of contents and indexes are not useful unless one is familiar with the content itself -- globally familiar, I mean.
Whatever the importance of subject matter and neatly tailored abilities, they are, they are considerably less so in mathematics than in any other teaching. Since I stressed mathematics as an activity my answer to the question "where to?" will be: "to an activity". In other words, the learner should reinvent mattlematising rather than mathematics; abstracting rather than abstractions; schematising rather than schemes; fonnalising rather than fonnulas; algorithmising rather than algorithms; verbalising rather than language -- let us stop here, now that it is obvious what is meant.
If the learner is guided to reinvent all this, then valuable knowledge and abilities will more easily be learned, retained, and transferred than if imposed.
For almost a century it has been known through experimentation that meaningful matter is more easily learned and retained than meaningless matter. Whereas those experiments primarily involved verbal matter, more recent research focuses on mathematics. on arithmetic, in particular. Multiplication tables are a striking example -- at least
as long as they are considered worth learning and memorising, which I still think they are. Didactical methods have changed. The oldest method was to have children build. say, the table of 7 in the natural order 1x7, 2x7, 3x7, ... , perhaps acoustically supported by unison recitation; a student who had memorised it in this way, was expected to answer "6x7=" by whispering the table up to the stop "6x7=42". This method has now yielded to methods of unguided incidental learning by unsystematic exercises of great frequency, much like memorising phone numbers and addresses. The newer method seems to be less successful than the old, but both of them are unacceptably wasteful.
More recently, attention has beCn paid to what is called "children's informal methods", such as doubling the better known 3x7 to get 6x7. Such examples of vertical mathematising should not only be pennitted (which is not at all a trivial matter if seen from the children's viewpoint) but indeed reinforced and encouraged, either directly or indirectly, that is, through the learners' interaction among each other5. ! i
50 CHAPTER 2
There are also indications that transfer is favoured by guided reinvention. in particular if word problems are to be solved by column arithmetic. We will present the evidence now available in due course.
The third member of this triplet deserves closer scrutiny. Once a more definite stage in the process of learning by reinvention has been attained, intermediate stages are likely to be wiped out of the reinventor' s memory; and as time goes on, the whole learning process may even be obfuscated as though it never took place. This is not necessarily a loss as long as its essentials can be restored in case of need. If not, there is nothing left to be transferred. What kind of measures can be taken to prevent this? We will try to answer this question when we deal with "retrospective learning" (2.4.5, 3).
When asked "where to" the reinventing learner should be guided, my answer was: to mathematising and its various aspects. The lack of more substantial objectives can be made up for by asking what the learner is expected to mathematise. This can be answered in one word: Reality. What kind of reality? The learner's own reality as laid open to him by his guide. This leads us to the next question.
2.1.2 Guiding -- where?
1. Counting is the child's frrst verbalised mathematics; verbal counting may even precede counting something. So many kinds of things are present in the child's world to be counted, so many are waiting to be counted, and so many new ones can be offered to be counted. Take the number of people around the table, the number of noses, eyes and ears, even feet, invisible under the table. Applying the sequence of numerals to such sets is horizontal mathematising. Wondering why some among these numbers are equal is asking a vertically mathematising question, which is answered by the extrapolating transfer of the "as many as" from one's own body to the bodies in a group. This is a valid answer, even if the underlying one-to-one relation is not made explicit, and asking to provide it would be schoolmarmish. The same holds if the "earlier" and "later" of the sequence of numerals is horizontally transferred to the "less" and "more" of sets counted or viewed as being counted. Transitivity may evolve from a horizontal mathematising experience into a vertical mathematising activity, only to become part of reality itself in the long run. For a long time in the long run, if not forever, the cardinal aspect may remain an implicit feature of number, which needs no verbalising, as it has been for millennia in the history of mankind; the same is true for transitivity of order.
The things counted are structured sets, rather than structureless ones. Such a set structure may be more or less distinctly visible in the given situation, or else, the task of structuring can be left to the learner.
The set of guests 1found the table or of children sitting in a circle on the floor is
·. ! ; ___ ; r_- --l _ - 1-'
DIDACTICAL PRINCIPLES
51
count themselves, each adding 1 to the number of his neighbour at the right. Or number one, as soon as it is his turn, may continue numbering himself, one more round, two, three, in infinitum -- unwinding, as it were, the cyclic. order. In a group of seven, which numbers does the frrst oue get? And what -d of numbers? And !he seventh, the third? And who gets number 100? Have 1t marked on the number line -- unwinding the circle as it were! This is a marvellous example of prospective learning (2.4.5, 3) of multiplication and its tables, as well as of division and, ifreflecte:l upon, of vertical mathematising. Strangely enough I have never seen this most natural example of guidance applied.
The set of eyes in a company is structured by the set of people. Or is it structured as a set of pairs? If counted by means of 2, 4, 6, . . . it is vertical mathematising, at least the frrst time it happens. How many seats in a theatre, how many occupied? How many places in the parking lot, how many cars? How many days until the holidays? How many pages left to read? To be sure, one can count all of them one by one, or more cleverly, by looking for structures or creating them. The basic arithmetic operations are likely to be applied in counting; they may even be given new meanings by the counting activity -- examples of horizontal as well as vertical mathematising.
Conversely, counting can serve to structure a situation: take !he third street comer from here! How many blocks are needed to build a tower as high as that? How many layers of briolts to build this house? A lot
How to count large quantities? Or is there any need to count them? It depends on what is worth knowing. On December 31, 1974, there were
13,599,082
people living in The Netherlands. How for heaven's sake did they count them?
Elsewhere their number is given in thousands of people,
6772 men and 6827 women.
Except for 82 people !he sum is correct. How far off could it ha-e been? .
2. Mathematics education developers, who believed m mathemaucs anmg m the reality, and in having this reality organised and mathematised by the learner, looked first for primordial sources. There are plenty of them. Make your ch0ice!
But isn't it a pity to choose one source, say of addition or subtraction, and to forget about the others? Well, the others may still get their turn. Once the said operations are mastered, they are to be applied. This is what they call word problems, disliked by students as well as by their teachers. Indeed, would you like to lea-e the safe harbour of routines and venture into the open sea? Each word problem is a new one and if you are not told how to solve it, you must then remember what addition a:.d subtraction mean and return to their sources -- which might have been clogged by the algor!hmic routines. .
There is an alternative. When mathematics education developers looked for pnmordial sources, they were nearly drowned by the variety they found. They could not make a choice or else they did not want to; if they did, they preferred not to make a single choice, but to have a rich variety. They did not want to narrow the wide real world on display, nor to degrade world problems to word problems. ! i
52 CHAPTER2
So an all-round approach is needed, or so it seems: at the very beginning a broad display of situations to be mathematised with a view to learning addition and subtraction, telling and drawing little stories, played by the teacher or invented by the children themselves. Wins and losses, spending and saving, growth and decay. jumps on the numberline (there isa big one in any classroom), bus stops with people getting on and off, signposts suggesting distances to be added and subtracted, block towers to be built and compared -- let us stop here!
3. Addition and subtraction are learned as activities, and there is no need to obliterate this origin, to freeze the dynamics of adding 3 to 4 into the static interpretation, prescribed by New Math, where 4 + 3 is merely another name for 7; even having a lry makes little sense as long as no situations are available where such ideas can be reinvented rather than being imposed upon the learner.
4. When addition is incorporated into the learner's reality, it may serve as a source for multiplication: adding a sequence of equal summands. Yet it should not be the only source, as was in lraditional teaching. It should not even be a primordial source but rather an auxiliary one. Indeed, why should one add sequences of equal summands? This "why?" is readily answered by numerous situations where summands are equal, and all of them are sources of multiplication, and for that matter, are richer than the more formal source of merely adding equal numerical summands. {Notice that this procedure may, thanks to the richer approach, afterwards even resemble vertical rather than horizontal mathematising.}
5. Division is rooted both in subtraction and in multiplication, more formally in the latter, that is, as its inversion. Elementary divisions are most easily performed by making use of just this fact. But this does not matter here. The root of division in subtraction is twofold: exhausting one measure copying a smaller one, and distributing. Formally, both look the same, even with regard to the numerical procedures applied. But division, like multiplication, requires the use of quite different sources: real-world exhaustion and distribution problems. Experimental research' has proved that disguising long division problems as "word problems" consistently and for the entire length of the learning period not only solves the old didactical "word problems" problem with regard to division, but also favours the process of learning long division: much better results being obtained in a much shorter time. We will try to explain this experience when we will discuss learning algorithms in general.
6. When the wealth of sources in reality is concerned.fractions is second only to ratio, and both of them are closely connected with each other in real-world situations. In cognitive development -- as I have often s1ressed -- similarity, thanks to its visual expression in proportionality, even precedes number, which in turn is much more easily verbalised than ratio. Although situations involving ratio and proportionality are as easily and as early accessible (in particular visual and visualised ones) as are those involving number, they are hardly considered worth paying attention in lraditional instrUction. Why? Number is so much more easily
- ... ~ .\;i-.,,,: !i,,-e_...,i_ th,,'1.f'l -.r;-'i ?:"~'b:::.'U -r.'.f.:'dr'r.r.J:'_,r; -- -r.;f ···r;:-> '?:r·r'r:i _:. 3 i-.,, (-- .. !"' :.._,i t::.::~' ,·-·;-r-"-: 1
DIDACTICAL PRINCIPLES 53
ucation developers are aware of the educational opportunities lost by the lack of attention to ratio, and research done in this field is negligible compared with that on number and separated as it is from development, hardly to the point One of the few exceptions is L. Streefland's Thesis", in which the learning of fractions and ratio are interrelated. Although the emphasis, even in Streefland 's work, is on the one lraditional didactical access to fractions -- cake divided into equal portions -- it is distinguished by the much more abundant exploitation of this source. In fact, in S1reefland's approach not one cake -- or rather pizza -- is divided by fair sharing but a varying number of them, which moreover takes place at a varying number of tables. By this simple artifice this single source of ratio and fractions is explored and exploited to such a great depth that a whole world of fractions and ratio is displayed.
7. I must admit that one important source [at the same time application) of fractions and ratio has amply drawn the attention of developers: probability. But where it did so this source has most often been tapped on behalf of probability rather than fractions and ratio. I don't feel that much progress has been made since the first attempts. We know nearly nothing about the individual learning processes by which probability as a mental object is constituted and eventually mathematised. I would guess that by necessity they are unusually long and depend on an unusually great variety of facts being experienced in reality. In spite of this, the examples of teaching probability I saw developed, were aimed at relatively short term and rather compact learning processes. As soon as long term learning processes will are considered, probability will have to be discussed anew.
8. It seems to me that the teaching of probability suffers from the emphasis on combinatorics, which through the feedback of the teaching/learning process is likely to be transfigurated from a tool serving probability into a safe algorithmic shelter, protecting against it. Of course, this does not mean we should reject combinatorics as such as a matter to be reinvented. On the conlrary, combinatorics - - and figurate numbers in particular -- is a most appropriate matter for reinvention: Starting with numerical paradigms, guessing general relations, experiencing and satisfying needs for good definitions and convincing proofs, encountering mathematical induction thanks to these efforts, and using mathematical induction, first instinctively, then intentionally, and eventually in a more or less formally verbalised manner -- all this together appears to be a most efficient course in reinvention.
9. Let us pass to less elementary mathematics! Nowadays exponential growth is on the verge of becoming an everyday idea if it has not already. On the other hand, mathematising the idea of growth has been a rather recent feature in mathematics history. Logarithm tables and the logarithmic function {the integral of- as a function of x) preceded exponential functions. If history is allowed to be rt.
invented, emphasis must be shifted from the exponential as the inverse of the logarithm to the exponential as a growth function. As a matter of fact, compound interest as an instance of discreet exponential growth had been cultivated much 54 CHAPTER2
longer; extending it to continuous growth is a historically rather recent acquisition, which only afterwards was formalised by means of the well-known exponential functions. In teaching, however, supported by a rich variety of examples,

it should be a source for and a guide to reinventing exponential (and in its slipstream, logarithmic) functions.
10. As a matter of fact, "growth" as meant here, includes shrinking --negative
growth as it were. "As it were"? It has become a linguistic habit (even far outside
malhematics) when speaking about values, magnitudes, forces, trends, or whatever, to quasi-malhematise opposite of -- in any sense whatsoever -- by negative
of. This transfer of an arithmetical relation is a most striking example of formal
transfer which carries momentous consequences for contents. Acquired as it is
much earlier in the learning process, it certainly deserves to be made conscious,
and growth and shrinking is perhaps the best opportunity to accomplish this.
11. At a more formal level, the isomorphism:; mediated by exponential and logarithmic functions between addition and multiplication are a matter of constructive reinvention. Indeed, it starts operationally in the interpolation process leading from discreet to continuous growth, only to become paradigmatical, and if
subjected to reflection, a generally formulated feature ofreal number.
12. Another case of history which must be revised by reinvention is the sine (and
other goniometric functions).
It so happened that the 75 year-old woman I introduced earlier on once asked me
what sines were good for. Though for many years I had already cherished ideas
on this subject at variance with the traditional ones, I was for a moment in danger
of relapsing into the old habit of citing trigonometry. Fortunately I did not Instead I told her about oscillations, vibrations, and superposing sine functions.
This is a more convincing answer, in particular if trigonometry as such is no longer remembered.
The sine (as well as other goniometric functions) was once upon a time invented
for the computation of triangles -- frrst astronomical and later also survey-geodetic ones. In the law of refraction it was still related to right triangles. Not until
the cycloide was studied and its equation discovered, did the sine occur as a function. Its importance greatly increased when it reappeared in the mathematical description of the oscillations of the pendulum, and of the shape and the vibrations
of the taut string. At present, vibration phenomena of all kinds is the vast domain
of application of sine and cosine.
Triangles are not the frrst and certainly not the only source for reinventing sines.
They should rather be reinvented on the level of functions, more precisely, as
graphically represented functions of time: While a wheel is uniformly spinning
on its axle, a luminous point on its rim moves periodically up and down. The
graph of its variable height is easily drawu and can be shown on a TV screen; The
graph's dependence on the wheel's radius, on its speed, on the spinning sense, on
the point observed (with consequences for the relation between sine and cosine)
DIDACTICAL PRINCIPLES 55
produced by instantaneous exposures of the spinning wheel. The occurrence of
sines in the description of phenomena of oscillation and vibration should at this
stage simply be accepted as an empirical matter of fact, which nevertheless adds
much \0 their importance.
(Note that I used the plural "sines" more often lhan the singular "sine". The plural
sounds like one is speaking about exponential and logarithmic functions alongside with the exponential and the logarithmic function. This is a mere consequence of the spinning wheel approach, with all its parameters. As soon as one
has settled on the unit for both the radius and the circular speed, on a counterclockwise spin, on the luminous point at time 0 at the "right" end of the "horizontal" diameter, and its height measured "above" the "horizontal" axis, one has got
the sine. Is this mathematical slang? I believe it is rather terminological flexibility.)
13. Neither Calculus nor Analysis is included in this overview, not because I have
renounced comprehensiveness, but because both of them, if taught at all, should
be preceded didactically by something I propose to call Differential and Integral
Metlwds. This topic deserves a place in an early stage of the learning process
where algorithmisation has not yet been developed far enough as to allow teaching Calculus or even Analysis. It is an approach (in principle by graphic representations) initially merely qualitative and later on quantitatively refined (if possible). It aims at understanding and interpreting sucff ideas as the steepness of a
graph and areas co-ered by the moving ordinate segment, maybe even curvature,
in contexts where the drawing of the curve mathematises a given situation or occurrence in primordial reality -- we hardly need stress the vast opportunities here
for reinvention. In our exposition, Calculus is better discussed alongside with algorithms. Analysis was once invented as a safeguard against false Calculus. It
still waits for justifying as a subject at Highschool level. By justification I mean
guiding the learner to avoid the pitfalls of automatically applied Calculus by reinventing more critical Analysis. As long as I have yet to see any didactical attempt at repeating this very historical origin of Analysis, I think that "Differential
and Integral Methods" is a didactically more trustworthy safeguard than Analysis
can be trusted to be.
14. In my overview I did not strive for comprehensiveness. Two serious gaps,
however, are still lefc Algorithms, and Geometry. There are reasons to delay filling them.
2.1.3 Guiding -- how?
Guiding means striking a delicate balance between the force of teaching and the
freedom oflearning. It depends on such a perplexing manifold of hardly retrievable and only vaguely discernible variables that it seems inaccessible to any general approach. Observational reports on guiding may be a source of understanding and a help for teaching guidance. Unfortunately, most of the reports available 'li'
56 CHAPTER2
are concerned with single lessons or short sequences, and little is known about
long term learning processes.
My own teaching experiences, on which I have reported incidentally and unsystematically, are concerned with individual children. Let me mention two more
syste-atic reports [73; – 54]. Th_e firs_t, though concerned with a 5 1 year-old boy's
expenments on a physical subject, is essentially mathematical reinvention. The
second publication is unfortunately only a short summary of a larger report on the
long-term teaching arithmetic and mathematics to a 12-14 year-old: fractions;
negative numbers and vectors; linear graphs, functions, equations and inequalities; powers. Let me quote myself from the above publication:
It was my instructional principle to put her in concrete. if possible, visual situations
and to let her work intuitively. Never did I explain anything to her. never did I formulate any rule, nor did I ask her to formulate rules. When I had the impression that she
;as s-II behaving as acting intuitively and insightfully, whereas she had already algonthmised the type of problem, I exaggerated the numerical data in the problem in order
to make the algorithmic procedure visible. I asked the question "why?" only if I was
sure she knew the answer.
The method was conditioned by the learner. With other children, for instance, I
insisted much more on reflection. With others I did on occasion suggest an answer, but when this happened with her I inserted this symptom of impatience into
the report and blamed myself for it.
Never -xplain anything -- how is it possible? Well, the situations this girl was
placed m were self-explanatory, and the only thing I added was something resembling the caption to a picture. For instance:
That is the x-axis;
that is a vector;
that is putting into brackets;
2.2.2.2.2 = 2
5
reads 2 to the power 5.
I can extract two principles from my report:
a) Choosing learning situations within the learner's current reality, appropriate
for horizontal mathematising.
b) Offering means and tools for vertical mathematising.
It may rightly be argued that individual instruction like the above cannot be normative for the reality of instruction in general. This is correct, not because of the
mere fact that it is individual instruction but because of the unlimited opportunity
the teacher for improvisation granted in this setting, by which he can reinforce
the learner's att-mpts at. reinventing. In the average classroom -- one would say
-- only pedagogical gemuses can act tllis way, but the average teacher needs ins?"ctio.nal plans, predesigned by able developers. Yes, indeed, but then predes1gned ma style that does not unnecessarily restrict the teacher's freedom to take
advantage of the class situation as it presents itself at any given moment, so that
tile sit-ation can be grasped by the teacher's intuition and experience, and fitted
according to the rec,cher' s princ-i?les. This requires a sv-tef1:1 of
DIDACTICAL PRINCIPLES
57
lation, but -- maybe even more so -- in that of a mutual relation between the learners, leaving the teacher in the background more room and time for efficient improvising. The teacher's apparent withdrawal is manifest in allowing and stimulating
d) The learner's own production, which includes the reinvention not only of solutions but also of problems -- a most effective kind of training. Viewed from the
curricular perspective, improvising is facilitated by intertwining teaching
strands, which should result in
e) Intertwining learning strands, an idea that shall be elucidated in connection
with long-tenn learning processes (2.4.5, 4).
The Five Tenets a-e are from A.Treffers
7
• I would not be able to formulate more
concisely what, in my view, guidance means in "guided reinvention". This brief
exposition covers the principles and at the same time leaves plenty of room for
further elaboration.
2.1.4 Algorithmising
1. Algorithmising aims at the mastery of particular algorithms to be acquired. Or
rather, let us con-ider it for a moment from this viewpoint Mastery of algorithms
is as crucial forindividual progress as it has been historically for that of mankind.
Algorithms allow us to act automatically for long stretches of time, avoiding the
perturbing or delaying interference of insightful thought. But algorithms are exacting; mastery means either complete mastery or none. Less than 100% mastery
can mean that everything is wrong. Of course, nobody is infallible -- not even
computers. Mastery includes the ability to identify and to correct one's mistakes,
casual ones such as computational slips, and fundamental ones such as applying
an algorithm where it does not fit. Mastery, moreover, includes lost mastery to be
recovered.
Algorilms can be taught. The learner is offered a paradigm to be imitated. One
paradigm may suffice. The paradigm donner suffices to teach the first conjugation of French verbs (except the irregular ones). One paradigm may suffice to
teach an algorithm. If not, a few more are offered, or as many as are needed. Usually it works. If not, the pupil is considered a failure.
Learn first, understand afterwards! For a long time this was tile adage for teaching, and maybe it still is to many teachers. Was the "first" ever justified by an "afterwards"? Anyway, instruction has proved to be a success story. Otherwise how,
for heaven's sake, would you explain the undeniable fact that so many mathematicians are ready to produce so much mathematics as is published today? Well,
there are people who can learn mathematics this way. I am one of this sort. Or
rather, I was -- up to the moment when I discovered that what I had learned was
no mathematics at all. (Let me forget geometry for a moment, which is our next
case.)
There are algorithmically gifted people who can learn a lot of algorithms in this 11"
58 CHAPTER2
way. Moreover some can apply them if needed, and a few can remember even
those they never applied. Still fewer somehow get the opportunity of experiencing mathematics to be quite another thing than they had thought it to be.
Algorithmically gifted people seem to form a small minority. Nevertheless, even
those outside this group still had to learn algorithms and to apply them. This is
still true in the age of computers and calculators, perhaps even more so. One has
to know which button to push, and hardware buttons are no easier than brain buttons.
Learn first, understand afterwards. I don't remember when I myself eventually
understood. Rather late, I guess. Too late, at any rate. I mention it, by the way, in
order to argue that the medicine I am going to prescribe is also meant for those
who will understand eventually.
As a matter of fact, "understandingfirst" isn't a new medicine. At the beginning
of our century (or even earlier) textbook authors started justifying the algorithms
they were going to teach (or have taught by the teachers) in advance, and so did
teacher trainers, or at least they pretended to. Did teachers follow suit? It is a useless question. "Justify beforehand" is not an effective medicine. "Justify beforehand" implies "forget afterwards". It is a tenet of the logic of separating form
from content which, if at all, works after rather than before understanding. Even
if argued beforehand, an algorithm is not better learned than if argued not at all.
Algorithmising means that arguing is left to the learner, even if it remains implicit
to the learning process for some time or forever. If argued, algorithms create the
illusion of simplicity because they were tailored to look simple. Reinventing algorithms, however, can be a tedious and time-consuming activity, and it sophisticated strategies are necessary to convince teachers, textbook authors, developers and researchers that the final result is worth the labour and time spent. Reinventing
algorithms involves a progression of schematisings, which is shortened
again and again by the reinventor, who is allowed to approach the standard algorithms as closely as learning needs and abilities urge and permit Let me illustrate
this by a few classic examples from teaching arithmetic/.
2. Palpable material, at present available to learners to fill the linguistically acquired formal number sequence with contents, is intended to stimulate schematising by packing units (fig. 6)
•1 Fig. 6
DJDACTICAL PRINCIPLES
Cl

and tens of bead units are readily exchanged for higher ones (fig. 8).
Fig. 9
again schematised by the position card (fig. 10)
Fig. 10
which is the last step before the final schematisation of column addition.
59
Actual reinvention is less streamlined than the above example. For instance, 60 CHAPTER2
choosing the order of processing the particular columns is left to the learner. The
latitude is even greater in reinventing column subtraction, where heterodox tools,
such as (implicit) negative numbers, are allowed:
43
-19
3Q
;24
where the underlined 6 means 3-9 ; - 6.
Column multiplication allows for an even larger number and greater variety of
reinvention paths. A problem such as
A directory of 62 pages has 45 names per page; how many names are there?
may first be interpreted as 62 times adding 45 -- a process that is gradually shortened and schematised by using (and at the same time improving) the knowledge
of multiplication tables, and by taking ever larger groups of tens in the multiplier
(fig. 11). The students are allowed to work on different levels of shortening and
schematising and to proceed at their own pace towards the standard pattern of
multiplication.

the progressive algorithmising of long division (fig. 12), which has already been
mentioned in (1.3.5, 9). The progression of shortening consists of subtracting
ever larger chunks of the divisor from the dividend.
During the entire process of learning column multiplication and division, all exercises are formulated by way of "word problems", which aid rather than impede
learning. Even when column addition has become part of the learner's reality, the
redundant support from a reality acquired earlier is still valuable, or so it seems;
and the same is true for long division with respect to subtraction and multiplication. When we put Reality in its didactical context, we will deal with this question
once more. Using Treffers' terminology we call this teaching strategy integrated
progressive algorithmisation. Experiments' have proved it to be much superior to
the traditional "isolated progressive complication", as labelled by Treffers. Jn
spite of the integrated learning, almost all children reach the stage where the algorithm can be detached from the learning context and attains the status of having
a reality of its own, although in the case of long division, however, not everyone
gets as far as the standard form, which can hardly be considered a "must" in the
age of calculators.
3. Fractions are a case apart, at least in the eyes of L. Streefland as set out in his
Thesis'. Fractions are a subject of schematising, not only to a greater degree than
the arithmetic of whole number, but also in a more sophisticated way, even
though this is less so with regard to algorithmising. Mastering the algorithms for 62 CHAPTER2
fractions is not aspired to, and perhaps in many cases not even desirable, lest it
be degraded to blind mastery. There is nothing lost if the goal of algorithmic fractions is relegated to those parts of algebra where they are really needed, although
I judge it feasible even in arithmetic, provided the teacher is allowed to observe
the uunost restraint in guiding the learner.
This view is based on the teaching experiences [154] I mentioned above (2.1.3),
where algorithmic rules were never explicitly formulated, but where the learner
acquired them by tacit generalising. For instance, after a large sequence of exercises such as
made on the numberline,
7
I I
and suchlike were made without any visual support. One operation after the other
was tacitly detached from its visual source. When, after a time the child's teacher
noticed her progress and taught her the algorithmic rules for fractions, she needed
three weeks to recover from this intervention, which had seriously damaged her
mastery of fractions. I must confess that I did not teach her division by fractions
until it occurred automatically in algebra. Although she never explicitly learned
the famous rule on the multiplicative behaviour of the decimal point, she did apply it correctly.
4. In the same vein I had her reinventing algebra, that is, by algorithmising. Indeed, algebra offers a profusion of algorithms, less standardised than those of
arithmetic, and for each particular problem a greater choice. One may question
whether negative number properly belongs to arithmetic or to algebra. In one respect -- computations with letters -- it does not. On the other hand, the algebraic
permanence principle is didactically crucial for operating on and with negative
numbers. I applied it in the form I have called the geometric-algebraical permanence principle in [146, Chap.15), from which I also borrowed the teaching slrategy: first the "thermometer", then vectors in the coordinatised plane, in order to
step fmally with linear equations and inequalities into algebra. Let me give a typical example of progressive algorithmising: Up to a certain day the same girl had
the habit of solving equations like
by first multiplying by 3, and then dividing by 2. On that particular day it so happened that she drew the direct conclusion
DIDACTICAL PRINCIPLES 63
which then became a tacitly applied rule. I never intervened to suggest such
short-cuts. She had, in fact, discovered them long before but didn't dare apply
them overtly because she was unsure of my approval; indeed, sometimes when
she took short-cuts, she cast a playful glance as though asking for my permission.
(I attach great value to the above experience, although pecple usually shrug about
the fuss I make ofit. "People" -- I mean non-mathematicians. Creative mathematicians have experienced similar developments by themselves)
Another example of short-cuttings: Exercises like
3 5
a -a =
were initially dealt with by way of
until larger exponents provoked short-cuts. Never was any rule formulated on the
behaviour of exponents under multiplication and division.
Still another example: For a long time she clumsily calculated expressions like
before applying short-cuts toward the usual formulas.
How fast do algorithms learned in this way stick? I will try to answer this question later on (2.4).
5. I promised to deal with Calculus from the viewpoint of algorithmising. As a
matter of fact, Calculus was invented as an algorithm, or rather, one of its inventors, Leibniz, was obsessed by a passion for algorithms. To his regret and our satisfaction, this passion was satisfied once and only once, by the invention of Calculus. The advantage of Leibniz' notation above Newton's is that, with its
differentials, differential quotients, and integral symbols, it candidly exposes its origin.
I know very well that Leibniz' suggestive notations are in the black book of authors who fear the wrath of the rigorous mathematician and I agree that teaching
differential and integral methods while doing justice to Calculus as an algorithm
requires more sensibility than imparted in teacher training. On the other hand I
firmly believe we are not allowed to deprive the learner of such great values. In
[40, chap. 17), I lried a synthesis of Calculus as an algorithm and as Differential
and Integral Methods. Reinvention is here a bigger problem than in the domains
I have dealt with so far. Reinventing something that since Archimedes has waited
for about two millennia to be invented the first time is not that easy. It requires
slronger but nevertheless more subtle guidance. It seems to me that we are just
beginning to understand and tackle this problem.
6. At the beginning of this subsection I announced a more comprehensive view
on algorithms and algorithmising. Algorithms are, as it were, the shop-windows
of mathematics, that is, of ready-made mathematics. For many, if not for most 64
CHAPTER2
people, the result of mathematics instruction is a view of mathematics as a basket
of formulas and recipes, which at a closer glance may be as full or as empty as
suits its owner. Algorithms are indispensable. One can get quite far with algorithms -- also far astray. Algorithms are tempting. Mastering an algorithm may
make one feel happy. Algorithms are easily taught and when taught as snch, they
are likely to be remembered in the same way. But how to rectify this picture of
mathematics as a basket of algorithms? How to cure this aberration?
An ounce of prevention is better worth a pound of cure. The treatment I propose
is: algorithmising. Reinventing algorithms may be a means of preventing them
from becoming calcified, and mathematics from being identified with algorithms. It may indeed be a means but will it suffice as such? Probably not, but
perhaps it will, provided the algorithm once acquired does not wipe out the memory of its acquisition. Keeping this alive, at least in a dormant state, is a subject
we will discuss when dealing with learning processes.
2.1.5 Reinventing geometry
Viewed developmentally, geometry is the direct opposite of arithmetic. Space
and the bodies around us are early mental objects, the results of structuring and
being structured. To what degree are they mathematical objects? To what degree
are distances viewed as lengths, chunks of matter as volumes, bodies as figures?
Name-giving is a first step toward consciousness. But a name for geometric similarity, for instance (which is one of the earliest geometric experiences), is still
far away at the time it is experienced. It has to be invented. The Greeks did this
by lending the general word for similarity a specific geometrical meaning, but
even nowadays this has hardly influenced everyday language. One says: copying,
reducing, enlarging. "They are the same, uh, this one is big, that one small, uh,
the same shape." Geometry, though omnipresent, too often lacks the linguistic
means for expression.
Arithmetic, however, starts as it were as a language, of counting, which eventually becomes the language of counting something. It is an algorithmic language,
which provides the first algorithm -- an automatism producing the number sequence. And so it goes on in arithmetic: Every idea is as quickly verbalised as it
arises, by existing as well as by fresh vocabulary. Verbalisation propels abstraction.
But abstraction starts earlier, as early as language or even earlier. It is implicit to
the processing of sensual and motor experience, and not until linguistic support
is needed, is abstraction adopted or created. I think that this is the reason for the
lack of geometric vocabulary in everyday language: it is simply not needed. In
our world there is a need for words like chair and table, and for words that help
us to distinguish diffeient chairs and tables from each other. There is a need for
topographical terms like above imd below, left aPd right, mside and 01 tside. GeDIDACTICAL PRINCIPLES
65
and palpable force that delays, if not impedes, their veroalisation. Moreover, various modes of geometrical abstraction are competing with one another and, in
particular, with the topographical mode. Pieces of a jigsaw puzzle are freely
moveable; all that matters is their congruence class, or so it would seem. But the
picture they are expected to compose may not be hung upside down, and this information imparts such stigmas (edges, sky blue, feet, smoke) to some of the
pieces as may support the work of composing the picture.
Geometrical abstractions are much more stringent than those leading to chairs
and tables. They depend on contexts, which as a mere fact is trivial. They depend
on a geometrical context, which as such is not at all trivial. I say ! ? geometrical
context because there are many, although which one is usually implicitly understood.
Verbalisation propels abstraction. This cannot be less true in geometry than it is
in arithmetic. Anyway it need not, but this need has been awfully wronged by traditional instruction. Indeed, all means of verbalising geometrical ideas and operations have always been available in little children's language. They were simply
not used because teaching geometry did not start until the age of 12 to 13 when
children were judged mature enough for Euclid -- forgive me this venerable British instructional terminology! They were judged mature enough, although almost
everybody knew they were not. The need for propaedeutic courses was felt; in
[40] I reported on s6me marvellous ones, but they did not solve the genuine problem. Propaedeutics as such is a preposterous view on mathematics learning. If it
is true that learning is a discontinuous process, then it is so by jumps rather than
by cuts: jumps of reinvention rather than cuts of indoctrination. There is as much
difference between schooling and preschooling as there is between suppositions
and presuppositions, that is to say, none at all. But let us not anticipate too much
what we still have to say about the unity of learning processes.
If it is true that arithmetic and geometry develop mentally as direct opposites of
one another, this does not imply that one of them should be dropped in favour of
the other. Instruction should instead continue this development, that is, help geometry to stride at a pace comparable to that of arithmetic, while respecting their
opposite origins. Instruction should pay as much attention to geometry as to arithmetic, though a different kind of attention: broader to arithmetic and more profound to geometry. Whereas in arithmetic algorithms should be pursued watchfully so as not to loosen the bonds with reality -- the primordial one included. Indeed,
reality is omnipresent in geometry, both visually and palpably, waiting for
non-algorithmic schematising, and supported by badly needed veroalisation.
Tue variety of situations where arithmetic can start and stay, although much richer than traditionally displayed, is utterly poor if compared with those in which geometry arises -- nay, can be made to arise: rather than gazing at "Euclid", let us,

in order to find out, pass in review the impressive row of more recent proposals
and attempts. It is a precarious wealth, however. Choices have to be made, not as
in arithmetic, of sources and approaches, but of subject matter. There is so much
available, and the danger looms large of choosing too many. Or even if there are i'
ii
66 CHAPTER2
not too many things to choose from, the choice may be too incidental: nice problems, one nicer than the other, and each of ready to stimulate reinvention but as
well ready to be lost in the stream of new experiences, a hapax /egomenon, a
nonce experience. Cautiously applied, the operational structure of arithmetic may
provide a global guide-line for reinvention. Geometry can be structured deductively, although this is of no use unless deductivity itself is reinvented. Little deductive steps -- why not? -- it is common sense; perhaps even a bit of local deductivity. But how to link together nice pieces of geometrical reinvention, to get
chains of long-term learning processes, rather than leaving the learners with
heaps of loose ends? I think that this is the very problem in teaching young children a kind of geometry that is likely to come too late for older children.
Posing rtice geometrical problems is particularly gratifying when little hints suffice to solve them Take, for instance, the following three:
Find the centre of a given circle!
The diagonals of a parallelogram bisect each other -- why?
The angle inscribed over the diameter of a circle is a right angle -- why?
The hint I have in mind is quite simple: cut out the figure! When cut out, a figure
can be manipulated, folded, moved, turned around. Symmetry proves a lot of
things, and as a principle it can concatenate quite a number of geometric reinventions. But this does not suffice to solve our problem. Or more pointedly, problem
solving does not solve the problem.
Let me recall the tenets d and e from (2.1.3)! One of them is the children's own
production, which includes reinventing not only solutions but also problems.
This tenet has successfully been applied in arithmetic; so why should it not be applied in geometry? The wealth of situations to be geometrised is an ever-lasting
guarantee.
The other tenet was the intertwining oflearrting strands. The strand "numberline"
is long enough, and it can be broadened to the co-ordinatised plane, which in turn
can be restricted to the geoboard. Ratio and measurement have geometrical components, which should be taken seriously: similarity and congruence.
But don't forget about it the very first key. I mean tenet b: offering means and
tools for vertical mathematising. In the case of geometry this means, as emphasised above: linguistic means and tools to geometrise spatial experience.
2.2 BONDS WITH REALITY
2.2.1 Primordial reality
Mathematics has arisen and arises through mathematising. This phenomenological fact is didactically accounted for by the principle of guided reinvention.
C-/.-;-,.-:^. -c-:-:.c. - -_ .;7"-,i.,,,,,,,,1-- ·-.;_.,, .. ·-.. "-:\("— .. ;·--\-.-- -- ·:·;·.. ·.·--:-.,,.;-,,-. "!-·!· -. c-[- "!"— -._-·.r;•;
DIDACTICAL PRINCIPLES 67
more perspicuous mathematising.
Mathematising is mathematising reality, pieces of reality. But reality is not just
one thing; it is as many things as there are people, and to one people it may be as
many things as there are states of internal understanding and external circumstances. Anyway, as soon as mathematising is didactically translated into reinventing, the reality to be mathematised is that of the learner, the reality into which
the learner has been guided, and mathematising is the learner's own activity.
What is reality to whom depends on many variables, as does what is mathematical, what is non-mathematical, what is mathematical enough or not enough, what
asks for more mathematising. Our world, described in a vernacular that shares
names for arithmetical and geometrical ideas with mathematics language, has already been mathematised so extensely that we are no longer aware of it unless it
is brought to our attention. Much mathematics in our reality is common sense and
taken for granted, and again, how much and how great its influence is depends
both on the individual mind and its specific environment
In the preceding section I spoke casually about primordial reality. Let us focus
on the learning process for the multiplication algorit/im! In our setting questions
like
A directory of 62 pages has 45 names per page; how many names are there?
are likely to be answered by clumsy procedures, to be shortened progressively,
such as adding 62 times the number of names per page (while adding 62 numerical summands 45 is already within the range of the learner's reality). What, then,
is the rationale of this mode of instruction? Why, if at all, should progressive algorithmisation take place in an integrated way, rather than in splendid isolation?
-- to use the former terminology. Why should clear essentials be disturbed by lot
of noise?
Simple as they are, both this particular piece of instruction and the query it provokes is no more than a didactical paradigm for a principle intended to prevail on
mathematics instruction in general. Noise is eliminated as soon as newly invented
mathematics is published, and for it has long been a didactical principle to avoid
noise as much as possible where basic abilities and concepts were ID be taught.
But when mathematics once learned is to be applied (even as schematically and
straightforwardly as it is expected to happen in word problems); then noise could
no longer be escaped, and its sound is likely ID become the more disturbing however less noisy the previous learning process had been. The world is noisy; mathematising the world means looking for essentials, sensing the message within the
noise. This, too, has to be learned, that is, reinvented by the learner, and the earlier the better; once the learner has fully been indoctrinated by ready-made
schemes and algorithms it may be too late.
This explains why mathematising should not start in a necessarily adjacent reality
but in what I called a primordial reality. In still another respect our example is
paradigmatic. Is there anything more obvious than having multiplication reinvented as the addition of equal summands? But as one stops to think about it, one 68 CHAPTER2
asks oneself why, for whatever reason should one add equal summands? The answer is obvious, that is, to whoever knows it But in fact there is not one answer,
or rather, if one, it is an abstraction from many. Primordial reality yields a rich
variety of answers to this question. Both are matters to be reinvented, the question
and its many answers.
With Treffers I distinguished horizontal and vertical mathematising. Vertical
mathematising is the most likely part of the learning process for the bonds with
reality to be loosened and eventually cut. Indeed, in the long run algorithmic habits, say in learning long division, will be formed to enfeeble the operative association of division with distributing or exhausting and to relegate it to the subconscious or even unconscious. It is this danger that should be prevented by a long
lasting insistence on formulating problems in the primordial reality. Not only the
product of the learning process but also the process itself are worth remembering
and should remain accessible to the memory if they are needed. We will raise the
question of whether this policy is indeed efficient enough when we deal with
long-term learning processes (2.4).
2.2.2 Odd worlds
Strange as it may seem, it cannot be concealed that the bonds with reality may be
endangered as early as horizontal mathematising albeit in another way than during vertical mathematising arises. The imminent danger is that of the wrong
bonds -- wrong in principle rather than due to grave or minor errors. In order to
explain what I mean let me cite a most interesting research entitled 'Que/ est
l' age du capitaine?" by the "E/ementaire" team of the IREM (Institut de la Recherche sur l' Enseignement Mathematique) of Grenoble.
The team had posed the question
On a ship there are 26 sheep and 10 goats. How old is the
captain?
to 97 CE 1-2 pupils (7-9 olds). 76 among the pupils succeeded in figuring out the captain's age on the strength of these data.
Encouraged by this "success" the team administered a battery of six similar tests to
seven classes CE and six classes CM (9-11 years olds):
I have 4 peppennints in my right pocket and 9 in my left. How old is
my father?
A shepherd has 125 sheep and 5 dogs. How old is he?
A shepherd has 360 sheep and 10 dogs. How old is he?
Jn a class are 12 girls and 13 boys. How old is the teacher?
On a ship are 36 sheep; 10 fall overboard. How old is the captain?
There are 7 rows of 4 tables in a classroom. How old is the teacher?
Every problem was followed by the question: What do you think about this problem?
I will spare the reader the statistical result. Anyway. the harvest was indeed reaped
(From: N 19, decembre 1979, or Bulletin de l'APMEP, no.323, avril 1980.)
DIDACTICAL PRINCIPLES 69
For illustration, the Grenoble team has added a collection of word problems gathered from old and more recent French textbooks; these will give you the creeps.
It is a welcome suggestion that instruction (and in particular instruction of acertain kind of word problems) is responsible for the non-mathematical or rather
anti-mathematical attitude adopted by the tested pupils, but I am not sure whether
one should accept it at face value. Is instruction the real culprit, or is it not too
easy to accuse instruction of having sinned, albeit only by negligence? Aren't
there more active causes that might have produced these failures, and if so which
ones? Is the culprit really those word problems that give you the creeps? I am not
that sure.
In my youth the Sunday supplements of most newspapers and most weeklies contained a kind of puzzles -- I don't know whether it still exists -- say, a drawing of
an English garden -- a foliage vault with garden furniture and tools underneath -
-- with the caption question: "Where is the gardener?" By turning the drawing or
one's head and looking closely, one could discern somewhere between the
branches, leaves and sunspots the contours of a person who looks like a gardener
hidden in the foliage. This then was the answer to the question.
Why do we accept such a solution and at the same time refuse similar answers in
the case of the captain's age? A gardener, even when hiding, does not hang himself askew, feet up and head down, in treetops. This isn'..t normal. But our question deserves to be taken seriously and tackled thoughtfully. It touches, or so it
seems to me, the fun-t'amentals of mathematics and mathematics teaching. The
word logic is likely to be dropped when discussing this matter. The problems,
parodied by that of the captain's age, are indeed vested with a kind of logic that
uniquely determines their solution, whereas problems like those of the gardener
seem to assume nothing but visual abilities. I cautiously said "seem" since there
are more sophisticated ones of this kind that do require intelligent reasoning combined with visual aptitudes. Anyway, the appeal to logic is too easy a solution.
"Logic" and "lack of logic" are bromides to lull in nagging sceptics.
I have dubbed this prob/ematique: text and context "Context" refers to (l.2.8.3),
where it is dealt with in particular in the sense of rich contexts. "Text' means a
linguistic vehicle, in particular of word problems or text problems as they are occasionally called.
The context of the gardener problem is well-defined: the Sunday puzzle page --
the same kind of problems week after week, one generation telling the next how
to solve them. The textbook problem "26 + 10 ="is first of all situated in the context of mathematics instruction, where one learns what these symbols mean, but
its most important feature is that it remains meaningful outside any context, or if
one prefers another formulation, that it fits or can be fitted into any .context This
is, indeed, what characterises mathematics, or at least its formal aspect.
Word problems are different:
John has 26 marbles; he wins 10 more; how many does he have now?
John is a boy, boys like to play marbles -- girls do too -- it is a game where you 70 CHAPTER 2
win and lose, and with each marble won or lost the number of marbles in your
pocket increases or decreases by one unit. The context is self-evident: the problem stems from the plain reality of the child's life, and whoever does not grasp it
is advised 10 stop playing marbles -- nothing prevents him from continuing to do
arithmetic.
But let us now turn to butcher Smith whom I crune across in a textbook (or was
it on an achievement test?). Here the problem is not about 26 marbles but the 26
kg of hrun Smith had in his shop and the 10 kg more he ordered, and the question
is about how much he has now. Again a context, let us guess, from the plain reality of a butcher's life. Obviously there is some isomorphism assumed between
two worlds, the child's and the butcher's world. "John" is replaced by "Smith",
"marbles" by "kg of hrun", "wins" by "orders", and so everything is settled. More
closely viewed, however, this isomorphism is all but perfect. Marbles are won
and lost, while hrun is bought and sold -- all right. But marbles won are put in
your pocket, whereas the ham ordered by phone does not fly instantly into the
shop, and when it arrives some of the 26 kg of hrun -- I don't know how much --
will have been sold. Indeed, this is why the butcher ordered more.
The context of the butcher problem, rather than the butcher's reality, is the textbook, or more precisely the vast domain of pseudo-isomorphic images of the
marble problem, and everything I have said about the butcher problem applies as
well to the whole treasure of word problems: the context is the textbook, rather
than reality proper, or in other words, it portrays a world of pseudo-isomorphisms.
In the textbook context each problem has one and only one solution: There is no
access for reality, with its unsolvable and multiply solvable problems. The pupil
is supposed to discover the pseudo-isomorphisms envisaged by the textbook author and to solve problems, which look as though they were tied to reality, by
means of these pseudo-isomorphisms. Wouldn't it be worthwhile investigating
whether and how this didactic breeds an anti-mathematical attitude and why the
children's immunity against this mental deformation is so varied?
Arithmetic applies because of true isomorphisms. In [146, p.58], besides the usual marbles added to each other in play I listed one under the other
5 steps and 3 steps (of stairs)
5 days and 3 days
5 km and 3 km
5 florins and 3 florins
5 times and 3 times
a list I could have continued ad lib. Even though the mental process of adding 3
to 5 belongs to the learner's reality, these elementary additions still have to be
performed and reflectingly understood in primordial reality in order to grasp their
isomo1phisms. Obviously this cannot be done in a mechanistic setting, which is
likely to generate pseudo-isomorphisms, nor in the New Math fashion of cardinal
'P-·•" •rc.-.i-.-nof :y-:_:n.1:--r _'PT: J -:' .. --cUtl-J71_
DIDAC1ICAL PRINCIPLES 71
is required. The tension between the contexts of reality proper and the textbook
does not suffice to explain such phenomena as those signalled by the Grenoble
team. There is still another context implicated in the evolution of that -- mathematical, or rather anti-mathematical -- attitude. Before giving it a suitable name
I will introduce it by a few exrunples.
"How old are you?" The answer -- "four" -- is accompanied by the gesture of lifting four fingers. The child does not know what "age" means, nor what the fingers
lifted have to do with the "age", with a number of years, nor with the question as
such. According to children's folklore a lady-bird is as old as one can count dots
on its wings. Counting the number of rings of a cross-section, one learns the age
of a tree, even though one cannot explain why. One asks the cuckoo the number
of years one may still expect to live. The picture of a birthday cake together with
the question "how old is she?" provokes counting the candles. A fly-agaric pictured as a gnome's home betrays its owner's age by its white dots. And, taking a
long step into the adult world, you come face to face with hosts of people, juggling the Number of the Beast of the Apocalypse and the dimensions of the
Cheops pyramid and the Stonehenge monument. This is a venerably old preoccupation, called hermeneutics if concerned with .. the Holy Scripture, but as a matter of even older than the art of reading and writing. Looking for marks on flowers and leave,,. in order to know what ills they may cure, foretelling the future
from the flight of birds and the livers of sacrificed animals, unveiling secrets of
J.S.Bach's profundity by counting beats and bars in his compositions, and -- let
us not skip it -- expecting discoveries in psychology and education by means of
regression analysis -- it is all cut from the same cloth: hermeneutics, or else the
term I would propose, the magic context. Stories about Pythagoras and his school
tell us they practised witchcraft through numbers. Is it too bold an assumption to
credit children with this kind of mentality? From my own childhood I remember
this context only too well, which I succeeded in eliminating from my mathematical activity. But what about many other people? To solve a problem they look
for secret marks, for signals hidden by accident or intention, and in particular, for
numbers that to put them on the right ttack.
How old is the captain? I gave this problem (with 18 sheep and 16 goots to make
it less easy and thus more stimulat1ng) to an 8 year-old girl who lived at that time
in a world of fairy tales and sorcerers where she played her small and large roles,
with gnomes sitting on each toodstool. She beamed with joy because she had discovered the secret, and had calculated the captain's age. Thanks to her enthusiasm she was unaware of the mockery of her two years older brother, who is as
sober-minded as she is imaginative, and so no illusions were cracked. When I
tried to explain to the boy how others reasoned when they calculated the captain's
age by adding, subtracting, multiplying, and eventually by dividing, he shook his
head: "I cannot understand what you mean; this yields at most the number of
sheep per dog."
This brings me to tell of another experience with these two children I had half a year 72 CHAPTER2
earlier. At the end of a stroll we came to a huge sandpit, bordered by a circle of thick
poles -- actually cuts of tree-trunks. I asked the children how many poles there were.
Resolutely the boy paced around the pit, counted 38 steps (each step being 7 poles according to his reckoning), and then concluded 38 x 7 = 266. (It is a nice example of
mathematising but this does not matter now.) Meanwhile his sister had effortlessly
solved the whole problem. She said "60", and when I asked .. why?", she answered: "It

looks like a clock-dial, does it not, and that is 60 minutes.
At the risk of being pronounced silly, I confess I like the girl's answer better than the
boy's. It is the most beautiful nonsense. which promises more geometrical imagination
than does her brother's solution. In her fairy tale world she did with her beaming eyes
what he had done in his prosaic world with his feet. I am sure that, had she been two
years older, she would have parcelled out at sight an arc corresponding to five minutes,
counted with her eyes the number of poles per arc and multiplied it by 12 (the direct
converse of her brother's kind of mathematisation).
How old is the captain? The 26 sheep and 10 goats on board are like the data used
by the astrologer to foretell the future. Children's realities are worth studying, in
particular the magic context as well as its influence on learning processes and the
shaping of attitudes. Framing the children's world in rich contexts may be a preventative measure. This has been tried in various ways. Plain word problems, if
disconnected, are probably not rich enough a context to prevent the pseudo-isomorphistic temptation; they should be interrelated by constructive and reflective
measures. Streefland's approach (cf. 2.1.2, 6, footnote) towards fractions, within
one single but deeply excavated context, is promising, although it has not been
continued as far as to reach formal fractions. IOWO's abundantly rich contexts
have been tried out successfully but dissemination of these ideas strongly depends on the teacher's conception of which realities are accessible to the learner.
We shall come back to this problem.
Let me illustrate it right now by an experience had by an IOWO staff member in a 4th
grade class with a worksheet which included:
Railroad fares according to the number of kilometres travelled (half-price for the under ten years olds), a railroad map of distances, a story about Mum's train trip with
John (10) and Mary (9) from Hilversum to Enkhuizen, and the question how much she
must pay?
Annette could not solve it, even after she had correctly found the distance HilversumEnkhuizen.
"What is the matter?"
"I don't know how old is the mother."
"What do you think?"
"I would guess: 39." (Her own mother's age.)
"All right. It is a good guess. Continue!"
So she added 39 + 10 + 9 = 58, looked up the price in the 58 km row, which at that
time was? 8.15.
"And if the mother were 50 years old, she would pay more?" our staff member asked.
"Of course she would."
"And the old people, the grand-dads and grannies, they pay even more, do they?"
"Sure, they do."

at all. What is the reason for this? My guess is that the reality to be conveyed by
this context is nothing but an adult prejudice. One should ask oneself at what age
the railroad trips, tickets sold at the windows, and the very thing travellers pay
for, represent a valid context. Or rather, under what condition, since it is not the
mere age that counts. Would practical experience be a better guide for answering
such questions? Our knowledge of instruction is covered by a thick layer of prej-
udices, but I am afraid that this holds as well for the so-called practice. Moreover,
people with much practical experience are prone lo premature interventions,
glossing over rather than revealing and bridging chasms between the child's and
the adult's realities.
Our colleague did not get the opportunity lo do this, or he simply didn'tdare because the chasm looked too wide. Remedial teaching starts at the roots, which
may lie unexpectedly deep. Yet let us ask what should be done in the Grenoble
case! The remedy lo prescribe, which for that matter, could have already been administered along with the tests, does seem readily available. I mean problems
where the applied methods will not work, such as:
250 sheep and 120 goats aboard -- how old is the captain?
360 sheep and one dog (or two, rather than the improbable 10) -- how old is
the shepherd?
I confess I arn not sure whether this would be of much help. The children might
object that there are not enough data available to answer the new questions while
insisting that the previous ones did provide enough indications. This is no miracle. Magic sometimes works and sometimes does not. Or do the fresh examples
provoke what is called a cognitive conflict? "Cognitive conflict" is an adult contraption. Cognitive conflicts have first to be experienced as conflicting realities.
If there are no bonds with reality, then conflicting realities cannot provoke cognitive conflicts.

2.2.3 Rich contexts

Fraught with relations was the term I chose in [40] for the mathematics I wanted
to be taught. In the mean time the term has become mathematics in rich contexts.
I used the term several times; for instance in 1.2.9.3, and again in the last subsection, I opposed rich and pool"• contexts lo one another. Let me briefly sketch the
evolution of the terminology!
As I pointed out in 1.3 mathematics, unlike any other science, has arisen and still
arises in common sense reality -- broad-minded common sense and broad-minded reality as I explained in l.1.6. Where it was once invented, mathematics
should now be reinvented. Contexts then means that domain of reality, which in
some particular learning process is disclosed to the learner in order lo be mathematised.
When in the early nineteen-seventies developers, in particular for primary education, looked within the reality they judged accessible to the learner, for sources '
!

of specific mathematics to be learned and taught, they were overwhelmed by so
rich a variety that they saw their task shifted from finding sources to choosing
among them. Not: choosing one and rejecting all others. But: allowing for a vast
space and a continuous flow, creating what was called context-rich mathematics
instruction. Language is more than mere communication; it influences thought,
whether one is aware of it or not Somehow, maybe under the influence of "rich
structures" (see 1.2.I), context-rich became rich contexts. Rather than discussing
the difference, I shall explain the situation, that is, what kind of wealth is meant
by "rich"?
Bonds with reality is the title of this section, shortened from Creating, strengthening, and maintaining bonds with reality. This, then, is what rich contexts have
to effect as domains of reality disclosed to the learner to be mathematised. We
once tried to group our experiences with contexts. Let me copy that unassuming
list!
First on the list, and at that lime the most striking item, the location: a meaningful
gathering of situations, which can be handled separately, or in more or less close
connection with each other. Our best known example
10
was "Waterland", a Disney-like island-- its large picture hung in the first grade classroom -- where lots
of things were happening: there were landings for ships to moor, bus stops with
people getting on and off, roads leading hither and thither, road signs placed and
to be placed, block towers and mountains to be climbed, networks of streets to be
walked on, play grounds, windmills -- a profusion of situations, where malhemat'
ics could be discovered and acted out -- an incentive to stimulate the imagination
of both teachers' and children.
A counterpart of this kind of rich context was the story, that is, rather than a gathering, something that, reeled off as a succession of worksheets, is structured in
lime. It may be a true story or fiction, a classic or invented ad hoc Examples':
"Gulliver in Lilliput", where one string -ratio- is played on over and over, or
"Grains on the Chessboard", with its powers of 2, or "Around the World in 80
days", where one tone -- travelling around the world -- is coloured by many overtones, or "Ralph the Buccaneer" with the area of islands as the main lheme, or
"Ship Ahoy" (geometrical orientation implicated in the rescue of a ship), and
many others.
The third example was the project, which means reality to be created, such as
building a bungalow (7th grade), or a peep-show box (kindergarten), or collecting and classifying all kinds of commercial packing material, or constructing regular bodies.
The fourth was the theme, a mathematically oriented strand of subject matter with
varying relations to reality, such as "Light and Shadow" (7th grade), "Flying"
(lhematising goniometric functions), "Exponential Functions" (wholly integrated
into the context of growth), "Matrices" (in various contexts, among which transition processes), "Two Variables" (that is, surfaces as though abstracted from
:-:;v-.-'f:':.'-)-f---.

time been tried out extensively and successfully. Let us call it: clippings -- mainly
from newspapers and weeklies, but also from books and other media. Anyone intent on it has little trouble discovering a lot of mathematics in the printed and published reality -- meaningful as well as nonsense mathematics. Thanks to this large
quantity, die small percentage that lends itself to mathematics lessons is still significant. Rethinking the author's thoughts, analysing whether they were right or
wrong, pursuing his ideas in order to review, strengthen, weaken, modify them,
may provide valuable mathematising activities in the upper grades and in teacher
training. Let me mention that each year one of the problems at on our final mathematics school examinations is of this kind. But even in the middle and lower
grades a variant -- let us call it pseudo-clippings -- may be useful. A pronouncement by somebody, or a quarrel in a group about some question, an explanation,
or pairs of contradictory explanations, in particular, if the mathematics involved
is still hidden, may be a useful context as soon as children are able to communicate. Should this happens in the classroom it deserves to be exploited, but inventing such stories can be an equally good idea. This then is what I would call pseudo-clippings.
Contexts were defmed as domains of reality disclosed to the learner in order to
be mathemalised. In the cases of location, story, project, and theme such domains
are purposefully -- and sometimes artificially -- delimited by the teacher or developer, who wants the learner to reinvent certain processes and products of
mathemalising. The case of clippings is a bit different Here it is not a domain but
a small piece that is cut out, although its paradigmalical value for mathemalising
and for acquiring a mathematical attitude may be enormous in comparison.
But in all cases it should be kepfin mind that context is not a mere garment clothing nude mathematics, and mathemalising is quite another thing than simply unbuttoning this garment. Or, to give a former metaphor a new twist: Viewing context as noise, apt to disturb the clear mathematical message, is wrong; the context
itself is the message, and mathematics a means of decoding.

2.2.3.1 Contexts versus "material"

No doubt once it was real progress when developers and teachers offered learners
tangible material in order to teach them arithmetic of whole number. (lo the case
of fractions it never did work properly.) Even now I would not like do without It
Whether unstructured, at the start of arithmetic, or structured, as on the abacus, it
is indispensable as part of the primordial reality. It is a small part, to be sure, one
source among many others of whole number arithmetic. Relying solely or too
strongly on it is dangerous, and since this is the habit in some kinds of instruction
I feel obliged to warn against it. Low achievers have great difficulty detaching
arithmetic from the palpable material -- according to remedial teachers and developers of remedial teaching. This may unfortunately be true, that is, for a kind
of inflexible instruction where from the start onwards learners have been tied too 76

tightly to palpable material. Flexibility should be allowed, and if need be, taught
rather than fought. Moreover, one may ask, what is the use of low achievers
learning an arithmetic they are judged in advance unable to detach from tangible
material.
Offering the learner tangible material was progress when drawing and writing
tools were too expensive to be handed out lavishly in the classroom, when teachers on a platform watched classes of children sitting on benches, when instruction
had to look like military drill and children's initiative and activity were suppressed and nobody even thought about Jiving contexts. Tangible material has a
tremendous value in teaching geometry, provided the learner is allowed to structure it himself. If we condemn the learner to the prison of prestuctured blocks --
whether counting ones or logical -- we should not wonder why they are not able
to put the mathematics learned to good use. The best palpable material you can
give the child is its own body.
At this moment I cannot resist quoting myself from 2.1.2, I:
The set of guests around the table or of children sitting in a circle on the floor is structured by its cyclic order -- .. didn't you forget anybody"? Or the children may count
themselves, each adding 1 to the number of his neighbour at the right. Or number one,
as soon as it is his tum, may continue numbering himself, one more rolDld, two, three,
in infinitum -- unwinding, as it were, the cyclic order. In a group of seven. which numbers does the first one get? And what kind of? And the seventh, the third? And who
gets number 100? Have it marked on the number line -- unwinding the circle as it
were! This is a marvellous example of prospective learning (2.4.5. 3) of multiplication
and its tables, as well as of division and, if reflected upon, of vertical mathematising.
Strangely enough I have never seen this most natural example of guidance applied.

2.2.4 Paradigms

"Paradigm" would have deserved a section or subsection of its own in the first
chapter, were it not that there, among the manifold occurrences of the term, it
would have looked like a needless repetition. The present chapter, however, offers an opportunity to reconsider paradigms as places where bonds are attached
to reality.
"Paradigm" means "example", although not as used in "for example", where it
properly means an after-example. If such a word existed, I would rather say that
a paradigm is afore-example. As far as I am familiar with the history of instruction the term "paradigm" originated in teaching foreign languages (including native language which may have looked or sounded to quite a few of the learners as
though it was a foreign one). In (2.1.4) I cited the French donner as a teaching
paradigm for the first conjugation, that is, for all the verbs ending in er (the irregular ones, of course, excluded). To what degree are paradigms really needed?
People acquire a great deal of their idiom -- structural paradigms included -- before, without, and even in spite of institutionalised instruction. This certainly
•,.,`'`-`-,,,, ,

learn languages by listening and by reproductive reinvention -- guided among
other things by corrective measures, and possibly reinforced by increasing
awareness -- and this process continues when listening and speaking are supplemented by reading and writing. As far as I am familiar with modem methods,
they take advantage of this experience by trying to approach an everyday life
style in language teaching. Structures, such as paradigms, rather than being imposed, are given the opportunity to be reinvented by the learner. A striking counter-example is our Dutch spelling. It is one of the easiest of the world. Its notoriously difficult part is the one governed by rules set in advance.

2.2.4.1 Paradigms imposed

Let us leave language teaching! The term "paradigm" has meanwhile conquered
wider instructional ranges, which is why it was applied frequently to mathematics
instruction in the first chapter. Why paradigms? Mathematics is a universal tool,
the most flexible instrument to be handled. But universals are no teaching matter,
or at least not in the manner of what is called concept attainment Universals are
learned by paradigms, and the most efficient paradigms arethose which allow the
easiest or the widest transfer. Improperly chosen, however, an intended paradigm
can as well block the transfer, by its singularity or by lack of flexibility, or simply
because of a wrong view on learning by means of paradigms.
In everyday life, in language instruction, in science teaching, etc., paradigms are
as abundant as they are unengaging. Mathematics can do with a relatively small
number of paradigms, which engage the learner unambiguously, or so it would
seem. Is an algorithm a paradigm? Of course not. But, traditionally, algorithms
are taught by paradigms, long division, for instance, by means of a numerical example (or if need be, by a few of them), which promises transfer by inviting imitation. Some children have a knack for algorithms and for learning them in this
exemplary way, and some among them will even, at least implicitly, understand
why they work, even though they are *not* interested in knowing why. Others will
fail to learn algorithms this way. Does it matter? Long division is now the job of
pocket calculators. But long division is only the bitter end. Let us look for the
roots of arithmetical algorithms!
Arithmetical algorithms used to be taught by numerical paradigms. I chose the
plural "algorithms", although properly understood, for one single arithmetical
operation one paradigm should be just enough, or if really more are needed, they
should virtually be one, in the sense of being somehow isomorphic. Indeed, nonisomorphic ones would instead endanger the intended uniform algorithmic-paradigmatic character and as a consequence confuse algorithmically less gifted
learners. The ever lasting trouble, however, with the strategy of teaching arithmetical algorithms by numerical paradigms, was that, a from column addition onwards, one paradigm was not enough. Neither teachers nor developers were
aware of the problems created by a multiplicity of paradigms needed for one and 78

the same operation, a multiplicity that in tum creates just as many sources of failure. I said "from column addition onwards", which would seem a bit exaggerated.
But do examples like
24
38+
24
35=
really suffice as paradigms (at least for additions below 100) or are not sums

taught in agreement wilh this strategy such as
24
. - i+
24
Jl.. +
5
32+
5
38+
very likely to suggest to learners that they are just as many fresh paradigms, and
wouldn't teachers think they are needed as such in teaching? And what about, say
24
39
19
24
3
12
24
9
19
2
24
-2
7
24
19
a list of new-looking paradigms, still far from complete yet long enough to frustrate learners, and for that matter their teachers as well? Long enough, I said, and
yet I have restricted myself to additions below 100 of two or three summands.
What about more summands, about more empty positions, multiple transfers, and
soon?
Although the other operations only involve two term, they certainly do not rank
second to addition with regard to the variety of what may be looked upon by the
learner as brand new paradigms. Think about all lhose perfidious zero digits involved in the other arithmetic algorithms, about decimal points, about comparing
decimal fractions with one another -- each new difficulty to be conquered by a
new rule, introduced by new paradigms! ·
How real are these difficulties? To tell lhe truth, I did not invent this story, but
took it from the literature; there has been plenty research to prove again and again
that something is wrong with teaching column arithmetic, while little attention
ha_s been. paid to ":hat is wrong and why, though one thing is clear: that teaching
anthmellcal algonthms by numerical paradigms heavily clashes with the essence
of what arithmetical algorithms are supposed to mean and to perform. Even if
teaching column arithmetic is not such a failnre as some researchers have concluded, learning arithmetical algorithms by numerical paradigms is a tremendous
waste of time.
I am not against numerical paradigms as such, and certainly not where they are
-eaningful -- see the numerous examples in (l.3.3 and 1.3.5). Numerical paradigms can be the key lllld stepping stone to general problems and algebraic relatJ, , .,,-,. V.:.
0
"I' r:-;-<-- ·:·;_;,"_S- r\1···,_' ·r-~" "-" ,· "- ·-·1-:-""". _,1 ,.-, f-' C:f ":..•-:'-'!". ":·,
DIDACTICAL PRINCIPLES
79
this principle must not be interpreted by numerically formulating ready-made
general rules. In the process of reinventing, algorilhms arise by progressive schematising, with the stress on shortening, and the very thing paradigmatical in this
process is progression and short-cuts rather than numerical examples.
Word problems are a similar case, or even worse if their context is a textbook
page, headed by one item that looks like a paradigm, that shows how to solve all
the other items on the same page. To be sure, it works. It does work until the context is extended to the textbook as a whole and the problem arises which page applies under which circumstances. Didacticians of yesteryear liked to embroider
all word problem paradigms on frames, intended as algorithms and looking like
them. Or at least they tried, albeit unsuccessfully since learning these pseudo-algorithms was even harder than understanding the word problems they were to facilitate.
Algebra looks a bit different, or does it? Cnneiform texts show how Babylonian
mathematicians solved linear and quadratic equations, or pairs of them with two
unknowns, yet all they left us is numerical examples. Did teachers use them as
paradigms, or did they explain to their students in general terms what to do? We
don't know anything about Babylonian didactics. Do we know any more about
teaching algebra today? We know textbooks -- good ones and bad ones -- but
what do we know about. teaching? What do we know about how paradigms are
used by teachers and ihterpreted by learners in instructional practice? Are they
seen as a form to be filled out or, even worse, as a sequence of acts to be imitated?
In [40, p.632] I gave an example of how problem solving is understood by students who might have been taught in this fashion. Let me repeat it!
To prove that ,,;z + 12x has a minimum and to determine the x where it is reached.
(I) 3,2+12x = 3(x+2)2 ↔ has a minimum, which is assumed for x= -2. Reason:
(x+2)2 must become 0 ---: -2 if this is multiplied by 3 ---still 0 then 4 added and
one gets the minimum which is assumed: 4.
(II) The expression 3,2 + 12x is a quadratic equation. If in both parts 3 is put outside brackets the expression does not change. Then inside the brackets is (x
2
+ 4x,l ,
that does not equal (x+2J2 for we have added 4. To make it correct, -4 must be
subtracted. The-4 must be multiplied by 3. Then we get 3(x+2)
2
-12 and this is
entirely equal to ,,2 + 12x. The expression has a minimum of -12 since a square is
always positive or O. It must be multiplied by 3, thus it is at least 0, namely if:x=
-2 one gets 3 (-2+2) -12, and this is -12. The value of the square is always positive, x 3 remains positive thus the minimum is -12.
(Examples by J.van Dormolen, reported by J.S.ten Brinke in Euclides 45(1970),
327-336.)
What is wrong here and who is guilty? Too highbrow a paradigm is sheepishly
applied in a common sense situation. Let us skip the question of whether the
whole problem is worth the trouble. Anyway, one thing is clear: that the students
acted out a paradigmatic sequence which had been imposed rather than reinvent-80 CHAPTER2
ed, or so they saw it.
2.2.4.2 Paradigms reinvented
We don't know how Babylonian mathematics teachers used their numerical paradigms. Let us take a long step. To prove the infinity of the set of prime numbers,
Euclid showed nothing more than how, given three prime numbers (indicated by
letters), one can find a fourth, but his celebrated proof is what I called quasi-general12, that is, such that everybody understands how to generalise it and then to
apply it to an arbitrary finite set of given prime numbers. For centuries general
theorems on figurate numbers were proved by quasi-general methods, that is,
paradigmatically, and even now numerical paradigms are a stepping stone to theorems and proofs, in number theory in particular. But mind, this function of the
paradigm vastly differs from the one I censured in the teaching of arithmetical algorithms and word problems, which was quasi-copying a pattern, while having
too feeble an understanding of its essentials.
Let us review a few examples from (1.3.3 and 1.3.5)! Finding the middle of 16
and 72 on the numberline was just a paradigm. So were the three roads joining A
and B and the four roads joining B and C, with the question of how many roads
there are from A via B to C. When arriving at figurate numbers, I was sick of numerical paradigms, or so it would seem, but in Fig. 4 -- 5, as illustration, the dots
represent five, rather than n odd numbers, and the fourth and fifth, rather than the
(n - 1)-th and n-th triangular number, as I would have done in teaching.
In the learner's mind such numerical examples may exert their paradigmatical influence unconsciously; it may be reinforced by consciousness, and even more by
verbalising, certainly if supported by labelling variables through the use of letters, which is quite easy with the first and second example --just say "the middle
of a and b", and "m and n roads". The other two cases aren't that easy. Euclid
didn't hesitate to denote numbers by letters (as he did with points and lengths in
geometry) but he didn't dare to speak about n prime numbers, and so he had to
proceed quasi-generally, which in a way is paradigmatically. Archimedes" didn't
do any better: where he needed an arbitrary number of line segments, he called
them A,B,C,D,E,F,G,H14
and even introduced new letters for objects derived
from them (for instance by addition) rather than create algorithmically constructed names. This then was the habit adhered to up to Vieta (16th century)". Nevertheless as late as in Hilbert's Grund/agen der Geometrie the Archimedean
style, though somewhat refined, is still witnessed in such a sentence as
Satz 6. Sind irgendeine endliche Anzahl von Punk ten einer Geraden gegeben, so lassen sich dieselben stets in der Weise mit A,B,C,D,E, .. ., K bezeichnen, daB der mitB
bezeichnete Punkt zwischen A einerseits und C,D,E, . . .,K andererseits, femer C
zwischen A und B einerseits und D,E, . . . , K andererseits, sodann D zwischen A,B,C
einerseits und E, ... K andererseits usw. liegt. . .
DIDACTICAL PRINCIPLES
81
in the sense of indeterminates and of variable objects), and where names for them
were required, Babylonian mathematicians used words like "length" and
"width". The Greeks did it with letters; yet there are not enough letters in the alphabet to satisfy the need for a potentially infinite number of names for variables.
Subscripts ranging through the entire infinity of whole numbers are a historically
late invention in mathematics, and letters as subscripts are even of more recent
date, as are subscripts of subscripts".
Why am I telling this story? I have repeatedly emphasised that history may be a
good advisor to teaching us that things are not as simple as they seem to habitual
users. History may be able to warn us against having the learner step in at the
present level of ready-made mathematics. In instruction too the use of letters for
variables should answer a need, and developers and teachers should create situations where this need is so urgently felt that it stimulates reinvention, and they
should this strategy as the use of letters for variables gets more and more refined.
Let me tell a story about a colleague of mine and his little son-- I don'tremember his
age, but in the mean time the son has become a distinguished mathematician himself.
The boy had calculated the number of diagonals of -- stop, one cannot tell this in English so let me use the German terms -- the number of diagonals of a Viereck, Filnfeck,
Sechseck -- I don't remember how far he had proceeded, -when his father asked him:
"What about an-Eck?" The boy answered: .. k times n divided by 2."
3 is subtracted from n-by going three steps back in the alphabet. Isn't it logical?
Even historically the trick for indicating the predecessor of n by n - l (and its successor by n + 1) had to wait for its invention, as well as for such things as indicating odd numbers by 2n - 1, but for a long while the sum of the first n odd numbers had still to be written as
l+ 3 + 5 + . . . +(2n - 3) + (2n - 1).
Even the invention of subscripts and sum symbols hardly changed this style.
Mathematicians have always been slow to change their notational habits, and
they never did so unless they felt an urgent need for change. I am pleading, as I
often have, for the same right to be granted to young learners, that is, to reinventors.
"The fifth triangular number", if understood according to its essentials, that is, as
a paradigm for any triangular number, changes from content to form, only to
change again into content in such statements as "any triangular number plus the
preceding one equals the square of the same rank". How to formalise and, in particular, to algorithmise such a clumsy statement? The learner has to be guided
along a road of alternating contents and forms, where no step may be skipped,
and none shall be longer than the learner's pace.
It would take me too long to describe this road in detail but at a later opportunity
I will try to make up for this. Combinatorics is of course not the only field (though
in my view it is the most excellent one) where subtle mathematical language can
be acquired paradigmatically, that is, as though it were one's vernacular. Teaching mathematical language is a problem worthy of our attention. Let me illustrate
this by a well-known example
16
• 82 CHAPTER2
Let S be the number of students and P the number of professors at some college, where
it happens that there are 6 times as many students as there are professors. Express this
by a formula!
The percentage of subjects (even among university people) that answered
6S=P
was distressingly large. What if S and P are replaced by X and Y or some other
pair of letters? I was told this made no difference but I could not check it. But
what about the following formulation:
At some college there are 6 times as many students as there are professors. Put this
statement into a formula!
None could tell me whether this has ever been tried. Indeed, it is not the traditional way to formulate problems. But this does not matter. We don't need new investigations to know that something is wrong; we do need phenomenology based
didactical research to know what is wrong and why. In the present case choice is
between bluntly confronting learners with letters and formulasl6a, and guiding
them to experience formulas as new content derived from paradigmatical form.
Let me add a brief note on what phenomenology based didactical research may
mean in the present case!
Letters and letter combinations are put to use in mathematical and similar texts
in various ways. Let me mention a few of these:
Labelling fixed objects in a given context, for instance, to answer the question of
how many orders are possible for three buses to leave a garage.
Labelling, and thereby fixing arbitrary objects in a given context, for instance,
points on a map in order to make statements on their particular mutual distance.
Labelling, and thereby singling out arbitrary, but somehow equivalent objects in
a given context, for use in general statements; points in the plane, for instance, or
line segments, or numbers (as did Euclid).
Labelling geometrical or physical objects that vary within a given context (abscissas, ordinates, angles, and so on in a figure; times, path lengths, and so on in
a kinematic process), in order to express their mutual relations by formulas.
Labelling numbers and other mathematical, or mathematised objects, that vary in
dependence from one another, in order to express this dependence by formulas.
Labelling fixed numbers, functions, and so on, by fixed conventional symbols such as
-. e, log, .J, -.Il(number of), $ (mapping numbers on monies), cm (mapping numbers on lengths), kg (mapping numbers on weights), and so on.
Labelling logical objects, such as propositions, predicates, and so on, as occurs in symbolic logic.
Labelling both some species and its members by the same letter or letter combination,
often chosen as abbreviations, for instance F for females, M for males; A for Americans, B for British, C for Chinese, and so on.
It is worth noting that the last kind is one of the oldest (or perhaps even the oldest)
symbolic use of letters, which in traditional logic, and even in mathern.ati.cs nro[>cr (a!-
-1 ___
DIDACTICAL PRINCIPLES 83
totle, and formalising such propositions as "all men are mortal", are -ot yet out of use.
Half a century ago, after such a definition as A topological space R is a set such that.
. . it was decent mathematical style to casually continue Le.t S be an Rand then to map
R on S. Yet in a few other contexts, computer science, in particular, similar formulations are still not unusual.
This is hardly surprising since it is a quite natural and therefore common use of letter
symbols. In my opinion that coexistence amply explains the ·:6s = p:· phenomenon,
even in the case of adolescents and adults who should be acquainted with the now prevailing mathematical fashion; in addition to this influence, however, the unsatisfactory
formalisation of the .. number of . . . " function in school mathematics should not be
neglected either. It goes without saying that children, unacquainted with the pres-t
use of letter symbols in mathematical formulas, cannot at all be expected to react m
the way the interviewer judges to be the only acceptable one, as happened in im.
In the preceding analysis I did not include computer science, which would have required a special study.
2.2.4.3 Acts, actions and activities as paradigms
If the fifth triangular number is taken as a paradigm for anr. triangular number, it
is so as a mathematical object. When I spoke in the first chapter of paradigms, the
things to be taken paradi1p11aticallY looked rather like activities. Let us reconsider
paradigms from this vieWpoint! Indeed, the mere act of taking the fifth triangular

number as a paradigm for any triangular number may again be a paradigm for
similar actions, for instance, if numerical squares or cubes are used paradigmatically for squares and cubes of whole numbers in general. Labelling some triangular number as the n-th in a sequence, its predecessor as the (n - 1)-th and its
successor as the (n + 1)-th may be paradigms along with other sequences for labelling terms together with their predecessors and successors. Getting then-th triangular number from its predecessor by adding n may be a paradigm for similar
procedures such as getting then-th square from its predecessor by adding the nth odd number, and eventually for the strategy of viewing sequences as series.
Stepping
from (n-1)
2
to n
2
as expressions for successive squares, and calculating their difference as then-th
odd number
2n-l
may be paradigmatical for all such procedures where a given sequence is interpreted as a series arisen from the sequence of the successive differences, and this
procedure may in tum be paradigmatical for forming second, third, or any order
difference sequences from a given one.
If the (n -1)-th triangular number has been constructed as the part below the diagonal of then-th square, that is,
(n
2
-n) n(n-1)
-2 --2-
finding then-th triangular either by replacing n - 1 with n, or otherwise, by adding 84
CHAPTER2
n may be paradigmatical. Anyway the trick
If the n-th triangular number is supposed
(n+l)n
-2- -
then by adding n +l the (••lI• triangular
number is proven to be
(n+2) (n+ 1)
2
which is the same as the result of replacing
n with n + I, and so it proves the expression
for any triangular numbers so ever
has a wide paradigmatical range. As a matter of fact, it is a paradigm for complete
induction.
The preceding exposition is not meant to be a didactical sequence. I was therefore
able to abstain from overburdening it with more details. I also renounced references to the many back and forth switches involved between content and form.
As a frame for viewing activities as paradigmatic, however, it is still too narrow
and deserves to be broadened.
"Looking for essentials" in (l.3.2) may serve very well as a check-list Situations,
problems, procedures, and so on, may be paradigmatical objects while the corresponding "across" may aim at a paradigmatical activity. Yet let us fix our attention on one special kind of activity. Inventions are edited, prior to communication, and so should reinventions as well. Redundancies are cut out, paths are
shortened, concepts and notations are smoothed out, the matter is rearranged, often to the degree of what I have called, putting things upside down. All this, as
far as needed, can better be learned paradigmatically than by filling out prescribed forms.
And, last but not least, what a paradigm is and how it works, 1s learned paradigmatically.
2.2.5 Applications
I began the first chapter with a historical explanation of the plural "mathematics".
The medieval quadrivium has now been superseded by a dualism: pure and applied. By their very names the two oldest mathematical journals claimed to cultivate both of them, although applied mathematics had still to wait one more century to get a journal of its own. Al universities there were (and in some places still
are) separate chairs for each of them. The famous mathematician G .H. Hardy
wrote a famous textbook "Pure Mathematics". He was proud to assert he had not
created m1ything mathematical that could ever be auplied. He was wro11- but he
DIDACTICAL PRINCIPLES
85
There are good reasons for researchers to specialise and for higher education to
be departmentalised. But pure and applied is an awkward dualism, as are theory
and practice, or (in textbooks) theory and exercises, or (in mathematics education) insight and drill, and so on. Reality is a virtual unity, where for practical
purposes at any moment some part is focused and others are out of focus. Yet
shifting focuses is no less important than focusing itself and it should not be impeded by what I formerly called isolating impermeable membranes. This applies
in particular to learning mathematics. So I propagated rich contexts, just to fight
impermeability.
The most serious trouble with dualisms like those above is the tendency to favour
one-way traffic. In instruction this means: first theory and then exercises, first insight and then drill -- the first for conscience's sake only and very likely to be
skipped. After all, the mastery of the first does not imply that of the second
whereas the second may bring about the first, or one would hope.
If history means searching for the roots of the present in the past, then history of
pure mathematics is a tree deprived of its strongest roots. Teaching is not different. In the past, most mathematics was never applied or meant to be applied by
those who learned it at school, but things have changed spectacularly. More and
more people use mathematics more often than they are aware of. When I said this
I continued: They use matllematics because they cannot do without it Indeed, the
amount they use is astonishing, but have they learned the mathematics they eventually use, only because they were once taught mathematics? Mind, I don't ask
whether they use the mathematics they were taught. One can readlily deny it, since
most of the stuff they learned is of no use at all for most of those who were supposed to learn it My proper question was whether learning the mathematics they
were taught has been conductive to educating mathematical behaviour. Or rather,
if there was some influence, could it not as well have been detrimental?
I agree that, in adaptation to social needs, views on teaching mathematics have
changed. Henceforth, one now postulates, students shall also be taught to apply
the mathematics they are to learn; so reformers and developers call and look for
more applied mathematics alongside the pure. As so happens in the course of
teaching, "alongside mathematics" is interpreted as "after", and this is true at various curricular levels: The eventual result is a pair of curricula, rather than one:
first, pure theory; second, application -- a menu of applications, that is. Or the two
curricula are shuffled into one another as packs of cards: parts or chapters alternate with one another -- theory first, applications after. Or every bit of theory is
followed by another bit of application.
It does not matter which variant is chosen. The view itself is wrong and it is even
worse if it is identified with mathematising, which is a learner's rather than a
teacher's activity, or at least should be. Applying mathematics is not learned
through teaching applications. The so-called applied mathematics lacks mathematics' greatest virtue, its flexibility. Ready-made applications are anti-didactical. Mathematising some problem situation in nature or society should not be
demonstrated by the textbook author or the teacher but left to the learner to be 86 CHAPTER2
reinvented. In this regard applications are no different from mathematics as such,
and for that matter the present section could as well not have been written, were
it not for the urgent need of using every opportunity ID propagate starting and
keeping mathematics in reality, while switching back and forth between realities
-- natural, social, and mathematical. Pure and applied is a highbrow dualism rather than a learner's concern.
DIDACTICAL PRINCIPLES 87
2.3 LEARNING PROCESSES
2.3. l "Learning process" as a didactical principle
What led me to deal with learning processes and their observation, in particular,
in a chapter on Didactical Principles? Aren't these rather tools and subjects of research? Unfortunately, whatever educational research may mean -- and it may be
quite a number of things -- one cannot but agree that little attention has been paid
in the past to learning processes and even less to their observation. Even at the
present state of knowledge with regard ID learning processes, didactics can hardly
draw on a substantial capital of educational research. This, then, explains and justifies the prevailing practice of short-cuts in education where, without much ado
(let alone any reflection) and trusting one's intuition, more or less conscious experiences on learning processes are applied wherever needed in didactical situations. Let me account for this fact -- and where I consider it a gap try to mend it
-- by dealing with learning processes in the present chapter! Mathematical learning processes, that is, although most of what I have to say is also true for the didactical ones.
Anyway, the use of and the emphasis on processes is a didactical principle. Indeed, didactics itself is concerned with processes. Most educational research,
however, and almost all of it that is based on or related ID empirical evidence, focuses on states (or time sequences of states when education is to be viewed as development). States are products of previous processes. As a matter of fact, products of learning are more easily accessible ID observation and analysis than are
learning processes which, on the one hand, explains why researchers prefer to
deal with states (or sequences of states), and on the other hand why much of this
educational research is didactically pointless.
Why can -- even dense -- sequences of states if appropriately inteipolated, never
be equated with processes? The reason is again a didactical principle. In [87,
p.165] I formulated and italicised the thesis:
What matters in learning processes are the discontinuities.
Inteipolation between states obviously applies only to continuous processes. The
process approach is fundamentally different, even if its scope is restricted to short
processes. Let this be enough for the moment, and let me delay justifying my thesis didactically and elaborating on it!
2.3.2 Teaching/learning processes
Since Herbart, if not earlier, views on teaching processes have influenced didactics and, though in instruction teaching and learning processes are strongly interrelated, there are few people left, even among practitioners, who profess the outright identification oflearning with teaching. Moreover, one cannot disregard the
large part of learning - - even at school -- which is independent of teaching. To 88
CHAPTER2
my mind, the amount of what is learned by formal instruction is grossly overestimated. But since my concern is didactics, more often than not when I speak of
learning processes, this will be shorthand for "teaching/learning processes", or
"instructional processes" (which includes both learning and teaching).
l . Pure and mixed learning processes
Knowledge of pure learning processes may greatly help us to understand and organise instructional processes, but whatever pure learning processes may mean,
this field still looks like a desert: shrubs of unconscious experience, incidental or
intentional observations, and sparse efforts to organise this experience. There is
one oasis in this desert: Piaget's early worlc
17
, based on continuous observations
of his own children during their first and part of their second year. Of course, active observation, too, is a kind of teaching but to a much lesser degree than the
influences of the social environment in general. It is a pity that Piaget's original
records have never been published.
Indeed, Piaget's material, as selected and offered by himself, is processed to fit into
the stream of his profound theory. It is chosen in order to describe what he calls the
sensory-motor stage. One strange feature should be mentioned: his complete neglect
of language. The subjects never say a word (as they never weep or cry). Did Piaget
reserve language for another volume that never appeared, or did he underestimate the
part language plays in the .. construction of reality"? By the quite sophisticated tasks
these little chilchen are able to perform they distinguish themselves from animals to
such a degree that one is inclined to conclude that this is due to their ability to name
things, events and acts, and by this way to imprint them more strongly in their memory. It should be noted that Piaget did not pay adequate attention to the part played by
language in cognition in his later work either.
Piaget's original approach was time-consuming. The laboratory research carried
out by his assistants represents methodologically another extreme: instantaneous
exposures, as it were, where learning is considered to be a disturbing nuisance
and therefore counteracted and eliminated as much as possible.
Let us add one remark: Rather than the population of subjects, the only constant in the
explored time sequence of states is the complex of tasks to be tested; yet, since they
are propounded at linguistic levels corresponding to the subjects' ages, one can, in
each particular case, question what has actually been tested: levels of task performance
or of linguistic proficiency.
Factual learning processes are mixtures, depending on the involvement of unintentional and intentional, informal and formal teaching. However important observations on everyday learning may be, didactics, which includes both teaching
and learning, is best served by knowledge of more formal teaching/learning processes and the interaction between the guides and those guided.
2. Participation and reservation
Another dilemma in learning processes is related to observation: Participation
":'t1 ---=<-c"---- ---- '--.,._.'1: `-.,,,, ,,,,.( `-, `- .-
DIDACTICAL PRINCIPLES
89
ure of his subjects in doing tasks was fed back into his strategy as an observer.
For instance, after an initial failure, the same task was offered anew, often ten to
twenty times. Piaget's assistants, however, used repetitions to make sure whether
a subject's reaction as was by chance or consistent
The teaching component increases along with the observer's participation in the
learning process, . Yet teaching/learning processes, say in the classroom, can be
attended and registered just as well by non-participating observers. Personally, I
do not like the idea of non-participatory observation. I even feel unable to refrain
from intervening, and I still regret some cases in the past where I missed the opportunity or lacked the readiness for intervention, for instance, when I failed to
ask the person observed why he did what he did, and why he did think what he
thought
3. S/wrt-term and long-term learning processes
As is the case with the interdependence of teaching and learning processes, I emphasise here that my proper aim with regard to !earning processes are long term
ones, which is in fact the title of (2.4). Short-term learning processes look as if
easy subjects, easier than they actually are. They are, indeed, easily accessible to
direct observation, which no longer holds true for their long-term effects, whether the short-term processes observed are embedded in long-term ones or not. Of
course long-term learning processes are the most difficult thing to observe.
When I objected, on the ground of the discontinuity of learning processes, to intePOlating between consecutive states as a procedure to grasp and to guide processes, I did not mean to exclude the reconstruction and the pre-construction of
long-term learning processes from sequences of short-term ones. The conditions
for realising these goals will be the main concern of this section and the following
(2.3/4).
2.3.3 Observation as a didactical principle
1. Observing
Observation is an indispensable tool for any research based on experience. Observing natural phenomena under the microscope is quite different from observing patients, or wildlife, or people in the supermarket, or children in the classroom. Inventive and influential methodologists have developed models for organising
classroom observations according to a pattern they themselves consider
to be as characteristic of the natural sciences. Assistants, preferably students,
armed with check-lists, are charged with observing teachers' and children's
classroom behaviour, and according to the minutes spent on certain activities
they are to classify the actors in a system of predesigned categories -- a methodology that is a caricature of observation as understood in the natural sciences.
Even the naturalist does not truSt check-lists to explain unexpected events, which
as a matter of fact may prove to be more important than the anticipated ones. His 90 CHAPTER2
strategy of observation is instead controlled by vast experience and a certain
amount of theory. Proceeding according to check-lists is a good thing for starting
an engine or any other predesigned and controlled process, but it is an impediment to acquiring new experience or to learning new behaviour.
All the same, educational research will be a subject of the next chapter. In the
present chapter the observation of learning processes will be dealt with as a didactical principle. For many years I have propagated observing learning processes, although in fact it is an art that is practised more often than people would admit -- the observers themselves included. What I meant to ask for was to report
on such observations, which presupposes getting conscious of them. Teaching
and didactical experiences result from observing learning processes. Teaching
and didactical behaviours are justified by experience, and more explicitly by observations inside and outside the classroom which have consciously been registered.
2. Observing and recording
Are conscious observations of learning processes as exceptional as they seem I
don't believe so. But if these are so many, then why do so few of them get a
chance to be reported? Are non-professional observers afraid that reporting observations would come across as telling classroom anecdotes? If so, they are right
to avoid this appearance. Indeed, telling classroom anecdotes will not acquire scientific respectability unless it is organised by means of all-embracing educational
or psychological categories. Or, rather, this postulate is the very reason why developmental research as practised by Piagetians is blossoming: classroom or laboratory observations are classified according to categories and hierarchies or at
any rate make a pretence of doing that. I admit there are no ready-made tools for
organising observations of learning processes but, as long as no substantial material is available, the quest for organising it is meaningless. Nevertheless, there
is one valid criterion for estimating whether observations are by chance worth being reported or not: whether they are paradigmatica/. As a matter of fact, this extends to educational research, where paradigms play a part unrivalled by statistics, but in the present chapter we are concerned with the paradigm as a didactical
principle. It was introduced here as an answer to the quest for experiences worth
being reported, though this is not at the heart of the matter. As valuable as reports
may be for those who are expected to read them, the didactical value of reporting
resides first of all in its being an incentive to observation, with the aim of becoming conscious of one's observations and having them analysed.
Learning by paradigmatising would seem to be a vicious circle: on the one hand,
the criterion for knowing what observations are worth recording resides in their
paradigmatical character while, on the other hand, learning what is paradigmatical, must take place in the course of observations worth recording. It lli circular,

yet so are learning processes in general. In this particular case we are, indeed,
-- tn.--o::[T]. --j "Vh. f 1. ?t--e-;_,r;r:: "-:'.<:::: .... "."\;;: "-;'),--.:'-: "" -v -,;:e-.1. f __ -:-.'.('-= f H '-- - tr-. "'-< .. "'. "-V. .-"".:.:--;f.-= _c!
DIDACTICAL PRINCIPLES
91
and didacticians; this process is guided by the experience of observed learning
processes -- those of their subjects -- and moreover, as happens or should happen
in teacher training, reinforced by exterior guidance. It is an apparent circularity
that is not vicious at all; and in the right perspective the process is a spiral rather
than circular.
Later on, we shall look for more objective criteria for what is worth being observed and recorded and at the same time fill in a gap in our argumentation.
Meanwhile, we will consider the described process of learning by paradigmatising, albeit lifted up to a higher plane.
3. Self-observation
Observing learning processes, whether formally recorded or not, is itself a learning process - a meta-process, as it were. It becomes an opportunity to learn how
to observe learning processes as soon and in the measure as the observer is aware
of details of this meta-process. What kind of details? The answer is again: details
of what is paradigmatical. (In [87, p.205] I described the paradigm in my own
learning process as an observer that led me to shaping the idea of paradigm.) But
this is too easy an answer. Observing oneself can be a difficult undertaking as
everybody knows who has ever tried it; in particular, any mathematician who has
tried to observe him)self solving a mathematical (or for that matter, any other)
problem knows that proving a hypothesis often means finding out the reason why
one believed it to be true. Let me therefore deal for a moment with self-observing
in a broader context than that of only observing learning processes; this anticipates themes to be dealt with in (2.4.2).
The difficulty of self-observation is that of being actor and spectator simultaneously. It can be learned, to be sure, and where it may mean the observation of
learning processes, teachers and didacticians should indeed learn it; but self-observation is also worth learning with regard to the acquisition of subject matter,
and particularly if this subject matter is mathematics. Anyway, it is a difficult
thing to learn, which may require considerable endurance. There is, however, a
short-cut Let me fust describe it in terms of fust line mathematics learning and
teacher training!
Observing others is definitely easier than observing oneself. In the past I have
fought individualised learning (which is fashionable today) even harder than the
traditional teacher-centred classroom variant. I will come back to this point when
dealing with "Mathematics for All" but let me say in advance that I favour small
learning groups of, say, four learners, and that this preference extends to teacher
training. Observing the learning processes of others is implicit to learning in
small groups, and what happens in such groups should be made explicit by the
learners themselves or by their supervisor, although this is hard to do and we
know little about how to do it systematically.
The counterpart for teachers and didacticians (and even for researchers) of what
the classroom and teacher training learning groups mean for pupils and student
teachers is workshops: learning to observe oneself by observing others. Indeed, t .
92 CHAPTER2
observing others and oneself is a source of consciousness for one's own physical
and mental actions, and this again is an important aspect: reflecting on what one
does and thinks. Of course, we would not be able to act in everyday life if tried
to plan everything in advance and think about it afterwards. A large part of our
incentives and intuitions are unconscious and will always remain so, but making
unconscious things conscious as often as possible is a way to improve the operational value of our unconsciousness.
Was self-observation a misleading title? No, its scope has been extended quite
naturally from the individual to the collective.
4. Discontinuities in learning processes
I promised more objective criteria than having a paradigmatic character for indicating what is worth observing and recording; at the same time I would like to fill
a gap in my argumentation. To do this let me repeat my self-quotation: What matters in learning processes is the discontinuities -- or jumps, as I prefer to call
them. In what sense does this matter? First of all, it is the jump in a learning flow
that superficially looks continuous -- the learners' overt or covert aha-experiences -- that strikes the observer and challenges him to participate by reinforcing
their influence.
How to recognise jumps in the learning processes? There may be objective criteria, such as in the cases I reported in (2.1.4, 4): for instance, a clumsy procedure
for solving linear equations like "first multiplying by the denominator, then dividing by the numerator", may after a long while be spontaneously shortened to
multiplying "upside down". Was this a chance event? To make sure whether such
an occurrence is a jump, the observer should offer the learner a sequence of similar problems and after a while and as it happens resume testing once it is clear
that the occurrence was not accidental. As a matter of fact, in all the cases I mentioned above (and in many others) there was no relapse whatsoever, which proves
that the jumps -- or what I had diagnosed as such -- were real. Clearly the girl did
not dare to leave the beaten track until she was sure she would not get lost I myself was satisfied to reinforce through mere repetition, lest explicitation of rules
should harm her. Indeed, as I mentioned earlier, her teacher (by supplying her
with explicit rules for operations on fractions) had managed to undo the effects
of many weeks of reinventive learning. So I was afraid that, unless she verbalised
by herself, rules would prove harmful rather than helpful. It seems that she never
had learned to verbalise mathematics on her own, in spite of her otherwise normal
mastery of language. Attempts to rectify this shortcoming might seriously have
confused her, or so I feared. Notwithstanding the lack of verbalisation, she understood very well what she was doing - later on I will report on how I tested her
insight
Good verbalisers are easier subjects where learning processes are to be observed.
My publications contain a large number of references to a boy whom I started oba fev,r ,rr_;r;nt-~~ :.:.:fterr h2-'. <Je13r.nd bi_rtt.:1 e_v (rr.c:-~~ ;;;•-r:.'.ern.?tJ.r: 71't'('rt';; "I1" - i'.:'i:- . - -
DIDAC1CAL PRINCIPLES 93
his intentions in advance as well as whatever plans he was going to carry out, and
to reflect on his own speech and thought, sometimes even while speaking and
thinking. On the other hand, great discoveries, or what he felt to be such, were
accompanied by heavy emotions and explosive utterances. He was a most appropriate subject for observing learning processes of all kind. Although my thesis
about discontinuities being the significant thing in learning processes dates from
long before his birth, he has taught me a lot, for which he has been credited in my
various publications.
I have just sketched two extremes of learners. From old material and as a "revisitor" I could add a few more reports". All they have in common are jumps with
paradigmatical consequences - anyway they do not provide enough indications
for attempts at categorisation. Still, let me mention what I personally learned
from these experiences: all together they have helped me to get rid of the prejudice that something learnable may be self-evident. What is now a matter of course
was once a matter of learning. It sounds trivial but then it is one of the trivialities
that one should be reminded of again and again. For this let me report a striking
example!
5. A group learning process
The two cases I just reported were learning processes of individual children. For
instance, if instead of the one girl, I had been teaching two together, I would have
followed an entirely different strategy: The need for communication between the
two of them would automatically have stimulated verbalisation, which I would
have cautiously guided.
Anyway teachers as well as developers are dealing in the classroom with collective, rather than individual learning processes. My own first experiences in this
respect, well over thirty years ago, are related to Dina van Hiele-Geldofs marvellous reports" on classroom observations. She took notes while teaching; and
I was astonished how many more -- and more important -- things she observed
than I was able to do. Since then, modem technical tools have become a great
help for observers in the learning environment. On the other hand, small groups
are a better environment for observing learning processes than large classrooms.
Let me give an example:
After measuring a few angles, it is time to draw angles of a given size. Mariska tries
to draw an angle of 200. She draws at random. She adapts the protractor to one leg,
carries the pencil to the other one, reads off: it is wrong. She erases the angle and draws
another random angle, while talting into account the first measurement. She measures
again, and again it is wrong. She erases the second angle, swearing at it Her neighbour
Monique is alarmed by her swearing. She watches the third attempt. and then she explains how to do it at one go. Anja is listening; --th-t is how I did it" she says: "So .I
have done it." Mariska draws the next angle -- 13 -- m the new way. Meanwhile, Cecil
has learned how to do it from Anja. Cecil consoles Mariska: "I didn't know it either."
The next misfortune is that a point to be marked falls outside the sheet of paper. Anja
helps. Anja and Monique always wait for the others before going on to the next task.
When I recommended observing learning processes as a treatment against unwar-94 CHAPTER2
ranted prejudices on self-evidence, the above proceedings were one among many
examples I had in mind; I found it a distressing experience, and at the same time
a warning. Thirteen years old and behaving like this just to draw an angle of 20',
isn't this sheer stupidity? Or were they really that stupid, these two among the
four 13 year-old girls? Would they have acted the same way if the task had been
to draw a line segment, say of 5.3 cm? Certainly not! Why weren't they able to
use the circular protractor in the same way as they would have used the linear
scale of the ruler? Thirteen year-olds who behave like Mariska and Cecil, what
have they missed in their most elementary education? In order to answer this
question more profoundly, it should be posed in a much broader context. What is
behind this distressing experience?
6. Change of perspective
It is not merely the switch from measuring to constructing. Il is a kind of jump,
which I have called change of perspective - an important and indispensable activity, characteristic of a mathematical attitude - in this particular case, from
measuring a given thing to making a thing with a given measure and, more generally, from examining a given thing and stating its properties to making a thing
with prescribed properties (and of course if need be, the other way around). In
traditional geometry teaching this duality was called analysis and construction.
Geometry, though not necessarily of the traditional kind, is an excellent training
field for changing perspective, although its domain of transfer is much wider,
both inside and outside mathematics. Change of perspective takes place as soon
as the child starts to conquer the so-called egocentrism which, in my experiences
happens much earlier than Piaget's laboratory experiments seem to indicate.
Learning processes are marked by a succession of changes of perspective, which
should be provoked and reinforced by those who are expected to guide them. My
diagnosis with regard to the failure of these two girls is: victims of rigid instruction that never left any room for individual initiatives. Change of perspective develops most naturally in reinventive learning and, if consciously trained, allows
for a wide area of transfer, as do all behavioural attitudes. Anyway one should
begin exercising it quite early. Is 13 too late to recover what has been missed?
Am I too pessimistic if I say it is? What a tremendous gap between the two girls
who succeed and the two who fail! Can we do anything to narrow it? Or better,
anything to avoid it? I am not at all hopeful as long as teacher trainers fail to teach
their students how to observe learning processes. Or shall I call it learning to observe when they send their students into classrooms with prefabricated questionnaires or have them observe classrooms on the monitor? But let us not say too
much about "teacher training" beforehand!
7. Communication
I almost forgot that the above story was meant as an example of a collective learnL1-fii" ;DIOCBS:'., It -S, hD -V-~.rp--, :\-;"" -<i-\P:-1" "l,. r-. --r":'t :-1;.'.f":-'-" t:--: >-->:; -1 cp,- -.(i -" ----; --,t.", ,.-.--
DIDACTICAL PRINCIPLES
95
the two others needed and received was too straightforward. I could repeat more
sophisticated examples from earlier publications but this would take me too far
afield, while high quality research is just now taking place in this domain. The
general feature of the observational evidence at my disposal is: four children cooperate more or less efficiently to solve a problem. An accidental remark of one
venturing may mean a hint for the other; or the one who, venturing the jump, cannot explain it herself but another can and thus enables other members of the group
to follow suit. Linguistic tools arise from the need for communication. Discussions evolve, and participants are compelled to reflect on their own utterances
and actions. The teacher, walking between the tables, whether or not requested
for by a particular working group, should not intervene actively before having listened to the - perhaps confusing - report on their previous learning process. The
mere fact of reporting may mean such great progress in the learning process of
the group itself that the teacher's intervention can be restricted to polishing language and adapting ad hoc invented terms to the conventional terminology. Or
the report may include keys to guide the group in the right direction. Or exchange
with more successful groups may be helpful.
This then is observing group learning processes - a scarcely explored field.
8. Thought-experiment
What use is the knowledge acquired in observing learning processes for the instruction developer? Certainly, there is some use. As a developer he can profit
from these pieces of knowledge, provided he views them in a broad sense as paradigms. As early as 1961, if not even earlier, I propagated the thought-experiment
as an instrument in educational development
Imagine a student, more or less distinctly defined, and have him in his mind reinvent
a mathematical idea, observe his actions and analyse them by logical methods. [14,
p.32]
That is the Socratic method, or as I would prefer to say, the method of the thoughtexperiment. The latter expression comes from Mach, who described it as a method of
theoretical physics; it was the central method from Galileo to Einstein (and maybe still
is today). In didactics, I mean by thought-experiment the attitude of a teacher or textbook author of imagining a student or a group of students and teaching them in mentally while reacting in advance to their probable reactions. The imaginary students are
active, and their activity allows the teacher to determine his way of proceeding. .In a
narrower sense I will assume, as Socrates did, that the teaching matter is reinvented or
re-discovered in the course of teaching. Rather than being presented dogmatically, the
subject matter originates before the students' eyes. Though the students' own activity
is a fiction in the Socratic method, the students should be left with the feeling that the
teaching matter arose while teaching, that it was born during the lesson, and that the
teacher was in effect only a midwife . . .
In the Socratic method "reinvention" was not understood literally; it was simulated
rather than being true reinvention. It could not have been otherwise, could it? The
teacher's authority was still dominant . . . The initiative was only on the part of the
teacher. Not only did he lead the student, he also showed him how rediscovery works,
he rediscovered on behalf of the student. (40, p.100-102]. 96 CHAPTER2
The variants I proposed were, of course, thought-experiments for real albeit
guided, reinvention. Moreover, I postulated that textbook authors and d-velop
ers, w-etheronn?t they shared my educational philosophy, would reveal the very
-sentials of -err thought-experiments (if there were any); this would; in my
view, be t!1e ng-t w-y to prove, as it were, the soundness of their approach or at
least to bring this --mt up for disc.ussion; and it would eventually lead to having
t!1- thought-expenm--ts checked m the classroom - let me stop here and not anlic1pate too much on educational development" (3.2/3).
2.3.4 Levels in the learning process
What matters in learning processes are the discontinuities - quoting myself - or,
another word that I ha-e frequently used: the jumps. I owe the conception of the
level structure of learnmg processes to my collaboration with the Van Hieles a
couple who embodied, as it were, the marriage of theory and practice. Let r:ie
quote from [40, p.121 sq.], which actually dates back to the spring of 1969, while
pieces relevant to the present exposition are mere translations from the French
[14, p.32-34], written in 1961, as I afterwards noticed to my own surprise:
When the Van Hie l es started teaching they were just as unprepared as many other
young teacher-; nobody had told them how to do it. They had, of course, passively undergone teaching, -d maybe even observed how their teachers performed, but this
-as ni't enough. As time went on, they had the opportunity to discuss their own teachmg with each other and with others. They subjected their own actions to reflection
they .obi:ervv- th-selves ".hile. teaching, recalled what they had done, and analysed
1t. Thinking is contmued a-tmg, indeed! but there are relative levels. The acting at the
lower leve- becomes an object of analysiS at the higher level. This is what the Van Hiel es reco-ruze- as a remarkable feature of a learning process, namely in the learning
process m which they learned t-ching_.They transferred this feature to the learning
process that w- the goal of -err teachmg, namely the learning processes of pupils
who were. learn.mg -athemat1cs. There they discovered similar levels. To me this
seems an nnportant discovery.
In my exposi-on -is is followed by a series of examples, which included the levels on the -- h1stoncal as well as individual -- road from the intuitive unreflected
and, as it were, incidental practice of complete induction (see 1.3.5, 14) to the
formulauon of Peano' s axiomatic system of natural number. Then it continues as
follows:

Here the levels o- the -earning process stand out in bold relief. On the lowest of the
levels under consideration complete induction is acted out. On the next level it is made
conscious as - organi- -inci-le and can become a subject matter of reflection. On
the same or -higherlevel it IS put mto a linguistic pattern. From here to the Peano system t?e path -s n? lon-er lo-ally determined. Now the data is no more a bunch of mathei:nat1c- d-1vations m whic- a -omrnon pr-ciple (like that of complete induction) is
hidden, it ,IS rather. the o-garuzauon of an entire field, in which linguistic formulations
(th-----f---om-lete n1ducuon? amon- other ma_thematical activ-tie- bet".-.0me the sub_-ect
DIDACTICAL PRINCIPLES
97
which, along with others, should characterize the natural nwnbers.
. . . . . .
How levels stratify this [the mathematical] activity has been shown by an example: the
means of organization of the lower level become a subject matter on the higher level.
Which phases the learning process passes through from one level to the next is apedagogical question. which should be answered in specific cases by pedagogical experience. The relation, however, between one level and the next is overwhelmingly logical
and accessible to logical analysis. Often the level-raising tools are heavy quantifiers -
- over all properties of natural numbers in the case of complete induction.
. . . . . .
The learning process is structured by levels. The activity of the lower level, that is, the
organizing activity by means available at this level, becomes an object of analysis on
the higher level; the operational matter of the lower level becomes a subject matter on
the next level. The pupil learns to organize by mathematical means, he learns to mathematise his spontaneous activities. Or rather it would be desirable to have him taught
in this way.
Let me stop quoting from what I wrote early in 1 '39 and turn to similar passages,
written in the late fifties and published in [13, p.26 sq.]:
The analysis of mathematics as a ready-made subject presents a deductive system in
which all steps are fundamentally equivalent. The analysis of mathematics as an activity, however shows a layered structure. This feature is accounted for by the level theory of the Van Hieles. The stages through which the le-gprocess passes from one
level to the next, are of pedagogical concern (which can be disregarded by the present
exposition). The rrlation between one level and the next, however, is preponderantly
logical. To discoVer it, we can use logical analysis . . . .
What it is that characterizes the level structure may be expressed in a few words by
saying that the operational matter of a lower level may become subject matter on a
higher level. If, on a certain level, complete induction has been a significant activity,
this activity may become a matter of conscious consideration and, finally. of explicit
formulation on the next level. The higher level is clearly indicated here by the heavy
quantification over all properties of natural numbers which occurs in the statement of
complete induction . . . . Operations with integers such that multiples of a certain m are
considered inessential, and operations with pairs of integers according to the equivalence relation for :fractions are unproblematic activities. On a higher level they can be
promoted to subject matter and finally described by the device of abstraction through
equivalence classes. On a still higher level the equivalence relation and the abstraction
by equivalence can become subject matter.
In geometry, space phenomena are studied on the lowest level. The properties discovered on the lowest level are subject matter on the next level, where these properties are
related to each other. The relations acquired on this level are then studied on the next
one, in order to build up what are usually called theorems. The logical connections be-
tween the theorems are subject matter on a yet higher level, which is still below that
of logic as a subject matter.
The level theory of learning is closely akin to what can be characterized in logic by the
words .. theory and meta theory". It is not by chance that the Van Hieles seized upon
this idea. To my knowledge they were the first who wrote a textbook in which the
learning process is purposefully initiated and kept up as a process of re-inventing. Traditional methods, however, often show the opposite tendency: to descend from higher
levels to lower ones instead of climbing from the lower to the higher level.
Let me fmally yield the floor to the Van Hieles themselves'' , for dealing with the 98 CHAPTER2
learning process in geometry at the secondary level:
. . . Take the example of the rhomb! Before learning geometry children possess the
"image" of the rhomb. They are acquainted with rhombs that are special concrete objects. Now they will experience what .. rhomb" means in the geometrical context. They
discover properties of this figure, which the teacher calls "rhomb". They form the
"symbol" rhomb. In this symbol they condense all internal properties of the rhomb
they have experienced . . .
Thanks to the possession of a stock of symlx>ls the pupil will be able to organize the
subject matter. Mainly as a routine the symbols become signals. From the properties
belooging to the symbol rhomb (equal sides, parallel sides, equal opposite angles, diagonals that halve each other under right angles) the rhomb as a signal (equal sides)
arises, or rather one property (equal sides) becomes a signal for the symbol rhomb as
the complex of all its known properties. The pupil is able to anticipate . . .
The pupil who has started at "level O" with undifferentiated visual structures, is now
at the first level. At level 0 concrete objects and images are the subject matter which
is organized by the use of symbols and signals. At the first level the symbols and signals of level 0 will become the subject matter. The system of properties of geometrical
figures will be organised by means of relations connecting the geometrical figures to
which the symbols and signals of level 0 refer. At the first level relations like congruency, similarity. parallelism appear. At first they have the character of symbols, later
on that of signals (e.g. congruency of two figures is a symbol for the fact that the two
figures cannot be distinguished in any geometrical aspect; a congruency theorem for
triangles may be a signal). However. at this level relations are not yet a subject matter
as are the properties of figures.
At the second level the relations which have been devices of organizing at the first level will become a subject matter. Here the organizing devices are relations between relations, mainly of a logical character. The symmetry of a relation between geometrical
figures. the interrelatedness between relations by means of implication can be used at
this level, but they can become a subject matter at the third only.
At the third level the pupil will be able, e.g. to distinguish formally between a proposition and its converse. Finally at the fourth level (hardly attainable in secondary
teaching) logical thinking itself can become a subject matter . . .
Learning is a discontinuous process. The discontinuities are, as it were, the jumps in
the learning curve. These jumps reveal the presence of levels. The learning process has
stopped. Later on it will continue, as it were, by itself. In the meantime the pupil seems
to have "matured". The teacher no longer succeeds in explaining the subject. He (and
also the other pupils who have reached the new level) seem to speak a language which
cannot be understood by the pupils who have not yet reached the new level. . .
The attentive reader will have noticed a fundamental distinction between the picture unveiled in 1969 and that of a decade earlier. There are common elements:
the discontinuity of the learning process; its level structure, discernable by a kind
of mathematical analysis; and the levels as determinants of the discontinuities.
The pictures diverge from one another with respect to the bonds by which successive levels are interrelated.
In the first version the learner's operational matter on the lower level becomes
his subject matter on the higher level.
In the second version the learner's lower level activity becomes an object of analrsis fo him on tJ"_e higb-r 1e-vel, or i,n oth.-r words: On the ne-:- leve! thh- nct_;vitv is
DIDACTICAL PRINCIPLES 99
The second version adds to the first the means by which operational matter on the
lower level is transformed into subject matter on the higher level:
Being made conscious and subjected to reflection is the means of level-raising,
which is applied, to the- still intuitive (operational)- activities of the lower level,
rather than to the subject matter.
When did this change of view take place and why, or is such a historical query
worth the soul-searching? There is some indication in the old exposition of a foreshadowing of the newer view, and some relapse in the newer exposition to the
older viewpoint, but I don't believe that this really matters. Was the change of
view caused by observations of learning processes made in between both events?
There are a few of these I might conjecture to have caused the change but I am
not sure whether they were really responsible for it. A great many observations
of learning processes relevant to the level theory were made after the crucial date,
although I would hardly have noticed them as such if I had not at that time been
in full possession of that theory, or so I believe. So my guess would be that the
theory was rationally acquired and only afterwards tested by observat1On.
What kind of considerations could have guided me? In the first paragraph quoted
at the start of the present subsection from [40], I related Pierre van Hiele's own
report on how he discovered levels in learning processes, that is, as a matter .of
fact, first in the process he and his wife went through as young teachers while
learning to teach, and -ow he transferred those levels and their features to their
pupils' processes of learning mathematics. The remarkable feature was that of
levels related by reflection: "At the higher level the acting at the lower level becomes an object of analysis." However, the levels as characterised in my first version, and as substantiated by themselves'' are of a quite different nature -- I will
come back to this point.
I think that the change between the two versions of level theory was influenced
by my drawing the full consequences of Pierre van Hiele's report on the discovery of the levels, which were caused by reflecting on their own learning process
and then made parallel with the learning processes of their pupils.
But there is more to it. While writing these lines, I discovered to my surprise that
the change between the two versions took place as early as 1961. Let me quote
from [14, p.33]:
Ce qui caractB!se l'hiBarchie des niveaux en general, c'est que la technique des
operations a uncertain niveau devient matifile a reflexion a un niveau supErieur - relation apparentee a celle qui, en logique, est caracterisC.e par les mots .. thC.orie et metathC.orie".
The main example illustrating this statement is what I described above as "the -
historical as well as individual - road from the intuitive, unreflected and, as it
were, incidental practice of complete induction to the formulation of Peano's axiomatic system of natural number", and with regard to which I asserted:
Here the levels of the /earning process stand out in bold relief. This, indeed,
seems to me essential for the reconstruction of the change from the first to the 100 CHAPTER2
second version. Obviously I judged the level theory important enough to be extended from geometry -- where it was discovered and in terms of which it was
defined by Pierre van Hiele -- to other domains of mathematics teaching and
learning. This, indeed, was in accordance with my main interest at that time, the
midclle and upper grades of secondary education.
For two millennia mathematicians had practised complete induction
12
-- the ancient "side and diagonal numbers" being the most profound example
12
-- when
Pascal (and independently, James Bernoulli) couched it for the first time in the
now well-known principle; there is not the slightest evidence for there having
been any conscious reflection on this practice during this long historical period,
although figurate numbers would have offered an excellent opportunity. The following steps on the road to the modem theory of whole number took much less
time in the learning process of mankind, but all of them seem to be due to reflecting on previously unreflected activities.
In the first chapter I repeatecily emphasised reflection as being characteristic of
mathematical thought, in particular in the interplay of form and contents (1.1.3);
this was substantiated by some "examples" (1.1.3.1). I don'J remember when I
discovered reflective thought as a forceful motor of mathematical invention. It
certainly happened by introspection, that is, by tracing my own ways of thinking
(which is itself reflective thought), long before I tried to discern it in the thoughts
of others and in the learning process of mankind. Let me save the topic of reflective thinking for the next subsection, where it will be dealt with more systematically! For the moment let me confine myself to one example, which will explain
why I attach such importance to reflective thought as the motor of mathematical
invention -- it is an example I have adduced many times in lectures and papers.
Why do the diagonals of a parallelogram divide each other in half each other? Of
course you can prove they do by applying congruency theorems, but that isn't the answer I expect to my question, since I am sure you were aware of this property of the
parallelogram long before you had any idea of geometry. But how did you know it?
What was the source of this knowledge? After so many years of mathematical instruction you will not succeed recalling it .. except you be converted and become as little
children". But such conversion requires greater effort than most people wish to spend.
It is much easier to observe the little ones playing with such toys as sets of mosaic tiles.
They know that any parallelogram turned around fits into its own hole, "which proves
the theorem"; indeed, by this tum both diagonals are turned around as well while their
intersection remains fixed.
Try the experiment! Draw a parallelogram with its diagonals! Have the child discover
properties of the figure. and if need be pave the way to the particular property you have
in mind: the diagonals dividing each other in halves! Ask: "why do you think they
do?" "Because I can see it." "How do you see it?'fusist on an answer! Depending on
the age of the child you will eventually get one, which at that age can be considered as
a valid proof, obtained by thought-searching, by reflection.
If reflective thought is, indeed, a forceful motor of mathematical invention, it is
only natural to put it to good use in such educational design as is based on the
. . . .r ---- --1'; fir ,I)ff . ,"'"-'', ,,, ...,-'-r- q • !-.'-' -'--'.. '0.,-.: T"'-f' '--.', I:'"', '-- .,'- ,,.-:-'-' -1
DIDACTICAL PRINCJPLES
101
But let us return to the start of this long story, where I asked when and why I
switched from the first to the second version of the level theory! My first version
is merely a report on the Van Hiele's ideas, altho-gh illustrated by e-ampl-s beyond geometry (to which the Van Hieles had restncted themselves), m parucular
examples of complete induction. In the Van Hieles' practice I had much earlier
identified reinvention as the leading didactical principle, unless my memory deceives me. I certainly knew the part played by reflection in mathematical invention and perhaps its level-raising function (at least with regard to my own mathematical activity) and I judged it important enough to transfer it to reinvention.
This then appears in my second version of the level theory; reflecting on the higher level on one's activities of the lower one.
I always knew that my levels differed from th?se of the Van Hieles an- at many
opportunities and I stressed this at many occasions; my levels were relauve rather
than absolute ones, I said, although I gave Pierre Van Hiele the full credit for the
level idea as such. I should confess that never before have I as consciously considered that difference as I am doing now.
This brings me back to a question I have delayed discussing. If you read my quotation from Van Hieles' text", you may notice that the last paragraph does not
properly link up with the preceding text. This may be a fault of mine since- edited
that text on the basis of their publications and other data, but I think there 1s more
to it than this. Discontinuities that reveal themselves by transitory stops in the individual learning processes are certainly more numerous and diversified than can
sufficiently be explained by structuring geometry-learning according to three or
four levels- these levels are moreover said to be determined by a structure of geometrical fuought which, though significant, is however too global. When I hit
on reflection as the thing responsible for the jumps in the learning process, the
road was prepared for as many discontinuities and levels in a multitude ofearning processes as there are significant occurrences of reflection. These, then, rather than three or four levels, were what I began to observe as levels in the learning
process. As I am now looking back on my various reports on learning processes,
I cannot but state that almost all of them include examples of learning by reflection. I dealt with reflection in [97,98,137] more systematically, the contents of
which will somehow be resumed in the next subsection.
I still have to add another remark. Mathematising and reflecting are closely connected to each other. Indeed, I mentioned reflection among the various aspects of
mathematising. Of course, routine mathematising does not require reflection.
Similarly, there is routine reflection, that Jacks the level-raising jump feature.
Moreover Treffers' distinction between horizontal and vertical mathematising
should no; be confused with the relative height of level. Horizontal mathematising may just as often mean a jump from reality to fresh mathematics and vertical
mathematising a mere routine, as well as vice versa.
When I asked the question of whether this whole story is worth that much soulsearching, I did so in such a way that the reader could have anticipated my answer
to be: No! Reporting on one's own learning processes (in the present context, 102 CHAPTER2
with regard to educational research) is likely to elicit the reproach of overestimating one's own importance; though it requires some courage, this is worth being
felt as a challenge. Self-effacement is good style in scientific reports. As I have
stressed often enough, keeping silent about the process of inventing may mean a
loss to those who are expected to learn by reinvention. This is even more true in
the social sciences than it is in the mathematical and natural sciences. The lack of
hard and objective evidence can at least partially be made up for by knowledge
of the soft and subjective experiences and considerations that were crucial in the
development of some theory; thanks only to this frankness can it become accessible to understanding and criticism.
By no means can I assert that I have been as faithful to the policy of disclosing
my own learning processes (in which I firmly believe) as I have asked others to
be. In the course of the years, however, thanks to my growing insight in the value
ofreflection, I have mended my ways. I could have shortened this subsection by
keeping silent about the fact that only during this historical search did I discover
I had introduced reflection as the bond connecting one level to the pext as early
as 1961. While preparing the next subsection, I met yet another explanation of

the divergence between the first and the second version of the learning level theory. It would be unfair to conceal this fact, but let me save it for the next subsection.
Meanwhile let me add another remark, which I could not put at the place where
it belonged without interrupting the historical report, that is, after the first quotation in the present subsection: The Van Hieles' discovery is a striking example of
a didactical insight obtained through horizontal followed by vertical didactising.
2.3.5 Reflection
1. Reflection discovered
My memory includes much of what I would now call reflection. The least insignificant discovery I ever made in mathematics -- more than half a century ago --
was the work of probably less than half an hour, including theorems and sketches
of proofs. Yet ittook me at least a fortnightto fill the enormous gaps between the
apparent mile-stones along the hazy road of reasoning -- soul-searching work that
consisted in asking myself why I believed in the truth of one or another particular
statement. To be sure, at that time I didn't use the word reflection. Von Neumann
once said: "A fortnight before you prove something, you have to know it is true,
since verifying is easier than proving proper." Maybe it stands for the same feeling as I -- and certainly many other mathematicians -- have experienced many
times in the course of their mathematical life.
I don't remember when I first used the verb "to reflect" for such experiences of
mine or others. I f I may believe a conjecture uttered in [98], I even shed away
from it for a long time because it seemed too colourless a term for a mental ac
DIDACTICAL PRINCIPLES 103
ple, simply use it synonymously with "to think". In [98] I even suggested that the
divergence between the first and the second version of the learning level theory
was due to my aversion of the term "reflection". The story I dug up in the preceding subsection was different but, as a matter of fact, not until the sixties can I find
any instance of "reflection" in my papers and, as far as I see, up to the late seventies it occurs only in the context of the level theory.
My paper [98] starts as follows:
About a year ago I suddenly realised that I may have overlooked precious evidence in
the past when observing children. Did I look consciously enough for symptoms of reflective thinking and of the growth of reflective thinking? -- this was my problem. The
idea of a possible shortcoming occurred to me while I was preparing a paper for a conference of which the theme was 'Proof in Mathematical Instruction".
I had set out to consider the activity of proving, not as an isolated activity with roots
of its own. but as the final stage of activities that develop naturally and might be developed didactically. The stage previous to proving I imagined was constructing
which, when it happens mentally, means implicitly proving the truth of existence. But
if constructing was a stage previous to proving, there must be an intenmediate stage,
which, I decided, was reflecting.
The paper mentioned at the end of the first paragraph was [97]. As a matter of
fact, the theme of that conference was: Beweisen im Mathematikunterricht. Anyway, I postulated that one should teach proving rather than proofs, as is the habit
in traditional instruction; my e-amples were taken from geometry, which explains why I considered constr1cting as proving existence -- as a matter of fact,
this still applies outside geometry, provided "constructing" is broadly enough understood. In no other field of reinventive learning does reflection play as conspicuous a part as it does in geometry. That what is in the eye of the beholder is transferred into the mind of the thinker, and this happens by reflection: Insist on asking
yourself -- or others, as I did above -- why you see it like this, why you think like
that.
My notes include so many observations on reflection that I now believe my fear
at the time that I could have overlooked precious evidence on learning by reflection was ill-founded. Indeed, the first note of this kind dates as far back as July
12, 1943:
It concerns three brothers I will call Yed (7;7), Matthew (5;10), and Tom (3;10). John
and Matthew attend different schools. Y eel tells his father that, while playing on the
street with Matthew, he was greeted by Matthew's teacher "Hi, Yed!" "How did she
know my name?", Yed asks his father. "What do you think yourself?", Father answers.
"Maybe Matthew once told her about his brothers". Yed explained and immediately
continued "How did she know I was Yed (rather than Tom)?" "What do you think
yourself?"Shesaw that I was older than Matthew, instead of younger, as Tom would
be", said Yed answering his second question himself.
My second relevant entry is a sentence taken from a technical exposition about fishing
by aforesaid Matthew (at that time 6;9;15):
Because then the fish think that the men are mistaken thinking they are dead.
With a view on the evidence now available, I would describe my state of mind at
the time I set out to prepare my paper [97] as reflecting more consciously than 104 CHAPTER2
ever before on the idea of reflecting, and more precisely, on how reflective thinking develops. At that time
21
, while wrestling with the problem of how proving
arises, I felt for the first time the need for a more compact term for thinking about
one's own [and other people's) thinking, and when I hit on "reflection", I realised
it was not as colourless as I had thought before. If I now use the term, there is an
undertone of physics in it: reflecting as mirrors do, mirroring.
I don't know whether philosophers or physicists were the first to pick up this tenn. In
any case Latin speculum for mirror was not useful since speculatio means exploring;
both. however, do have the common root specus, which means eye socket.
Indeed, when I use the word "reflection", I mean mirroring oneself in someone
else in order to look through his skin, to explore him, to take him in. And, consequently, since somebody else is like oneself --a human -- this is an experience
about human behaviour and, finally, knowledge about one's own behaviour. So
from mirroring oneself in someone else follows -- as the night the day -- the mirroring of oneself in one's own person, that is, introspection. It becomes reflecting
on oneself, on what one did, felt, imagined, thought, on what one is doing, feeling, imagining, thinking. Reflecting, once started, is an activity we perform every
moment, in order to determine our course of action, yet, as a mental exercise, it
can become an aim itself.
2. How does reflection arise?
At the age of three, children start asking "why?". It can be meant causally or purposively even though the adult may interpret it in a logical sense. The child's
"why?' may ask for arguments. If however, you wish the child to argue something, you had better ask, "how do you know?' Perhaps authorities will be cited,
parents or friends. Sometimes, in the cognitive field, the answer may be "I just
know it", or, if it is a representation "I see it". May we find fault with the child
for such a short answer? As adults, do we always know why we know something
or haven't we exercised reflection and introspection for a long time?
I coupled the question of what is reflective thinking to that of its origins. In fact we
know little about them. Lack of means of expression is one reason and the other --
more important -- is lack of attention to how we experience what we experience. Or
rather than lack of attention shouldn't I say: inability to pay attention? Nevertheless I
ventured to assert that reflecting in one's own mind is triggered by reflecting in another's mind.
I feel that this view is fortified by Piaget's research on the origin of imitation
22
, which
is based on observations of his own rather than of others. Imitation starts reflectively,
or as Piaget says, circularly: initially the child imitates only those sounds and motions
of the adult that are more or less faithful reproductions of soWids and motions produced by his own, perhaps haphazard, activity. (The importlllnce of this discovery is
unfortunately obscured by such arbitrary terminology as "assimilation and accommodation", which has been overextended in its application.) Imitation starts reflectively,
that is not as self-imitation but the mirroring of one's own behaviour in someone
else's. Wh-t about ollier utter.a."l.ces, intentions. thou.-hts? For instance. ex:periencin-
i-·:.:.
DIDACTICAL PRINCIPLES 105
haviour may or may not lead to questions like "why did you do it?", "did you rightly
do so?", or "would other people do the same in this situation?" Is it a long step from
here to asking oneself the same question? And, even then, what is asked for may be a
reason rather than an intention.
There is one argument why reflective behaviour in general should start with mirroring someone else's mind. The argument is language, or more generally, communication. The child learns to say "I feel, I want, I think" from other people.
Well before saying it the child must interpret it How does it succeed? The analogy -ith what happens in imitation would indicate that the child succeeds interpreting " I feel, I want, I think" as his own action because he is prepared _to, because somehow he "knows" what it means. But even then, the outside stimulus
is needed to make it explicit.
Let us shelve these questions! We simply know too little to be able to answer
them. Learning how to observe children is a prerequisite to more knowledge. The
little I know are (translated) quotations from diaries.
3. Modes of reflection -- shifting standpoints
Let us turn to more easily accessible questions! Reflection unfolds itself under
many aspects. One of them is what I would call shifting one's standpoint-- shifting mentally though the standpoint itself may be physical or mental, while the
shifting may take place in,space, time, or any other, say, mental dimension.
With respect to the "points" considered let us distinguish a few possibilities of
shifting -- without any pretence of being exhaustive. One is
shifting from A to B in order to look back at A,
which I call
reciprocal shifting.
Another is
shifting from A to B while considering C,
which I call
directed shifting.
And finally
shifting A's environment to B's,
which I call
parallel shifting.
The most concrete realisation of reciprocal shifting is looking into a mirror in order to know how one appears to others. Another example is a reciprocal shift in
time, concretised by a shift to an older or younger person: when I grow older, I
will be able to climb higher than now; when I was younger I could not yet do what
I can now. The mental reservation is also a reciprocal shift of standpoint: after I
receive supplementary information I shall judge the present situation better.
An example of directed shifts of standpoint, and then in succession, is describing
a path. Well, the easiest way to do this is by pointing.
We took our walk. Bastiaan (2;8) found the top of a bike-bell. When he dropped i- it
made a sound. So he dropped it repeatedly. He threw it, he kicked it. I found it danger-106
CHAPTER2
ous. "Let us go to New Clarenburg!" (a building with a broad terrace), I said and put
the bell in my pocket. At New Clarenburg he asked for the bell. I warned him that it
could fall down from the (one metre high) terrace, which indeed eventually happened.
Bastiaan looked down at the bell and then said 'get it, down the stairs" while pointing
the way with his hand. This took place at a distance of about 10 metres from the stairs.
Not only did he make a plan of how to recover the bell, but he also disclosed it verbally.
Describing a path is an example of a directed shift of standpoint or of a sequence
of such shifts in succession. As I said, the easiest way to do this is by showing,
as Bastiaan did to recover the lost bell, albeit complemented by the verbal explanation "down the stairs".
Monica (4;4) wants to define some place by means of the walk leading to that point.
Her forefmger raised yet motionless, she exclaims: .. and then you go so, and then you
go like this, and then you go like this, . . . ". Her wide eyes betray her intuitive vision:
she clearly sees the path in her imagination but she both lacks the mimic and verbal
resources to describe it. Bastiaan (6;4) in a similar situation shows with his hand which
direction to follow .. after crossing the sluice gates ...
Describing or explaining a real or imagined situation may require mentally shifting one's standpoint.
We passed a spot by car where an accident had happened: there was a damaged car,
and across the road something I could not identify, a tube or a pipe. Bastiaan (4;2) said
something like: "It was a streetlamp, and I could see that because I am sitting on this
side and you couldn't because you are sitting on that side."
Bastiaan shifted as it were to my seat in order to explain why I couldn't identify
the fallen streetlamp. But, in general, one may ask whether shifting one's standpoint is facilitated by assuming another standpoint or may in fact sometimes be
blocked by this. In order to draw a child's attention to some object, one may point
to it or turn the child's head in the desired direction, or move or lift the child to
overcome some obstruction. The child is well acquainted with these procedures
-- it is kind of baby language -- which may stall its learning what is relevant in
particular cases and developing more sophisticated means.
When the sun had just set, Monica (4;8) asserted she saw Venus near the crescent
moon; probably she was right, whereas my eyes' acuity failed. So she wanted me to
sit on my heels in order to see the planet from her -- lower -- viewpoint.
Her sister Daphne has always resisted having her body or her head moved as a device
for showing her an object, and she refuses to be helped in almost all physical activities.
Asking preliminary questions before tackling the main question may also be an
example of directed shifting of one's standpoint. Before interviewing someone
on a certain subject, one tries to find out where be is standing, and in order to do
so, one changes one's own standpoint. In the long run, this may be the most striking feature of reflective thinking.
Reflecting oneself in someone else may be facilitated by family relations. The
generation shift is an outstanding examnle of what I called parallel shifting.
DIDACTICAL PRINCIPLES
107
very yo\Dlg age he mirrored his relation to his younger sister Monica in the relation
between his parents; (this was reinforced by the relation between his grandparents,
who lived nearby). When they grew up, he said. both of them would live in a certain
now vacant house nearby and would have a little Bastiaan of their own. From the intrageneration relation the stress was soon shifted to the inter-generation relation: when
his mother was a child. Grandpa was her father and took walks with her. and when
Grandpa was a child, he had also a grandpa. Quite early, Bastiaan structured the past,
in particular the technical development. by means of the generation shift: .. what did
cars look like when you (grandpa) were as old as I am now?". "was there T.V. when
Mum was my age?", and many more and more complicated questions.
Of course in general, young children are not in Bastiaan's situation to perform
such clear double generation shifts. It is perhaps this situation that explains his
early differentiation of the past. As a contrast let me cite a teaching experiment
with third-graders, the vast majority of whom were unaware of any differentiation of the past until they were taught it (which also happened by means of generation shifts)!
4. Conclusion
I could continue in this way for many more pages, although when rereading what
I had written I asked myself repeatedly whether I should.not spare the reader
these stories. Indeed,. most of what I have recounted here about reflection does
not properly belong in a chapter titled 'Didactical Principles". Or does it?
I finally decided to include these stories (albeit shortened). I did so because of the
concluding paragraph of [98] (from which these examples have been extracted):
Reflective learning at school
Unfortunately. this section, which should be the most important, is almost empty. Observations of other children (except for Bastiaan, then 9;2) would not fit into the
present frame. I never observed Bastiaan at school, nor did he grant me more than a
few glances into the growth of his scholastic achievements. At that age he fully widerstands the meaning of the arithmetical operations, he knows how to perform them,
though his performance is not yet flawless. He accepts all he learns without any criticism, and in scholastic matters he never asks the question "why?", though he is still
asking it in any other maner. He is not interested in questions like "why does 3 x 4 =
4 x 3?". let alone in reasoning about spelling.
However, I think this is a transitional stage. School is a phenomenon he has still to
learn to cope with.
To what degree he eventually succeeded I am unable to judge, although later on
I noted splendid examples ofreflection in his diary [124, 137, 140, 141, 142, 143,
145, 148, 160, 166, 184, 185], most of them related to mathematical experience
though none of them to school mathematics, which, as a matter of fact, he managed to master as indifferently as easily. This was thanks to the character of the
curriculum and instruction, which matched his algorithmic talent on the one hand
and on the other lacked any bonds with reality, and moreover any challenge to
reflect on his own activities.
This is not exceptional. Little attention is paid to reflection in mathematics in-108
CHAPTER2
struction, although this can hardly be blarued ou the teachers alone, since not
much more attention is paid to it in research, development, and teacher training.
Let me characterise traditional mathematics instruction by copying a sentence
from a few pages ago:

In order to draw a child's attention to some object, one may point to it or turn the
child's bead in the desired direction, or move or lift the child to overcome some obstruction. The child is well acquainted with these procedures -- it is kind of baby language -- which may stall its learning what is relevant in particular cases and developing more sophisticated means.
2.3.6 Reflection and observation
The present section started with my demand to observe learning processes.
Jumps, I claimed, are the most striking 'observables' -- blockades are perhaps
just as easy to notice but less easy to appreciate and explain -- jumps to higher
levels. Look for the level-raising reflection, concealed or manifested in the
jumps! The reflecting mirror is the observer's most powerful tool, which closes
the circle. Let me quote myself:
So from the mirroring oneself at someone else it follows as on the night the day, mirroring oneself at oneself, the introspection. It becomes reflecting on oneself, on what
one did, felt, imagined, thought, on what one is doing, feeling, imagining, thinking.
Reflecting, once st- is an activity we perform every moment, in order to determine our course of action, yet, as a mental exercise, it can become an aim itself.
Observation is the converse: mirroring the observed one in oneself. Or are things
more intricate? Who is the actor, who the observer in a learning process? Look
for the interaction in a learning group, while involved in solving a problem!
Whether involved or not, it is easier to observe others than oneself. Does the other
person understand you, does he approve or disapprove? Does he feel what you
feel, can he help you better than you can help yourself to understand what you
mean? What can a third person listening to the exchange of vague arguments
learn from and contribute to it? Why do I not understand you, why don't you understand me, why do these persons not understand each other? Is it lack of information, or what information does one of them possess and consciously or unconsciously conceal, which prevents the other from understanding? Or is the other
feigning that he does not understand? How can we know what to tell and what is
too trivial to be told?
We are driving by a shop belonging to the Jamin chain. The name "Jamin" appears
twice in Neon letters on the front of the building, horizontally and vertically, but separated. fu the horizontal version the letter Mis missing. I drew Bastiaan's (8;2) attention to it. He said: This is only possible with [an] odd [number ofletters]. I didn't understand what he meant He became angry: .. You know very well what I
mean." I told
him, as I had often done in the past. that I never lost my patience if he didn't underst:mrl m-. (He shon1d flo l.i.kiev-ii;;:e a.'l.d th5;'l\ abnut t:he reason -vhy I didn't JJT1de:rst2-nd.)
DIDACTICAL PRINCIPLES
109
number of letters must be odd if the words are to be put together to form to form a regular cross. -- Let me add that at that period the ideas of even and odd strongly occupied
his mind.
2.4 LONG-TERM LEARNING PROCESSES
The present title was announced in (2.3) as being my actual aim. Again long -
term learning processes means: long term teaching/learning processes. How
long? Life long! Extending beyond the limits of school life? These questions are
not lo the point. The limits, whether reached or not, are set by the teaching goals
as viewed by the designer. Well, there is no absolute limit: each goal, as definite
as it may look, can be outdone by more ambitious ones, which, however, are
meaningful only from the viewpoint of those previously viewed as definite.
Textbook series are examples of long term planning of teaching/learning processes. I mean another thing: planning long term teaching/learning processes. Later on the difference will become clear.
2.4.l Learning to forget
. .
An ambiguous heading: learning lww and what, or in order to forget? Both of
them are worth discussion. As every teacher knows, breaks in learning processes
may cause total losses of learning products. Starting a new school year often
amounts to starting with a clean slate. In my country successful final examinations are celebrated by hanging satchels at the flagstaffs. Indeed, after the examination, most of the stuff learned may be forgotten never to be remembered, and
this extends even beyond the narrow limits of what was taught with the sole aim
of the examination. It is too old a story to be told again: people who, though failures in school mathematics, succeeded in life, or so they claim. Or even worse:
people who assure you that, thanks to a mathematics they never used explicitly,
they learned a lot of valuable things (especially logical thinking) and, whether
asked for or not, substantiate this assertion by examples that are as many proofs
to the contrary.
No doubt, in every respect, discarding is no less important an issue than keeping.
Beyond a multitude of subjects and activities, one has to learn which ones are
worth forgetting and which ones remembering. Much depends on the learner, on
individual inclinations and aversions, that foreshadow the learner's future life.
This does not absolve teachers and educational developers from the task of steering and designing the process of forgetting as well as that of recalling. Mathematics can again be distinguished from other areas of learning by this fact itself and
by the way this task is to be tackled.
We viewed mathematics as an activity, and learning mathematics as guided reinvention. In contrast with traditional instruction, the stress was shifted from instructional products to instructional processes. This shift cannot but influence the 110 CHAPTER2
line to be drawn between potential remembering and forgetting. Anyway, if
learning processes are so important that they are specified by guided reinvention,
it is quite improbable that their ultimate destination should be obliteration by
their products, although this feature does seem characteristic of mathematics. I
am going to explain why this is a serious misapprehension, caused by a wrong
perspective.
Let us take an example from geomelry! A famous theorem, by folklore ascribed
to Pythagoras, is learned by the great majority of young people, and the fact that
it is famous proves that it is even remembered by a great many adults, or so it
seems. Many teachers and even more textbook authors feel obliged to provide
learners with some proof, though it is an undeniable fact that the theorem is successfully applied innumerable times by people who never learned proving it or
forgot the proof they learned. To be honest, even in the highest regions of mathematics, people often apply results obtained by others without checking the
proofs or caring at all how to prove them.
So why learn proofs if afterwards they may be forgotten? Once one of my colleagues was asked by a freshman: "Excuse me, Professor, isn't it a curious habit
of yours that in your course you prove each of your statements? Why do you do
so? Are you afraid your students don't trust you?" It is a question that can be answered in manifold ways. Mathematics is different, I claimed. It is a remarkable
fact that, in mathematics, each statement can be corroborated by a proof, although
it is not the fact that matters here where we are concerned with teaching and
learning mathematics, rather than with mathematics as a deductive system. As we
noted several times, the relation in mathematics between theorems and proofs is
not akin to that between products and processes in mathematics instruction.
What then can be the didactical value of mathematical proofs? The answer depends on how a particular proof is expected to function in a course as a whole. A
proof can be held up as an example to what proving properly means, and let us
hope that as such it is paradigmatical enough to convince the learner! Or a proof
can be an opportunity to teach a number of isolated facts or activities in an integrated way, that is by logical linking, although the course of reinvention itself
may be as forceful a linkage, or even more so. And finally, by analysing its proof,
the teacher may discover how to guide the learner to reinvent the theorem it is to
prove. Proofs refashioned for this aim are valuable in themselves as sources of
insight On the other hand, proofs with the sole aim of being forgotten after having produced the theorem they are to confirm, are didactically worthless.
This, then, is the intrinsic didactic fallacy of traditional teaching of mathematics,
as well as that of its all time high in New Math: the large extent of subject matter
learned solely in order to be forgotten, aggravated by the eventual criterion of the
examination. In addition to this there is the extrinsic problem of what school
means for life: How to adapt the relation between remembering and forgetting to
the diversity of demands of future lives?
DIDACTICAL PRINCIPLES 111
2.4.2 Remembering learning processes
" If learning processes are so important that they are specified by guided reinvention," I said, "it is quite improbable that their ultimate destination should be obliteration by their products". Learning processes have a value of their own, which
entitles them to be remembered. Not in detail., of course, as there are very few
things we remember in detail, if any at all. Rather than details, we record essentials, or what we take to be such. Anyway, that is all we can recall and, if need
be, put to good use.
Learning processes, or at least part of them, can be more essential than their products. As far as they fulfil this condition, and in the way they doe this, they should
remain accessible to memory. Not in detail, to be sure, but to the extent and in the
fashion that they are essential. Few people, if any, remember how they learned
arithmetic. This is a good thing if they learned it thanks or in spite of bad teaching. Fortunately there are people who can reconstruct the learning process as it
would have taken place if they had been allowed to reinvent arithmetic. It is those
people to which the old adage, cited in (2.1.4) applies: first learn, then understand. And the others? They are better served by guided reinventive learning,
duly recorded.
Written records, even the most circumstantial ones, are far from being complete,
but a good record allows others and oneself to repeat the process recorded, maybe
in a more streamlined way than it actually took place. Mental records are no different Mental records are due to reflection. This, then, is what makes processes
of learning by guided reinvention accessible to memory: built-in opportunities to
reflec- which can be reinforced by verbalisation and by communicative interaction with the guide and between the guided ones.
Mathematising is to a great degree liable to obliteration by its result, that is,
ready-made mathematics. Once schemes and forms have been consolidated, once
concepts have been attained, once short-cuts have been performed, the stages of
schematising, formalising, constituting mental objects and short-cutting may be
dismissed as dispensable nuisances. Algorithms are an utterly extreme case.
Once mastered, or believed to have been mastered, they are most likely to disavow their origin. Indeed, it is the great virtue of algorithms that they can be performed mechanically, as it is their drawback that they become useless or even
dangerous as goals in themselves: mathematics identified with performing algorithms. It is algorithms that created what looks like the fundamental antinomy
within didactics of mathematics: insight versus drill.
2.4.3 Insight"
A cherished antinomy in teaching and learning mathematics is putting on one
side of a deep gorge such noble ideas as
insight, understanding, thinking, 112 CHAPTER2
and on the other side such base things as
• rote, routine, drill, memorising, algorithms.
If I were malicious, I would add another pair of opposites
• theory versus practice,
suggesting that learning by insight is a noble theory while base practice is learning by rote and memorisation. However, it is not that simple, and it has never
been so. Even in our computerised age, children memorise tables of addition and
multiplication and acquire certain skills by rote, though one might argue that the
balance has shifted in favour of the nobler activities due to the rise of the computer.
It is not that simple, firstly because the question is not which side of the gorge to
choose but rather to bridge it by the learning process that I called schematising
and formalising. Secondly, I do believe that, at any time more mathematics has
been taught from the viewpoint of insight and more has been learned by insight
than we are aware of -- indeed, common sense is insight. Everyone agrees and
textbook writers have witnessed that elementary arithmetic cannot be learned in
any other way than by insight, whether it is taught that way or not. But it is also
true that, as things go on, as teaching proceeds to ever higher grades, to column
addition and multiplication, to long division, to fractions (ordinary and decimal),
to algebra, to learning mathematical language -- the part played by insight changes. The learner's insight tends to be superseded by the teacher's, the textbook
writer's, and fmally by that of the adult mathematician. And the same tends to
occur on the long winding road which leads from concretely understood word
problems to highly formalised and badly understood applied mathematics.
This is why people who advocate learning through insight, disagree about what
insight is. New Math's wrong perspective was to replace the learner's insight
with the adult mathematician's.
Yet this is not my main point. I have still to explain why we are not aware of how
much is learned by insight nevertheless. It is quite natural that, once an idea has
been learned, the learner forgets about the learning process, once the goal has
been reached, the trail is blotted out. Skills acquired by insight are exercised and
perfected by training, intentional and unintentional. This is a good thing. What is
bad, is
sources of insight clogged by acquired routines, never to be reopened,
though that is what usually happens. It explains why upper grade teachers so often complain about teaching habits in lower grades. If it is restricted to the first
acquisition of some idea, learning by insight does not deserve this name.
What is crucial, is
• retention of insight,
which is gravely endangered by drill, that is
• premature training,
too much training,
r\~") SJJC-'.
DIDACTICAL PRINCIPLES 113
how to keep the sources of insight open during the training process,
how to stimulate retention of insight, in particular in the process of schematising and formalising.
How can this goal be pursued? The solution I have proposed is
having the learner reflect on his learning process.
As I explained earlier, mathematics is to a great degree reflection on one's own
and other people's physical, mental and mathematical activity. The origin of
proving theorems is arguing things that are apparently obvious. Nobody tries to
prove a thing unless he knows it is true. This he knows by intuition, and the way
to prove it is, as I claimed, to reflect on one's intuitions. Successful learning processes, if observed, should be made conscious to the learner in order to be reinforced and in order to be recalled if needed. This, however, is not what usually
happens. Let me illustrate this by an example I have cited many times.
Many children and adults can tell you that in order to multiply by 100 "you have to
add two zeros" (which is only true for whole nwnbers) yet most of them cannot explain why. Even worse: most of them don't even understand that the matter can be argued and why this should be done. Did they learn such rules by rote? I don't believe
so. I have observed too many children applying such rules intuitively before they were
verbalised and formally taught at school. Rather than be-g taught the rules, they
should have been taught to argue their intuitions, to reflect on what appears to be obvious. But this requires more patience than teachers can afford. Indeed, compare this
with my story of the girl' who was taught the rules on fractions after she had acquired
a good working knowledge of fractions. (See 2.1.4, 3.)
2.4.3.1 Testing insight
When, in 2.1.4.3, I discussed the jumps in the learning process of the girl I had
been observing for a few years, I promised to provide an example to show how I
tested her insight, that is, to see whether its sources had not been clogged during
a period of training.
She had come to the point that she solved equations like
l l 1 1
---: :t=-:c--
2 3 2 3
according to the rules of the art, automatically as it were. I had a strange feeling:
the better she performed, the more urgently I asked myself whether she still understood anything. Finally I was terrified by her excellent performance. On the
other hand, as explained earlier, I dido 't dare to have her verbalise her behaviour.
Then I got an inspiration. I drew a horizontal numberline, that is, without numbers, having only an origin and equidistant marks. I took an interval between
thumb and forefinger, around the origin yet not symmetrical, and asked her: " If
xis here in between, show me where 2x is!" She did it with her thumb and forefinger. "Where is i• ?""Where is x ÷ 2, x - 2?" "Where is -x?" This was the first
hitch but it was soon conquered. Then I asked the converses. " If 2x is here in between, where isx? I f 1• is here in between, where isx? After a series of questions 114 CHAPTER2
like these I gave her wriuen problems. She already knew the notation -3 < x < 2
for "x between -3 and 2". Step by step I led her to sums like
if-5<-x-1<6
what can you tell about x? Or
if 1-lx<lx-1
2 3 2 3
what can you tell about x?
So I became convinced that her insight had been preserved in spite of training.
As an afterthought, the above seems to be the didactically most promising means
of formalising the mental object of variable. (Cp. [ll9a] .) It is a pity that I didn't
mention it in [146].
2.4.4 Training
Advocates of insightful learning are often accused of being soft on training. Rather than against training, my objection to drill is that it endangers retention of insight. There is, however, a way of training -- including memorisation -- where
every little step adds something to the treasure of insight: training integrated with
insightful learning. If I compare our mathematical textbooks -- from the lowest
to the highest grades -- I cannot but notice a historical trend toward this kind of

integration, In the past there was a clean separation between so-called theory (often nothing more than a model) and its so-called applications (or rather, imitations of the model), which were as numerous as the theory was meagre; and the
closer one gets to the present day the more deliberately a more vigorous theory is
broken up into insightful steps, each of which may contain both a training and a
reinventive aspect Big problems, posed in contexts, can serve large scale training
better than a flood of small applications. In other words, textbook authors have
shifted from extensive to intensive training. For teachers who learned mathematics the old way and accuse the new style of being chaotic, it is difficult to use such
textbooks adequately. Students, however, adapt to them more easily.
At the primary level there are clear indications' that reinventive learning -- learning column arithmetic by progressive schematisation, for instance -- is far less
time-consuming than extensive training. This even extends to pure memorising,
say of multiplication tables'. where children are allowed to use their own, socalled informal, methods. At the secondary level, comparisons are not so easily
made because of the interweaving of subject matter and teaching style. A more
fundamental divergence is, indeed, whether, for instance, exponential functions
are introduced as a formal subject or as the result of exponential growth in realistic contexts. The most intimate long-term integration of reinventive learning
and intensive training with which I am familiar, is L.Streefland's research
6
on
teaching fractions in grades 4 through 6; this research, moreover, include- 13 glo-
- ...
DIDACTICAL PRINCIPLES 115
(2.1.2, 6) (dividing a number of pizzas among a number of children sitting at a
number of tables, where the symbolic recording proceeds from a suggestive pictorial notation towards the standard one by means of formal fractions) as shown
in fig. 13-15 from 6, p.203, 269, 302. The learning process is an alternation between what Streefland calls the children's own constructions and productions,
which may roughly be distinguished by catchwords like: open end and open start.

2.4.5 Organising the learning process
l . Levels
Why did we pay so much attention to the level slructure in learning processes?
Let me quote myself from (l.1.2):
Sure, some. algorithmically gifted people, learn to apply even imposed algoritluns adequate!-; others -- perhaps -e majority -- fail to identify the new algorithmic procedur-s -1th the commo---ens1cal one- from which they should have originated through
abr!dgng and streamlining. They fail because some time in the past they were asked
to take mental leaps which exceeded their mental powers. Even though they flawlessly
learned the algorithm, they will fail to use it in true life situations where common sense
counts; they will instead depend on less efficient lower level operations. Researchers
have signalled this .. relapse" and marvelled on it. Rarely, however, has it been diagnosed '.15 a con_seque1!- of instruction. since no alternative instruction was envisaged
alongside the l!ilpo51tlon of the new algorithm (which was sometimes embroidered
with explana-ions for conscience's sake). The new algoritlun, however, never did have
-e opportuni- to reac- the state of common sense; afraid of applying a wrong algonthm or the right algonthm wrongly, the learner instead relies on what has remained
common sense to his mind.
What I stated there ';ith regard to inl"_lsed algorithms applies more widely, l
daresay, lo almost all imposed mathemaucs,. Indeed, the fact that researchers signal and marvel at such relapses is shared by a variety of fields. Whatever levels
may mean theoretically, it is the duty of the organisers of learning processes to
respect them. The fact that a few -- gifted people -- can get along on levels to
which they have been lifted inconsiderately, does not justify ignoring levels in a
teaching strategy. The question of how jumps in the learning process can be diagnosed, has already been answered. Teachers (or peers in learning groups) need
to insist on the justication of what appears to be new knowledge or new procedures, thereby requiring the inventor to reflect on what he -- consciously or unconsciously -- performed. This need not necessarily be done by verbalising,
which anyway should not be enforced; a paradigmatical status, witnessed by repetitions, is enough to prove the jump in the learning process.
If levels are to be respected, than learning processes must be organised flexibly
enough to be adapted to the needs of learners or learning groups. This demand for
flexibility also applies to the goals of the learning processes.
2. Differentiation
How fast and how far learning proceeds, depends greatly on the learner and on
which way and whether the goals staked out are eventually attained. Reinventive
learning cannot possibly be planned rigidly, but lack of planning may be even
worse. in Z.1.2 both didactical extremes were presented within one examole: the
-·-·:-'" 0'•7 .',' 0f ''Pl'');:.:..'-'l'- .,,;_-:-.. -, +_'t'··C>' 'l' -·1-J<-'·:'..-l-';';'.C/ - r..-1 t---:::- 'L-.c ii_f _ - -:-l-':' ·' '. -r----. --'.': --1 ---;--- -.,, '; --.t'''':'i
DIDACTICAL PRINCIPLES
117
ate ones, a widely branched network of possible learning roads is then opened lo
them. It becomes even wider in the case of learning the algorithms of column
arithmetic. The standard algorithms are theoretically much less compelling than
is usually assumed; there are variants, indeed, which don't commit teachers and
learners beyond their didactical function as guidelines. Comparative research on
such variants, if viewed didactically, has never been more than a hobby, and is
unlikely to survive in the computer age. The advantage of reinventive learning,
and in the present case of progressive algorithmising, is that individual learners
or learning groups may advance at their own pace and eventually reach the best
of the goals accessible to them.
In general, this means organising inslruction so that, rather than it being differentiated in advance, the learners differentiate it themselves, and do so on levels as
high as are accessible to them: spontaneous versus imposed differentiation. In the
insiructional design, branches are preferred to dead ends and branches that may
lead back to the main stream, to branches that lead nowhere. If we may use metaphors I prefer that of the jump, if necessary produced by change of perspective,
to the not unusual one of the sharp turn, where no perspective at all is involved.
3. Prospective and retrospective learning
It is a well-known experiential fact that column aritllinetic may function both as
a motivation and an opportunity to improve one's knowledge of addition and
multiplication tables!: This experience will be viewed in a broader didactical context, as is indicated hy the above heading.
In former times, mental addition, subtraction, multiplication, and division were
taught one after the other and separately; arithmetic teaehing was divided into
stages "up to 10", "up to 100", "up to 1000", and so on; fractions, measures, proportions were dealt with as separate subjects. Things have since changed and will
change even more in the future. As everybody can observe, children who have
just mastered additive arithmetic up to 10, are proud ID tell you that 10 + 10 = 20,
or even that 20 + 20 = 40, that 3 x 3 = 9, and to recite the multiplication table of
l, of 10, even perhaps of 5. In their informal arithmetic, doubling and halving often precede systematic learning of the multiplication tables, with as next best,
squares which occupy a particularly cherished place in the tables. Rather than
suppressing such predilections by premature systematisation, mathematics inslruction should take advantage of them, which is actually happening in more and
more textbooks
24
•
This is what I call prospective learning. (Other terms are "anticipatory learning"
or "learning by advance organisers".) There are many more examples. Ratio, for
instance, has profound visual roots, which can be arithmetised early on by estimate and measurement. There are many informal opportunities in contexts for
common sense ratio in everyday language before it is dealt with more systematically and formally. Long before fractioning the traditional "cake", the clock dial
is divided according to halves and quarters of an hour, which, unlike the cake segments, have an existence of their own. Functions have visual and numerical roots 118 CHAPTER2
in graphs and tables, and describe situations and processes, long before they are
focused on as such. In general, deep roots should be preferred to virgin soil, and
opportunistic to systematic learning.
I chose the term prospective for this organisation of learning as a counterpart to
what I call retrospective learning, which means recalling old learning matter
whenever it is apt to do so and worth being reviewed from a higher stance or in
a broader context. Retrospective learning serves dual purpose: it roots the new
matter in the old one, and it strengthens the old roots. Learning a new idea is often
nothing but becoming more conscious of a complex of previously less conscious
pieces of knowledge and abilities and of their interrelatedness. If experienced as
such, it is retrospective learning. When the laws concerning the arithmetical operations are formulated, their former occurrences should pass the retrospective
review in full. This means including -- besides those of an arithmetical character
-- also such geometric experiences as: when pacing a circumference to measure
it, it does not matter where I start; when measuring areas of rectangles or volumes
of beams, the length, width and height are interchangeable data. Combinatorics
is a particularly fertile domain in which single paradigms may rule broad fields
of isomorphic problems (cp. (87, chap.IV, 9]), antedating for a long stretch of
time their general expression and its verbalisation; but as soon as this goal is
reached, the old experiences should be renewed and their paradigmatical character should be understood as a general feature of isomorphism.
It has been a habit of adult mathematicians to review old ideas over and over just
as it has long been experienced that this activity leads to ever deeper understanding. Young learners should not be treated differently. Prospective learning should
not only be allowed but also stimulated, just as retrospective learning should not
only be organised by teaching but also activated as a learning habit.
4. Intertwining learning strands
Just as prospective and retrospective learning aims at an integration of past and
future learning processes, so does intertwining learning strands" locally, yet
with a view on the involved learning processes as a whole. Rather than running
on separate tracks which, except for incidental references and loans, are independent of one another, learning should be organised in strands which are mutually intertwined as early, as long and as strongly as possible. When loose ends are
inevitable, they are taken up at the first opportunity where they can be connected
to other ones in order to be continued. In a sense, examples of prospective and
retrospective learning can also serve as such for intertwining learning strands, or
at least for points where intertwining can start in order to be continued more consequently. But let us look for other examples!
Ratio and fractions can go together right from the beginning -- and I do mean the
very beginning: visual comparison of separate objects is paralleled by comparing
the parts of one object Double scales on the numberline and proportionality tah-·,--s :- -of--- e "2-1"1"- -_,.-.!"--_ ?.:- ,,.1/e-H "1.S ---;;tiI"i -"---::it.: t ---c"1--,,,, - ::.,+--) ___ _.:.;.- _Y-"'--:.
DIDACTICAL PRINCIPLES
119
twined in various ways. Functions, graphs, and equations, which in many textbooks form separate chapters, should be intertwined as learning strands. Thanks
to the geometrical-algebraical permanence principle (cp.(146], chap.16]), learning negative numbers, vector algebra and geometry, and linear graphs and functions can be so closely knitted that they appear to be one subject
26
• The intertwining of algebra and geometry must not be restricted to traditional analytic geometry; plane and solid geometry must not be dealt with as separate subjects.
Teachers who prefer systematic instruction are likely to accuse this approach of
being chaotic. They forget that systematics is an a posteriori contraption. What
looks like chaos may be well-organised didactically, while, on the other hand the
system as such may be a subject of guided reinvention.
5. Active learning
In the first chapter I approached mathematics phenomenologically as an activity,
and the overruling principle of the second chapter was to do justice to the first,
which I tried to do by advocating guided reinvention. Modern textbooks and other recent literature are a wealthy source, providing examples of mathematics as a
learner's activity which can be stimulated and realised by guided reinvention.
Rather than quoting some of them and keeping silent about others I preferred to
look for a paradigm that displays as many features of the reinventing activity as
possible. I didn't fmd it in the literature, although I can hardly believe that it is
indeed as new as it looks to me.
Eeny, meany, miney, moe.
Catch a tiger by the toe.
If he hollers let him go.
Eeny, meany, miney, moe.
Isn 't this a way of counting? As a matter of fact, in a few languages with which
I am familiar, the term for this game of reciting such a rhyme while moving the
forefinger in the round is derived from the word for counting. It is counting; only
the words are different. But how much do words matter in counting? After all, the
children playing the game give the numbers different names, depending on their
mother tongue. In some languages I know counting rhymes that start with an ordinary number sequence; in German one even goes up to 20 and then continues
in normal language, where eventually Danzig rhymes with zwanzig.
So why not all the way count with genuine numerals? How far? One can agree
on a limit. For instance, up to 100. This "why" or "why not" may become a point
of discussion -- I mean in the classroom, before or after the lesson or sequence of
lessons I have in mind. 120 CHAPTER2
Fig. 16
Let the children be seated in a circle; let them count themselves rather than be
counted off by one of them or an outsider but to count themselves. One of them
starts with l, the neighbour says 2, then comes 3, each adding l to the number of
the predecessor, going on up to . . . No "up to", because after the last in the circle
the starter simply continues counting. One round, a second, a thin!, . . .
In the drawing in figure 16 I numbered the four stages 0, l, 2, 3: at the start 0,
after the frrst round l, after the second 2, and after the third (and a little bit more)
3. (I apologise: I drew it as though I myself had counted off the children, that is,
clockwise. I venture a bet that if they coumed themselves they would do it the
other way round. As in writing things are being done from the left to the right.
Two variants or additional activities: During the counting process a pile of
number disks (bingo cards) are passed around, and each child takes one in turn
while saying the numberout loud. Or each writes his numbers on a sheet of paper.
The sketch shows 16 children. Most classes are larger. But the circle need not include the whole class. On the contrary, it is just to the purpose to start in a small
way, preferably in pairs, speaking or writting down in turn the odd and even numbers. After that, groups of 3, 4, 5, . . . ; 10 is particularly nice.
What has this game to do with mathematics? *My* answer is: all you can make of
it. To prove it I will give you a list of questions I would put to individual children
or the whole class:
DIDACTICAL PRINCIPLES
121
two rounds, after three, ... ? What did you get a round ago, two rounds
ago, ... ? What in the first?
2. What numbers would you have got, if number 1 had started as ... ? What if
number ... had started as 1?
3. Who gets number 100, and after how many rounds?
4. What will your first number above 100 be, and after how many rounds? What
your last below 100, and after how many rounds?
5. How do your numbers change if counting is inverted?
6. If you did the game with ... as many mates, how much faster would they reach
100?
And a more general question:
7. What catches your eye if you look at your set of numbers? Any pattern, any

regularity?
It will be clear what I meant when I asserted that this game has as much to do with
mathematics as one can make of it. Certainly the four fundamental operations --
the multiplication-tables, and even more striking, the division with remainder
stand out in bold relief. What kind of division? N numbers divided among n children, or N numbers arranged in circular groups of n? It doesn?t matter, and this is
one more aspect that does matter.
Remember, the idea was to.start with small groups, but in the long run it is didactical wisdom to resume the game again and again, as long as the children enjoy
counting out So it can serve as meaningful training. But since even little children
can do it with large numbers, as can older children with small ones, it is a marvellous opportunity for prospective and retrospective learning. Another striking
feature is the tight intertwining of learning strands. The learning processes will
be differentiated according to how the problems are tackled on various levels,
which can be discovered as such by reflection and transmitted by group cooperation. Last but not least, it is a rich context, the richest one can imagine: a children's game.
As for the guide: an excellent opportunity to observe learning processes.
2.4.6 Acquiring a mathematical attitude
The original heading of this subsection was: Products of learning processes. Indeed, learning processes are not aims in themselves. But how to define their products? Hard products, though interminable in high level mathematics and valuable
as objectives of mathematical research, are not the motive for teaching and learning mathematics at school, nor is their number significant. The pupils are expected to develop certain abilities. Detached from the learning processes by which
they were acquired, these abilities may lead lives of their own as methods and
skills, and as such they may be exercised, studied and tested. One can try to list
and classify them, but what is the use? It would not answer the question of why 122 CHAPTER2
they should be products of learning processes. After quite a few false starts I decided to attempt a comprehensive answer under the above heading.
In 1975, in Hungary I happened to take part in a conference Evolving a Mathematical Attitude in Secondary Education -Age Range 14 -18 Years. I started my
contribution27 by taking exception to the general theme. I did so for two reasons:
First, 14 years is much too late to shape a mathematical attitude, although it is not
too late to develop it further, provided one knows on what basis one can continue
from 14 to 18 what was achieved at lower age levels. My second, and even more
important argument, was that a mathematical attitude is more easily described for
lower than higher ages if such descriptions are to be based on observations rather
than on logical analysis. Indeed, what matters is the interior rather than the exterior attitude, and the older people grow, the more their interior and exterior lives
will diverge from each other; the most extreme instance of this phenomenon is
found in publications on mathematical discoveries, where any intellectual or
emotional detail of the discovery process is carefully avoided. The only access
left to the interior life of adults, is introspection, but this is a hard thing to realise.
So, if attitudes are to be described on the basis of observations, one is very likely
to find more useful material in the lower age bracket than in the one.
How to describe a mathematical attitude? Such descriptions have often been attempted, though most often in too general terms -- thinking clearly and distinctly,
criticism, looking for problems, killing problems. It is the drawback of such descriptions that by the way they are formulated, they do not properly refer to mathematics. The opposite of this procedure can be found in Polya's repeatedly mentioned work, whose tendency, rather than whose details, can be a source of
inspiration -- though less of subject matter -- for didacticians of mathematics.
Mathematical attitude can, in my view, be described most efficiently as the mastery of big strategies, and this is the way I will use the term. I will deal with five
strategies, while referring to experiences in actual teaching, most of them related
to 3-13 year-olds, but viewed as an initial condition for developing attitudes at
higher ages.
1. Developing language above the ostensive and linguistically relative level, in
particular at the level of conventional variables and functional description21.
Although linguistic levels are reached by learning processes they should not be
confused with the levels in learning processes. Levels in learning processes are
there for staying on unless, for some particular reason (for instance as an education developer), one is required to descend. Linguistic levels, on the contrary, are
there to for moving on however it works out, that is, at each opportunity on the
level that best fits the situation.
Besides the levels, I also distinguish two modes of expression: describing something by means of an action or as a state of affairs. For instance:
To get the mirror image of P with regard to! , drop the perpendicular from P upon
l and extend it as much behind l as P is in front!
DIDACTICAL PRINCIPLES
123
I distinguished the following levels:
ostensive language, where pointing with the index finger or pointing mentally
may be accompanied by words like "this" and "that";
relative language, where objects are described by their relation to other objects;
conventional variables, which make relative language function more smoothly;
funcrionallanguage.
To make things clear let me quote an example from algebra: define the square
root!
Ostensive:
P = ' so 3 is the square root of 9,
s2 = 25 so 5 is the square root of 25, and so on.
Relative:
The square root of a number is found by looking for a number that squared reproduces the given number. Or, in another mode:
The square root of a number is the number, the square of which is the given
number.
Such clumsy names for variables as are "number" and "given number" are avoided by the use of
Conventional variables:-
x = Ja ?if x
2
'" a.
By means of a new concept the language becomes
Functional:
Taking the square root is the inverse of squaring.
2. Change of perspective, a complex field of strategies whose common feature is
that the positions of that which is given and that which is sought for (of data and
unknowns) in a problem or a field of knowledge are -- partially -- being interchanged; this includes the recognition of wrong changes of perspective
27
•
3. Grasping the degree of precision that is adequate to a given problem21
18
•
4. Identifying the mathematical structure within a context, if any is allowed, and
barring mathematics where it does not apply2'.
In fact, there are large fields where mathematics is more often illegally than legally applied.
5. Dealing with one's own activity as a subject matter of reflection in order to
reach a higher level. CHAPTER3
. THE LANDSCAPE OF MATHEMATICS EDUCATION
3.1 THEORY OF MATHEMATICS EDUCATION
The heading is wrong but I could contrive no better one. What is wrong is the
word "theory" that -- used by so many people on so many occasions with so many
different meanings -- needs circumstantial explanations that do not contribute
factually much to our subject I recently read a paper on theories of "theory"
where the author claims:
When a mathematics educator studies the effects of lax and restrictive learning environments on children of different anxiety levels, she preswnably has a theory that relates achievement to both anxiety and the structure of the learning envirorunent. Or,
when a cognitive psychologist examines classification tasks in the learning of early
number concepts, the psychologist most likely has a hnnch as to how these tasks are
related. Or, when a doctoral candidate designs an experiment in which children are
taught several different problem solving heuristics, she preSUmably has a theory that
predicts which of theSE', treatments will be the most effective.
The middle sentence attests a terminology where a "hunch" may have the status
of a theory. Indeed, in colloquial language the word "theory" is occasionally used
in this way, although under these circumstances most people would prefer the
word "hypothesis". However, this is only one extreme of a broad spectrum of
meanings. The other extreme (which will be described in what follows) deserves
a name as well, and I would not know any name for it if "theory" is used in too
liberal a way.
3.1.l Theory
l . Domains and theories
People familiar with the terms and with the domains they cover will agree about
number theory being a theory, and about distinguishing, if need be, between algebraic and analytic number theory. All the same, they might disagree about
some concept or proposition, for instance, whether it falls under analytic number
theory or under complex function theory. In fact, depending on the context in
which it occurs it may be attributed to both of them. The infinity of the number
sequence is neither a theory nor a hypothesis but a mere fact, which nevertheless
may be the subject of sophisticated theories. The infinity of even or odd numbers
is a fact as well, as is the existence of an infinite number of primes, which -- requiring a non-trivial proof -- has the status of a theorem in number theory.
Neither mathematics nor physics nor chemistry nor biology are theories, al-
125 126 CHAPTER3
though there are a great many -- sometimes competing -- mathematical, physical,
chemical, biological theories, that cover various domains and sub-domains of
these sciences or deal with their foundations. Mechanics is not a theory but Galilei-Newton mechanics is, as are the theories of elasticity, relativity, and quantum
mechanics. Originally, biological evolution was not a theory but a mere tool for
organising fossil evidence, which proved successful long before the discovery of
evolutionary mechanisms. On the other hand, almost from the onset, astronomic
evolution has been a theory.
History is, of course, no theory. Historiography, rather than being a theory, is the
technology of historical research. There have been attempts to develop theories
on history. "History does not repeat itself' is a theoretical statement on history,
as is "History does repeat itself but then as a farce" (Hegel). Although theories
on history are more sophisticated than such statements, I doubt whether they have
been more successful. Or, in other words, they were topical as long as they did
not have the time to outlive themselves.
Language, or any particular language, is of course no theory, but there are a great
many theories on various aspects of language and of particular languages, that is,
on origins, structures, recording and social functions, interrelatedness, artificiality, and so on.
Economy is no theory, though economics includes a large number of -- competing -- theories. Strangely enough "education" is used in both ways, like "economy" as well as like "economics". Rather than interpreting this twin use as ates-
timony to integration, I see it as evidence of a shortage of relations between them.
2. "Theory versus practice"
The saying "that's mere theory yet practice is different" may mean various
things. It may be used if an actual state of affairs does not match the one reported
on or desired, or if some tool or recipe does not work the way it was told or expected to. Pure theories are descriptive rather than normative, even though they
might have been created under the influence of norms or with a view to establishing norms, and even in spite of a virtual interrelatedness between norm and description. For instance, the all-embracing aristotelian-scholastic theory of potentia and actus, which arose from opposing female passivity to male activity, was
both the result and the cause of social and sexual norms, although it was formulated to be understood as part of an ontology, that is, as a profound description of
the way things are.
The saying may as well be meant to express the more fundamental dissatisfaction
about a theory or something like a theory that does not really apply. This can
mean that it falls as a description of reality or that there is no reality at all to which
it can be tied. In this case, the theoretician is very likely to charge the complaining
practitioner with the crime of the so-called confusion of reality and (descriptive)
model (see [87]), which is simply a lame excuse. It can also mean that the theory
r- cc:=-- '-?V)t nr.r--,--rle ::'?"-.o::;h r--o r,?-.-,, f0-; -1-(;.):-'; 0.,.,,, 0tt !-- -?'<'-1{?- -"--r": ".\-?.- : ; '--1--"t].· ;·--- ---:: ·:·, ::·<::::: ", ,, ... ,,.--,
THE LANDSCAPE OF MATHEMATICS EDUCATION 127
The theoretician might then appeal to the restrictions inherent to the use of models -- an apology that may be accepted provided there is any use at all for the model in question.
3. Pure versus applied -- descriptive versus normative
Antinomies can be illuminating. Yet rather than pitting theory against practice, I
would like to pit the desire for cognition and understanding against that for action and change, pitting pure against applied research, descriptive against normative models. To be sure, the interaction between them may be more frequent
and fruitful than their contrast Chapter I of the present book was written under
the first aspect, chapter 2 under the second, but the result was not a clean separation. Items such as mathematising, mathematics as an activity, mathematics in a
context can be introduced as descriptive, pure concepts, even though they were
created with application» in mind, in particular in education. Levels are descriptive structural features of learning processes, which are meaningful only from a
particular didactical point of view.
In (1.1) I signalled the difference between shades of meaning of the word "arts"
in "arts and sciences" and "arts and crafts". From the performer's perspective,
"arts" in the two pairs is interrelated, as are "artist" and "artisan". If an integrating
rather than differentiating term is desired, one may choose the word technique,
as performed by technicians, which is derived from the Greek tee/me for art. Then
the interaction;between what was announced as opposites is known as technology.
Education is a technique, and so is mathematics education. A teacher is a technician, as is an engineer, a medical doctor, a lawyer, a clergyman, a social worker.
They depend on more or less advanced technologies, which in character extend
across the entire range from the mere mastery of a professional language to applications of hard science. In [87] I discussed this and many other related ideas
in abundant detail, and with as much sophistication as I was able to produce, so
Iam wary of repeating myself, even in paraphrases, which I am afraid would not
be any better or more convincing than the original. I didn't even get the opportunity to defend my ideas since they were, as far as I know, never questioned. Far
from believing that any of them was accepted, I even wonder whether they have
been noticed at all -- silence does not imply consent".
4. Theorising
The question that should occupy us here is not whether and under which conditions or circumstances a theory might be true or applicable. We should instead be
concerned with the ill-founded belief that mere theorising in itself, if profound
enough, produces theory. As valuable as theoretical statements and conceptual
tools may be, they do not necessarily, even though assembled to form an extensive collection, constitute what to my mind what is worth being called a theory.
As I see it, a theory should pursue understanding in a reasonably well-defined domain, the extent of which does not matter much. It should do so in a reasonably 128 CHAPTER3
coherent and consistent way, and it should in principle provide its adepts with
guidelines on how to tackle questions, relevant to that domain, and how to answer
them with unequivocal explanations or by proposing appropriate instruments for
action.
This restrictive definition does not intend to underestimate the merits of theorising, which I admitted may be the source of valuable theoretical statements and
conceptual tools. But by granting more latitude I would then lack a tenn for what,
in my eyes, is a full-grown theory. Indeed, much of what now rightly claims the
status of a theory was for long periods no more than a collection of theoretical
statements and conceptual tools, which in the course of time or by some lucky
stroke was eventually forged into a lheory.
This statement is relevant to our general theme in so far as education, and mathematics education, in particular, is a field of extensive and intensive theorising.
The preceding chapters are an example. They display more conceptual tools than
would be sensible to enumerate here, such as phenomenological approach, mathematising with all its aspects, context, guided reinvention, levels in learning processes, paradigm, reflection, insight, prospective and retrospective learning, intertwining learning strands, mathematical attitude, and many more. All the same, I
would not dare to claim that all together they constitute a theory.
After writing the last paragraph I happened to remember a dozen occurrences --
even in the plural -- of "learning level theory" in 2.3.2. I could plead that these
occurred in a context dating from more than a quarter of a century ago, while, in
the mean time my way of using "theory" has changed. I cannot exclude the last
possibility. Indeed, the lavish use of the tenn, in particular in education, might
have aroused an increasing suspicion with regard to the prevailing pretensions,
or at least doubts about its suitability; so I may have become more demanding in
granting something the status of a theory.
Yet this does not discharge me from the obligation to check whether learning level theory is, indeed theory in the restricted sense proposed. My answer is: yes, it
is. And although this answer may extend to other items mentioned in the same
context, which I did not label as theories, but I am wary of checking it. What I
actually denied was that they together constitute a theory of mathematics education, and I would now add: not even together with other conceptual tools that I
dealt with in the past and did not recapitulate here (see, for instance [87,
Chap.IV]).

The fact that, with regard to theorising in education, I focused too sharply on my
own results deserves an apology and an explanation: I am not nearly as well-acquainted with other people's work as I am with my own. But it seems to me that
I am not the only one who has lost his grasp on the abundant literature, although
I guess that on closer inspection (if this is possible) one would find less diversity
in results than in terminology. Long lists of references can be misleading. Theoreticians are isolated or restricted to small groups where each understands the
THE LANDSCAPE OF MATHEMATICS EDUCATION
129
Let us resume this question later on!
3.1.2 Theoretic frameworks
I should confess that I don't feel at all happy with the gulf I created between what
I called results of theorising (such as theoretical statements and conceptual tools)
and theory proper. Theorising is organising fields of experience, and the result of
this organisation, unlike a heap of sand, will be gifted with a structure, thanks to
its origin in connected experiences and the processing that took place when they
were organised.
The tenn I propose to bridge the gulf is: Theoretic framework .. I took the -om
Treffers who indeed uncovered and analysed frameworks of vanous educauonal
theories;. I will use the term here in a broader sense, that is, by also applying it to
models of educational practice, such as those exhibited by textbook series or by
products of experimental educational development, as well as by less fonnal
classroom practice.
Indeed there can be little doubt about the theorising origin of models of mathematicai instruction. From the outset they must have been framed, consciously or
unconsciously, by cogitation, reflection and argumentation. If need -- sue-
framework can be uncovered by interviewing the authors or by analysmg therr
production. Beside; and beyond this, theoretic framework can be designed rationally beforehand in order to be realised by models of instruction, but most often the frameworks will be shaped in an incessant interaction with the matter to
be framed. Their relation is comparable to that between form and content or between theoretically essential and accidental properties.
Indeed, in any model of instruction we will notice pieces that are less essential
than others, and which may be replaced by ones which are somehow eqm.valent.
How far can we go with substituting and rearranging, while at the same ume respecting the spirit of the model? What do the eventual pieces de resistance look
like? The answer to this question is an a posteriori definition of what I mean by
theoretic framework. . . .
I f! am asked an a priori definition of theoretic framework I would say it 1s a more
or less connected set of theoretic statements and conceptual tools, obtained by
theorising (and maybe even including mini-theories), and reflecting the essentials
of an actual or imagined instructional system in a way that allows the expert reader a reasonably faithful reconstruction. (In order to match the case in which Treffers used it, one has to replace "system" with "theory" in the last sentence.)
"Theoretic framework" is a weaker notion than is "theory". On the other hand,
by its mere defmition, it is bound more tightly to educational practice, which fact
need not be a drawback. As a consequence, by the first token, it applies more
broadly and by the second more narrowly than does "theory". Goal description,
when extended to all its dimensions (as understood by Treffers') certamly matches my defmition, although the expert reader can be satisfied with less detail than 130 CHAPTER3
the novice. (By an expert reader I mean someone familiar with the theoretic background, for instance, thanks to familiarity with the framework of the underlying
theory.)
3.1.3 Background Philosophy
The first question I asked in [87] was: What is science? I tried to answer it somehow by means of certain necessary criteria (relevance, consistency, publicity),
but otherwise I dido' t do much more than to oppose science to -- among others -
- technique and faith, without involving any comparative appreciation. I could
not, nor would I, restrict "technique" (or "practice" as I called it occasionally) to
inanimate nature. Since, together with biotechnique, I had to include medical
practice, I saw no reason why the term "technique" should not be applied to the
practice of teachers and other practitioners, those of the so-called humanities not
excluded.
Until quite recently, almost all technique was practised with no technological
support at all, or supported at most by some technology that for its part lacked
significant scientific support. This still holds for many techniques, in particular
for that of education and instruction -- a statement that again does not mean to
suggest any kind of appreciation.
In the past, even up to modem times, much of what is now called science, was
part of philosophy -- just think of Newton's Philosphiae Natura/is Principia
Mathematica, published by the Royal Society, whose fellows called themselves
philosophers. Step by step this all-comprehensive science has 'de-umbilicated'
the present specialised sciences -- to use a suggestive term of O. von Neurath's -
- but even today a great deal of what claims the name of science for itself still
dwells in the womb of philosophy. I dido 't make this statement as a gesture of
condescension. On the contrary, what I called background philosophy in [87] (or
else ideology) is indispensable as the rationalisation of a faith that in tum comprises the faithful one's picture of world, man and society. It is indispensable, not
only to any technique and wherever philosophy decides (implicitly or explicitly)
on the choice of technical tools and objectives, but also in "pure" science with its
rich choice of goals and methodology.
Did I start my exposition too far from mathematics and mathematics education?
Shouldn't I speak rather more specifically about the picture of mathematics and
mathematics education? In a sense this is true, since this is my proper aim. Yet
more things taught than just mathematics, and in this totality, pictures of subject
areas and their instruction are somehow related to each other by their relation to
pictures of world, man and society.
For any picture of mathematics and mathematics education one has in mind, it is
important where one localises mathematics -- inside or outside the world, bracketed (if out of bracket-. within brackets that close and open more or less easily.
THE LANDSCAPE 01' MATHEMATICS EDUCATION
131
pected to acquire their mathematics, how freely or slavishly, under guidance or
bridled. They all determine the manner in which one thinks mathematics can contribute to the mutual benefits expected by society and its members from one another, and they depend, at least partially, on one's picture of society and its inherent hierarchy.
Do not misunderstand me! I say "picture of society" rather than merely "society".
In primitive societies -- as well as iii "primitivising" ones (Freyre, Mellin-Olson)
-- "society" and "picture of society" coincide, as they do with the picture of world
and man. In our society, a broad sjlectrum extends between the naive and the utopian picture of society, and even "realistic" ones can differ widely from each other.
3.1.4 Pictures of mathematics and mathematics education
Yet the picture of mathematics also influences that of mathematics education. in
a direct way. Whoever cherishes a picture of mathematics outside the world -- a
deductive system or a catalogue of formula -- is likely to systematise or to interpret mathematics instruction in the same spirit. On the other hand, whoever experiences mathematics something in the making, vibrating under the impulses of
world and society, will be inclined to teach it in tile same way -- directly or as an
educational deve,l9per. There is little need to refer to literature that shows this
correlatior. between the personal characteristics of teachers; but it is perhaps
worthwhile recalling something of a more historic-anecdotal character. It is even
great history I am referring to. The colloquium (Melon, 1952)2, which was crucial
on the one hand, for the development of mathematics education in the sixties and
seventies, and on the other hand, significant for Piaget's first meeting and confrontation with Bourbaki, personified there by Dieudonne. At his colloquium,
E.W.Beth claimed -- with far-reaching consequences for the future of mathematics education -- that
Le rOle de la formation mathCmatique dans l' enseignement secondaire consiste
presque exclusivement. me parait-il, a familiariser les e1eves avec la methode deductive.
Although this claim was disputed by no one -- implicitly or explicitly -- it nicely
characterises the logician Beth -- the only thing that interested him about mathematics was its deductive system. Dieudonne, on the other hand, confronted the
much more encompassing mathematics, exercised and represented by him, with
traditional instruction, which, in his eyes, had run aground due to its lack of deductivity (in particular in geometry -- a bas Euclide!). New shipwrecks could be
avoided, provided one trusted older and wiser people who have explored the
world to the benefit of the young, and used Bourbaki's compass to sail from the
poor to the rich structures; many believed this along with Dieudonne.
With the claim quoted above, E.W.Beth only followed his father H.J.E.Beth,
who, as a designer of a new mathematics programme, had declared (text
30
ttans-132 CHAPTER3
lated):
It is the main objective of mathematics education to contribute to mental culture and
development; transferring useful knowledge is a secondary objective.
In the 19th century (and even before that in The Netherlands) the fonnal value of
mathematics learning was claimed by preference by "modern" schools in their
competition with grammar schools where Latin enjoyed a similar reputation. I
cite here the fonnal value of mathematics as an instance of a faith that usurped
the state of a theory, while in fact being a hypocrisy. Only a few people dared to
unmask it as such -- teachers as well as research mathematicians like D.van Dantzig as is shown by the mere title of one of his articles
31
(translated) "The social
value of mathematics instruction", which at that time (1925) was disregarded if
not considered an insult.
All my life I have fought this faith in the fonnal value of mathematics, only -- I
confess -- to convert to in the end, although (and this is my excuse) with in mind
another kind of mathematics instruction, which has its roots in the most recent
past and where deductivity is assigned the place it rightly deserves.
I called it a conversion, and this is no metaphoric language, because it happened
in the sphere of faith, where the picture of mathematics is framed by the picture
of the world, the picture of the mathematician by the picture of man, and the picture of mathematics education by that of society.
Pictures of mathematics education are made explicit and rationalised by frameworks. Later on (3.1.6), I shall discuss how they are related to background philosophies (3.1.3). Meanwhile, the question arises of whether designing mathematics instruction presupposes making a decision on a background philosophy.
The answer is that it does not. Everything can remain implicit: it is a faith that is
not being rationalised. On the other hand, the relation between a theoretic framework of mathematics education and the philosophy behind it now looks much
closer. But beyond it one can imagine theory (or metatheory) charged with the
task of relating theoretic frameworks of mathematics education to background
philosophies. An excellent starting point here is Treffers' classification'.
3.1.5 Classifying mathematics education
I never did like classifying, and I still distrust it for what I consider are sound reasons: I suspect it as both too easy an approach to problems and as too low a bid
to buy scientific respectability. In (1.3) I explained my fonner resistance to Treffers' distinction of horizontal and vertical mathematisation. Eventually I did accept it as an effective tool to characterise various kinds of mathematics education.
The present section shall be concerned with this subject.
Treffers' four types of mathematics education are distinguished by a double dichotomy with regard to horizontal and vertical mathematisation: presence or abTHE LANDSCAPE OF MATHEMATICS EDUCATION
133
a view to global orientation, yet accessible to refnement, depending on the degree to which the yes-no contrasts are toned down Treffers applied his -lassifica
tion to primary mathematics education, but this is in principle no restnction.
The lack of horizontal mathematising characterises mechanistic and structuralist
instruction: in the first case even the vertical component is lacking, whereas in
the second it is in fact cultivated. Horizontal mathematising is fostered in the empiristic and the realistic approach, in which the fonner neglects_ the vertical component and the latter does full justice in the second kind. Seen m a table:
horizontal vertical
mechanistic
- -
empiristic + -
structuralist
- +
realistic + +
Fig. 15
Let me illustrate this classification by a somewhat anecdotal report [176,180], a
Gennan educational tragedy, as it were:
Lisa Hefendehl-Hebeker" tells about a fifth-grader who could not answer the
problem
Why is 4 < 9 ? Give three arguments!
and the child's desperate family that, equally unable to do it, made an appeal to
her as a mathematics education expert. By looking for the context, that is, the
homework in which this problem was one item, she succeeded in suggesting
three possible arguments, such as "because in the number sequence 4 preced-
9" "because on the number line 4 is to the left of 9", "because the 4-arrow IS
sh--rter than the 9-arrow". One could also have suggested such answers as "because 9 > 4", "because 4 < 5 and 5 < 9", "because 9 -4 > 0",
though it is unlikely that these would have been accepted by the teacher.
Let me remark that, in Gennan, the <-symbol in "4 < 9" is read as what corresponds to "smaller than". So a smart pupil could have objected that both figures
are equally large. I mention this in order to point out that all three symbols mean
something, and in order to know what they mean one has to consult the context,
which is indeed what Lisa Hefendehl-Hebeker did.
What has this to do with classifying mathematics education?·
Well, neither the mechanist nor the empirist would ask such a "why", whereas
the structuralist and the realist possibly would. The teacher who set the problem
was obviously a structuralist; the answers as reconstructed match this view. The
empirist and the realist would notice that 4 and 9 belong to the vernacular as do,
say, 4 marbles and 9 marbles, 4 florins and 9 florins, 4 kg and 9 kg, 4 hours and 134
CHAPTER3
9 hours, 4 floors and 9 floors, 4 metres and 9 metres, and then, depending on the
context, "4 < 9" can mean that 4 marbles are less than 9, 4 florins is cheaper than
9 llorins, 4 kg lighter than 9 kg, 4 hours shorter than 9, 4 years younger than 9, 4
floors lower than 9 floors, 4 metres shorter, smaller, shallower than 9 metres.
Mathematics taught and exercised in rich contexts would provide for all of these,
and many more, comparatives, and realistic mathematics instruction, as opposed
to the empiristic version, would account for their isomorphism by vertical mathematising. Then a question like "Why is 4 < 9?" may validly be answered by "be-
cause4 marbles are less than 9", 4 florins is cheaper than 9 florins, "4 kg is lighter
than 9 kg", which would already be three arguments out of many more possible
ones.
Due to its rough schematism Treffers' classification applies to theoretic frameworks rather than to theories. The lauer should be uncovered- by more profound
search in actual instructional systems if they are not presented in detail by the desiguers themselves. Moreover, this classification describes ideal types. In textbooks of the mechanistic trend, which boast a long tradition in teaching arithmetic, concepts and operations may in some way be related to reality but this usually
happens in a way that neither teacher nor learner are likely to take seriously. It is
often an intellectual alibi for the developer's or the teacher's conscience, a misty
cloud veiling an ideology, which in spite of its venerable age can best be described by a modern metaphor. This I will do in the next sub-section
32
•
Meanwhile, let me add an indispensable remark. In Treffers' double dichotomy
it pays to replace "mathematising" with "didactising" in order to characterise
styles of teaching mathematical didactics (rather than mathematics), which happens, among other places, in teacher training and retraining. Philosophies of
mathematics education should be judged according to both interpretations. This
is not at all a triviality. More than once I have read and heard proponents of realistic mathematics trying to implement their ideas in a way that, didactically
viewed, appeared to be mechanistic-structuralist rather than realistic. The didactical attitude was not matched by its mathematical counterpart.
3.1.6 Philosophies of mathematics education
I . Mechanistic
According to the mechanistic philosophy man is a computer-like instrument, that
can be programmed by drill to perform, on the lowest level, arithmetic and algebraic, maybe even geometric operations, and to solve applied problems, distinguished by recognisable patterns and processed by repeatable ones. This, then, is
the lowest level, where man is placed within a hierarchy of ever more skilful
computers, which are related to one another as are programmers and programmed
subjects. Skinner has forcefully propagated this kind of human society. New
prospects ';ve n-: been opened for this ideology by computer controlled inTHE LANDSCAPE OF MATHEMATICS EDUCATION
135
should be educated to perform tasks on a level where, by many orders of magnitude, computers are faster, cheaper, and more reliable than humans.
2. Structuralist
The structuralist view is also historically rooted, in particular in the traditional

teaching of geometry. A well-structured system of mathematics or a mathematical domain shall be taught. It is a human right and dignity to learn by insight and
understanding and as a rational being be is judged able to perform deductions
more efficiently the more systematically the subject matter is structured. In the
ideal case, however, of the socratic method he needs the midwife who delivers
him of his mathematical ideas -- Socrates says explicitly about the slave, "you see
he has expressed nothing but his own opinion". This, then, was mere "theory"
since, in (Socrates' and) the classroom's practice, the learner was expected to
obediently repeat the master's deductions. In order to check the quality of the repetition -- whether it was mere parroting or full of insight -- problems were set,
which in turn were deactivated by drill. In the nineteen sixties and seventies of
our century, under the name of New Math, the structuralist view was advertised
and propagated. Yet it became soon clear that this wrong perspective -- from the
poorer to the richer structures -- was an obstacle to any kind of genuine mathematising. On behalf of the prestructured mathematics to be taught, a correspondingly structured world was invented of Venn diagrams, arrow schemes, "games"
and so on, to be mathematised by the learner. This was, indeed, a kind of horizontally mathematising activity, yet it started from an ad hoc created world,
which had nothing in common with the learner's living world. It was mathematics taught in the ivory tower of the rational individual, far from world and society.
3. Empiristic
To the empirist the world is a reality, where man can acquire useful experiences
-- a respectable point of view provided reality and usefulness are broad-mindedly
interpreted. Empirism is deeply rooted in English utilitarian education. Provided
with material from their living world, learners get the opportunity to acquire useful experiences, but they are not prompted to systematise and rationalise these experiences in order to break the barriers of the environment and to expand the reality they are familiar with. This matches the picture of a society stratified into
layers that correspond to separate realities.
4. Realistic
In realistic instruction the learner is given tasks that proceed from reality, that is,
from within the learner's ever expanding living world, which in the first instance
require horizontal mathematising. The individual's and the group's progress in
the learning process -- how far and how fast -- determine the spectrum of differentiation of learning output and the position of the individual learner therein. One
example: If, in the course of progressive algorithmising, column multiplication is
first carried out as successive addition, in order to gradually be shortened (by using the tables of multiplication and the positional system), individual learners--
in the social context perhaps the whole group --- will eventually acquire the
standard algorithm. In the case of long division, the learning output of progres-136 CHAPTER3
sive algorithmising may be more differentiated -- an unavoidable differentiation,
which nonetheless deserves a positive qualification.
The realistic picture of mathematics fits without brackets into the world picture.
The picture of man is that of the reinventor, who is stimulated to put his abilities
to good use. The corresponding society is differentiated continuously, rather than
by artificial layers.
3.1.7 Use of the classification
Two criteria have been singled out for the design and the analysis of mathematics
education: horizontal and vertical mathematisation. There are many more. The
choice of these two criteria may be justified by their relevance to background philosophies. It may be useful both for creators and reviewers of instruction to localise instructional creations within a non-trivial scheme. This may help creators to
better understand themselves, and reviewers to more easily examine explicit or
implicit pretensions of the creators. Whatever the objections may be to comparing instructional creations that start from different didactical -- and, basically,
philosophical -- principles, they do not affect the submission of each of them to
the test of their own principles. Wherever in the past the mechanistic view prevailed, textbook authors often pleased themselves by embellishing their production -- implicitly or explicitly -- with realistic or structuralist touches, and the
same is likely to happen in the future as a defence of mechanism against a realistic trend that is gaining momentum. The classification can prevent educational
developers from misleading themselves and others.
3.1.8 A matter of faith
We put forth a theory that relates kinds of mathematics education to philosophies.
It is determined by the theoretical tool of (horizontal and vertical) mathematising
and thus presupposes faith in (guided) reinvention. It is open to anybody to brand
this faith as "irrealistic": "Where in the world are those reinventors and those who
are able and willing to guide them?" "How well-founded is this faith?" Answer-
ing such questions is not easy. In matters of faith tolerance is becoming. I f somebody believes in the hierarchical society of programmable human computers, that
is his business, although of course tolerance does not extend to incorrect computer programmes.
Detecting errors in computer programs is no great feat, but it is quite another
thing to evaluate instruction without any regard for its own basic principles. How
to test whether one kind of instruction is better than another? Instruction serves
goals. But what to do if the goals are formulated in terms of a philosophy, thereby
being a matteroffaith? Isn't it a vicious circle? No, it is not if the testing criteria
»l?<P: t)"'et:. ler -.1i-h thB •»n ;iP?Jiik:-i, (7:' -:"; .p!],--r ,.: Cb-e,,-t-ve:,.- r-7 th;: -rl-tr-i-ct!: 11,'1,
THE LANDSCAPE OF MATHEMATICS EDUCATION
137
the most favourable case, the term may extend up to graduation.
Is there any way to at least compare the quality of various instructional systems
under these favourable circumstances? Given an instructional system, collect all
those exam items which are judged representative for it, each with its weight
within the system; in order to compare two of them, form their intersection and
put it to the test! For the higher levels and with regard to the mechanistic and re-
alistic approach, one can safely predict that this intersection will be almost empty
or at least negligible if compared with the remainder, and one can do so with even
more certainty if the main goal of the realistic instruction is learning to mathematise. At lower levels, in particular if one restricts oneself to pure and applied elementary arithmetic, the intersection might still be considerable and accessible to
empirical comparison.
Although some of the research carried out in my country seems to strongly suggest the superiority of the realistic view, I am still cautious of generalising its conclusions. In one case' a small sample of classes and schools adhering to the realistic style were compared with those of other styles (or with the average of that
half of schools which were taking a nation-wide test). Meanwhile, a large scale
investigation" took place, which also suggested the superiority of the realistic
style. Unfortunately, because of flaws in the provisiolJJll report I must postpone
my final conclusion. Yet this is not what matters.
Realistic textbook sepes for primary education, patterned on the Wiskobas made!!• 11, are a relatively recent feature in my country; they are supported by a majority of educationalists. Realistic textbooks are gradually beginning to supplant
older ones; and it is not far-fetched to assume that this process started at "better"
schools and gradually began to affect more schools in an order corresponding to
their quality. At present, somewhat more than 50% of the schools use realistic
textbooks. If, in the course of this process of substitution, low-quality schools get
involved, the trend that now seems to prove the superiority of the realistic style
may become reversed -- a similar phenomenon has been observed in Hungary".
In the last paragraph I spoke about good and bad schools. This I did for simplicity's sake. I was not referring to their overall quality but to the measure in which
schools that switch textbooks -- in the present case most often from mechanistic
to realistic -- are prepared to correspondingly switch philosophies and teaching
habits. Indeed, one does not automatically imply the other. Working with realistic
textbooks in the mechanistic instructional style to, which one is accustomed may
even make things worse; in fact, this may explain the failures as mentioned
above.
We shall deal with implementation in due course: rather than selling textbooks,
one has to sell a faith.
3.1.9 Learning theories and philosophies
Let me first remind the reader that learning theory is meant as shorthand for 138 CHAPTER3
teaching/learning theory or instruction theory, which, for the moment, will include theoretic frameworks.
There are a great many general learning theories, where, according to the authors,
"general" means subject-area-independent; only as means or domain of exemplification and concretisation do subject areas -- by preference, mathematics, or
what generalists consider to be mathematics - come into play. Usually the view
is even held that the general learning theory leaves no room left for learning theories specific to any subject areas, other than those derived from the general one.
I strongly distrust general learning theories, even if their validity is restricted to
the cognitive domain. Mathematics is different -- as I emphasised before -- and
one of the consequences is that there is no didactical analogue to guided reinvention in other fields. I don't know about learning theories for other areas. I can imagine some general learning theory derived from learning theories specific to a
variety of subject areas. This inductive process is primarily the one by which new
theoretical knowledge arises, rather than the other way around in a pseudo-deductive way.
As I have emphasised repeatedly, I am allergic to armchair hierarchies of phases,
stages, types, levels, and so on, often illustrated by examples from mathematics
instruction. Very few of them have ever been properly and successfully applied
or empirically corroborated. In [87] I analysed the only one I knew at that time to
have been put to the test by its author (or perhaps by his ignorant assistants). It
was a most amusing job. Unfortunately, more an more textbook series and models of instruction are allegedly being based on such theories, which are arbitrarily
interpreted in order to eventually be degraded to a kind of billboards. Treffers
7
more patiently analysed such general learning theories and convincingly showed
how to justify any kind of mathematics instruction -- I mean each of the four
styles -- by each of those general learning theories. Maybe one can also do the
converse: justifying any general learning theory by any kind of mathematical instruction.
A particularly striking example is Piagetian instruction. In his early work
17 22
Piaget developed an empirically based descriptive learning theory, which has hardly received any notice
17
-- it seems that he himself even forgot about ii. A great
many normative theories and practices claim the label "piagetian", although it
seems to me that they have borrowed words rather than ideas from Piaget, by
preference terms like operation".
As promised in the heading, I will focus on the philosophical background of a few
learning theories.
3.1.9.1 Gal'perin, and materialism
I . Gal'perin's levels
The levels distinguished by Gal'perin
36
in any learning process are
' . . . li
THE LANDSCAPE OF MATHEMATICS EDUCATION
139
an act based on material objects, or their material representations or signs,
an act based on audible speech without direct support from objects,
an act involving external speech to oneself (with output only of the result of
each operation),
an act using internal speech.
"These levels indicate the basic transformation of an act as it becomes mental."
Tue terms require some explanations, which are easily extracted from Gal'per-
in's exposition (a few ambiguities may be ascribed to the translator). Western instruction designers who base their wmk on Gal'perin usually describe his hierarchy as follows:
orientation basis,
material act,
verbal act,
mental act,
which in no way does justice to Gal'perin's intention.
The philosophical materialism behind Gal'perin's level structure of the learning
process is unmistakable, or so it seems to me. But is it as operational as it looks?
"Material act" -- as it is called by Gal'perin's followers -- evokes associations
with manipulability as a way (particularly in arithmetic) to start with concrete,
that is solid, material, which today is available in a great variety, indeed. If Gal'perin was aware of any of this material at all, he must have considered it irrelevant.
It is clear from his description that material or -- as he later says -- materialised
has a rr.uch broader -- or even quite different-- meaning from palpability. As emphasised once more later on", p. 253, he also admits -- or even prefers -- material
representations or signs, which he equates straightforwardly with materials. To
state this in the extreme, a tree the child can touch, a picture of a tree recognisable
as such to the child, the printed word "tree" as soon as the child can read, a printed
definition of "tree" as soon as the child can understand it, all belong to the same
learning level (albeit in different learning processes), but as soon as they are
voiced audibly or inaudibly or internally, they belong to the next levels, respectively, in the corresponding learning processes.
In the same way is "verbal act" a misleading reproduction ofGal'perin's intention. According to Gal'perin, written or printed material is as "materialised" as
are pictures. What matters at the third and fourth level is speech (to others or to
oneself), and at the fifth its elimination. (This interpretation is confirmed by",
1977, p. 33-38.)
Although this sounds mad, it is absolutely rational and intelligible, as I will
promptly explain. In order to understand it, one has only to forget about one's
own ideas on learning. The impression of madness is due to the extreme example
of "tree", which doesn't fit in this context. The context that fits is that of teaching
arithmetic, in particular column arithmetic, which becomes clear from the one
example that has been elaborated in detail", p. 270-273. Or, more precisely, Soviet instruction of aritlunelic as it was familiar to Gal'perin at the time he applied
his psychological ideas and wrote the article we are concerned with. Middle-aged 140
CHAPTER3
readers in more Western countries will perhaps be able to relate column arithmetic as they learned it themselves, to this frame -- it is a kind of instruction that is
likely to have become obsolete much earlier in Western countries than in the Soviet Union, where it is now equally outdated, or so I think. The wine of gradually
renewed instruction had better not be bottled in a dated learning theory, unless
the "bottle" is adapted to the new contents, which implies a preposterous use of
the original label if it should happen.
"Dated" is not meant to blame Gal 'perin. As a psychologist, he registered and analysed the then prevailing instruction, and did so carefully and not bent on educational additions and ambitions. Maybe he emphasised the level structure that
resulted from his analysis too strongly, and extended it too widely, but if somebody is to be blamed for this, then it is rather those who believe that such level
structure is suitable lo frame instruction of a quite different character.
2. Gal' perin, and initial arithmetic
Let us consider initial arithmetic as framed by Gal 'perin' s levels! From the very
start "material" means quite another thing than what is available as such in our
classrooms. The "orientation base for action" in "abstract counting" (without
numbers) is an instruction card with stairs picturing piles of an increasing
number of objects, and the instruction:
"Next number .. means "one more object than on the pile shown"!
"Preceding nmnber" means .. one less object than on the pile shown"!
(Notice that the number of objects on the pile "far exceeds the arithmetical
knowledge" of the pupil!)
At any assignment the pupil first consults the instruction card in order to fulfil the
task, which, when this is done, is materialised action. Then the card is turned
over and eventually removed, in order to have the pupil repeat the task interpretation orally while fulfilling it, which is the vocalised form of action. Then the
pupil is asked to "solve the problem silently, reporting only the result", which is
action at the intellectual level.
This is to say that, after the instruction "name the next (preceding) number", the
pupil acting at the materialised level reads the card and points to the next higher
(lower) pile (or does the whole class do so in unison?); at the level of audible
speech, he does so without consulting the card; next he acts the same way while
whispering before pointing, and finally he points immediately to the "number"
asked for.
It becomes clear from the above that, rather than referring to piles of objects,
Gal'perin's "material" refers to instruction cards. This is confirmed by the next
example.
3. Gal' perin, and column arithmetic
Here the procedure looks somewhat different One might expect t.hat the way of
THE LANDSCAPE OF MATHEMATICS EDUCATION
141
from "materialised" to "mentalised", but things have now become complicated
by a gradual transformation of the card itself. After a start restricted to two-digit
numbers, the pupil gets a sheet of paper divided into columns to learn numbering,
addition and

Billions Millions Thousands Sin e Units
100 10 I
~
I 100 10 I 100 10 1
Fig. 16
subtraction. He also has small ready-made numerals at his disposal, which, when
placed in the columns, create numbers to be read or formed, added and subtracted
by the pupil. After the orientation basis has been laid he enters the stage of the
materialised action.
Next, the verbal descriptions are removed from the triple columns while the pupils still have to pronounce them. Then the thick lines are.replaced by thin ones.In
the next step, the figures above the columns disappear, while still being pronounced by the pupils.,One step further, the horizonlal lines are also removed,
and eventually the entire grid disappears; the ready-made numbers are laid out on
the table or else corresponding digits are recorded directly in the notebook but vocalisation of numbers and operations is still maintained. Here the audible stage
ends, and that of external speech to oneself begins, from which, finally, that of
menial action takes over.
4. Gal' perin, and geometry
Gal'perin's interpretation of"material" also extends to teaching geometry". It is
the most traditional and the barest form of concept formation: reading and learning to apply definitions, such as those of straight line, angle, bisector. The GDR's
Lompscher" has described this kind of instruction which is aiming at concept attainment. Although the example set forth in
37
reminds one of a catechism rather
than of geometry instruction, our point is how it fits into Gal'perin's hierarchy,
rather than its intrinsic quality.
In this type of geometry instruction, geometrical figures don't play any significant part as a material element. The materialised level is represented by written
or printed orientation cards that disclose the various definitions of geometrical
objects. With these instructions before their eyes the pupils have to decide whether something is a straight line, an angle, a bisector, and so on. At the next level
they must answer such questions without using the cards, while reciting aloud the
defining criteria. Via the stage of whispering the pupils arrive at that of directly
armouncing the result; only if need be -- for instance in testing - -are they to reproduce the definitions. 142 CHAPTER3
5. Gal' perin: conclusion
Gal 'perin' s learning theory distinguishes itself by the refined elaboration of all
details by means of the given examples and by the straightforwardness of the intended learning process. Properly stated, it is a pure teaching theory, inspired by
a kind of instruction that allows the learner no initiative. If Gal'perin starts his
article, saying
Our basic hypothesis is that the formation of mental acts passes through a series of
stages. At each stage a given activity is carried out in a new form and undergoes
changes in several directions.
and subsequently specifies this, among others, by his stages or levels, he undoubtedly has in his mind a certain instructional system in which his basic hypothesis can possibly be tested. Within the limits of this system such a model can
be considered to be descriptive, but in a broader frame it is a quite restrictive normative model. Could it have been more liberal than suggested by the above examples? Probably not! To corroborate this judgment let me quote Gal'perin"
himself:
If, however, we reproduce the material activity systematically step by step, first in its
verbal and thanks to it in its ideal form, we can keep supervising it, whereas in the case
of"spontaneous" transition we don't know what has happened nor how it did. As soon
as we lose the command of the process, we can no longer understand it.
Gal'perin's main concern is the checkability of the learning process; which is
considered to be mere interiorisation. What is the use of it and what can one expect from it? The answer depends on one's picture of mathematics and mathematics education, that is, on one's philosophy. If it fits philosophical materialism
at all, then it does so according to a strange interpretation of "material", or so it
seems to me. In Treffers' classification, Gal'perin's learning theory is an extreme
example of mechanism.
For justice's sake, let me add I.hat more recently Gal'perin's level theory-- in particular his strong insistence on the material and materialised level in the teaching
process -- has experimentally and with great success been challenged, which in
fact has happened in his own school"-
3.1.9.2 Constructivism, and "Kant"
-The plenary sessions of the PME-11 meeting41
, Montreal 1987, were dedicated
to constructivism. Through personal talks during the meeting and by afterwards
studying the literature I tried to find out whether and in what respect "constructivism" were more than a new slogan. To no avail --1 must confess. What follows
is the result of my analysis.
THE LANDSCAPE OF MATHEMATICS EDUCATION 143
of I.hem. This doesn't matter as long as it has a clear meaning to whoever pronounces, writes, hears or reads it -- clear not in analytic isolation but in a clear
context. For topical words one creates a fitting context for oneself, which is not
bad as long as one is aware of this fact What is bad, is being unaware of I.he need
for a meaningful context, at least for the user, who risks being deemed a misuser.
I don't aspire to the offlce of linguistic judge, and even less of legislator. On the
contrary, flexibility is a great virtue of language, and can hardly be overestimated. Pictorial and metaphorical language can enrich both language and thought.
But flexibility does not mean weakness; pictures should be focused.
2. Language: Construction.
"Construction" was soon extended from the building trade to other manual work
and to mental work as well. It even came to signify poor work: artificial, a mere
construction.
"Construction" presupposes a maker. Who has made it? The designer, the foreman, the bricklayer slave, the drawing board slave, the assistant to the architect
or the architect himself?
"Constructing" rings like "creating", and if this is no more than a ring, then reconstruction is mere re-creation. But reconstructions caii also be of greater value
than constructions. For instance, efforts to reconstruct a dilapidated or destroyed
building, or an obscwtcourse of affairs can by far surpass the efforts that once
were needed for the original construction.
"Construction" does not reveal anything about the constructor's own contribution, nor does the fmished product do so. The "Do it yourself' package contains
every little part as well as directions on how to form I.he desired object Only by
reflecting on the own activity can the re-creator become a re-creator. If the directions are missing, the reconstruction of a decomposed jigsaw puzzle can require
more inventiveness than many constructions.
3. Constructivism --philosophically
is our world picture a picture of the world, and if so, how faithful is it to the original? Since olden times this question has been asked again and again. How many
tricks does not Nature play on us, and is not Reason the means to unmask Illusion? But how reliable is Reason? How often has the lie not been given to Reason? Yet there is one thing that cannot be denied: that in the course of history our
world picture has become widely extended -- in the macro-world of the universe,
in the sub-atomic micro-world, and towards ever and ever greater wealth in the
intermediate dimensions of our direct sensation.
Yet we have to put up with people who object that this whole picture is a mere
reconstruction of what, albeit unconsciously and unintentionally, was constructed by ourselves beforehand -- reconstruction by the very means by which it was
first constructed. Well, we need not bother about B question and an answer that
are equally meaningless. But what about poor Kant, to whom the problem and the
answer are ascribed by people, who probably never read a single word of his? My 144 CHAPTER3
answer to this question was to surround his name in the title of the present subsection with quotation marks. This, of course, does not refute what philosophically some people call constructivism. Jns1ruc1ionally it refutes itself by its irrelevance.
4. Construction and constructivism - - mathematically
In Euclid, besides theorems (quod erat demonstrandum) we find constructions
(quod eratfaciendum) - -constructions by means of the ruler and the pair of compasses. Although, in the past, definitions and theorems arose by construction as
well, they are presented here as ready-made articles; yet this does not prevent
constructive activities, such as drawing and producing lines and assuming points,
from sneaking into the proofs.
To be sure, in mathematics (and not only in mathematics), inventing and reinventing must be distinguished from reporting. As emphaised repeatedly, a variety of styles are possible. Reports can be restricted to the ready-made matter, but
they can also do more or less justice to the process of making. Less, if it is mere
phraseology; more, if the reporter tries to play the part of inventor, and thus
smooths the road for the reinventor.
If, from a given infinite set, Cantor forms the set of its subsets, is this a construction or idle verbosity? Language on behalf of itself or transmission of something
that can be transmitted in no other way?
Constructivism in the foundations of mathematics means restricting oneself to
activities that take place in lime, or that are understood as such: In an unrestricted
time, in a restricted lime, arbitrarily accelerated, or reeling off with theoretically
or practically constant speed.
The set of subsets of a set is formed in one breath, provided these words are pronounced fast enough. With the natural numbers one can progress towards eternity, or towards the endpoint of an interval halved again and again; with ever faster
computers one gets a grip on ever larger numbers, whereas number language conjures up an exhaustible number sequence.
5. Constructivism in developmental psychology
Construction starts as reconstruction, to wit by imitating oneself or others, yet the
required physical-mental tools must first be shaped and improved by ever more
purposeful efforts. At the same time, and entangled in this process, a powerful
cognitive tool is developing and maturing: interpretation. With a profundity that
can hardly be matched, let alone surpassed, Piaget, in his unnoticed early work
17
22, uncovered the roots of interpretation. Unfortunately, and for incomprehensible
reasons, he didn 'teven touch here on the role played by language, which is equally entangled in the process - • the children he observed never babble nor weep. Is
this indifference to vocal utterances somehow related to his later habit of taking
linguistic failures of his subjects for cognitive ones, as though this were obvious?
-t. L[`.:;]n. 1ce '9. Yle-1t--'ifl T"Curistr--:-. t..ic- ,1Jf t1l:.e if thi:l. (`.l-j-d •v-;--.hi"' --. `·'-r-n- d1e
THE LANDSCAPE OF MATHEMATICS EDUCATION
145
play-pen is so obvious that it provokes this cyclic interpretation. Invisibly structured playthings, in particular mechanical ones, are different: most, if not all of
them, are black boxes, where the reaction on the stimulus is a datum, inaccessible
to analytic interpretation.
We have already discussed construction in the sense of slavish obedience to assembly directions. The development of language is to be viewed quite differently: it is a reconstruction rather than imitation, which is extrapolated by the creation of words and clauses never before heard, the novelty of which is wimessed
by sins against morphology, grammar, and syntax.
Reconstruction is again most productive where it is guided by global structures.
An exatnple we mentioned already is that of the first mathematics (or is it the
first?) to emerge in development. When, by listening and speaking, the child acquires the number sequence (that is, the sequence of spoken numbers), counting
starts with a verbal imitation of a fragment or of fragments, separated by gap.
This is then superseded by imitation of the structure, introduced by interpretation
into the linguistic system, which allows the learner himself to close gaps and
playfully continue the sequence. Playfully, that is, beyond need and necessity.
Without limit? New milestones are needed; million, billion, trillion, etc. suggest
something fading away in limbo. More profound analysis is-needed to transform
" . . .illion' into a recursion exhausting the number sequence. (As a matter of fact,
even with regard to the deHmal positional system nobody bothers about the feature that the size of numbers runs far ahead of the size of the means by which they
are defined - - on a higher level, a source of paradoxes.)
The preceding is cited as an exatnple uf where re-creation stands out in bold relief against the kind of construction and reconstruction •. manual or mental· · that
is mere imitation, e.g.copying a drawing, blindly obeying assembly directions.
What does the self-styled constructivist mean here by "construction"? "Construct
the perpendicular bisector!", whether the one charged with the task, already
knows how to do it, or not?
6. Constructivism - - didactically
What matters here is teaching and learning, pedagogy and didactics. Only in order to show their irrelevance did I regard the constructivism of an empty philosophy and of a poor developmental psychology.
For shaping teaching and learning processes there is as little need to discuss
whether the world is a mere construction and the world picture a reconstruction
of what was constructed by oneself as there is for the claim that the individual in
his development constructs or reconstructs his world, that is, as long as this is a
mere claim, and as long as this claim is not substantiated by any explanation of
how the individual manages to do that· - indeed, only this knowledge could help
one to better understand and to exploit the constructivist thesis.
If "constructivism" is to mean anything didactical, it must indicate the one who
is expected to "construct". There are people who call themselves constructivists
because they allow the teacher (rather than the textbook author or some other au-146 CHAPTER3
thority) to consfruct education. Constructivism also means an artistic, say Bauhaus, style. The teacher who adheres to this necessarily creates structuralist mathematics. If I were to accept the term "constructivism", I would mean a programme having a philosophy that grants learners the freedom of their own
activity. Then it doesn't matter whether this activity is called construction or reconstruction or whatever, as long as such words do not prejudice anything that
concern the learners' freedom. Whatever is imposed upon the learner remains imposed, whether this is called consfruction or reconsfruction or something else.
There is no use pleading here that learning in freedom is more dignified than under coercion, since the hope that the first is more efficient than the second is being
strengthened daily by an increasing number of examples. Lacking a convincing
context, such terms as construction, reconstruction, and constructivism are
doomed to remain slogans. The only context that counts didactically is instruction itself, that is, instruction developed from the direction of the design onwards
towards its realisation. If a term is, indeed, needed I prefer guided reinvention,
which I discussed in (2.1).
7. Von Glasersfeld
One would expect Von Glasersfeld's name to appear in this exposition. I didn't
mention him originally because I didn't know where to place him, but a recent
publication of his has made things easier. His paper starts as follows*•:
During the last three decades faith in objective scientific knowledge. a faith that formerly served as the unquestioned basis for most of the teaching in schools and
academia. has been disrupted by unsettling movements in the very discipline of philosophy of science.
Indeed, and this is a most striking symptom of the ever broadening and, to my
mind, most deplorable gulf between the philosophy of scientists and the philosophy of philosophers of sciences, at least as preached by the noisiest among them.
Would any scientist who lacks faith in objective knowledge have ever had Voyager 2 launched for a visit of the big planets -- as far as Neptune -- to gather
knowledge about them? Would he have had big accelerators built that are to discover missing elementary particles? Would he analyse long DNA strings in order
to manipulate them? Would he excavate ancient cities and decipher ancient inscriptions? These are just a few questions out of an interminable variety, and yet
I did not even mention the mathematician searching for new knowledge.
Rather than trying to uncover the scientist's implicit philosophy and methodology, philosophers and methodologists of science, if unacquainted with real science
or frustrated by it, dream up their own fancies. To be sure, Von Glasersfeld is in
good company, but it is a company of spectators rather than of actors in science.
Yet, in his particular case, it is a third kind of philosophy that should count: philosophy of education. These three may be mutually related provided they are not
confused with each other. At any rate, I cannot see any bond between mathemat-
~ ~ ~

exact sciences. Yet, whatever beauty may mean forits creator, it is aimless unless
there are more people to enjoy it, and somehow they will have to pay for it, either
as a buyer or as a taxpayer. Is beauty measured by its return? Few people are
ready to appreciate the beauty in low-level mathematics, and fewer, including
even experts, mathematics at the research level. Therefore, as far as mathematics
research is concerned, beauty is not a convincing answer to the question "What
is the use of it?".
There is, however, another aspect: mathematics is true. Wis en zeker -- sure and
certain. Research results can be checked, errors can be tracked down, and, if experts disagree, they may do so about good or bad, rather than about true or false.
In the so-called exact sciences, checking becomes more troublesome the farther
,'i 148 CHAPTER3
away one moves from mathematics. Anyway the ultimate judge is Nature, who
rewards good questions with good answers.
Man and Society are much less co-operative and reliable than is Nature, and this
is the very reason why, in the social sciences research is a tremendously bigger
problem than in mathematics and the natural sciences. It is a problem that, unfortunately, bothers the assiduous researcher less than it does the not so compliant
user -- as long as it is useful to the former, in one way or another.
As early as the beginning of the 17th century Thomas Mun and Edward Misselden discovered and explained the fluctuations of exchange rates by the balance
of foreign trade
42
• It was true and useful; as a discovery it was beautiful and historically it is still so since it happened in a period where money meant coined
metal and paper currency was at most embodied by bills of exchange. In the 20th
century this is no longer true, let alone useful or beautiful.
Research on Man and Society badly needs and distressingly lacks criteria of
truth, which are present in all kinds of research on Nature. Just when the following lines were being written, it so happened that both professionals and the public
al large were surprised by the announcement of a new and almost trivially simple
method of nuclear fusion. Lo and behold, within a few days researchers all over
the world undertook to imitate the experiments as described and to check the alleged effects. Not even for a second did I doubt that, long before these same lines
would be printed, it will have been settled for ever what was and was not true
about it To be sure, most often it is not as simple as that: it can take more time,
greater trouble, and bigger machinery to test an alleged effect. Where Man and
Society are concerned, however, each experimental falsification can be met by
the objection that it is a fact life that two situations can never be the same; moreover, once an experiment has been terminated, later discovered mistakes in design or execution (if admitted at all), cannot be undone, because the costs of repetition would be prohibitive.
Can the lack of criteria of truth be reduced by trust in the capability and honesty
of the researcher? The question is loo rhetorical to be answered. Man and Society
are developing at a much faster pace than Nature (if something al all like the social version of evolution applies to Nature). Nature is more uniform, or so it
seems to the investigator, who can profit from centuries of experience provided
by a stable Nature. This, to my mind, justifies or even requires a more utilitarian
attitude towards social and societal research than one is inclined to grant the natural sciences if the question "what is the use of it?" is to be answered.
Keeping the problems we are concerned with here in mind, let me disregard what are
called humanities. on the one hand, are as much an art as are their subjects, and, on the
other hand, are on no score that matters here inferior to the so-called exact sciences.
There are, however, examples of psychological research I like because of their beauty.
For instance - I forgot the author's name - the experiment where subjects were given
a weight,, a string, and a nail to be fixed on the wall in order to construct a pendulwn:
whether the subjects did or did not succeed to solve the problem depended on whether

THE LANDSCAPE OF MATHEMATICS EDUCATION 149
There is a kind of inquiry that characterises itself by such attributes as listing,
stock-taking, registering, recording and fact-finding. If carried on at secretary
level these can be enormously useful. They can also be useful at research level,
provided the attributes attest to modesty or are as critically handled as they deserve. They can be useful as rough material according to the degree to which they
are still rough material. The question "what is the use of it?", however, becomes
more urgent the more theorising attitudes dominate or reshape what once was (or
never was) rough material.
Henceforth where research is concerned, my crucial question will be "what is the
use of it?" I mean here its use for the consumer rather than for the producer, albeit
in a broad-minded interpretation; so broad-minded that the mere intention of being useful is counted as high as the result
But let us now approach the actual aim of our discussion more closely!
3.2.2 Educational research
l . What is the use of it?
By education I mean a practice, though often enough this word is used as a synonym for "research on education"". For the present moment, when I speak about
educational research in general I intend it to include reSearch on mathematics education as long as, for the researcher, mathematics is no more than an easily
available and easily handled subject matter, chosen to test and apply general ideas
and methods, with no regard for the specific nature of mathematics and mathematics instruction.
The enormously rich and useful educational literature, which addresses itself
most directly to its presumed users - parents, teachers, trainers, counsellors - is to
such a degree and so straightforwardly the result and the expression of everyday
experience, craft and philosophy that however they might have been influenced
by research, these influences can hardly, if at all, be retrieved nor their impact be
evaluated in this vast and wealthy field. This is the reason why I shall restrict myself to the more professional literature on education. Let me summarise my negative feelings beforehand: as a general trend, the greater the pretention with
which something is presented as research, the less satisfactorily it comes across
as an answer to the question "what is the use of it?' Mind, I do not expect all research (or even a substantial part of it) to be somehow useful. I would simply like
the researcher, whatever his undertaking, to ask himself the question "what is the
use of it?', and then in a way as though he were one of the intended users himse~f.
To be sure, a great deal is demanded here. It is a hard thing to place oneself m
another person's environment, let alone in his mind; and, on the other hand it is
a long way from the researcher's armchair or laboratory to the user's classroom,
even though both of them may be located in the same building. Indeed, their mutual distance is properly determined by the length of the chain of mediators leading from the one to the other, provided there are any mediators at all; or otherI i i
;-.-
: I
-
,, 150 CHAPTER3
wise, by the depth of-a gulf that nobody is able or cares to bridge. In both cases,
mediation means interpretation, either of facts, which is the most fortunate case,
or of words, which can be preposterous -- producing a situation not unlike the one
I depicted in (3.1.9).
My statement about the long way from the researcher's workshop to that of the
user may be a source of misunderstanding. Rather than "from" I should have said
"between". It is a symmetric relation. Or rather, wherever fresh trails are to be
laid, the trail-blazing should start in the classroom; it makes a difference here
whether it is the researcher himself who starts the trail-blazing, or some delegates
who are expected to carry out his prefabricated instructions, as well as whether
the teacher is considered lo be a fellow traveller or is expected to stay home.
I failed lo mention curriculum developers among the users of educational research; this gap will be closed in 3.2.3. Nor did I mention decision makers, policy
agents and legislators. In what respect, if at all, can they be counted among the
users of educational research? I do not know about other countries but at ours two
kinds of government-advising bodies are lo be distinguished: Fact-finding and
opinion-shaping commissions on the one hand, and, on the other, councils of --
presumably scientific -- advice. When asked, they will commission groups of researchers to write reports, which, in the case of education, are no more than
sources of vocabulary; this helps them to pretend that their final advice, whatever
it may be, is not merely a product of common sense. Policy agents behave in a
similar way. Whoever their advisors are and whatever their advice may be, they
are not used for anything else than rationalising a politically based decision.
2. Methodology
Too much metaphorical language? Yes, because as far as I have been informed,
trail-blazing is not what the future researcher is told and taught is his business in
education. His business is rather: collecting data and processing them according
to ever refined standard methods, which are neither argued nor questioned, but
simply taught with the aim of being obediently applied to a variety of themes, depending on the prevailing fashion or the whims of the researcher, his director, or
his client. I don't remember when it happened but I do remember, as though it
were yesterday, the bewilderment that struck me when I first heard that the training of future educationalists includes a course on "methodology". This is at any
rate the custom in our country but, judging from the literature in general, this
brain-washing policy is an international feature. Please imagine a student of
mathematics, of physics, of -- let me be cautious, as I am not sure how far this list
extends -- impregnated, in any other way than implicitly, with the methodology
of the science he sets out lo study; in any other way than by having him act out
the methodology he has to learn! In no way do I object to methodology as such -
- I have even stimulated the cultivation of it, but it should be the result of a posteriori reflecting on one's methods, rather than as an a priori doctrine that has
bf:-.;'_-J' :fT'1-.-"-- ;_.-.-rl 1;;'.'l 7h'':-10-2-r,;.-<·
IBE LANDSCAPE OP MATHEMATICS EDUCATION
151
methodology no better than it ever did in mathematics, that is, where it works it
does so to the benefit of a small minority of learners only -- the future specialists
of methodology. Yet, fortunately, the intimidated majority can count on the precious assistance of this authoritative guild, the pure methodologists, whose
strength consists in knowing all about research and nothing about education.
They gladly leave the educational researcher a responsibility of his own to fill
empty methodological vessels with educational contents, and they are unconcerned with the question of whether these fit or not. Mathematics can afford a
vivid interplay between form and contents because in playing this game they can
be neatly separated from each other. In educational research, however, separating
form and content is not feasible, and, wherever this is attempted the consequence
is estrangement. This is covered up, ifneed be, by distinctions like those between
validity, which is the researcher's business, and reliability, which is the methodologist's responsibility and which by mere convention is measured by a formula
that, in fact, does not measure anything that deserves this name. Please imagine
a biologist who has defined a measure for immunity against some plant disease
that can be determined with a high degree of precision while it is most doubtful
whether it has anything to do with resistance against that disease! Who would accept such a measure, reliable up lo the third decimal if nothing is known about its
validity? This mIJY be a rhetorical question in biology but not in educational research, where it can only be answered historically: formalised testing was first
concerned with intelligence; when the query what, if anything al all, the I.Q. did
measure, had to be shelved, one became satisfied with measuring this same thing
as reliably as possible. From the I.Q. this easy answer spread to psychometric
measures in general, as did the habit of measuring first and trying lo explain later.
This is a bad habit, since it might be a short step from bad to worse: as soon as
scientific scruple and honesty are degraded to mere formalities, it is almost unavoidable that precision and accuracy will count only as far as they can be expressed in numbers of decimal positions.
This may sound exaggerated, and in a sense it is. Let me quote myself from [87,
p.145):
According to a well-worn joke there are three kind of lies: lies. damned lies, and statistics. When the joke was invented. mathematical statistics had not yet come into being. Otherwise one would have added three kinds of surreptitious credibility: by word
of honour, by oath. and by mathematical statistics. Or, three methods to assume a
learned air: footnotes, bibliography, and correlations tables.
This is a witticism, to be sure. But even so it is the gist of many years of -- sometimes disgusting -- experiences, which I gained as a reader, reviewer, referee, and
editor, and of which only a small but paradigmatical part has been published. At
no point have my detailed scrutinies of small and large pieces of educational research ever been refuted, nor, lo the best of my knowledge, has anybody ever seriously tried to challenge them on minor or major points, whether published [99,
102, 116) ornot.
Matters are even worse. The collection of poor research I criticised was nothing 152 CHAPTER3
more than a sample chosen from what I came across. My actual target was the
underlying research method, imposed by means of the authority of a misleading
and misled methodology, which is still taught today, although I feel its authority
is waning. Anyway, I don't know of any attempt ro defend this methodology or
parts of it against my criticism. Or is this a policy of killing by silence? Yet I received no positive signals either. As far as I know, up to now nobody has ever
tried IO explain the mathematical meaning and the cognitive function of correlations within the various contexts -- where educational researchers have computed
them by tens of thousands and arranged the min tables -- and their use other than
for impressing laymen and sponsors. Nobody has ever tried to vindicate the normality of distributions that, by definition, are not normal, or IO justify linear regression as such, in particular, if applied IO connections which are obviously nonlinear, as in the case of stable equilibrium. I have never seen any explanation of
how mathematical methods from biotechnics -- where their applicability is warranted by models from physics, chemistry, and biology -- can be transferred ro
education, which lacks any fundamental insights for building intermediate models.
I cannot but recognise the fact that some things have changed in the mean time.
Taxonomy, for instance, has fallen into disgrace (though not because ofits inherent weaknesses but because it is too strongly a contents-dependent tool) and is
now successfully being shipped to developing countries. Test theory and technology, on the other hand, have boasted ever new successes in fighting sound education. Qualitative research is gaining ground, but we are still far from the point
where mathematical methods can add a finishing touch IO qualitative knowledge,
and many researchers are even farther from the insight that mathematics is not
able to do more than just this. But it is hard to fight the prevailing superstition that
ready made mathematics can solve all problems.
Reluctantly I reiterated my old complaints on educational research. My intention
was actually IO review them while asking the question "what is the use ofit?',
other than cultivating professional and public relations.
There is a hard struggle for life and grants going on in the community of educational (and some social) research. One cannot do without advertising and the
headlines in newspapers, or so people think. Is this a necessary evil, and if so,
why can it not be used for good things? Or do people who are wary of this policy
suffer from allergic reactions to it?
Are good things not expensive enough to be supported? When the first IBA cycle
started it was the most pretentious project ever undertaken in educational research, and the most costly -- some 50 million dollars if corrected for inflation, I
would estimate - and when it was fmished it turned out IO be a mess: a heap of
spurious data, processed by means of nonsense mathematics, and - what is worse
-- useless IO such a degree that after a few years even in the most extensive bibliographies ignored it. What was the use of it? Was the road IO New Math paved

THE LANDSCAPE OF MATHEMATICS EDUCATION 153
was really a major factor, although years after New Math's eventual failure,
T.Husen, proud of the hundreds of headlines it had earned him in the American
newspapers, still thought it was.
In my country, IBA received even Dutch TV coverage because our Netherlands
pupils had scored so badly in a subject area they had never been taught -- a fact
unknown to the inexpert researchers -- and because they had performed so excellently in other areas, thanks to international test instruments, debased by translators, who had not been informed about the aim of the translation.
As far as I know, no international report on the second - much less pretentious -
IBA Mathematics Study has been published. In our country it made the headlines
because we finished second or third in the international field, albeit thanks to the
fact that among the various types of schools the possibly lowest scoring one had
been left out of the tested population: this was "special" education, which, according IO our (by international standards unusual) definition includes about 10%
of the school population under consideration"".
A similar mistake has marred an otherwise excellent national study of ours on the
quality of primary mathematics instruction. For our daily papers girls score much
lower than boys was the most important news it revealed. As a fact, this contradicted worldwide experience at the primary level, but rather than being a fact it
was an artifact, due to the same omission as menti<1ned above, and easily explained: only behind the desk do researchers forget that, in our "special" education, boys form the,overwhelming majority. The blunder could easily have been
avoided, but the report was not even made available under embargo IO experts,
who had to wait one more day than the press IO get information and to discover
the blunder. This in fact happened at an educational meeting the day after the
press conference. Too late, of course, since girls equal to boys or even better is
not worth the trouble of a correction.
Who does not remember the Coleman report -- the most extensive, pretentious,
expensive and impressive report, ever carried out in the USA? Or rather, who
would at present still remember it for any use whatsoever, even if it had not been
wrecked by sophisticated analysis [68] 44.
3. Comparative research
A large part of educational research is comparative. Cognitive or affective results

of education are compared with one another according to such variables as nationality, instructional system, educational philosophy, schools and school system, gender, ethnicity, race, socio-economic background (of pupils or teachers), the teaching and evaluation methods applied, the aids, instruments, textbook series used -- a list that is all but complete. I do not object to comparisons. Whoever judges a given kind of education, will relate it somehow to the experiential or ideal models he has in mind; the more consciously and systematically this is done, the more valuable the result may be, in particular, for enriching experience and improving models. But "systematically" should not mean: according IO a preconceived system, in the mechanically thoughtless way, as taught by methodologists. 154 CHAPTER3
In education, comparing is a most precarious business. What are comparable situations and how to get them? We just gave examples of rather simple and transparent situations where researchers overlooked obvious differences. How to avoid this? One way is lo hold strictly controlled instructional experiments; this
is, in fact, both the most efficient and the most useless way, since rigid instruction
is the worst instruction one can imagine. One can try to eliminate disturbing factors, and if this is done by common sense, I would not object either. But common sense is suspect to methodologists bent on employing refined mathematical
methods such as factor, variance, and regression analysis. To the best of my
knowledge they have never been rationally justified, either in general or in some
particular case, and, depending on the way they are applied, can often be used lo
prove anything and its opposite. Moreover, little if anything at all is known about
influential factors, for want of a fundamental theory on the subjects under consideration. Some people try to make up for this by the sheer number of factors,
chosen ad lib, a policy that increases the impressiveness and decreases the credibility of the applied mathematical technique. However it is done, this is merely
an attempt lo apply mathematics lo bunches of numerical data, irrespective of the
way they were gathered, with no intervention of any model based on theory. People who know that this is wrong excuse themselves by bestowing the dignity of
model on any linear regression equation they write down; they do not bother to
justify the hypothesis of linearity, even where common sense suggests that it cannot be trusled, as in case of equilibrium.
4. Tests
Rationality requires statements to be lesled for their truth instructional methods
for the benefit of education, and individuals, for their own benefit and that of so-
ciety. Tests should be trustworthy, and what is more trustworthy than numbers,
obtained by measurement, and moreover amenable to mathematical processing?
I already emphasised that, in the study of Nature, measurement is rather a finishing touch, applied lo models of physical reality. These models are there to explain
what has to be measured by what yard-sticks -- the more rigid the better -- and
for what aim. Man and Society are much less accessible lo such models, and often
enough, in particular in education, they are not accessible at all; yet in no way has
this hindered the tremendous growth of psychometry in education from its first
roots onwards, from early in our century to its present state. Let me quote
RS.Bloom & A.W.Foshay4' as witnesses for the high esteem in which rests were
(and by many still are) held.
There is one field in which a considerable sophistication has developed since 1920:
the field of achievement testing. It is possible now to study the degree and nature of a
student's understanding of school subjects with a subtlety not previously available.
Modern objective achievement tests. when properly developed and interpreted, offer
one of the most powerful tools available for educational research. Findings have been
made through tli.eir use that rise far above common sense.
THE LANDSCAPE OF MATHEMATICS EDUCATION 155
who co-operated in the same IBA-study from which this quotation slems; yet, as
far as tests are concerned neither Bloom's celebraled Taxonomy6, nor work accomplished under his guidance [cp.99] can be looked upon as paragons of sophistication. And what about the last statement of the quoted passage? Where should
one look for such "findings"?
It cannot be denied that, bit by bit, a highly sophisticaled testing technique has
been developed, and measuring sticks have been constructed, which, from the
viewpoint of rigidity, can compele fairly well with those of the natural sciences,
although this might probe to be a disadvantage rather than an advantage. In the
narrow sense of this technique, the word "test" now belongs to the common vocabulary of most languages. The attribute "objective", which is only added when
strictly necessary, nowadays means that the formerly expensive job of resting can
be left to the much cheaper computer. (In my own country, objective examiner is
a governmental-hypocritical euphemism for cheapest examiner.)
Objectivity, if opposed lo subjectivity, is indeed praiseworthy, if people are to be
judged. Yet, rather than at people to be judged, resting rechnique aims at objects
defined through tests or lest batleries and allegedly independent of human caprice, although they are given names, which suggest connections to human life
and learning. It is a process of rectification by which new objects are created,
with the sole aim" of being studied numerically, and where no regard is paid lo
their effectual stale nor their usefulness for understanding and explaining phenomena. This process is started, sustained and sleered by a quite natural tendency
to detach form from conlent, which, although it has proved enormously fruitful
in mathematics, thanks lo its, as it were, self-controlling character, is condemned
to sterility wherever it escapes control.
Although the present exposition starred with a quotation involving achievement
tests, it applies to any kind of tests in the lechnical sense, including opinion polls,
such as preposterously used for research in the affective domain.
The above criticism of formal testing lechnique with regard to research in mathematics education may appear lo be outdaled: There is an unmistakable trend
away from it among educationalists with a strong mathematical background, who
have good reasons to do so and are courageous enough to no longer be afraid of
being reprimanded by methodologists for neglect of "objective" methods. Open
testing, inlerview, and observation of learning processes are gaining ground, and
well-designed intersubjectivity has is given a chance to supersede ill-conceived
objectivity. Little attention, however, has been paid to the methodology behind
the new approach -- J. de Lange's work" is here qui le exceptional. Anyway, there
are promising perspectives on fresh approaches. Will they be successful in the
long run?
Technique and lechniques are indispensable and beyond praise in our society, at
least as long as they deserve praise. If they are blamed, it is for what nowadays is
called pollution. How far has the pollution by testing techniques spread in education? The negative influence examinations can exert on education by their mere
existence is a well-worn truth, and nobody can tell how much resting technique 156 CHAPTER3
has added to iL How much has diagnosis and how much have diagnostic abilities
suffered under the influence of badly understood diagnostic tests? And how
much profound qualitative research has never been undertaken because it could
not compete with shallow quantitative pseudo-research?
3.2.3 Developmental research
l . Change
Formally, the present subsection looks like it is one more part of the preceding
one. I could have formally separated them by simply adding the adjective "traditional" to the title of the former subsection, but I preferred to avoid this because
of its negative connotations. Moreover, what we are now accustomed to define
as developmental research is by no means a new thing. On the contrary, it is perhaps the oldest kind of educational research, though it has not been recognised as
such.
The question on educational research I started with was, "what is the use of it?"
I didn't ask the question "what is the use of education?", which is almost rhetorical as Jong as it aims at education as such rather than at a special kind, say, actual
or topical education. No doubt, education is meant to prepare one for future life,
yet neither the future of individuals nor of society are predictable well enough to
provide a solid basis for any choice of education, which, conversely, is influential
as a condition of this future. Once, when asked by an interviewer whether I
thought that attempts at innovation have improved education, I hesitated for a
short while, only to eventually stamp this as a wrong question. Pictures of education, taken at different moments in history, cannot be compared. Each society at
a given period got the education it wanted, it needed, it could afford, it deserved
and it was able to provide. Innovation can effect no more than to adapt education
to a changing society, or at best it can try to anticipate the change. This alone is
difficult enough. If any proof was needed, it can be seen in the efforts, vaccillating between childish and spasmodic, to prepare for what is commonly called the
computer age, though in fact the computer is only one of the features of this age.
Or, to take an example from the past, a past that started after World War JI: Even
now innovation has not yet succeeded in coping with the fast growing demand
for education, which is too readily answered by "more of the same", rather than
by diversification of the supply. So the gist of this paragraph is to give a the first
answer to the question "what is the use of it?": Change.
2.Errors
If I am not mistaken the first subject formally studied in mathematics education
- which means, as early as the turn of the century- was errors, that is to say, /earners' mathematical rather than teachers', developers' and researchers' didactica/
errors, and according to research published up to a few years ago this is still the
THE LANDSCAPE OF MATHEMATICS EDUCATION 157
hardly been noticed. Even now failure rather than success is the main discriminator in many research papers. Even though, the variety of investigated errors has
increased in the course of the century. It is remarkable how much attention has
been dedicated to the same kinds of errors over and over, albeit more and more
related to an increasing number of other parameters, such as age, gender, peer
groups, ethnicity, race and social-economic status of parents and teachers, -r
formance in other subjects, intelligence, affective features such as mathemattcs
love or anxiety, and so on.
Tue attention to errors is as indispensable as to physical or mental diseases, provided it is guided by the wish to cure or to prevent and is undertaken in a context
in which this wish has a chance to be satisfied. I recently attended a meettng
where a researcher presented a new diagnostic instrument for mental arithmetic
in the domain 20 to 100. He modestly added that instruments of remediation were
not the researcher's but the expert teacher's concern, and he didn't change his
view even after a teacher in the audience urgently asked him about the use of diagnosis.
Mere diagnosis of diseases is a most valuable statistical tool of epidemiolog- on
behalf of medical policy but in education the epidemiol_ogical approach to failure
testifies to a trust in educational policy that is hardly justified. Diagnosis may be
important for employers and insurers, and it cannot be ignored where the product
of education is what hlatters, but even then processual diagnosis should be given
a fair chance. The trend in medicine to focus on health rather than on illness is
almost too obvious to warrant being mentioned. There are no vaccines against
mathematical errors. On the contrary, and in particular if mathematics is to be reinvented under guidance, errors are unavoidable or even welcome provided they
are used to stimulate resistance against their own consolidation and recurrence.
Ideas on the need and possibility of retiology - to stick to the medical terminology
- are as rare in research on errors as is the attempt to recover the past of the learning process and insight into the relevance of long-term learning processes.Errors
as 62 - 45 = 23 have been signalled hundreds of times, but the strong suggestton
that they are due to a premature separation of form and content - positional system and subtraction context, in the present case - has not even been a subject of
research as interpreted by the majority of researchers. In education, it does not
yet go without saying that retiology is a condition for effective remediation and
prevention.
Tue inclination to study error is quite understandable. Normal things need no explanation, but what really strikes the beholder are deviations from the norm: -at
is from what is felt or agreed on to be normal. Education, as looked upon m its
p;esent state, is taken for granted, and against this background of certainty its actual or potential diversity can be a matter of study that handles liability to success
or failure as its criterion - comparative research, which is questionable as such -
rather than retiological.
Are educational researchers indeed as conservative as that? Or wasn't New Math
a historical counter-example? If at all, this example was research on how to put 158 CHAPTER3
new wine into old bottles -- is it Enseignement des mathimatiques modernes ou
enseignement moderne des mathimatiques? I asked in 1961 [14].
3. The cradle of developmental research
Most research is on factual education. Developmental research is different, and,
as I already claimed with some reservation, historically it even preceded formal
educational research in mathematics (and other fields). In the past, mathematics
instruction progressed by the activity of educational developers, in general documented by textbooks, which are still to dale the main agents of change. When I
claimed that educational research started developmentally, I admitted as well that
it was not recognised as such, and I meant -- not even by those who carried it out.
I didn't actually say it was the oldest kind; I said "perhaps", which means that the
statement depends somehow on what is understood by "research".
In (2.3.1) I recalled that, as early as 1961, I propagated thought- experiments as
instruments of educational development I should rather have spoken about drawing attention to their function in this activity. Indeed, it is clear from the context
that I took it for granted that thought-experiments had always functioned this way
and that the only thing lacking was consciousness of it. Observing their lhoughtexperiments and reporting on them would have transformed educational developers into educational researchers, who present their findings togelher with the
arguments, rather than dogmatically.
Although factual experiments would be more convincing, thought-experiments
will remain indispensable (at least in order to prepare factual ones) as long as educational development is being undertaken, and this will happen as long as the
need for change is felt Tradition and change, and their mutual relation, are fascinating subjects. In [40] I dealt with their role in malhematics and in education.
A good teacher, who does not blindly follow traditions dictated by bis own past
or by prescribed and prescribing textbooks, acts as an educational developer, who
most often is unaware of this role. In fact, awareness of the motives of one's own
activities can be either useful or harmful, depending on the situation, the action
and the actor. A teacher can be struck after school by the idea that "today it was
different". Was it really different, and if so, what is the "it" lhat was different and
why was it so? Soul-searching isn'teverybody's business, but change lhrough accident can be a source of search, just as search can lead to change.
Is this simply a bunch of trivialities? I wished to argue that even nowadays research can start at !he grass-root level, lhat is, under no olher conditions lhan !hat
of becoming aware of one's new experiences, as well as !he wish to understand
them in the perspective of a change for better, and that at any time it can restart
under !he same conditions. This is not to belittle high -level research but to prevent it from clogging its most abundant sources.
4.R&D
Th,- t1rle :D4' tl!- ""'"\ -h1;i::tP7 'c(,,,.:,, •d :l:"J ····:i:-::R ?•". .-h ?'.< <:..<:..;'r:;·.'J h; .r":·--r·>r th-r- c,.:7
TIlE LANDSCAPE OF MATHEMATICS EDUCATION 159
former. This, then, characterises developmental research: it takes place wilhin !he
educational environment, which is expected to undergo and to activate change.
"Development" made its entrance as a technical term in !he nineteen-sixties,
when educationalists were trying to take advantage of the then noisy call for
change. It appeared in !he combination R&D - research and development - whlch
was soon amplified by another D, !hat of dissemination. The terminology itself
was borrowed from the natural sciences and their technology, though, as I have
often emphasised [e.g.80], this happened with little regard for its meaning in that
field, and without asking whether it adequately applies in education. In the natural sciences it alludes to the road leading from lheoretical work to technical applications: the test tube replaced by retorts of more and more industrial dimensions, the laboratory by ever bigger workshops, !he researcher's desk by the drawing board and the computer. This is not the way it takes place in the social
sciences -- except perhaps in economics. Theory may be a source of inspiration
but seldom, if ever, the place to look for germs of development towards applications. There is research for creating means of organisation and processing information, such as terminology, methodology, test theory, statistics, but all this is
applied in a descriptive and inventorising, ralher than in a developmental way.
For a discovery in chemistry or biology to be developed industrially, buildings
get designed in one way or the other, though whai really matters is not the structure but what it contains and what is intended to happen !here. In education, however, the R of R'&D is concerned with the formal element of the building rather than with its contents.
The problem with the educational R&D terminology in everyday practice are the
strange consequences, as nicely illustrated in the following example: creating
new courses of instruction is filed under "development", even though it requires
-- at least implicit -- fundamental research, whereas the mere routine of testing or
adapting a given course on behalf of, say, level differentiation, mastery learning,
and so on, falls under research, which is likely to be held in higher esteem and
correspondingly be subsidised more easily and more generously than development
The R&D mania stimulated productions like curriculum theories, general goal
description theories, taxonomies, hierarchies, model designs. In [87] I still judged
these worth punished, while nowadays it is hard to find anybody who even cares
about them; so I can only hope !hat !he same will happen to system lheory, "cognitive psychology", and other lhings, which are imposed on or proposed for
malhematics education by general educationalists. Indeed, even though the R&D
terminology has been dropped, the R&D mentality still subsists, by which I mean
the mentality of separating research and development.
5. Cyclicity
It still subsists, that is to say, in stale theory. Practice, at least in education, requires a cyclic alternation of research and developmen- which can be more efficient the shorter !he cycle. What was developed behind the desk is put to the test 160 CHAPTER3

in the classroom in order IO be analysed, and development is resumed with the
results of this analysis.
This seems IO be a trivial statement, and indeed the alternation between thinking
and doing, planning and testing is nothing more than the everyday way of life.
Developmintal research means that this alternation is understood as a macro feature, rather than a micro feature of the domain where it takes place and of the flow
of events. By this broad field and long-term feature it distinguishes itself fundamentally from what is sometimes called constructive research.
How essential is the fall-out of development to deserve the name of theory, how
essentially fertile is the development stimulated by such theory? The feature that
gives developmental research the right to the name of research is its bringing to
consciousness that what is fundamentally new and essentially fertile in research
that is arisen fro educational development.
But I should not leave it at this. Educational research as fall-out of educational
development - this again erects a dividing wall, which even if only a curtain, is
not flexible enough to do justice to what developmental research means. "Development ensuing from research" and "research as fall-out of development" is too
weak a synthesis. How can we achieve a stronger and more efficient synthesis in
order to answer the question "what is the use of it?"
6. Proof by process
Rather than R&D, I borrowed another feature of research in the natural sciences
on behalf of education: the thought-experiment. Design, even if undertaken behind the desk, is a better start than stale theory, but it also better than a long series
of thoughtless experiments. Physics, as we know it at present, originated neither
theoretically nor experimentally, but in a rational way nevertheless: from ideas,
suggested by the analysis of nature and tested later-- often even much later. The
double helix was a splendid idea for the mental reconstruction of DNA, and it became the model for numerous successful reconstructions before it was actually
proved, that is, a quarter of a century after it had been proposed the first time.
The high tide of attempts at educational change after the Sputnik shock flooded
mathematics education with new programmes, new teaching matter, new courses, all of them contrived behind the desk, discussed at symposia and, as a matter
of urgency, pushed into classrooms. Little was ever put to the test, and still less
survived even the most benevolent trial. In fact, innovation is an arduous process,
and gives the lie lo the most cautious predictions. My criticism at that time did
not aim at the "behind the desk" origin of the innovation projects -- how else
should one proceed? -- but at the lack of any report on the underlying thoughtexperiments, if any. Researchers publish products of their activity, rather than the
processes by which they were created; the knowledge of these processes is considered to be their private domain; and so did it happen in this case loo.
This policy may work in mathematics, where a proof, if sound, justifies the theO'f'm [Hl_;-- -_f-.:o,..-lf, ru-t,!-1-1-_-_-gh v-_e-v-,.'11 -t -_s l-:::'S' _.,.f'R-- ---._ _ ;":VC"'"_ 1'--f'"':-, 1
1: 1'", 18"
THE LANDSCAPE OF MATHEMATICS EDUCATION 161
scribed, can be reproduced by others more or less easily. In the social sciences,
however, such a situation is quite exceptional. How, in any case, can one reproduce thought-experiments that have been kept secret?
Knowledge can successfully be presented as a product If the process of its acquisition is reproducible - a characteristic of "hard" science. Wherever this condition
is not fulfilled, knowledge presented without any indication of the process that
brought it about, lacks all characteristics of rationality that distinguish genuine
knowledge from dogma. It is unproven, unargued, unfounded, or so it seems.
How to transfer such a knowledge, how to have others reinvent it if one keeps
silent about that which is the most essential?
This question is particularly pressing in the case of educational development.
Taking notice of the product, which allows for many interpretations, is not
enough. In order to apply the product, one must know how it came into being.
Not in detail, of course; the point is not to get stuck in blind alleys but to be
warned against them. Reproducing does not mean parroting.
7. Dissemination as an agent of synthesis
Above I claimed that "development ensuing from research" and "research as fallout of development" is too weak a synthesis. For reasons I just expounded, the
idea of dissemlllllition, which in the RDD conception is a separate component,
should be kept in mind the entire time that the developmental process lasts. In
short,
developmental research means:
experiencing the cyclic process of development and research so consciously, and
reporting on it so candidly that it justifies itself, and that this experience can be
transmitted to others to become like their own experience.
In contrast, constructive research is a more modest conception than developmental research of which transmission is an essential feature. To be useful, constructive research trusts its results to implementation. In education, or at least in mathematics education, little that can be transmitted with impunity as mere
implement. Developmental research asks for more by including the view on
dissemination.
Anyway, dissemination should not be separated from development. This requires
a continuous awareness of what is happening in the ongoing process, a state of
permanent reflection, recorded as much as possible". Dissemination is one of the
aspects under which hard and soft knowledge differ from each other. Hard, that
is wrought iron - it does not matter how it was wrought. Products of educational
development can also feel hard - loo hard to be applied. Hard science shall meet
hard criteria. Where should one look for criteria for soft products? The answer is:
among the hard facts of the developmental process. They are needed to bear witness for the product in order to make it plausible and transferable, which demands
an attitude of self-examination on the part of the developmental researcher: a
state of permanent reflection. 162 CHAPTER3
8. The Landscape
Dissemination is a misleading tenn if it suggests sowing after harvesting. In fact,
from the outset it should be closely connected to the educational development itself, while the seeded territory is expanding in step with it. Both teachers and pupils are partners on equal standing with the professional developers in the rapid
alternation of activities behind the desk and in the classroom; they are simultaneously sowers and harvesters and educational developers, like the professionals.
(Let me add that I never did like experimenting with human subjects other than
while giving them a chance to profit from the experiments themselves.)
Developmental research includes
development on behalf of
first line instruction
teacher training, guidance and retraining
guidance and retraining of teacher trainers
guidance and retraining of counsellors
testing
media
advising and supporting
educational development by other agents (schools, working groups, text
book authors) in a broad sense, with the emphasis on co-operation
creating cadre for the increasing territory of dissemination research
within the development
as fall-out.
Developmental research covers
longitudinal developments with a view on
long-tenn learning processes
and is itselfa
long-tenn learning process.
9. A bit of history
In order to do justice to a repeatedly professed philosophy by me, I ought to tell
in a few words how developmental research, born by necessity and owned by reflection, was baptised.
In 1961 the Dutch government installed a Commission on Modernising Mathematics Education (CML W), which as late as the nineteen seventies was followed
by similar commissions for other subject areas. The way CML W interpreted its
task foreshadowed later developments [24]. Soon the need was felt for a centre
that would combine and co-ordinate their numerous activities. Early in 1971 the
CML W was finally given an Institute on Developing Mathematics Education
(IOWO), which was loosely connected to Utrecht University. The mere name of
the institute implied a programme: its focus would be on educational rather than
on curriculum development From the start onwards, the task of IOWO was in-
--e"'''- 7e•e,-;-1 '1.'S -=-1P13)f i.n,l--'i:_--tce.r} -----'-'fhi -;:}"'.:---<?"';----_UT "3-----r::;'"-"'" -'-- ,./_-:'.-
THE LANDSCAPE OF MATHEMATICS EDUCATION
163
look into the future [37, 44, 46].
General educationalists found fault with this heterodox unprofessional approach.
Indeed, IOWO people could not answer questions about the curriculum or learning theories they adhered to, nor could they produce catalogues of learning objectives, simply because they did not have any. The only things they had to show
were a philosophy on mathematics and mathematics education -- this had never
been heard of -- and a grand experimental design, which, to make matters worse,
failed somehow to mention control experiments. To be hones- I admit that
IOWO was taken seriously in the long run -- or even dreaded -- by general educationalists, even by those who had other ideas on educational development and
research.
Before IOWO's arrival the educational "Landscape" had neatly been divided into
sectors of Training, Counselling, Retraining, Development, Innovation, Test Production, and Research, each represented by a single institute or a group of institutions, or this was the theory. At IOWO all this was integrated. So IOWO was a
notorious case of unfair competition. As such it was particularly feared in the politically most powerful among these sectors, which up to the present day has unsuccessfully struggled for a genuine educational identity of its own.
Anyway, one day the government decided to put an end to this chaos and, as behooves bureaucracy, tb'neatly divide the landscape (as far as subsidised) into sectors that were to respect each other's borders -- a ruling that afterwards was even
written into law. Although this law strictly forbids any integration, it allows cooperation between workers or working units of two or more institutions of different sectors, which in any particular case requires a tedious procedure of approval
by managing directors, boards and councils of the respective institutions. Yet bureaucracy is not almighty. Meaningful work is still being done and subsidy obtained on behalf of this work by people who know the loop-holes, though it is not
an easy way of getting work done.
For the IOWO the clearing of the "Landscape" meant its death sentence. Only a
short "research" leg should be spared, which was implanted (together with theeducational computer centre) as a department into the Faculty of Mathematics of
Utrecht University; since that time this leg has grown quite a bit stronger. Formally stripped of educational development, it is now known as Institute for Research on Mathematics Education and Computer Centre (OW tiOC).
IOWO, of course, had fought back against its own death sentence, and this struggle gave birth to the tenn "Developmental Research", which is the reason why I
told the story. Under pressure of public opinion and parliament the death sentence was commuted from decapitation into mutilation; as mentioned before, a
research leg should be spared so a broad definition of research was in the best interest of IOWO. Our integrated approach had been successful, and none of our
people could imagine or trust nor feel able to try another approach as promising
as the proven one. What's in a name ifonly it covers a good thing? If it was a lie,
it had short wings. Though it was not, it did not help. Even though the name
looked new, Developmental Research was not an ad hoc invention, or so I hope 164 CHAPTER3
to have convinced the reader. Il simply was the approach that had proven successful in the past and promised success in the future. Through its struggle for life
IOWO, understandably became conscious of its true identity, as well as of the
need for a name to distinguish it from others.
10. Developmental research - a conclusion
Did I emphasise developmental research unbecomingly and to the detriment of
other views in this section on Research in Mathematics Education? My proper
criterion for judging educational research was formulated as early as (3.2.2, 1):
What is the use of it?, interpreted in a broad sense. My answer, in general, was:
Change. How much can research contribute to this? Or rather, how far should research participate in change? My answer was: As Developmental Research. (Notice the switch from "can" to "should", and from "contribute" to "participate"!)
"Developmental research" is meant as an ideal yardstick and a critical touchstone, and it will be used as such in the next section, where developmental research implicit IO practice will be made explicit
3.3 PRACTICE OF MATHEMATICS EDUCATION
3.3.1 Practice
In (3.2.3, B) I described in detail the Educational Landscape, which along with
first line education includes what in my country is called Service for Education.
In the Netherlands this is quite an extensive, and for the most part govemmentsubsidised, bureaucratic structure, strictly compartmentalised by law (WOV),
comparable to the guild system of crafts of former centuries (3.2.3, 9).
In the preceding section I dealt with the Research compartment of the Landscape
(that is, with the emphasis on Mathematics Education). As a name for the remainder! could find nothing better than that of Practice, which on the one hand is or
should be the customer of Research, and on the other hand looks like the counterpart of Theory, which was dealt with in the first section of the present chapter.
"Practice" has both a descriptive and a normative meaning. If it is understood in
the descriptive sense, its qualitative evaluation covers such a broad range that it
defies any attempt at description, even when restricted to one single country and
one single type of institution or part of it. So the normative element cannot be dispensed with in organising a description. Moreover, individual practitioners or
groups of them act according to explicit or implicit norms, which compete with
or are derived from more general ones.These norms are subjected to change either pursued by the practitioners, or demanded by the public, the authorities and
the theoreticians; and, after all, if there is any use for descriptions, it is in general
-, `"'''-:--.-!>-. - "'0_!-.;"GT:":. -!-"-J-}•"' -.-P.:--'!':-:. -,,-----!=-- '---, f-- -";
TIE LANDSCAPE OF MATIIEMATICS EDUCATION

tion.
3.3.2A background of competence
How competent may I feel to deal with practice in its descriptive or normative
aspects or in a synthesis of both? Not until 1970 did I shift my interest fully to
education, and even though I participated for a decade in the everyday activities
of a number of schools and training institutions of various kinds, I should confess
that I have never taught school nor even teacher training classes. Although I tried
to look inside as deeply as I could and as is needed for being a participant, I remained an outsider, one who casts glances into the educational system and acts
within it, without factually being a part of it.
To make things worse, I know almost nothing about other educational systems
when compared with my knowledge of the Dutch one. Of course, I have read
quite a bit about some of them, but what does this mean? If I were to judge our
Dutch educational system on the strength of written and printed documents, I
would get a severely distorted picture. Not because people who write about education are liars, but for the simple reason that the bulk of what is written is wishful
thinking rather than description. As far as it is descriptive, it is most often written
from a distance where details, among which perhaps the most important, are
blurred, clouded and obscured. So I must warn you with regard to all that I am
going to say -- about what in practice is right or wrong, what can be improved
and how it should be done, what should be changed and what is better kept as it
is -- that I am my own spokesman and the interpreter of my own experiences,
which were acquired in my own country at the places I just happened to visit.
This, then, may involve ideas that apply nowhere else or, the other way round, it
may mean labouring the obvious.
To be honest, I am not as pessimistic as all that. ! fi were, ! would not dare to tackle practice. Even if various educational systems appear more different than in fact
they are, I firmly believe that these are deceptive appearances. In particular, if our
gaze is focused on nations that share similar social conditions, it is quite improbable that their educational systems diverge as much from each other as they make
it appear. Even in one and the same country, with a narrow or broad scale of diversity, attempts at producing change are defined to a higher degree by social determinants than by individual or group efforts, which of course, cannot at all be
dispensed with. To repeat a joke I am proud of: I believe that in my life-time nothing has had as much impact on education as the ball-point, the overhead projector, and xerox -- inventions that have not primarily been made on behalf of education. Or am I exaggerating? In a sense I am. Besides the ball-point, overhead
projector and xerox, one needs people who use them, and preferably, people who
use them in a creative way.
This restores my confidence: we are living in one world, most of us under similar
social conditions, and even though learning one's own language and learning to 166 CHAPTER3
teach it may mean different things in countries where people speak other languages, mathematics is the same all over the world, and so learning mathematics
and learning to teach mathematics and to develop mathematics education are the
same as well.
3.3.3 Taught and learned-- the subject matter
Let me reconsider my last sentence! Is that what I just claimed to be the same,
really the same all over the world? Or is, if anything, the teaching subject the
same? If one compares mathematics as taught in various countries, certainly at
the secondary level, one would be inclined to say it is not The Bourbaki caricature taught in France strongly differs from the Kolmogorov version in the Soviet
Union (or are they really taught as such?), and both of them differ from what is
taught at British O and A levels, and still more from what pupils are expected to
learn in highschool in the USA.
Well, there are broad chasms between what is being taught in various countries.
But does it matter? I don't think so. As I see i-- if things are to be compared, the
proper question to be asked is not what is taught here and there but what is
learned, what is really learned, what lastingly affects the minds of the learners. I
cannot believe that it differs that much in different countries. I don't believe it because I think it cannot possibly be so. How can people in various countries differ
intellectually so much that whatever they are taught they can learn such different

!!tings as those different kinds of mathematics? I would prefer to say that people
on the whole, and in particular young people at a certain age, are all the same under similar social conditions -- even beyond comparing averages. We need not be
haunted by feelings of inferiority when confronted with the awfully abslract
mathematics that, say, sixteen years olds are supposed to understand and to master according to, say, French, Gennan, or Soviet textbooks. Tests have made it
clear beyond any doubt that the vast majority of pupils have not the slightest idea
of what is meant by this highly sophisticated mathematics that they are supposed
to have learned. Every year at the national examinations of 16 years olds in my
own country I am struck by the wide gap (extending over many other subjects areas, indeed) between the boastful pretensions of the tests and the poor perfonnances -- a gap possible thanks to an evaluation of the results that belies the expectations of the test producers.
I like to call it the big lie of our educational system, and I am afraid that this characterisation applies to quite a few others: there is a wide gap between the inflated
demands and the allowable passing levels. Exams serve selection: they single out
those who can satisfy the most exacting demands. Formal tests are constructed in
order to discriminate, as test producers call it, which means a 50% failure rate.
But why should we ask the great majority to aim infinitely higher than they are
able to reach? Not only infinitely hi-her, I should say, but also in 'the wrong di-

ing simple mathematics at a reasonable level is a more dignified pursuit than
learning complex mathematics at no level of understanding at all.
It sounds almost trivial; this focusing on what learners did learn, rather than on
what they did not. It is the most natural thing during the learning process, so why
should it not be natural at its end? Why not adapt the demands qualitatively and
quantitatively, and with regard to substance and depth, to the learners' ability, as
proven by their accomplishments?
I used the plural "learners" intentionally, and if this is taken into account, my
statement is less trivial than it sounds. We teach classes, so why shouldn't we expect classes to learn? Life is cooperation. Why do examinations focus on individual performances and entirely disregard collective ones? But let us delay answering this question!
The wide gap between what is claimed to be taught and accepted as being learned
. . the big lie . . is inherent to any system that strictly relies on exterior control.
The gap is reduced or absent at institutions that are trusted to set standards of their
own. This is true in any case for my own country, where uniformity of teaching,
learning, and examining stops at the doors of institutions of higher learning and
the prospect of the examination is the only measure, that puts restrictions on the
freedom of teaching. I don't know enough about other countries, but I still remember tests at FRG universities a few decades ago, where the majority of freshmen who had learned a vast amount of Calculus at school, didn't master the most
elementary algebra. Have things changed in the mean time? I am still puzzled by
the conlrast when I look at the kind and level of mathematics that future primary
school teachers are supposed to master in my own country and in the FRG. Are
their students so much more mathematically minded than ours and is teaching 6-
10 year-olds elementary arithmetic so much more demanding in Germany than it
is in Holland to justify requirements in mathematics as high as theirs? Nowadays,
students who are able to fulfil such requirements are not very likely to aspire to
primary school jobs . . this is the case in my country, and! doubt whether they are
more likely to elsewhere.
3.3.4 Taught and learned -- the agents
Leaming and teaching -- aren't these not outmoded tenns? In Education the fashion is now to call it change and transformation from novice into expert, although
this is more than a merely linguistic fashion. Two well-defined states are assumed with respect to a certain knowledge or ability: the clean slate, and mastery.
The agent, responsible for this transformation, is supposed to be an expert himself, which means a product expert. The intended process that transforms novices
into experts is likened to that which takes place on an assembly line. It has been
well-designed on the strength of cognitive or instrumental analysis •• a kind of
thought-experiment, where the subject to be transformed from novice into expert
is supposed to be acted on, rather than to be an agent 168 CHAPTER3
To be sure, one can imagine more refined versions of the expert-novice model,
which may grant the learner more freedom: choosing among several assembly
lines, for instance, or even within a predesigned network -- the more complex the
more costly, and nobody can say where the break-even point is. Can the computer
be of great help? I doubt whether enthusiasm alone justifies optimistic expecta-
tions".
The expert-novice model is a way to organise learning processes. Learning is
time-consuming. To be efficient it must be organised, but organising is also
something that has to be learned. Machines in which a lot of learning is firmly
and flawlessly invested are different; they need not learn themselves, or if they
are of the kind that do need to learn, then the required learning process is invested
just as firmly and flawlessly. The technological progress is accompanied by an
ever increasing estrangement Everybody can make some tool like a hammer as
soon as he needs it. A lot of people can repair electrical switches, radio sets and
cars, but few people know how computers work, and still fewer dare repair them.
Yet, even in this context, one can try to account forlearning as a human activity.
Von Neumann once claimed that, in principle, any human activity can be taken
over by computers, provided it has been analysed in detail. No doubt this applies
to physical activities, taken over by robots. But brain and mind are different. Although the first computers were copies of human reckoners, albeit adapted to the
understanding of the computer, our contemporaries in this field apply strategies
of their own in order to more efficiently use those facilities by which computers
distinguish themselves from humans. Yet chess computers, when first designed,
owed nothing to any analysis of human chess; as a matter off act, such an analysis
had not even been attempted, and even now there is a difference between the
computers' strategies and the more complex ones of humans, which are less accessible to analysis.
Computers are human-made and some humans know how they work. There is no
fundamental knowledge about the working of the brain, and hardly any phenomenological knowledge about that of the mind. Nevertheless, we are able to predict
and influence our own and other people's mental activities, without being able to
say how we acquired this ability. The computer metaphor of brain and mind is
therefore mistaken in both directions. All in all, computers are much too streamlined, much too prestructured and too reliable to be useful as paradigms for learning to mathematise little worlds.
3.3.5 Taught and learned-- interlaced
Let us recapitulate: At the assembly line of the expert-novice model, the learner
is supposed to be acted on, rather than to be an agent On the other hand, the computer model lacks descriptive validity as required for its being normative; and as
a tool in the expert-novice relation, it still fails to even approach the measure of

back between teaching and learning is still a most promising way to improve instruction.
Indeed, through personal experience we know about individual learning processes, through generalisation about general ones, and through history about those of
mankind. It depends on one's viewpoint whether one qualifies this statement by
adding "a little" or "a lot". Anyway, the greater part of this knowledge cannot be
verbalised, let alone formalised, and this is the very reason why programmed in-
struction -- whether by computer or not -- has made little, if any, progress. Fortunately, just as modern travellers need not follow to the trails of old time voyagers, so learners ueed not repeal all the learning processes that were once required.
Most of these processes can be shortened or even reduced to merely accepting the
bare product, and teaching is a way of organising this reorganisation The big
problem is to distinguish the products which admit the strategy of transfer from
those for which the strategy of what I called guided reinvention is indispensable.
To what degree may estrangement be either useful or harmful?
All one needs to know in order to use a computer is its exterior reactions to one's
acts. This is astonishingly simple, although the style -- either formal or childish -
- of the manuals conjures up an image of complexity, which only betrays bad didactics. Even oral explanations may be counterproductive if supplied by experts
who lack the ability to place themselves in the shoes of the novice. Until further
notice the fasfest manner to learn to use computers is to use them and to ask for
help only if some problem seems to demand too much of one's solving ability.
Although this is an unsatisfactory and certainly not paradigmatic example of
guided reinvention, it should not be surprising that teaching how to use computers has not kept pace with their rapid evolution.
Other teaching subjects can boast a longer history. But history is not yet done; it
continues as times goes on. The learning paths leading from here to there form an
intricate and never completed labyrinth and each fresh learning process, be it individual or collective, asks for new teaching processes. Even assembly lines, as
useful as they may be, require modernisation, which can be a costly venture.
Teaching/learning processes, observed and reinforced, entangled and isolated,
necessarily require and fortunately allow more flexibility. To be sure, as a whole
they must be organised carefully, but the care needed does include caring for
flexibility. Interactivity means that both teachers and learners are agents as well
as being acted on. Taught and learned should coincide, or, even better, compete
with each other on equal terms. These are high demands, and even higher if learning is to mean long-term learning.
3.3.6 Change
"Taught and learned" is just one facet of the familiar antonym 'Theory versus
Practice" as I recalled in (3.1.l, 2). Let me now turn to Research as a source of
Practice! My answer in (3.2.3, 1) to the question "what is the use of it?" was:

Change.
Change, in particular under the name of "innovation", is tacitly understood to involve improvement Rapid changes are known as revolutions, yet revolution need
not imply innovation. Anyway the innovatory speed depends on the circumstances. This is even true in industry. There it lakes time to sell innovation to their directors, to develop new tools, to buy new machinery, to insiruct workers how to
use them, and to advertise the new products. Even if the time needed is considerable it is nothing when compared to that needed in education. (An estimate I just
heard was I to 10.) The reason why, is the greater amount and complexity offeedback required in education, and the lack of past experience.
Innovation, when thoroughly planned, affects each level in the Educational Landscape, a big hierarchy extending from first line instruction to research, where the
taught-learned relation is the glue that connects subsequent levels to one another
-- a large number of feedback spots here, each of which is of a high complexity.
Curriculum theory as developed in the sixties tried to account for this structure,
but in formal educational innovation projects the amount and complexity of required feedback are easily underestimated, which has happened in the past and
which still happens. This, then, is the reason why most of them failed in the past.
The few that somehow succeeded, did so because all levels of what I called the
Landscape were involved in the process of change; they underestimated, however, the time required for teaching/learning at each particular stage of dissemination. In fact, innovation itself is a learning process for the Landscape as a whole
and for its particular agents, some of whom may be subject matter experts who
nevertheless lack the expertise to recall their own learning processes and to analyse them in order to know what has to be transmitted to learners and how it
should be done. I f innovation is a learning process, it is quite a singular one, rather than one of guided reinvention. As far as it may be guided, it is so internally,
which requires a high measure of flexibility.
3.3.7 The agents of change
3.3.7.1 The educational developer as an organiser
Leaming is time-consuming, indeed. It depends on the learner and the learning
matter how much time is required, that is, how much estrangement can be allowed if learning processes are to be shortened. Strangely enough, as history has
shown us, this is a bigger problem in the service regions of the educational landscape than in the first line. Disregard for this fact is, in my opinion, the actual reason why time estimates at the various stages of the process of change have been
so far off the mark.
Though under another aspect, it was already discussed in (3.2.3, 6) how the "ex-

the researcher-- to "prove" the validity of proposed instruction to the satisfaction
of those who are expected to get acquainted with the proposal. In projects of developmental research the researcher need not rely on mere thought-experiments.
As such a project proceeds, thought-experiments are gradually superseded by series of ever broader factual ones, only to cede their indispensable role to farther
reaching and more profound new ones. At any stage, the results of the preceding
stage, rather than being imposed as products on the participants, need to be transmitted as inventions, in order to enable participants to reinvent them.
After (3.2.3), where gradual dissemination was to serve the progress of developmenial research, the tables were turned: research now serves dissemination. Even
so, dissemination is not understood here as something that happens once, after research and development have been completed. It is a gradual and, in a way, openended process. From the start onwards, dissemination is part of any developmental research: at firrst, this lakes place within the restricted company of the initial
actualisers who perform thought-experiments behind the desk. In the developmental process they compete with the professional developers in the activity of
adapting and modifying preconceived ideas. As dissemination begins to affect
ever extending circles of participants, developmental research includes keeping
a grip on wh-tjs occurring at an ever more distant periphery. Yet it not a one-way
influence. Signals from the broadening circle are fed back into the developmental
process -- this aspect of dissemination has already been brought to the fore in the
preceding subsection.
With regard to practice I made a distinction between descriptive and normative
aspects. Since educational development as such is not a widespread conception,
it is no wonder that norm by far outstriped description in the preceding exposition. At closer glance and regarding details quite a few realistic aspects may be
recovered as a description of what at present is subconsciously and unintentionally being carried out as educational development Yet let us now turn to other
agents in the process of change!
3 .3 .7.2 The teacher
In the Educational Landscape the teacher is the least specialised actor (not counting, of course, the frrst line learner), and the less specialised the teacher the lower
the age bracket of the instruction in question. Less specialised is likely to imply
less self-conscious of one's role, and for that matter, maybe less conceited. Was
the apparent lack of specialisation the reason why curriculum developers, in particular those of New Math, trusted the teacher to be able to implement brand new
subject matter in the classroom? On a tabula rasa one can write all one wants,
and this is what they did in the retraining courses with the subject matter to be
taught in the classroom -- somewhat broadened or seen from a higher viewpoint
When this strategy failed, some developers conceived the idea of"teacher-proof
curriculum". My dictionaries are not up-to-date enough to include items like 172 CHAPTER3
"teacher-proof' but, looking for related items, I feel inclined to believe that it
means stuff that even a teacher cannot spoil. Other developers realised that a
teacher was no more a tabula rasa than anybody else and that the deeper the imprints, the more likely they were to withstand attempts to change or erase them.
In the cognitive domain, background philosophy (as I called it in (3.1.3)) is the
totality of the deepest imprints. As far as mathematics is concerned, there can be
little doubt that such aspects as mathematising are lacking in pictures of mathematics which traditional instruction created in most people's and even in most
teachers' minds. The mechanistic style (3.1.5-3.1.6) of the mathematics they
were taught pervades the mathematics they learned. If they chose to become
teachers, they will continue teaching the mathematics they were taught, in spite
of new subjects unless emphasis in retraining is shifted from subjects to attitudes.
Most attitudes are acquired unconsciously. The easiest and most efficient way to
change them is actively participating in change this need not remain a privilege
of that group participating in projects of educational development which I characterised as the initial actualisers of thought-experiments. Participation can be
transmitted. At every stage of dissemination teachers are guided to reinvent primordial changes, aJbeit modified by the experiences at intermediate stages. AJthough unconsciously acquired attitudes are reinforced by reflection and knowledge of them may be helpful for transmission, the true thing to be transmitted in
the course of dissemination -- if it is to be efficient -- is the behaviour itself rather
than knowledge of it
Guided disse-inatlon aims as far as the ultimate frontiers. At every stage it is endangered by its own success. I f stopped too early, the campaign can be lost and
the instructional system be worse off than before. What does "too early" mean?
In medical terms: if the mechanistic view on mathematics is a disease then it
matters to judge how many and how large areas of reinfection may be I -ft with
impunity. But what about prevention?
3.3.7.3 The teacher student
Malhematics teacher training is a newcomer in the Landscape of Mathematics
Education. At any rate, this is true in my country. If there are other countries
which can boast a longer tradition of mathematics teacher training, I am not sure
what its impact has been on first line mathematics education. In most countries,
teachers were educated either as educational generalists in order to function in
primary education, or as subject matter specialists with a professional future in
secondary education. The first were educated at teacher training institutions, the
second at universities, although in my country extra-universitary examinations
kept a continuous stream flowing from the first to the second pool of teachers. As
a consequence, in secondary level mathematics, the majority, rather than being

However, the number of those who, prior lo the extra-universitary examinations,
had not had any training as a teacher was steadily increasing. Not until a few
years after World War II was some teacher training made compulsory for future
secondary school teachers, but, even so, for years this was thwarted and kept

down by universitary people in charge of the various disciplines, who jealously
guarded the scientific status of their students -- indeed, in this respect didacticians
had still to qualify themselves. At the present state of teacher training for primary
education, mathematics is integrated with its didactics; teacher training for lower
secondary education has mathematics and its didactics taught simultaneously and
by the same persons, while, for the upper secondary level, students are trained by
didacticians after the accomplishment of their study of mathematics, which is
still an unsatisfactory state of affairs.
I have re-counted the above in order was to draw attention to two basic issues regarding the relation between the two components of teacher training -- the scientific content and the didactical form. These issues are
equality of status,
the measure of integration that respects the level of both components.
Only where the mutual respect of scientific and didactic trainers and their cooperation can be taken for granted, can students be expected to take both components equally seriously and lo integrate them by themselves.
In [115], when dealing with "Major Problems of Mathematics Education", I
made the parallelism between mathematising and didactising explicit by drawing
a parallel between each of the problems in first line mathematics instruction and
its counterpart in teacher training, between each learning problem and a teaching
problem, which in turn shows up as a learning problem for the teacher student
So I started with drawing a parallel between
Why can Jennifer not do arithmetic? and
• Why can Jennifer not teach arithmetic?, only to continue via the pair
reflecting on one's own learning with its counterpart
reflecting on one's own teaching and, among many others,
developing a mathematical attitude with
• developing a didactical attitude to
• How can calculators and computers be used to arouse and increase mathematical understanding? paired with
How can calculators and computers be used to arouse and increase didactical
understanding?
To explain why I changed the paradigmatical "Johnny" into Jennifer, let me
quote myself from [115]:
Why can Johnny not do arithmetic?
Does this sound sexist? I will not change it into
Why can Mary not do arithmetic?,
lest it may sound even more sexist, suggesting that girls are less able than boys. As a
matter of fact both are wrong. My problem is not John Roe and Mary Doe. The prob-174 CHAPTER3
lem is, indeed, why many children do not learn arithmetic as they should, and it is a
major one because, more than anything else, failure in arithmetic may mean failure at
school and in life. My concern, however, is not, or not primarily, what is wrong in
classrooms and textbooks today that creates a host of underachievers.
Let me change the question! I now ask:
Why can Jennifer not do arithmetic?
Rather than an abstraction like John and Mary, Jeonifer is a living child (though I have
changed her name) whom I can describe in every detail. The two details that matter
here are that she was eight years old and could not do arithmetic. Meanwhile the question
Why can Jennifer not do arithmetic?
is not a question any more, because today Jennifer is eleven and excels in arithmetic.
Yet when she was eight, somebody who was observing her stumble with numbers succeeded in answering the question and after ten minutes of remedial teaching, Jennifer's problem had ceased to exist. Was it a miracle? Not at all. It was just an easy case.
But there are so many such cases. Noticed and unnoticed, cared for and uncared for.
But what about the less easy cases? They have grown out of those easy ones that remained unnoticed and uncared for.
Indeed, the parallelism between learning mathematics and learning lo teach
mathematics is the leading principle of what I have to say about mathematics
teacher training, which in practice is acted out by the parallel between mathematising and didactising. Still, in accordance with the tabula rasa metaphor, the second kind of learning is more difficult than the first Teacher students, in general,
belong to the large group of adults where the sources of what they once learned
by insight -- be it much or little -- are likely to have been clogged by the knowledge and skills they acquired in the meantime. To say it more concretely: they
neither care why multiplication by 100 is carried out by "adding two zeroes" nor
about the fact that you can argue about such a piece of knowledge, or why you
should do so. So they have to undergo remediation: thy must relearn such facts
while teaching children and observing their learning processes. The higher the
level of learning, the more paradoxical this conclusion may sound. I have often
argued that knowing a piece of mathematics too well may seriously impede one's
ability to teach it decently; as a teacher one should be so conscious of the learning
process that produced one's own excellence that one can reinvent it So the teacher student needs to relearn by observing the learning processes of less skilled people -- in fact, of children. But if this is so important, we are faced with one of the
big problems in teacher training. Although one can easily arrange for observing
short-term learning processes in the school environment, it is impractable and
hence impossible to do the like for long-term learning processes. Thought-experiments, as undertaken by textbook authors, cannot fill the gap if undertaken by
unskilled people. Lack of experience in long-term learning processes is the actual
cause for the depending of young and even older teachers on textbooks as their
dilly sources of Innowledge on 1011+-tenn learning processes. Inservke guidmce

and getting them to re-create.
Anyway, there is good reason to shift the centre of gravity of teacher training
from theory to practice, from the training institution to the classroom. From personal experience I know about such efforts in my own country. All I know about
them elsewhere stems from written sources. As far as such sources are theory, I
am not satisfied. I am afraid that the so-called classroom-based teacher training
is too theory-laden to be helpful. Yet, is it still a topic?
I believe that teaching should be learned in the classroom. This is more than a belief; I think it is a fact that almost all of what practising teachers have learned in
their lives about teaching and about how to teach was learned in everyday classroom practice.Teaching is learned by teaching -- one could claim -- like walking
is learned by walking. But this simple truth is an outright falsehood. It cannot be
denied that walking is learned by walking, but as soon as "walking" is replaced
by "swimming", it is clear that things are not that simple. To learn to swim one
needs aids, material and personal. Learning lo speak presupposes listening, and
learning to speak better requires personal and material interventions lo improve
speech; for that matter, even "walking learned by walking" does not apply to
handicapped persons, who, without help, would never learn to walk as we would
like them to do. But when I claimed teaching to be learned by teaching I meant-
- and people who if!ree with me likewise mean -- that actual teaching is an indispensable component in the process of learning to teach.
Not so long ago teaching, certainly at the secondary level, was learned by imita-
tion, and by trial and error. Imitation was here a crude form of observation, that
is, one repeats one's own learning processes, which were recorded from one's
own school-life, and supported by the textbooks used in the classroom. The trial
and error provided as much feedback as the guinea pigs in the classroom could
offer and the teacher was able to process.
No doubt passive observation and active trial and error are still the essential features of learning lo teach, just as they are of any kind of learning not sufficiently
supported by general theory. The one thing that has changed and should change
even more in order to further improvement is the organisation of both observation
and trial and error.
A forceful means of doing this is to observe learning processes, which I dealt with
in a larger context (including teacher training) in such detail in (2.3.i) that I need
not repeat it here.
I think that all would agree that a trainee should get in touch with the practice that
is to become his future practice, at the earliest opportunity. Training institutions
diverge in answering the question: how early is "early". After three years, four
years? Well, this may be correct if it is required by the quantity of the new subject
matter the student has to learn in order to teach. Primary teacher training is certainly not such a case.
On the other hand, being confronted with the practice (someone else's or one's
own) without any preparation may be counter!.Iroductive. Even trial and error pre-
suppose some knowledge about what is to be tried. But if the aim is to observe 176

learning processes, and mathematical ones, in particular, one has the opportunity
to start within the walls of the training institution, or even at home -- I mean by
observing one's own learning processes: Take a little mathematical problem,
solve it, tell me how you did it, and think about what you have learned while doing it! Isn't this a marvellous idea?
As early as (2.3.1) I answered this question. When applied to teacher training, we
may conclude that, even before being introduced to practice, the trainee has and
should have opportunities in the classroom of the training institution to observe
and to analyse learning situations. By this, however, I do not mean what in my
country is called institution practice: one of the students playing the teacher and
the others simulating being the pupils who are being taught a certain subject in a
similar way to what would happen in the genuine classroom. This is too artificial
an approach to be successful, and anyway it is not what I mean.
To make clear what I do mean, let me tell a little anecdote, a story from a lesson
in a teacher training institution I was observing. While solving a mathematical
problem at the blackboard, a student had committed a grave error but neither the
trainer nor the other students had intervened to correct it. The student went on and
on, and the trainer let her proceed as she did up to the unhappy end when she ran
into a flat contradiction, which proved that all she had done was wrong and that
the entire work would have to be done over again. Finally, when all this was finished, I intervened to pose the question of whether somebody had noticed any re-
markable feature. Nobody had. My guess is that even the trainer hadn't noticed.
Anyway, he hadn't asked this question -- I had. Even after I had specified my
question a bit and added hints, nobody could answer it. Finally, I myself had to
disclose the answer, that is, to draw their attention, and maybe even the trainer's,
to the fact that the trainer had not intervened to correct the student's mistake.
Hadn't they noticed that mistake as soon as it was made? Did they believe that
the trainer hadn't noticed it? For what reason could he have passed over that mis-
take? Was it a good reason? How should one act in such a situation? Nobody had
asked themselves such questions. So I simply had to explain the trainer's didactical trick and to reveal his intention of letting the student proceed as she did until
she ran into trouble.
What does this story mean? Observing learning processes is indispensable to
learning to teach, and it should start at the earliest opportunity: observing one's
own learning processes and those of one's learning group. But in order to beef-
ficient, observing as horizontal didactising has to be complemented vertically.
3.3.7.4 The textbook author
When I discussed change and its agents, I did so from the high viewpoint of Developmental Research as presented in (3.2.3). How far can it be approached by
Practice? Formal projects is the closest approach; the question of how close, is

possible. Projects that are designed too narrowly, in particular with respect to the
size of the instructional landscape involved (as most of them were in the past)
may be useless if not harmful.
So far, in practice, the most efficient agents of change were textbooks, and by the
look of it, they will maintain this status for the time being. So I may narrow my
former question by asking: "How far can textbooks approach the view on change
taken by developmental research!"
Mathematical textbooks -- including similar teaching aids -- have changed in the
last few decades. To conclude from reviews and the ways of reviewing, however,
they have changed less fundamentally than one would have liked in the wake of
their remarkable predecessors dating from at least half a century ago. I admit that
my first-hand knowledge of the present textbook literature is quite restricted, but
among the few textbooks I do know, I could signal some that have done the utmost to take the desirable view on change, or so I would guess. This is indeed
guess work. I never reviewed textbooks and with all respect to the host of reviewers, I wonder how much teaching experience is required to undertake the task of
reviewing textbooks before or without having used them. My reluctance stems
from confrontations at a semi-teaching level with a few of them: when asked for
help by children who had to work with these books, I suddenly saw, as it were,
through the lellfl!ers' eyes, how bad these, at frrst sight good-looking textbooks
were: they were "shaky from questions onwards I myself was not able to understand, to didactical tricks that backfired, up to an ill-conceived build-up of the
teaching matter as a whole.
I agree that what I called my "semi-teaching" experience is hardly representative.
Whether one likes it or not, textbooks are merchandise, and in the marketplace
good quality is what appeals to the needs and tastes of prospective customers. In
the present case, said customers are teachers who need these books as teaching
aids and who prefer to use what they like. This would seem to be a gloomy perspective for change and for the textbook author as an agent of change, were it not
that needs can be stimulated and tastes can be educated.
The traditional way to try this is teacher manuals. As far as they supply additional
information and disclose richer sources, I do not object to them, but as didactical
aids I do not trust them much, because of the serious doubts I have about their
factual use. In [87, p.119-121] I cited an investigation into the use ofteacher manuals, which included four mathematical textbooks. Only one quarter of the teachers questioned claimed to have used them. This does not look like much, but even
it is an over-estimate, since none of the four textbooks could boast a teacher's
manual. Not that this prevented the 25% self-styled users from answering the
most detailed questions about their ways of using them.
I prefer a textbook style where both learning and teaching at all levels of the
teaching/learning process, as well as local and global reflection on it, are implicit
in the text itself. For instance, the task of posing meta-questions should be shouldered by the textbook author, rather than leaving it to the teacher. This is at the
same time the most effective way to implicitly influence the teacher's attitude, 178 CHAPTER3
which incl-des asking ."ore of these questions wherever they are needed. By
meta-quesuons I mean, m the present didactical context, questions that start like
why do you think
and continue like
did I claim that . . .
did I call this . . .
did I supply you with this . . .
did I ask you . . .
did I include the condition . . .
did I not add this conclusion . . .
did I define this by . . . rather than by . . .
did I deal with this in this order rather than . . . ,
did I prescribe this task for a group of four
or start like
what do you think
and continue like
did you learn in . . .
did you unlearn in . . .
is the use of this . . .
should be added
could be missed in !his context?
For short, I mean didactising questions as the textbook author has asked himself
as an educational developer and implicitly answered by writing the textbook in
the w-y he eventually did. Framing these questions to fit the layout of the textbook is the way to have users reinvent !he educational development !hat produced
the textbook as though they had participated themselves in its production process; and by users I mean both teachers and learners, each on the level that is suitable to that group.
I started discussing the textbook author as an agent of change with a reference to
(3.2.3). From the above it has become clear that I would like him to bear witness
to his -ctiv.it7 as developm_en- researcher (whether he did so explicitly or not)
m !he !mphc!t way of !mpnnung the process into its product, thereby leaving the

users _as much freedom as they deserve, among other things by means of metaquesuons that suggest alternatives.
Would this strategy be understood and its tactics put to good use in the class-
-oom? I_t all depends on the existing infra-structure of teacher training and retrainmg, which should be accounted for as boundary conditions in any educational development whatever, and certainly in textbook production -- this is all part of the
Landscape I have been trying to deal with.
3.3.8 Mathematics for all
mE LANDSCAPE OF MATHEMATICS EDUCATION
179
has been the !theme (or one of the themes) of innumerable meetings and conferences -- national and international -- and it has not ceased to be the subject of research and development. In discussions on general education, numeracy has become the companion of literacy. Indeed, as badly as literacy is needed in a world
full of written and printed matter, so indispensable does numeracy seem to be in
a world where number emerges at every turn to be used and -- maybe even more
often -- to be misused; a world which looks like it is ruled by number. But let me
add that, just as literacy is no more than one aspect of language, so is numeracy
one aspect of Mathematics for All -- which certainly does not cover all of it. Yet
as much as I have refrained from discussing subject matter in the present books
so little will I deal with the contents of Mathematics for All. Anyway, it will not
be the same thing for each particular learner; there is a great deal of diversity not
only of contents, but also or even more so, of breadth and depth of understanding.
As a matter of fact, this may already have been asserted with respect to numeracy,
and if you wish to add it, for literacy, as well.
Literacy and numeracy are spoken of as companions, but is this really a company
of equals? There is a habit of distinguishing what is called tee hnical reading from
reading comprehension. I f we do so with technical numeracy and number comprehension, and consider how closely reading comprehension is knitted to life
and reality, shouldn't we ask for numeracy to have an equally strong grip on
number in the real world? Or are literacy and numeracy different in principle?
Literacy is a relation between two expressions of language -- spoken and written
(or printed) -- or so it would seem, whereas numeracy is having the competence
to relate a manifold of manifestations of number to each other, which is harder to
learn; and this might be an argument to be satisfied with less numeracy than what
is required as literacy.
In fact, neither literacy nor numeracy are uniquely defined. Being illiterate can
mean many things, depending on the environment and circumstances; so what is
meant to be understood by literacy heavily depends on individuals and groups,
communicating with each other in all kind of situations. Numeracy is hardly any
different.
But what about mathematics for all? The answer to this question, even if it depends on the group in question, is not given by the mere intersection of all the
particular mathematics that concern !he individual members of the group, whether as subject matter or as competence; and this again is a property it shares with
literacy.
A most striking feature of language is the abyss between passive and active mastery. Each of us, whether illiterate or literately gifted, understands tremendously
more language than he is speaking or writing, and than he would ever speak or
write, or be able to speak or write, and this difference extends from mere vocabulary to grammar and style, and certainly to the mastery of foreign languages.
Nowhere in our mental and instrumental structure does passive mastery exceed
its active counterpart to such a degree as in language, and mathematics is no exception to this rule. No wonder -- one would say -- for language is the vehicle of 180 CHAPTER3
communication, and communicating vessels, whether wide or narrow, are in
some respect each other's equals.
Under the aspect of communication I shall look at Mathematics for All. Mathematics can boast a language, so specific that it looks like mathematics itself is a
language (which is often, though wrongly, identified with mathematics as such).
Language is mainly learned in the course of strongly interactive communication-
even reading, thanks to contents, is more interactive than it looks at first sight '
This is the reason (or one of the reasons) why I have pleaded for learning in small
groups of say, four learners and, for that matter, in groups of mixed ability [B7
p.60-63]. Relieve me of the task of repeating my arguments! In fact, these argu'.
ments are the direct consequences of my view on learning processes: they are
steered by reflection on one's own mental activities, which is stimulated by ob-
serving oneself by means of observing others, and reinforced by the distant levels
of the participants in the learning process.
Cooperative learning foreshadows cooperation in adult life and professions. In
this perspective Mathematics for All means: as much and as good active mathe-
matics as is needed to participate in even more and even better passive mathematics. I asked:
We teach classes, so why shouldn't we expect classes to learn? Life is cooperation.
-y do examinations focus on individual performances and entirely disregard collec-
uve ones? But let us delay answering this question!
The answer is, as you may expect: They should not This is a verbal answer, in-
deed. It will take much time and trouble before these words become deeds. A first
step on this long path is to formulate, besides individual objectives, cooperative
ones of Mathematics for All, and to describe specific tasks to be performed in cooperation with others.
EPILOGUE
Did I do justice to what I promised and explained in "Apology and Explication"?
I myself was astonished how little revisitation could add to the yield of former
visits except reorganisation of the contents.
Publishing "Lectures", which are no lectures at all is an old and venerable habit,
but I did not realise early enough that nowadays "Lectures" are even less suited
to reflect lectures. Indeed, lectures on subjects like those dealt with in this book,
are centred around a rich variety of overhead sheets, and elaborated on by informal talk that provides for the indispensable concreteness. Sometimes I have tried
surrogates but I could not continue this way indefinitely. In particular, I had to
refrain from dealing extensively with teaching matter. -
The reader might be disappointed that I did not tackle computer education, in-
eluding informatics afit is called on the continent. In the perspective of the
present book this does not distinguish itself from other mathematical subject mat·
ter. And the computer as a teacher is still a far cry away, or so it seems to me.
181
1'
' I APPENDIX
Solution of the problem 1.3.3 , 15 (fig. 3)
1. The first step to deal with such problems is distinguishing states, and operations moving states into each other.
2. Under the conditions of the problem some states may be indistinguishable.
This is the case for states that arise from each other by rotations of the barrel
and by interchanging white and black. This remark also holds for the operations.
3. As a consequence one considers classes of states and classes of operations.
Two states (operations) belong to the same class if they arise from each other
by rotations or colour change.
4. This leaves us with four classes of states and three classes of operations, each
defined by a representative:
States Members in the class
v
• • O=o o 2
• 0
S=oo
8
• • P=oo
4
D=•o 2
0.
Operations Members in the class - means inverting the .di,sk,
+ means leavng 1t as it u
s=
- -
++
p=
++
d=
- -
- -
5. Although it is not strictly needed, one can draw up a table recording the possible results of operations applied to states:
183 184
D p
s
d 0 p
s
p p D,O s
s s s P,D,O
6. The system shall be moved into state 0. If it is state D, the operation d does
the job. So we first apply d. If it happens to be in state P, it then moves into
state D or 0. So if is not yet in state 0, we can move it into state Dor 0, and
if need be, by another d into 0. Anyway if the system was in state Dor P, it
moves into 0 by means of dpd (or part of it).
7. If, however, it is in state S, thens moves it into state P, D, or 0. So if we now
apply s, and if need be, another dpd (or part of ii), we are finished.
8. The solution is
dpdsdpd (or part of it).

PREFACE

In Dutch "WISKOBAS" stands for a particular kind of mathematics in the elementary school (ages 6-12). In turn Wiskobas was one of the departments in the IOWO, the Institute for the Development of Mathematics Education. This institute was concerned with the development of material for mathematics education as well as the related research on the possibility of change from the then existing arithmetic instruction to the future mathematics education. The present publication Three Dimensions has three aims: to give a picture of the goals Wiskobas set for future mathematics education, at the same time to show how such goals can be described, and to show the theoretical framework of the Wiskobas curriculum.

The problem at hand is not at all simple. What is more, Wiskobas' ideas about mathematics education cannot literally be translated into strings of words. So how can we face the accusation that our objectives are unattainable and the goal itself irrational? In order to avoid this vagueness as much as possible and for-the sake of clarity, this book makes continuous use of illustrations of mathematics education. In these examples both the subject-matter and the methods of description of the goals are illustrated as explicitly as possible, while at the same time creating the opportunity to read between the lines. The reader is urged to follow carefully the mathematical material at the start of each chapter. This advice applies both to the more general education oriented, and to the more mathematical/ didactical reader.

In the completion of this task I received assistance from Jelle Sixma, Hans Freudenthal and the former Wiskobas team of the IOWO (now the OW & OC at the State University of Utrecht). A special word of thanks is due to Rob de Jong, Sylvia Pieters, Betty Dekker and Els Feijs, and to Hetty and Guus Vonk, Hans Freudenthal, Alan Bishop and the late Arthur Morley for their help in translating the Dutch version into English.

Chapters 1-V are translated from the original version. Chapter VI is new and was written in 1983. It contains an example of the goal description of a course, as opposed to the examples of goal descriptions in the other chapters which have a bearing on themes. Chapter VII was appended in 1986 with the idea that the three-dimensional goal description propagated here only becomes transparent when a clear view is provided for the framework of instruction theory. In our case, this concerns mathematics education as realised by the Wiskobas project. This theoretical framework is also described in three dimensions, which

Xlll 256

CHAPTER VII

Regarding or disregarding certain context factors, which is the essence of modeling the problem, is in fact a non-negligible part of the process of mathematising. Of course, this does not mean that each problem should be heavily contextually loaded or fitted into a larger thematic context. Sometimes it would even be undesirable, in particular if an elementary problem situation were to be assigned a model function.

A context problem is not merely a dressed-up word problem, with its application subordinated to mathematics. Alongside the logical connection a phenomenological one by which mathematics becomes ancillary to the

real problem is possible. In this case reality counts first, and mathematics
is a mere derivative. Any context problem, whatever it may be, includes a
(subjective) variable aspect which can elicit a realistic reconsideration or
motivation as soon as the answer is translated back to reality.
Context problems fulfil several functions, to wit:
- concept formation: at the onset of the course they offer the pupils
natural and motivating access to mathematics;
- model formation: they support the learning of formal operations,
procedures, notations, rules, together with providing other material
and visual models which fulfil an important support function for
thinking;
- applicability: they uncover reality as source and domain of application;
- training specific arithmetic abilities in applied situations.
Take, for instance, division: an elementary division problem can be the
start for learning long division. Conversely, it can be chosen as a concrete
base for a bare division problem or for understanding a specific property
of division. In both cases the context conveys significance in such a way
that the procedure and the operation will in the long run become
meaningful within the formal system. Moreover, such a division problem
can function as an application of tables learned previously or of long
division procedures, as well as an exercise in the applied situation of
money arithmetic. In brief, context problems function both horizontally
and vertically. On the one hand they serve to make mathematical knowledge and abilities applicable, and on the other hand they impart meaning
to formal operations. The urgent need for the latter function is witnessed
by the test scores of two division problems taken from a National Assessment research (NAEP; 1980):
- 6 /608 . . . was correctly answered by 69% and 65% of the 13 and
17 years olds, respectively;
- the problem 'Zé children, four per car; how many cars are needed?'
was correctly answered by no more than 3% of the nine years olds

(handheld calculators were allowed); 12% chose for the answer 6.5
and 7% for 65 cars.
20
Whitney's comment on the result:
These examples furnish further evidence that, right through the elementary schoolyears, the
attitude that 'schoolmath is something for itself, not for life outside school' is becoming
entrenched.
21
Children evidently do not always imagine a situation in connection with
the bare arithmetic problem (608 7 6) as, for instance, that of distributing
6 dollars and 8 cents among six persons. Conversely, m a realistic
transport situation they do not know what to do with a 'bare' answer (6.5).
In fact, a vast phenomenological exploration is not a luxury one_ can
dispense with but, on the contrary, is a sheer necessity. This necessrt.r. is
shunned by the formal, seemingly logical approach, devoid of any meamng
and leading to a kind of mathematics detached from and isolated m
reality. The phenomenological approach, on the contrary, does lustice to
all phenomena in which the mathematical concepts and structures under
consideration reveal themselves.
It would take us too far afield to sum up how-many-sided embedding in
the spirit of Freudenthal's didactical phenomenology of mathematical
structures takes pface in each particular theme and course of those we
displayed above and what, among others, Sawyer, Vergnaud, Hilton,
Winter have contributed to it. We only mention the broad embeddmg of:
- ratio with a reference to 'Gulliver' (Chapter I) and to the description
in the Mathematical Material for the present chapter: geometric
aspects, drawings, puzzles, stick-shadow, mixtures, densities, scale,
percentages, ...
- combinatoric problems (Chapter II): roads, tree diagrams, clothmg
combinations colouring, lattice, probability, . . . ;
- division (Ch-pter VI); extensively discussed in the preceding and
present chapter; .
- fractions described extensively in the present chapter: breakmg,
dividing,' distributing fairly, measuring, ratios, probability;
- many more examples of a many-sided approach in the other courses
sketched in the Mathematical Material for this chapter.
However rather than restricting our attention to the form, contents and
functions' of the particular context problems belonging to a certain teaching subject, we shall also consider them in their totality. _An important
criterion is completeness, in other words, whether the vanety of mathematical phenomena in the real world is sufficiently expressed .. In particular, problem situations should be viewed which, thanks to then mherent 50 CHAPTER II
The number of routes from a to bis 15, b to c is 3. The total number of
routes from a to c is 15 X 3 = 45. The difficulty with this problem lies in
the modeling, which means, in this case, taking goals as being "moves".
The problem is then replaced by an isomorphic problem, for which the
solution is partially known, in so far as it concerns the separate consideration of the goals in each half of the game.
Then the product rule from section 1.2 must be 'seized' with the
network. All in all this is quite a job. The mathematicians among the
readers have a different model at their disposal. This is a model from
probability, which gives: "Before half-time six goals were scored, two for
Heereveen, the possibilities for the score progression are (I) = 15: after
half-time GJ = 3: the total number (I). (I) = 45.
But even this reasoning is not as automatic as it looks. And why not?
Because, in any case, It must be discovered that the progress of the score
before half-time (4-2) - as far as the possibilities for the sequence are
concerned - is similar to the manner in which two marbles of the same
size can be placed in a row of six holes. And . . . that there is a formula to
fit this: (j), to be pronounced as "two out of six", meaning: (6 X 5)/
(1 x 2) = 15.
Another question is how to find such a formula. It is a fact that
knowing a formula does not imply its use in situations in which it can be
applied.
1.10 Families
Acting on the assumption that the chance per family of a boy being born is
as great as the chance for a girl, indicate the boy-girl situations that can be
expected in a sample of 160,000 families with four children. For example:
20, 000 families with four boys, 30, 000 families with three boys and one girl,
etc. Explain the answer!
The road highway network can also be used here. The boy/girl ratio
can be seen as the end of one route on the network:

Each of the 160,000 families is asked to follow one of the routes. The
route cannot be read from the destination - with the exceptI0n of the
extremes. i i 'th th e boys
For example, there are four possible routes for a fam y Wl. re .
and one girl (the first, second, third or fourth child can be a gu:. therefore.
four possbilities). .
The total distribution IS:
- one possible route for four boys; . .
- four possible routes for three boys and on.e glfl,
- six possible routes for two boys and two gu!s; .
- four possible routes for one boy and three girls,
_ one possible route for four girls.
_ Total: 16 possible routes.
From this it follows that:
- There is a chance of 1/16 for four boys; .
- there is chance of 4/16 for three boys and one glfl;
- there is a chance of 6/16 for two boys and two g1rls;
- there is a chance of 4/16 for one boy and three girls;
_ there is a chance of 1/16 for four girls;
To inte ret this calculation we have used the law .of large numbers.

;;i::::c-b-ms e:c!unt:i:;ed in mathematising can, depending on the level
. . e ac v1ty t es place, be very different. Sometimes it will be
difficult to detect the mathematical aspect of a problem as in th f
the family problem, where it is essential to fit the -roblem --tset-
network of the route problem. On another occasion it would be h-d t-

generalise using a specific case and to apply the discovered rules to
another problem, as occurred in the complicated "to and fro" problem.
It is also possible that the difficulty will l!e in detecting essential
similarities between a series of problems or of fundamental elements
within one problem, thus finding underlying structures at a greater depth.
It is a case of raising the level, which allows the original problem to be
seen differently.
This ever-progressing process of expansion and raising of the level is
essential for the mathematical activity; new problem areas are explored
and old areas are considered from a different point of view. Thus it can
happen that lower levels are used as an algorithmic basis for higher levels,
as has happened with the intersection-grid. It is also possible that initial
problem.s become the model for the solution of new problems.
We have given a short characterisation of mathematising. It will
however be apparent that rather than starting autonomously, this mathematisation process must be prompted and supported through didactical

action.
2. ACTING DIDACTICALLY
This sub-section gives a description of a mathematics lesson and a
reflection on it from the didactical point of view.
What was stated previously about mathematising is once more illustrated here by using a concrete piece of mathematics instruction. Where
previously the emphasis lay entirely on the learning aspect, now the
teaching aspect is also taken into consideration.
It will become clear how the teacher initiates and stimulates the
learning process, thus generating a learning process that has certain
specific traits.
2.1 A Mathematics Lesson
The problem treated in the mathematics lesson reads: A person travels
from a to c via b daily, taking what he considers to be the shortest route.
One day he decides that he will take a different "shortest" route abc. How
many times will he be able to change his route?
We will describe the most important moments of the lesson as it was
given to two sixth graders - Jolanda and Tineke. Neither girl had
encountered a combinatorial problem before.
8 238 MATHEMATICAL MATERIAL VII
metry, because of the motivating force of the problems arising in perceived
reality - this, at any rate, is the experience of Wiskobas.
For the sake of completeness and as a finishing touch to this short
description of the Wiskobas programme we repeat the question asked at
the end of the introduction in an adapted form:
I> Please check how the didactical characteristics of Wiskobas as outlined
in the introduction are globally expressed in the preceding description of
the six subject matter areas.
In the following basic text the specific question, as well as the general
one we have just asked, is placed in a framework for instruction theory.
CHAPTER VII
FRAMEWORK FOR INSTRUCTION THEORY
Wiskobas Viewed Three-dimensionally and Seen from the Outside
1. PREAMBLE
In the first chapter we distinguished four trends in mathematics education,
to wit the mechanistic (arithmetic), empiricist, structuralist and the realistic, represented by Wiskobas.
The fundamental ideas of these trends are to be c9nsidered as frameworks for instruction theory, embracing the basic views on mathematics
instruction, determining the architecture of the various courses, and
directing the didactical activity.
In what follows the framework for instruction theory, in particular
of the realistic trend, is described. We start with the global starting
points. Then we sketch the main lines of this framework in general terms,
that is paying no attention to the six subject matter areas described
above. Following our former terminology . ThiS .. is appropriately called a
one-dimensional description. The two-dimensional description shows the
impact of the general theory on the character of various courses as
concretised globally in textbook series. With the three-dimensional description we place ourselves on the level of the concrete instructional practice.
Throughout we use the examples of instruction and course descriptions
from preceding chapters of the book.
Finally, we discuss the place of the prevailing cognitive-psychological
theories with respect to the instruction theory of progressive mathematisation outlined here.
As emphasised before, the following description of such a theory also
serves to clarify the third dimension of the goal description, that is, in a
broader sense, the teaching/learning component. Indeed since we earlier
asserted that the instruction goals are, or can be, comprised in the
teaching/learning process itself, it would seem useful also to explore the
content-related characteristics of the teaching/learning process in the
Wiskobas curriculum, after the sketch of the formal characteristics in
Chapter II. Tiris turn to a more content-oriented and systematic description is now possible thanks to the solid foundation of concrete examples
and considerations which has in the meanwhile been laid down in this
study and on which the following description can be based. Tiris a
posteriori description of a theoretic framework reflects the historic process; indeed, only after the curriculum development had for the greater
part been completed were we able to discover the theoretical- patterns of
239 240 CHAPTER VII
the development and actualisation of instruction behind the three-dimensional goal descriptions.
1.1 Starting Points of a Realistic Instruction Theory
The starting points of a theory of realistic mathematics education can be
seen most clearly when placed against the background of the structuralist
viewpoint.
In 1962 a group of 7 5 prominent mathematicians from the USA
and Canada published a memorandum in 'The Mathematics Teacher',
directed against the oncoming movement of the so-called 'Modern mathematics education' of structuralist character. A few fragments from this
memorandum:
To know mathematics means to be able to do mathematics: to use mathematical
language with some fluency, to do problems, to criticize arguments, to find proofs, and
what may be the most important activity, to recognize a mathematical concept in, or to
extract it from, a given concrete situation.
Therefore, to introduce-new concepts without a sufficient background of concrete facts,
to introduce unifying concepts where there is no experience to unify, or to harp on the
introduced concepts without concrete applications which would challenge the students, is
worse than useless: premature formalization may lead to sterility; premature introduction
of abstractions meets resistance especially from critical minds who before accepting wish to
know why it is relevant and how it could be used . . .
. . . There are several levels of rigor. The student himself should learn to appreciate, to
find and to criticize proofs on the level corresponding to his experience and background. If
pushed prematurely to a too formal level he may be discouraged and disgusted . . .
. . . the best way to guide the mental development of the individual is to let him retrace
the mental development of the race - retrace its great lines, of course, and not the
thousand errors of detail . . .
. . . Of course, not all mathematicians have the same taste. Mathematics has many
aspects. It can be regarded as an instrument to understand the world around us: mathematics presumably possessed this value for Archimedes and Newton. Mathematics can also
be regarded as a game with arbitrary rules where the principal consideration is to stick to
the rules of the game: some such views may be considered suitable for certain problems of
foundations. There are several other aspects of mathematics and a professional mathematician may favor anyone. Yet when it comes to teaching, the choice is not a mere matter
of taste. We may expect that the intelligent youngste-r wants to explore the world around
him, but we cannot expect him to learn arbitrary rules: why just these and not others?
1
Here are Polya, Sawyer, Pollak, Courant, and many others.
Was there at that time unanimity among prominent mathematicians?
Within one year after this appeal for realism the first volume of Papy's
spectacular 'Mathematique moderne' appeared - the structuralist wave
proved irresistible.
2
But the opposition of prominent mathematicians continued.
Thom turned against formalism, premature introduction and, in particular, pleaded with much passion for geometry instruction.
3
FRAMEWORK FOR INSTRUCTION THEORY 241
Whitney stressed the need for meaningful instruction, full of motivating
tasks bound to reality, as opposed to the stiff formalistic problems in
actual education. Moreover, he asked for selfrestraint from the teacher
when explaining things: the children should selfreliantly move towards
concept attainment.
4
Hilton equally stressed the crucial significance of long lasting learning
processes and the patience needed to abstain from pushing too hastily to
too high a formal level.
5
The learning process can only be continued as
long as, again and again, it is started from a concrete basis: there must be
some underlying matter to be abstracted from, to be generalised, to be
unified. At the same time he stipulated the importance for teachers,
counsellors, developers and researchers of doing their own mathematics in
order to avoid losing contact with mathematical activity.
Lakatos turned vehemently against a dogmatic mathematics of eternal
and unimpeachable truth, where quest, failure and adventure are suffocated.6 In his view textbooks should be rewritten in order to exhibit the
growth of discovery. Heuristically organised instruction need not necessarily follow the precise course of the historical emergence of the concepts
under consideration; it comes about by a rational reconstruction of the
process of their coming into being, and then keeping the learner in mind
- that is globally Lakatos' course of thought.
In the same sense Freude"nthal judged that 'one should recognise that
the learner is entitled to recapitulate in a fashion the learning process of
mankind.
7
This entails instruction not starting with the formal system,
which in fact is a final product, nor with embodiments (materialisations of
structures) nor with structural games. On the contrary, the phenomena by
which the concepts appear in reality should be the source of concept
formation. These actual phenomena elicit, as it were, the mathematical
structuring - this was the way it happened in history and so it should
happen in education too, according to Freudenthal. This so-called principle of reinvention in his course of thought is strongly associated with the
levels distinguished by Van Hiele in the learning process of the individual
and of mankind, to be dealt with later on.
Overall the global starting points of realistically oriented mathematics
education can be summarised as follows, in accordance \Vith the earlier
mentioned formal starting points in Chapter IT:
- paying much attention to 're-invention', that is recreating mathematical concepts and structures on the basis of intuitive notions in
the making or made (active),
- carrying on at various levels of concreteness and abstraction ('differentiated'),
- the programming of the instruction is guided by the historical-genetic
:1
I
I 242 CHAPTER VII
rather than the subject matter systematic method ('vertically
planned'),
- reality bound, meaningful ('and mathematically rich') instruction.
Stating these principles localises them globally within the framework of
instruction theory without, however, imposing a sharper outline. This will
be done later on by one-, two- and three-dimensional descriptions.
2. ONE-DIMENSIONAL DESCRIPTION OF THE FRAMEWORK
FOR INSTRUCTION THEORY
We shall start by describing the levels distinguished by Van Hiele in
the learning process. Then we shall sketch Freudenthal's didactical phenomenology. Subsequently we will show how the theoretical construct of
the gradual progressive mathematisation can be fitted into that broader
connection of the level theory. And, finally, we shall view the onedimensional theoretic framework of realistic mathematics instruction
against the background of the three other trends of mathematics instruction mentioned above.
Strictly speaking we will be concerned with realistic mathematics
instruction as actualised by Wiskobas, viewed a posteriori. In fact when
that project of educational development was started, its theoretical conception could only be made visible by paradigms of teaching/learning
units. All the time the theory was still implicit in the action, that is, in the
creation of instruction. Gradually the produced instruction became a
matter of discussion. Communicating within and reflecting upon the
concrete activity of educational development required developing an
appropriate didactical language. Only as the work went on could a
theoretic framework be constructed, into which the well-known Van Hiele
levels could be fitted in and reinterpreted. One may even assert that,
until recently, the level theory in our interpretation had not played an
explicit role for the group. By this feature the progress of the Wiskobas
work in three phases reflects exactly the learning process on three levels
such as described by Van Hie le.
2.1 Van Hiele's Levels
As an analogy to the learning process of the Wiskobas group alluded to
above, here is a quote concerning that of the Van Hieles:
'When the Van Hieles started teaching they were just as unprepared as many other young
teachers; nobody had told them how to do it. Of course they had passively undergone
teaching, may be even observed their teachers' performing, but this was not enough. As
time went on, they got the opportunity of discussing their teaching with each other and
with others. They subjected their own actions to reflection. They observed themselves
FRAMEWORK FOR INSTRUCTION THEORY
243
-hen teaching, recalled what they had done, and analysed it. Thinking is continued acting,
mdeed, but there are relative levels. At the higher level the acting of the lower becomes an
object of analysis. This is what the Van Hiele s recognized as a remarkable feature of
the learning process, namely of that in which they learned teaching. They transfered this
feature to the learning process of pupils who were learning mathematics. There they
discovered similar levels.'
8
In the Dutch literature levels of didactical activity are sometimes described
as follows:
- didaxis, the level where thinking is still embedded in didactical
activity;
- didactics, where acting is subjected to discussion and objectivation
though in a still incoherent and inconsistent language;
- didaxology, where acting didactically is viewed in the framework of a
coherent theory based on research results.
Van Hiele distinguishes similar levels in the process of learning mathematics, which, to point out the analogy, could be called mathemataxis,
mathematics, mathemaxology.9
According to this view learning proceeds
through these levels, whose order is respected in instruction - the level
theory is therefore both descriptive and prescriptive. The order interpreted by Piaget as levels of development according to Van Hiele rather
_represents phases in a learning pn;tcess that can manifest itself at every age
and every level.
What do the levels look like, and what are their characteristic features?
Each level has its specific organisation of thinking matter. At each level

the objects of mathematical thought represent different things. At the first
level, in the primary grades for instance, they are embedded in operations
with material, observable objects such as concrete quantities of numbers
of things, measuring numbers, visible models and figures. At the second
level, relations between numbers and figures are the object of investigation. The result of this exploration is that numbers and figures symbolise
properties. In other words, a certain organisation applies in the network of
relations. At the third level, the relations themselves are objects of thinking: the character of relations and the connection between properties are
settled, which makes it possible to derive them from each other. The
organisation now fits into a logical and connected system.
The bonds between the various levels across different courses are fairly
complex. So the third level of the arithmetic system represents the concrete basis for the first level in algebra instruction, and the third level of
'fractions' is the basis for 'probability', according to Van Hiele.
In general he asserts that true learning on a higher level is not feasible
as long as the learning process at the lower level has not, or not sufficiently, been completed. More specifically: traditional arithmetic instruction is insufficient and ineffective because it almost always starts at the
I
I
I 244
CHAPTER VII
third, the formal level. The symbols used refer insufficiently to first level
notions, for the simple reason that these notions have not been developed
to a degree that the connection can be made. The signal character of the
symbols is too weak, they do not refer to concrete (mental) objects, they
represent nothing, they are properly said to be no symbols at all, and at
that moment they don't allow the pupil to profit from the system of formal
rules according to which they are operated on. As Hofstadter would say,
there is a lack of active as well as of passive 'meaning'.
10
One cannot even
raise the question of real formal significance - it is merely formalism and
verbalism.
Compared with the traditional manner, instruction according to Van
Hiele goes in just the opposite direction. Instead of starting with formal
operations at the second, or even third level, and trying to apply the
matter learned in appropriate first level situations, one starts at the first
level with the phenomenological exploration of the manifestations of
mathematical concepts and structures, in order to continue with formal
operations on the second level, and subsequently on the third. Essentially
it is the same teaching/learning process by reflection and recursion, as
typified by Kilpatrick.11 The lower level is the basis of the higher; the
(mental) actions on the lower level become thinking matter at the higher
one.
In order to rise from one level to the next, the pupils pass through five
phases, to wit: information, constrained exploration, explicitation, free
orientation, integration. Still in brief, this means:
- getting acquainted with the subject;
- getting in touch with the relevant structured elements by means of
tasks;
- developing appropriate linguistic means for the field under consideration in order to describe and verbalise relations and structures;
- free e;ploration of the total field in question by using the now
available means of organisation;
- and, finally, condensing the learned matter and fitting it into the total
inventory of knowledge, abilities and insight.
Ths:se are briefly, and in rather general terms, the levels and phases of the
learning process distinguished by Van Hiele.
Let us now, even more briefly, indicate what we appreciate as valuable
and stimulating in Van Hiele's conception as well as point out instances of
incompleteness and imperfectness - in particular from the viewpoint of
educational development as carried out in the Wiskobas project.
To start with, let us say that, in our view, the levels distinguished by
Van Hiele in the macro learning process, that is, viewed in the long term,
are still of great value for learning and teaching mathematics as well as
FRAMEWORK FOR INSTRUCTION THEORY
245
other subjects. If we restrict ourselves to mathematics, we may state that
Van Hiele's triad is well founded in the developmental and learning
process with respect to various subjects. This, then, is the reason why we
have decided to integrate it into our theoretical framework. And, anticipating the last part of this chapter, we venture to state that, bearing in
mind the most recent theoretical developments and research data, the
level theory is now even more topical than it has ever been since its first
publication in 1957.
12
It should, however, be pointed out that there are no strict criteria for
delimiting macro-levels independent of the contents (concepts, structures,
and so on). In short, more often than not there is no way to exactly
diagnose whether an actual teaching/learning process takes place on the
third level - that is, of the systematics of subject matter - or on the"
descriptive second level or the intuitive first one: there are no sharp
delimitations, and we will soon show why not. As a heuristic tool,
however, the principle oflevel structure applies fairly well.
On the other hand, one should say that the vulnerable spots in the
materialisation of the three levels in the teaching/learning process as
envisaged by Van Hiele can now also be more sharply identified than in
the past. At the time when Van Hiele launched his level theory, the
contents of mathematics education were constantly under discussion. At
any rate, there was no questipn at that time of mathematics-for-all, or
mathematics in primary school, mathematics for slow secondary school
students or - to stay close to the work of the Van Hieles in those days -
of geometry instruction in primary school. The question, in fact, of what
mathematics-for-all should mean and comprise was not under discussion
in those days. Therefore, when at the end of the sixties the question
became topical in the so-called modernisation of mathematics education,
this obstacle was bypassed in Dutch secondary education (and elsewhere)
by focussing primarily on new subject matter. In primary education,
however, Wiskobas could not avoid the central question. In other words,
with regard to primary education the development was not forced into an
- even somewhat loose - structuralist straitjacket. It gradually became
clear that we could not find in Van Hiele's level theory and its concretisation in his textbooks a ready answer to the following two questions:
1. How to shape concretely the phenomenological exploration at the
first level?
2. Which didactical acts should be performed to raise the pupils as
efficiently as possible from one level to the next?
Or, condensed into one question: What really is mathematics-for-all and
how should mathematics education essentially be structured?
These questions will be discussed in the following subsection. First via
Freudenthal's didactical phenomenology and then in the light of the
I
I 246
CHAPTER VII
concrete work of Wiskobas in which, for that matter, Freudenthal has
been strongly involved.
2.2 Freudenthal's Didactical Phenomenology
Freudenthal set out his didactical phenomenology with regard to Dienes'
structuralist procedure as follows:
In opposition to concept attainment by concrete embodiments I have placed the constitu-
ti on of mental objects based on phenomenology . . . .
What a didactical phenomenology can do is to prepare the converse approach: starting
from those phenomena that beg to be organised and from that starting point teaching the
learner to manipulate these means of organising. Didactical phenomenology is to be called
in to develop plans to realise such an approach. In the didactical phenomenology of length,
number, and so on, the phenomena organised by length, number and so on, are displayed
as broadly as possible. In order to teach groups, rather than starting from the group
concept and looking around for material that concretise this concept, one shall look first
for phenomena that might compel the learner to constitute the mental object that is being
mathematised by the group concept. If at a given age such phenomena are not available,
one gives up the - useless - attempts to instill the group concept.
For this converse approach I have avoided the term concept attainment intentionally.
Instead I speak of the constitution of mental objects, which in my view precedes concept
attainment and which can be highly effective even if it is not followed by concept
attainment.
13
Such a didactical phenomenology is of course not new. On the contrary it
is as old as instruction itself. Even the most mechanistic arithmetic instruction uses it when looking for appropriate applications. Even there subtraction, for instance, is not restricted to merely removing a part of a
quantity from a whole, nor does applied division appear only as fair
sharing of a quantity among a number of persons.
The novelty in the realistic conception is that reality does not only
function in applications but also serves as a source of concept formation,
that is, in order to first develop intuitive notions, or in Freudenthal's
terminology, to constitute mental objects. The emphasis is on laying a
solid basis for learning rather than only on a posteriori applications at the
end of the learning process. By this peculiarity more weight is placed on
this didactical phenomenology in the realistic approach than in the nonrealistic ones. For the same reason, the demands made on phenomenological analyses are higher. One is obliged to pay attention to the subtleties
required for the functioning of learning processes in which mental objects
or intuitive notions are formed - subtleties which we are not usually
conscious of, due to the simple fact that we ourselves have far outgrown
the first level of the mathematical concept under consideration or, conversely, because we have never discovered the wealth of the related
mathematical structures. In brief, we need knowledge of mathematics as a
phenomenon of phenomena, where mathematics is understood as a human
FRAMEWORK FOR INSTRUCTION THEORY
247
activity, tied to reality: mathematics-for-all. This phenomenological orientation answers the first question posed with regard to Van Hiele's level
system. The didactical credo of Freudenthal's realistic approach is: put the
pupils in touch with the phenomena for which the mathematical structure
is the organising tool in order to let them shape these tools themselves in a
process of re-invention, and learn to handle and use these mathematical
organising tools in concept formation.
Freudenthal does not, to be sure, distinguish levels in the learning
process which are attained by reflection and recursion in the same way as
Van Hiele. In his view, however, there is no rigid tripartition but rather an,
in principle, unrestricted progression according to micro-levels which are
only relatively delimited against each other. This is a view to which we
subscribe too in the 'progressive mathematising' to be discussed later on.
Besides, we also support the macro-structuring according to Van Hiele's
levels which is in fact an adequate tool for describing the rough structure
of instructional courses. In particular, it is of fundamental importance to
distinguish between the level of subject matter systematics and, on the
lower levels, between an intuitive phenomenological level and a locallydescriptive one.
The desire to have reality function as a source of mathematising
together with the structuring acc;ording to micro-levels by reflection and
recursion processes, as well aS according to Van Hiele's macro levels,
gives the first outline of our framework for instruction theory.
In order to give an overall answer to the second central question 'How
does the teaching/learning process proceed from one level to the next?',
we will first look at the concept of mathematising and will then describe
the kind of instruction devised by Wiskobas in this respect.
2.3 Progressive Mathematising Guided by the Five Instruction Principles
Chapter I I described mathematising as the organising and structuring
activity in which acquired knowledge and abilities are called upon in order
to discover still unknown regularities, connections, structures. We distinguish horizantal and vertical mathematisation in order to account for
the difference between transforming a problem field into a mathematical
problem on the one hand, and processing within the mathematical system
on the other hand. In the horizontal component the way towards mathematics is paved via model formation, schematising, symbolising. The
vertical sketch is concerned with mathematical processing and level raising
in the structuring of the problem field under consideration. We admit that
this distinction between horizontal and vertical components is a bit
artificial given the fact that they may be strongly interrelated.
Progressive mathematising, both horizontally and vertically, as under-
stood by Wiskobas, is inspired by five educational tenets which are 248
CHAPTER VII
logically related to the realistic starting point of the level theory and the
didactical phenomenology. .
Jn brief, and leaving aside the subject matter, they are the followmg:
1. phenomenological exploration . .
In the first instructional phase of a relatively new sub3ect an extensive phenomenological exploration is undertaken. The mathematical
activities take place within a concrete context. The real phenomena
in which the concepts and structures under consideration manifest
themselves are explored as multifariously as possible. The aim is _to
acquire a rich collection of intuitive notions in which the essential
aspects of concepts and structures are preformed. This, then, is
laying the basis for concept formation.
2. bridging by vertical instruments .
From the very start, in elementary problem situations, a vanety of
'vertical' instruments such as models, schemas, diagrams and symbols
are offered, explored and developed. This is done with the i_ntention
of helping to bridge the level difference between the mtm!ive,
informal context bound operating at the first level and the reflective,
formal s-stematic one on the third. In conformity with the theoretical
construct of gradually progressive mathematisation this is more a
step-by-step progress rather than a single jump from one level to
another. This means that from the start more formal elements may
be involved in the learning process, although they take place 'locally',
that is are bound to specific cases and within a concrete reference
frame.' In other words, horizontal exploration is not free of vertical

features in the teaching/learning process, as illustrated by the following picture:
level 3
I
I
level 2
I
.
I level 1
This sketch intends to show that, besides the macro-levels in the
learning process within a certain course, one can distinguish finer
FRAMEWORK FOR INSTRUCTION THEORY
249
meshes and a stepwise structure of mathematising at the micro-level.
Paradigmatic context problems, models, schemas, diagrams and
symbols are the vehicles of progressive mathematisation. On the one
hand the sum of horizontal components in the above sketch represents the variety of real situations in which the concept under
consideration may manifest itself, and the abundance of notions
required for concept formation. On the other hand, the sum of the
vertical components represents the more formal, subject-areaoriented systematic knowledge and abilities acquired in the learning
process. Admittedly, this schematising of the process of mathematising is a bit artificial: the passage from one mental level to the next is
not a neat lattice path but rather a patch-work of paths, if not a
labyrinth, although one where the teacher, knowing the right path,
can help the pupils to find their way up to the top.
3. selfreliance: pupils' own constructions and productions
Nonetheless, the trip should be made by the pupil on his own two
legs, which means that a decisive influences comes from the pupils'
own constructions and productions in the learning process. The
individual contributions can in general always be seen in the differentiated production procedures used: solving problems on various
micro-levels as well i)S producing their own ideas with respect to free
tasks and problems within the subject matter area under consideration. In both cases the pupil indicates by bis activity at each moment
his location in the learning field and his progress in the process of
mathematising. This provides the teacher as well as the learner
himself with knowledge about the course of the learning process. In
brief, in this view, the constructive element, although often stressed,
is more than a credo, a nebulous thought, an elusive principle. It is
clearly distinguishable in the pupils' own constructions and productions; it is visible in the concrete work presented by the pupils.
4. interactivity
This means that the pupils are also confronted with the constructions
and productions of their fellows, which can stimulate them to
shorten their learning path, to help themselves up on the procedures
of others, to become aware of the drawbacks or advantages of their
own productions, and that copying others' work slavishly will not
aid their own progress. In brief, the learning process is part of
interactive instruction where individual work is combined with consulting fellow students, group discussion, collective work reviews,
presentation of one's own productions, evaluation of various contructions on various levels and explanation by the teacher.
5. intertwining
However, when outlining a course one should be fully aware of the
I 250
CHAPTER Vii
global connection of the various domains, the intertwining of learning strands. This involves preconditions for the possibilities of
progressive mathematisation which lie to a certain extent outside the
course under consideration. Such conditions can include skills and
algorithms, as well as aspects of insight.
These then are the five general principles to be generally observed with
the intention of making the transition from one level to the next in the
progress of mathematising according to Wiskobas. The progress is realised
by reflection and recursion, by a cyclic process of phenomenological
exploration and mathematical structuring, by a stepwise articulation of the
teaching/learning process.
At the first approach, context problems are elementary but nevertheless
paradigmatic, which means that they function as forceful mental models.
Or, in the terminology of mathematisation: they possess a strong vertical
potential, they lend actual significance to more abstract models and to
symbols, while as context problems their horizontal range is broad
because they represent a broad domain of real phenomena, which may
emerge as applications. The pupil's own contribution to the learning
process is an essential factor. The cognitive intertwining of learning
strands, which may be relatively separated from the viewpoint of subject
oriented systematics, is accounted for. And finally, this view on and theory
of the process of mathematising implies interactive instruction.
This ends the abstract one-dimensional description of the tenets of
instruction theory connected to Van Hiele's level theory and Freudenthal's
phenomenology. We were able to risk making the exposition in general
terms because the concrete basis of orientation had been laid in advance
- a precaution taken in order not to sin conspicuously against the
principles of phenomenological theory adhered to. In fact, this theoretical
framework will be given a more concrete filling as soon as we proceed to
the two- and three-dimensional descriptions. But before tackling these, let
us cast a glance at the three other instruction theory trends, indicated
above.
2.4 Schematic Comparison of the Four Trends in Arithmetic/Mathematics
Instruction
At the close of this section we venture to pose the question: How is the
instruction theory construct of progressive mathematisation related to the
instruction theory conceptions of the three other trends of arithmetic/
mathematics instruction?
Well, mathematising with its horizontal and vertical aspects is shaped
according to the four trends as follows:
FRAMEWORK FOR JNSTRUCTION THEORY
Frameworks for instruction theory
Mathematising
Realistic
Structuralist
Empiricist
Mechanistic
horiz vert
+ +
+
+
251
In realistic mathematics instruction careful attention is paid to both the
horizontal and the vertical component of mathematising. This means that
the phenomena from which the mathematical concepts and structures arise
are implicitly used both as source and domain of application. This,
according to the tenet of the theory, creates for the learner the possibility
of concept attainment by orienting himself to a variety of phenomena,
which benefits the building of formal mathematical concepts and structures and their application. Mathematising proceeds step by step. A
number of specific micro-levels can be distinguished whi.ch, considered
over a larger domain and in the long run, are gathered into the three Van
Hiele levels.
In structuralist instruction, organised by subject-oriented systematics,
the vertical component is dominant: operating within the mathematical
system is the principal part of the mathematical activity. The horizontal
component manifests itself only in an a posteriori application of what was
learned before within the formal system, and then only in a restricted way.
As a consequence, the real phenomena do not and cannot function as
models to support operating within the mathematical system. Instead of
the real phenomena, one uses embodiments and materialisations of mathematical concepts and structures (see Chapter I) or structural games in
order to create a concrete basis of orientation. There is, indeed, a structuring according to levels, although mainly by means of vertical connections in the sense of Bruner's 'modes of representation', 'enactive, iconic,
symbolic', which we will reconsider later on.
Following the empiricist trend, the horizontal component predominantly determines the course of instruction. This is already clear from
the brief characterisation in Chapter I . There is relatively little pressure to
pass from the first to the second level. Or, as Morley says: the emphasis is
on environmental rather than on mental operations.
14
Empiricist instruction cares little about formal mathematical goals. Many ideas are taken
from Piaget's psychology. Maturing of cognitive opportunities in a stimulating environment is preferred to consciously aiming at higher levels of
thought by offering paradigms, schemas, models and symbols as 'cultural
amplifiers'.
To end, the mechanistic approach is characterised by weakness of both
ti
i ! 252 CHAPTER VII
the horizontal and the vertical component: no real phenomenon as a
source, little attention paid to applications, much emphasis on blind
memorising and automating of numerical facts and acts, no use for insight
in the operations of the formal system. A moderate form of this approach
is based on Gagn6's cumulative learning theory, but stricter forms most
often lean on behaviouristic principles. In instructional practice the
mechanistic approach promotes 'individually prescribed instruction', that
is the cultivation of solitary formal calculations. The subject matter is
offered in such an atomised and fragmented way that the pupils master the
petty instructional goals step by step under their own steam. Sometimes
this method is called 'mastery learning' but this is a very narrow interpretation of mastery, compared with that described in the preceding
chapters.
In what follows we will have the opportunity to refine the somewhat
schematic picture of frameworks for instruction theory sketched above by
adding subject areas (themes, learning strands) to the picture.
3. TWO-DIMENSIONAL DESCRIPTION OF A FRAMEWORK
FOR INSTRUCTION THEORY
In this section we explain the framework for instruction theory by means
of examples of themes and partial courses taken from the Mathematical
Material of the preceding chapters and the present chapter.
We start with a description of the various levels in the teaching/learning
process of the most important courses. We continue with a description of
the five tenets which determine instruction according to progressive
mathematisation. Again, the present section is closed by a brief comparison of the four principal trends which can be distinguished in the
textbooks of arithmetic/mathematics instruction. The comparison, then,
will be guided by the five tenets.
3.1. Progressive Mathematisation in the Wiskobas Programme
In all six areas of the Wiskobas programme as described in the introduction to the present chapter, we can discover progressive mathematising
according to Van Hiele's macro-levels, as well as the phenomenological
foundation required. by Freudenthal.
We shall review the corresponding six courses while restricting ourselves to the phasing on macro-level.
Remarking generally on the six subject matter areas, it should be
observed that, in most cases, the pupils do not aim at the third Van Hiele
level of subject-matter oriented systematics. Numbers and figures, relations between them and structures around them do not, for the pupils,
FRAMEWORK FOR INSTRUCTION THEORY 253
reach the degree of concreteness needed for systematic operating and
reasoning. This is certainly true with regard to ratio and percentage,
common and decimal fractions, the metric system and geometry. For the
majority of the pupils concerned, only local organisation in the areas is
feasible and the application of the operations will not be developed in its
full breadth. The symbols have the character of signals of context-bound
situations, schemas and models, but they are not yet sufficiently detached
to be able to operate on them within the system with no reference at all to
the underlying concrete infrastructure. In short, in these cases the pupils
do not reach the instruction level that is chosen as the start of the
instruction in the mechanistic and structuralistic approaches, mostly after
a short 'concrete' introductory phase.
Thus far our characterisation has been 'negative', that is, in terms of
what pupils cannot do in the presystematic phases. We could however
also discuss in a positive sense, that is, as regards the applications they are
able to make and the essentially mathematical abilities they develop,
interpret meaningfully and apply, which are not attained if the starting
level is too high. This is so, at any rate, from the viewpoint of mathematics-for-all. After these general remarks on the macro-levels we will
now consider each particular subject area separately.
Basic abilities starts with a or~ad phenomenological exploration, followed
by schematising and structuring of calculating methods.
15
Even memorising is embedded in a process of progressive mathematising and the same
holds for the various forms of skillful reckoning. Many pupils, in the long
run, can operate at the 'pure' number level, discover properties, apply
them within the arithmetic system and recognise the basic operations in
various context situations, thus reaching the third level.
Column arithmetic offers the same picture that has been painted in detail
in Chapter VI. A number of pupils develop the standard algorithms, can
apply them broadly within the system of whole numbers, can use them in
context problems, and are able to make the algorithms themselves an
object of investigation.
Ratio activities start at the first level with qualitative and informal comparisons in mainly visually set problems and gradually pass into the stage
of more numerical and calculation strategies. The gap between is bridged
by all kinds of models. Finally, arithmetic processing becomes more and
more schematised, shortened and endowed with numerical precision, in
particular when dealing with percentages. It should be added, as said
before, that in primary school only a certain number of the pupils reach
the third Van Hiele level of more profound investigation of ratio, propor-
tion and percentage.
16
.I
.1
ii
! ! 254 CHAPTER VII

Fractions shows the same macro-feature of progressive mathematising: a
broad phenomenological exploration, a well-knit coupling with ratio and,
from the outset, a great deal of attention lo the qualitative comparison of
fractions as the result of fair sharing.17 All ways of symbolising ratio
situations and fractions results, as well as their descriptions, are extensively stimulated. Models and model situations are offered, the pupils' own
production on the symbolic level is stimulated while, on the other hand,
the focus is not directed to ready rules. It is a long way from the first to
the second level, which means that some pupils can hardly transcend the
stage of context-bound calculations with fractions, while others are able to
perform and even interpret and apply them meaningfully. Formal fractions
are not used as a subject of extended investigation into the rational
number system at the primary school.
Measuring passes from !lie context-bound, qualitative work to more
formal numerical precision. Areas, for instance, are compared in the
following sequence: on qualitative grounds, with the naked eye, by estimation, and by covering with and transforming of figures. This leads to
measuring, first with natural, then with standard units, which in the long
run are to be refined.18
Finally, formulas are used for the areas of
rectangles and then of half rectangles, that is right-angled triangles, other
triangles, and quadrilaterals. In the latter cases structures and patterns -
which on the second level lead to certain rules and formulas - become a
subject of investigation and are extended to other instances. LIkewise, the
relation between perimeter and area can be investigated at various levels.
The phenomenological exploration of area is started by connecting area to
other magnitudes, such as weight, price and so on.
Geometry is not begun in the traditional way, at the second level, by
introducing mathematical objects such as point, line, plane, plane figures,
the angles, angle measures, translations, rotations, reflections, but by
offering the natural phenomena of spatial perceptions as the starting point
of instruction.19 Geometrical notions are developed by looking, building,
experimenting and trying out, which are later supplemented by reasoning
and reckoning. It is not assumed that elementary geometrical entities such
as point, line and plane are mentally constituted, nor are they defined.
They arise from activities concerning light and shadow.
That describes progressive mathematisation as a general characteristic of
certain Wiskobas courses. Of course the principle extends to secondary
education, where it has been concretised in the Wiskivon work of IOWO
and then in the Hewet project of OW & OC and of SLO-projects
(Foundation for Curriculum Development). In the next subsection the five
instruction tenets that are to shape the overall process of mathematising
FRAMEWORK FOR INSTRUCTION THEORY 255
and mathematical instruction are made more precise with the intention of
relating them to the themes and courses sketched above.
3.2 The Five Tenets of the Framework for Instruction Theory Revisited
(1) Phenomenological exploration by means of contexts
With regard to form and function context problems is a broader conception than traditional word or text problems. A context problem looks like
a word problem, or may be embedded in a play, a game, described in a
story, offered as a press-cutting, represented by models and graphs, or as
a combmatton of such information resources. They can be part of themes
or proj-cts, _of ;"-ich the present study contains a variety of examples,
such as Gulliver', Roads problems', 'Grains on the Chessboard'.
As far as content is concerned, 'context' means:
a. that, in the case of an isolated, self-contained problem, one looks for
the 'surroundings' of the text or the presentation of the problem, in
other words, for that which is not explicitly formul<-)(ed or presented,
but does belong to the background assumptions;
b. that, in the case of a non-self-contained problem, one looks for the
surroundings explicitly evoked by the story, the theme, the location,
which, as a matter of fact, also carry their own background assumptions with them.
Thus with the context a (subjective!) variable element is introduced into
the problem, and this variable can be stronger or weaker depending on the
kmd of problem. For instance, in the problem of the fair sharing of 230
items among 10 persons, the variable is relatively weak, although the idea
of_ fairness is,. not necessarily unequivocal (among the 10 persons there
might be babies and adults). On the other hand, in the case of 234 items
to be shared among 10 persons the context may be more essential and it
will certainly be so as soon as the items are more precisely defined. The
context counts even more in a problem like 'our car does 1 O to the liter
(that is 1 liter of petrol for 10 kilometers); how much does it use during a
trip of 234 kmi'
In re.alistic mathematics instruction the pupils will certainly not have to
put then relevant knowledge and experience aside; on the contrary, they
will be. able to use them by noticing that the 10 is an average (driving on
the mam road 1s more economical than in the city unless one disregards
the 100 km/h limit) with the intention of arriving at a well-considered
answer. In _brief, we should be aware, at least at the first level of phenomenological exploratton, of the part played by the context in which the
problems are proposed - a part which may be subordinate as well as
principal. 256 CHAPTER VII
Regarding or disregarding certain context factors, which is the essence
of modeling the problem, 'is in fact a non-negligible part of the process of
mathematising. Of course, this does not mean that each problem should be
heavily contextually loaded or fitted into a larger thematic context. Sometimes it would even be undesirable, in particular if an elementary problem
situation were to be assigned a model function.
A context problem is not merely a dressed-up word problem, with its
application subordinated to mathematics. Alongside the logical connection
a phenomenological one by which mathematics becomes ancillary to the
real problem is possible. In this case reality counts first, and mathematics
is a mere derivative. Any context problem, whatever it may be, includes a
(subjective) variable aspect which can elicit a realistic reconsideration or
motivation as soon as the answer is translated back to reality.
Context problems fulfil several functions, to wit:
- concept formation: at the onset of the course they offer the pupils
natural and motivating access to mathematics;
- model formation: they support the learning of formal operations,
procedures, notations, rules, together with providing other material
and visual models which fulfil an important support function for
thinking;
- applicability: they uncover reality as source and domain of application;
- training specific arithmetic abilities in applied situations.
Take, for instance, division: an elementary division problem can be the
start for learning long division. Conversely, it can be chosen as a concrete
base for a bare division problem or for understanding a specific property
of division. In both cases the context conveys significance in such a way
that the procedure and the operation will in the long run become
meaningful within the formal system. Moreover, such a division problem
can function as an application of tables learned previously or of long
division procedures, as well as an exercise in the applied situation of
money arithmetic. In brief, context problems function both horizontally
and vertically. On the one hand they serve to make mathematical knowledge and abilities applicable, and on the other hand they impart meaning
to formal operations. The urgent need for the latter function is witnessed
by the test scores of two division problems taken from a National Assessment research (NAEF; 1980):
- 6 /608 . . . was correctly answered by 69% and 65% of the 13 and
1 7 years olds, respectively;
- the problem '26 children, four per car; how many cars are needed?
was correctly answered by no more than 3% of the nine years olds
FRAMEWORK FOR INSTRUCTION THEORY
257
(handheld calculators were allowed); 12% chose for the answer 6 .5
and 7% for 65 cars.
20
Whitney's comment on the result:
These examples furnish further evidence that, right through_the ele-entary sc--olye-rs, -he
attitude that 'schoolmath is something for itself, not for hfe outside school is beco011ng
entrenched.
21
Children evidently do not always imagine a situation in connectio.n with
the bare arithmetic problem (608 -7 6) as, for instance, that of distnbutmg
6 dollars and 8 cents among six persons. Conversely, .m a realistic
transport situation they do not know what to do with a 'bare' answer (6.5).
In fact, a vast phenomenological exploratt0n is not a luxury one. ca.n
d
. th but on the contrary is a sheer necessity. This necessity is
ispense w1 , , . .
shunned by the formal, seemingly logical approach, devmd of any meamng
d 1 d
. to a kind of mathematics detached from and isolated m
an ea ing . .
reality. The phenomenological approach, on the contrary, does 1us!ice to
all phenomena in which the mathematical concepts and structures under
consideration reveal themselves. . . .
It would take us too far afield to sum up how .many-sided embeddmg m
the spirit of Freudenthal's didactical phenomenology of mathematical
structures takes place in each particular theme and course of those we
displayed above and what, among others, Sawyer, Vergnaud, Hilton,
Winter have contributed to it. We only ment10n the broad embeddmg of.
_ ratio with a reference to 'Gulliver' (Chapter I) and to the descriptio.n
in the Mathematical Material for the present chapter:. geometnc
aspects, drawings, puzzles, stick-shadow, mixtures, densities, scale,
percentages, ... ; .
1
th'
_ combinatoric problems (Chapter II): rn.ads, tree diagrams, c o mg
combinations, colouring, lattice, probabilhty, . . . ;
_ division (Chapter VI); extensively discussed m the preceding and
present chapter; .
_ fractions, described extensively in the . present chapter: breakmg,
dividing, distributing fairly, measuring, ra!los, probability;
_ many more examples of a many-sided approach m the other courses
sketched in the Mathematical Material for this chapter.
However, rather than restricting our attention to -e form, cont-nts and
functions of the particular context problems belongmg to a certam teaching subject, we shall also consider them m thelf totality . . An nnportant
criterion is completeness, in other words, whether the vanety of mathematical phenomena in the real world is sufficiently expressed'. In parlicular, problem situations should be viewed which, thanks to thelf mherent 258 CHAPTER VII
manysideness, fulfil a number of different functions at the same time:
concept formation, modeling and applicability.
Such model problems - in the literal as well as in the technical sense -
are the core of realistic mathematics instruction because of the multitude
of horizontal and vertical impulses which they contribute to the process of
mathematising. They help to bridge the level difference in the learning
process. Let us give some examples:
- the handkerchief problem in 'Gulliver' (Chapter I);
- the roads problem in organised counting (Chapter U);
- the chess board for exponential growth (Chapter HI);
- the Walt Disney drawings for number systems (Chapter IV);
- the lattice in Freckleham (Chapter V);
- the fair sharing situations in long division (Chapter VI);
- the distribution situations in table arrangements (Chapter VII).
We will return to this from another viewpoint in what follows now.
(2) Bridging by vertical instruments
Among the vertical instruments, models primarily fulfil a bridging function
between the phenomenal appearances of mathematics in the physical,
social, imagined and 'real' reality on the one side and the formal system on
the other side, as handy, visual, verbal or symbolic representations, and
real world situations (paradigms), which reflect essential aspects of mathematical concepts and structures.
Besides serving as thought models in the service of concept formation
and applications, models can also serve to facilitate calculations to learn
algorithms, to explore regularities, and so on. In the present -tudy we
encountered a large number of instances of this last category, such as:
- the roads model, the tree diagrams, the rectangle model (Chapter H);
- the abacus and the number line (Chapter IV);
- the arrow diagram and the lattice (Chapter V);
- the distribution pattern (Chapter VI);
- and many more in the Mathematical Material for the present chapter.
As a consequence, the character and function of models have already been
discussed incidentally, especially in Chapter II. For this reason we now
restrict ourselves to the kind of models we would like to call situation
models. Situation models are context problems with paradigmatic value
which, thanks to this property, are able to function as models in the sense
of prototype rather than of mould. To this end, the problem must be
investigated and analysed sufficiently in order to be able to recall the
prototype to be copied. Because of this peculiarity they are particularly
important for the level theory of progressive mathematisation. In fact, in
FRAMEWORK FOR JNSTRUCTION THEORY
259
this view on instruction, they are typically first level - at least in pnnciple
since, as the pupils advance, many parts of mathematics can acqmre the
same concreteness, but let us disregard this for the moment.
Instead, we give one example of this kind of model from each chapt_er.
The handkerchief problem from 'Gulliver' is first of all an obtect of
exploration and functions later on as a model for the behaviour of area
and perimeter under linear magnification. . . .
The road problem functions similarly, together with the tree diagram m
organised counting as a model for combinatoric problems. .

The chessboard problems with grains of corn is an important basis for
(expo-imtial) growth problems (growth by. a certain percentage per year).
As a JTirst step an (approximate) doublmg time is figured out m order then
to use the chessboard model further. . .
The context of the Walt Disney drawings (characters with four fingers
on each hand) helps the pupils learn to count and reckon in base eight. The
fingers-hand model is then retained in order to do the same calculations m
base six and other number systems, and eventually, for instance, also in
base twelve, where two new symbols are needed - a unique opportunity
to demonstrate the force and function of digital symbols. Let us add that
the fingers-hand model, which initially provided strong support, might
later on block the process of generalisation - a feature inherent m the use
ofmodels. . .
In Freckleham if 'was seen how linear ordering can function m problems when reasoning rests on awareness of transitivity. In not_e 27 of
Chapter V we dislayed four isomorphic order problems which notwithstanding their isomorphism, differ considerably m difficulty. This is
because in certain cases, the linear order is not obtrusive enough to
impose the global thought model on the learner who, therefore, proceeds
by chains of local deductions, that is, on a higher level than neede_d.
Nmnerous psychological experiments have revealed the enormous difference arising from the way isomorphic problems are proposed, that
is whether they can be solved on a concrete and meaningful level or
whether, thanks to their specific adornment, it must b_e done on a more
formal level. The availability and possibility of using thmking models is of
crucial importance if a difference of level in such reasoning problems is to
be bridged - not only in reasoning problems but m mathemansmg as a
whole. - ff -
If the tong division procedure is to be developed, the situation o mr
sharing and distributing plays a principal part. This is true of the first
phase of the course, but just as true in later phases if shortemng ' s
stimulated and procedural mistakes are to be overcon:ie. More precisely: it
is the combination of fair sharing with its symbohsat10n m a schema that
opens the road to self-reliant development of the algorithm. . .
Table arrangement is another opportumty to make similar observa-260
CHAPTER Vll
tions. Table arrangement (ratio) is symbolised in such a way (- means
three pizzas on a round table for four persons) that the pupils can easily
imagine the portions and the arrangement behind the symbol. Moreover
the ratio is clearly distinguished from the fraction (- in the present case) as
the result of the distribution per person.
In many of the preceding cases the main thing is the construction of
a meaningful situation (say at level one) with a fitting materialisation,
visualisation, and symbolisation (in some cases on a higher level); thus the
integration of an elementary situation and a model. This makes it possible
for similar models to fulfil both a horizontal and a vertical function. In
other words: abstracting, generalising, unifying, schematising, shortening,
reflecting, anticipating - all these can be made possible by modeling.
Not all models can function in so many ways. Artificial materialisations
and visualisations of mathematical concepts and structures, which primarily or exclusively function within the mathematical system, may lack
this breadth of power: MAB material, 'machines', sticks and similar
structural models, schemas and diagrams can be useful thanks to their
strong vertical power, yet phenomenologically viewed their power is
restricted. They lack the bridging quality required for the transition from
the first to the second Van Hiele level, on which we have insisted. (Not to
mention the traditional pancake models, which fulfil only a transitory and
onesided function.) As a matter of fact, the bridging function of situation
models consists mainly in conveying meaning to symbols, procedures,
formulas and so on: they stand as models for something real, which is
signaled by them. The degree to which this is indispensable was shown
earlier by the division problems from a NAEP investigation.
(3) Pupils' own constructions and productions
In the instruction theory of progressive mathematising the pupils' own
constructions and productions occupy a key position. Horizontal and
vertical mathematising comes about by the pupils' actions and their reflections on the actions. When speaking about their own constructions, we
stress their actions, while in speaking about production the stress is on
reflection. Of course, this is only a matter of more or less emphasis, as
they are inseparable. In any case, the examples show clearly that the
pupils' contribution to the design of the courses is quite essential. On
closer inspection, it is essentially the pupils themselves who construct the
courses, albeit guided by the teacher. Take for instance number systems,
long division, fractions - examples that have been discussed broadly. At
certain stages in the instructional process the pupils are stimulated to
produce their own problems. Producing simple, moderate, complex problems means that the pupil reflects on the path he himself has taken in his
learning process, and at the same time anticipates its continuation. These
FRAMEWORK FOR INSTRUCTION THEORY
261
productions derive part of their enormous significance from. the fact that
the instructional course is essentially the result of the pupils' own contributions. The mere possibility of their own production protects pupils
from being forced into a subject matter oriented straitjacket. They are
relatively free, that is, as far as the space in which the pupils can construct
the instructional course permits.
Within the frame of their own constructions, their own production is, as
it were the condensation point of the teaching/learning process. For both
the pu-il himself and for the instructor the pupils' own contributions are
of eminent importance, both for mathematising and d1dact1Csmg . . The
reflective moment for the teacher as well as for the pupil 1s the s1gmf1cant
factor in the production. The pupil's production, as the result of instruction functions as the mirror image of the teacher's didactical activity. Its
prognostic
'value is unmistakable. .
In brief, the pupil's own production is both a learning and a teachmg
tool - that is to say, in instruction where pupils' own construct10ns
determine the progress of mathematising. This, in fact, is one of the most
characteristic features of realistic instruction theory.
Other trends in mathematical instruction, in particular the structuralist
one, pay no attention to pupils' own constructions, let. alone productions.
On the contrary, after a sometimes playful introductory penod little space
is left for the development of informal approaches and the!T gradual
transformation into formal methods, and consequently as little for own
productions.
(4) Interactive instruction
The pupils' own constructions and productions, as well as phenomenological exploration and modeling, can be efficient only 1f they are reahsed
in interactive instruction, that is, instruction where there 1s the opportunty
to consult - to participate, to negotiate, to cooperate, with review afterwards and where the teacher holds back from providing explanations. All
the examples of instruction we have presented. in this study involve this
interactive element, which clashes with the solitary rote calculat10n and
focus on pencil-and-paper learning of so-called individualised instruction.
In realistic programmes and textbooks mstruc\Jon 1s d1dac\Jcally organised in such a way that interaction and cooperat10n between the pupils and
with the teacher are coexistent with individual work. Various differentiation models are proposed, among which that of internal differentiation
within the classroom is considered as the most appropriate in The Netherlands. The subject matter is divided into blocks of more or less selfcontained units, each covering a few weeks of instruction. The members of
a year group always start together with such a block and for the most part
stay together during their way through the block. Each block mcludes 262 CHAPTER Vll
opportunities for differentiation according to subject matter, level and
speed, which are strongly determined by the specific content. It is true that
vertical classes wher- th- teacher is responsible for two or even more year
groups, are. a comphcatmg factor. In this case, quite drastic organisation
measures w1H need to be taken at class and school level in order to adapt
the system to interactive instruction.
. Realistic courses have to pay attention to this organisation aspect of
mstruct10n, and this obligation consequently extends to the theory of
instruction.
We -estrict ?urselves to these general points, as a more detailed
elabornhon of .differentiation would take us too far afield, in particular if
we WJSh to. do 1ustice to the great variety of possible practical elaborations
based on different textbook series.
. For a. more concrete example of unity in supply of instruction combmed w!th differentiation in demand we refer to column arithmetic,
realised accordmg to internal differentiation in interactive instruction
(Chapter Vl). The_ pupils start and stay together, they can help one
another up, there is opportumty for consultation and cooperation and,
conseque.ntly, for reflect10n and recursion. Each pupil gets the opportunity
to work md1V1dually and, within certain limits, to construct his own path
without isolating himself from the group.
(5) Intertwining of learning strands; the broader connection
The intertwining of learning strands has its deepest origin in the phenomenological start, that JS, m the real phenomena in which mathematical
structures and concepts manifest themselves. Rarely are the phenomena so
pure as to comprise one structure or one concept Only.
On the thematic level, intertwining of a number of mathematical
elements is clearly visible in 'Gulliver', 'Grains on the Chessboard' and
'Freckleham'-_ On the course level intertwining is visible in column arithme.1'c and_ skilful reckoning, in calculating and measuring, in fractions and
ratio, and 1n measurement and geometry.
Earlier on we remarked that the prerequisites for promoting progresswe m_athematisation are often partly found outside the course under
con.s1derahon. These prerequisites may concern arithmetic abilities as well
as those of a conceptual and insightful nature. The basic abilities in
particular pervade almost all partial courses - which is why they are
called basic. But, the conceptual connection is equally strong in the
subjects ment10ned above - measuring and arithmetic, fractions and
decimals.
The_ p_rinciple of many-sided embedding of concepts and structures,
which is inherent to the phenomenological level theory and to progressive
mathemahsmg unavmdably leads to intertwining.
FRAMEWORK FOR INSTRUCTION THEORY
263
Yet in realistic instruction the ancillary function of mathematics in
reality does not lead, to subordinating mathematics to the contents, say, of
a project as it does according to the empiricist view. This instruction
hardly leaves any room for relatively self contained courses.
Giving in on this point means that the vertical component of mathematising is not sufficiently cared for. Mathematically and phenomenologically natural intertwining aims equally at promoting vertical mathematising. These general considerations with regard to this subject together
with the reference to the concrete examples of themes, courses and the
sketch of the Wiskobas progranune may suffice, since -laboration in detail
would certainly be as long as a complete textbook series manual.
3.3 Comparison of the Four Trends
In the foregoing sections we have shown with parts of a realistic
programme (Wiskobas) how to discern the features of progressive
mathematising, and how the five tenets that direct instruction are to be
recognised in such a prog'amme. The themes and courses described in
this study have continually been used as illustrations. If however, we
wished to contrast sharply and in detail the three oth-r trends with the
realistic one, we would have to describe how themes and courses are
shaped in textbooks wh!h represent those trends. We cannot possibly go
that far. All we can do is to check how the five tenets are dealt with in
mechanistic, structuralist and empiricist textbooks, one after the other. To
this end we will refine the schematic description by means of the
horizontal and vertical structure of mathematising.
In textbooks of the mechanistic trend one is struck by the scantiness
of its supply of problems: stereotyped word and text problems, as a
posteriori application of the subject matter learned within the formal
system, scholastic and preconceived, dressed-up arithmetic, where reality
is subordinated to applications. For this reason they are scarcely motivating in general and terribly insignificant. Little use, if any, is made of
models, let alone pupils' own constructions and productions. No interactivity is pursued and instruction is mainly individual. Speed is the main
criterion of differentiation. Rather than being intertwined, the partial
courses are isolated. Summarising, we may state that on each of the tenets
which direct progressive mathematising, the mechanistic trend diverges
from the realistic one.
Textbooks and programmes representing the structuralist trend are in
general not interested in context problems, except as a posteriori applications, where reality is a derivative of the mathematical problem. Material,
visual and symbolic models are used but only in a vertical function. That is
to say, they fulfil the bridging function between the formal system and its
natural and materialised 'embodiments' by means of structural material 264 CHAPTER VII
and games around it. In the initial phase, pupils are allowed to make their
own constructions; this is even stimulated, only to disappear later. Pupils'
own productions are not systematically used in the intermediate stages of
the learn1n- process. Instruction is, or at least can be, interactive. Partial
courses which are conn_ected might be intertwined if this is suggested by
some aspect of the subject matter, but phenomenological aspects do not
count in this respect.
In the empiricist methods all five tenets are active, although a strong
vertical component of mathematising is lacking. This implies that relatively
little use is made of situation models in modeling, schematising and
symbohsmg, that the pupils' own productions are not related to problems
of a more formal symbohc nature with situations in the background, that
mteraction takes place on too low a level since the pupils have no
su-1c1 -nt formal linguistic means of description and communication at
then disposal and_ finally, that the mathematical activities are integrated in
problems set withm themes and projects which do not allow any resolution of the intertwining.
While mechanistic and structuralist instruction methods are too formal
empiricist instruction is bound to remain too material. And while isolatio-
prevails in the first and second, integration dominates i- the empiricist
presentation. If the first two start in at too high a level, the third stays too
long on one that is too low.
This, _sharply outlined, is how_ things look from the perspective of a
realistic mstruction theory, which has itself been ontlined by the Van
Hiele s macro-levels and Freudenthal's instructional principle of phenomenology. In the present two-dimensional description of the framework
for mstruct10n theory some attention has also been paid to the microphases m . the teaching/learning process with regard to progressive
mathematisng and the tenets which direct the instruction. In the description, however, we have stayed at the textbook and teacher-manual level
that _is, rather far away from classroom practice. Or rather: we hav-

restncted ourselves to referrmg to descriptions of courses and of the
organisation of subject matter. But in some cases we were concerned with
more con-rete descriptions of themes. In this way three-dimensionality
was mphcitly present in the description of the framework for instruction
which will now be made more explicit. '
4. THREE-DIMENSIONAL DESCRIPTION OF A FRAMEWORK
FOR INSTRUCTION THEORY
In our experience and according to research the four trends which we
distingmshed in the textbook literature are also reflected in the minds of
FRAMEWORK FOR INSTRUCTION THEORY
265
teachers. This is not surprising as textbook authors often are, or have
been, teachers.
This does not mean that teachers' ideas always harmonise with the
intentions of the textbook they use, firstly because, for various reasons, the
teacher might have no say in the choice and, secondly, because the basic
ideas of textbooks are not always clearly enough outlined to prevent
preposterous, and as often happens, obnoxious interpretations.
For our purposes the following questions are momentous:
- What connection does there exist between views on instruction and
instructional practice?
- How can the teachers' views on instruction be refined, and if need
be, adjusted?
- How could the main features of the theory of realistic mathematics
instruction be more efficiently described to teachers, counsellors,
authors and so on?
A few remarks on the first question. It appears from the research of
Thompson and others, that there is a direct relation between teachers'
views on mathematics and mathematics instruction on the one hand and
their school practice on the other.
22
This may lead one, as expressed by
Cooney, to consider whether it would not be advisable to pay more attention in training and retraining to instruction theoretic forming of future
and present teachers-" This could be done by having them work on their
own level and then reflect" on their work, acting didactically and again
reflecting thereon, discussing alternatives to certain courses, presenting
research findings and so on, but also by the exposition of instruction
theory.
We are now concerned with the last of these options, and especially
with the three-dimensional theory description by means of one or more
examples of instructional themes or courses.
Let us start with long division (since this links directly with the threedimensional goal description in Chapter VI) and continue by summing up
the most salient points of the theoretic framework.
4.1 Progressive Mathematising of Long Division
First the preparation for long division: .In the first phase of initial instruction, division is anticipated, namely by way of fair sharing. Indeed, fair
sharing leads to the relations of more, less and equal. It can be evoked on
by counting and grouping. Fair sharing between more people leads to the
questions 'How many does each of them get?' 'How many are left?' What
to do with the remainder? At this stage dividing is not yet a formal
operation. Not until the basic operations of adding and subtracting, and to 266 CHAPTER Vii
a lesser degree multiplying are widely explored, can formal division
become an explicit objective.
Even then division is deeply embedded in context problems which
involve fair sharing, as well as partitioning and inverting the multiplication
represented in the rectangle pattern.
As this continues the field of bare division tables is explored, structured
and gradually memorised, using all kind of reckoning strategies. From the
very start much attention is paid to context dependency of the result in the
case of divisions with a remainder.
Why do we insist on the link between solving context problems (side by
side with bare sums) and the learning of multiplication and division
tables?
Often pupils do not discern the division in the context problem.
Instead, they try more primitive additive and subtractive methods or
multiplicative mixed with additive ones. By using the context problems as
a source, division formally viewed is thereby associated with repeated
addition and subtraction as well as multiplication. In other words, the
association with the other basic operations and their integration makes it
possible to form the concept of division by progressive schematising and
shortening from the other, already known, basic operations. Division
arises as it were via these 'primitive' operations, informal strategies, and
context dependent procedures. On the other hand, pupils can orient
themselves, when structuring the field of division tables, to the real
phenomena of dividing, which is essential in discovering properties.
In this way the horizontal mathematisation of learning to discern the
division in appropriate problem situations and the vertical mathematisation of more and more skilful and shortened reckoning go hand in hand.
Research has proved that, as a consequence:
1. context problems can function as models for operating within the
arithmetic system;
2. formal operations are anchored in the informal procedures used by
the pupils when solving context problems. Both together support
formal arithmetic as well as applications thereof.
Long division is approached according to the same policy of progressive
mathematising. Context problems still cover the first phase of orientation.
The long division scheme is developed by the pupils themselves as an
extreme way of shortening the distribution pattern (see the more detailed
description in Chapter VI). Bare arithmetical problems are a useful
exercise but they also motivate reducing the division 'tail' more and more.
Given bare arithmetical problems, pupils contrive elementary context
situations for distributing and partitioning, which conversely give them
support in bare arithmetic and help them to shorten procedures.
FRAMEWORK FOR INSTRUCTION THEORY
267
Finally the long division schema itself explicitly becomes an object of
research. Schemas with empty places or dots in various places are helpful.
Equally important is calculating the remainder If, together with the problem itself, the answer is supplied as a decimal fraction. The remainder
itself is an object of investigation if criteria of divisibility by 10, 5, 2, 4, 9,
3, 6, and finally 11 and 7 are to be established. These, therefore, are
investigations in the formal system on Van Hiele's third level, which,
however, will not be attainable in the primary school or at least, not in its
full breadth and depth. Model situations of fair sharing and partitioning
can even form the background for the divisibility criteria. Attention is then
focused on the remainders in the various positions (10, l 00, 1000, . . .
divided by 2, 5, 10, 9 and so on).
More lines can be drawn connecting division with other subjects:
fractions, decimal fractions, ratios, percentages, averages. Altogether we
notice a diversity of horizontal and vertical mathematising moments and
their mutual links. Context problems are helpful in the gradual development and shortening of the long division scheme. Moreover, they contribute to linking division more solidly with adding, subtracting and
multiplying by means of the informal solutions offered by the pupils. The
phenomenological diversity also penetrates the pro-lem series: division as
distributing, partitioning, as the nverse of multiplymg, particularly 1f
related to magnitudes pr remainders. .
In the first phase, division is preponderantly context-bound, m the
second it is also performed as bare arithmetic within the system, and in
the third the schema of long division becomes a subject of investigation.
These are again the three Van Hiele levels, the phenomenological
foundation according to Freudenthal, and the progressive mathematisation
such as realised by Wiskobas, that is in the present case: mathematising
the procedures and shortening them under the influence of context
problems.
The fact that the standard algorithm is taken as the final product of a
process of algorithmisation rather than as starting point is, in a way,
paralleled by the historical development with its succession of divisio
ferrea, divisio aurea and galley division, each of which underwent processes of schematising and shortening.
24
Here long division is adduced to illustrate the framework for instruction
theory, sketched above. In particular, it reflects the five tenets of instruction directed towards progressive mathematising. The pupils themselves
construct the algorithm while starting from elementary context problems
and a notational schema of distributing, developed by themselves, and at
certain stages in the course they produce bare and dressed-up problems of
their own; the intertwining of division with the operations and other
activities is unmistakable, and interactivity is an indispensable prerequisite
for schematising and shortening. 268 CHAPTER VII
This three-dimensional description of the framework for instruction
theory could be completed by:
- a sketch of the results;
- a comparison with other approaches to long division instruction.
In order to avoid needless repetitions we refer instead to the Mathematical
Material of Chapter VI. As a matter of fact, the brevity of our exemplary
three-dimensional description is a consequence of the fact that we are able
to rely heavily on previous descriptions.
4.2 Two More Examples: Number Systems and Fractions
These two examples are again chosen because they offer the opportunity
of finding support from previous descriptions (to wit, number systems in
Chapter V and fractions in the present chapter). We can, however, give
one more reason: in both cases the pupils' own productions are clearly
seen. This then is the point to which we draw special attention. It appears
that the pupils' own productions in particular are especially suited as a
means for describing three-dimensionally the framework for instruction
theory. Those lessons enable us to look over the shoulders of the pupils at
a long stretch of the course.
With regard to the Land of Eight (see the Mathematical Material as
well as the description of the evaluation lesson in Chapter V) we draw
attention to the following point of theoretic relevance.
- The three Van Hiele levels can be seen in:
1. unreflected imitation of the counting sequence and in its notation,
particularly the carrying over algorithm;
2. consciously using the peculiarities of the decimal position system in
column arithmetic;
3. reflecting on the decimal system via non-positional and other positional systems.
- the phenomenological exploration takes place within mathematics;
- progressive schematising is made possible by the paradigm of Walt
Disney drawings functioning as situation model, and the pupil's own
production is stimulated by the desire to obtain passports to as many
number system countries as possible;
- all kind of micro-aspects of mathematising and its inherent difficulties can be demonstrated by using the pupils' own productions:
the asymmetry of the fingers-hand model in base three, the specific
difficulties of the system of base two, breaking the blockade of the
decimal system in base twelve - an inexhaustible wealth of examples
of progressive mathematising, progressing from level 2 to level 3.
FRAMEWORK FOR INSTRUCTION THEORY 269
Moreover, the meaning of reflection on the micro-level (how did I
do it in the Land of Eight?) and on the macro-level (what did I do in
the past when I added columns?) is elucidated.
- by the interactivity attention can be drawn to didactical action, as
well as to levels of didactical action that reveal a certain analogy with
the levels of mathematical action and thought with regard to the
positional system. Mathematisings are, as it were, reduced to the
same denominator, that of the phenomenological level theory.
'Denominator' evokes 'Fractions', our second example in this subsection,
which was dealt with circumstantially in the Mathematical Material of the
present chapter. Again we stress the importance of the pupils' own
productions.
Well then, to start the three-dimensional description one could conveniently present one of the production lessons as an example, though this
might also be a drawback, considering the complexity of the subject of
fractions. On the other hand, there would seem to be no better method of
doing justice to the subtleties of mathematising than just to display pupils'
own productions. As examples we choose more advanced stages of the
course, where larger parts can be scanned to give aft overview of the
pupils' work. For this reason we will restrict ourselves now to the pupils'
own productions at the 'symbolic level, that is problems on decomposing
(l - . . .) and composing (H - - - - -) and will try to ascertain what the
pupils are actually thinking about with these operations.
The viewpoint of instruction theory suggests the following:
- within a group of 11 years olds, say, a considerable difference of
level is manifested in symbolic expression: some children relate the
symbols closely to situations of table arrangement, concrete partitioning or money problems (within the cluster of activities described
in the Wiskobas programme) whereas, for others, the symbols have
become meaningful in themselves. The last group are able to operate
adequately with them in the mathematical system, that is, as they do
with whole numbers, although even in this group there are gradations of abstracting, generalising and unifying. The first group,
however, have not yet (or not yet sufficiently) freed themselves from
the concrete embedding. But in this group also there exist (local)
gradations. A pupil may be able to operate entirely symbolically with
halves and fourths without any concrete representation, while not yet
succeeding with other denominators. Thus the progress of progressive mathematising can in a way be gathered from the pupils' own
productions;
- the various mental representations as concrete background for the
pupils' own productions on the symbolic level can be made the
subject of a discussion on the various aspects of the fraction concept
|
|

and its appearance in reality. Moreover, they can be points of
motivation for making clear the objectives of the phenomenological
exploration within the four clusters of activities;
- the momentous power of 'natural' symbolisations, such as that of
table arrangements, as well as both the kinship and the distinction
between fractions and ratios are elucidated. The last point again
touches on intertwining as a means of mutual support;
- the opportunity for making their own constructions is used in the
pupils' own productions, for instance for adding fractions by using,
among other things, the 'payment model': the 'abstract' search for a
common denominator or the 'concrete' one for an equal table
arrangement, are superseded by the search for an appropriate pizza
price which permits paying for the portions (of pizza parts) in order,
after this settlement, to then convert the price into a fraction. The
pupils can proceed in various ways; the price can vary, as can the
calculation of the price and the relevant table arrangements; prices
can be replaced by areas representing chocolate pieces; some problems are already being solved at the symbolic level.
- in interactive instruction pupils can advance various possibilities and
thereby benefit themselves by reflection;
- by means of a similar outline of levels, phenomenological explora:
tion, moments of progressive mathematising, verification of the five
tenets, a background description of alternative approaches, as well as
exposition of research results, is made possible.
Altogether, in an advanced stage of the course the pupils' own productions supply good opportunities for a three-dimensional description of the
framework for instruction theory in question. We have already given some
indications as to how to perform such a description based on previous
sketches. Under these circumstances a complete three-dimensional description would have given too many redundancies here. Moreover, it would
have been partly superfluous because, as we believe, the foregoing instances
show clearly enough what we mean by a three-dimensional description and
how it can be realised.
4.3 The Most Conspicuous Elements of the Framework for Instruction
Theory Seen from the Viewpoint of Implementation of Instructional
Ideas
The five tenets probably provide the most significant contribution to a
first acquaintance with the framework for instruction theory in question: context-models-constructions and productions-interactive instructionintertwining of learning strands. They can be used to throw light on
mathematisation at micro-level, Van Hiele's level theory, and Freudenthal's

phenomenological starting point. Such an introduction should be illustrated by examples of lessons and courses. Moreover, one can appeal to
the teachers' own experiences when doing the mathematical work on their
own level, on probability, say, where the disadvantages of too high, too
formal, too subject matter oriented approaches can be experienced personally. Difficult schoolwork and extensions thereof can also be useful in
this respect. Another tool might be the parallels between mathematising
and didactising, at micro- as well as macro-level. As a counterpart to
pupils' own production one can propose the design of lessons and formative and summative tests by the teacher. The impact of reflection and
recursion can be stressed for mathematising as well as f-r didactising.
Finally alternatives allied to the other trends could be used to show the
greatest contrast with the realistic trend.
These, then, are the main lines we have followed over the past years
when describing our framework for instruction theory in statu nascendi.
This description can be extended rather arbitrarily of course: the importance of doing mathematics self-reliantly, the reserve the teacher should
observe when explaining things, the accord between teacher's and textbook author's ideas, the importance of organisational measures with
regard to differentiated instiuction, the instrumental or constructive use of
textbooks.
7
An additional point might be the description of general teaching/learning theories and of specific theories which are represented by the four
trends (for text book a-thors this might even be the main point). The
relation of such theories to that of the phenomenological level theory of
progressive mathematisation should then be discussed. This is the subject
of the following and last content-oriented section of the present chapter -
an opportunity to view the framework for instruction theory from another
perspective than the realistic viewpoint.
5. THE BROADER FRAMEWORK FOR INSTRUCTION THEORY
Although both components of the teaching/learning process determine
each other, it would be an exaggeration to consider instruction as a selfreferential system. Indeed, learning exists independently of teaching. And
at school, at any rate, there is a strong mutual dependence. For this reason
we often speak of teaching/learning theories where theory building is
concerned. There are, however, shades of emphasis with regard to teaching and to learning in various theories. We shall discuss them, in particular, with an eye on their theoretical value for didactical action and
educational development. What kind of principles and rules for developing and implementing instruction can be obtained from various subject
matter-oriented didactical theories or more general information processing and activity theories, and how do they agree with or diverge from 272

the framework for instruction theory of progressive mathematising as
presented above?
This, then, is the central question we will try to answer in what follows.
We will start with ideas of Gagne, Dienes, Piaget and Bruner which have
had a considerable influence on curriculum and textbook development
and consequently on instruction of the particular trends we have distinguished. Then we will discuss approaches towards theory building,
emerging among others in the recently established TME group 'Theory of
Mathematics Education'. Finally, we will analyse the more general cognitive psychological research with reference to our central question.
5.1 Gagne, Dienes, Piaget, and Bruner
(l) Gagne and mechanism
Gagne's early work fits into the behaviourist tradition. His cumulative
learning theory consists of eight types of learning. The ordered set of
lower types is the prerequisite for learning the higher ones:
25
Problem solving (type 8)
requires as prerequisites;
Principles (type 7),
which require as prerequisites:
Concepts (type 6),
which require as prerequisites:
Multiple d'iscriminations (type 5),
which –equire as prerequistes:
Verbal associations (type 4) or other chains (type 3),
which' require as prerequisites:
Stimulus-response connections (type 2).
It is probable, though not yet proved - Gagne says - that the basis of this
learning structure is formed by the type 1 'signal learning', that is, Pavlov's
classical conditioned response.
Overall the foundation of Gagne's learning theory, that is, the sequence
of the first three to five types of learning, is about the same as that of
Thorndike, Tolman, Hull and Skinner. And these were primarily the types
of learning which appear in many New Math projects of the sixties and
seventies, partly guided by Gagne for designing curricula. Use was made
of task analysis as sketched by Gagne, which starts with the question:
What knowledge and ability is the learner required to possess at the start
of instruction?
This analytic question led Gagne to decompose a complex task into
a hierarchy of simple tasks, which can be interpret;ed as parts of the
complex one. Mastery of the elementary tasks simplifies learning to
perform the complex ones, according to Gagne. The cumulative learning

theory is reflected in this hierarchy: the lower it is in the hierarchy, the
more elementary is the learning type.
The influence of this neo-behaviouristic learning theory on instruction
and, in particular, on mathematics textbooks, is momentous. Not only
numerous well-known projects of 'he sixties such as UMMaP and IPI are
modeled upon this theory, but alirlost all the more recent individualising
programmes are deeply rooted in it. This holds even for more traditionally
oriented textbooks: organisation of the subject matter according to the
principle of progressive complication as we called it above. Both mechanistic and structuralist textbooks display this feature, although the second
kind aims at higher learning types than the first.
It should, however, be acknowledged that the third edition of 'Conditions of Learning' (1977) reveals a drastic change in Gagne's views: the
eight learning types are not even mentioned.
With respect to mathematics Gagne's most recent views are clearly
expressed in an 'Invited Address', published in 1983. Here he presents a
three phase model for instruction in the frame of information processing
theory(!), which should also serve as a guide-line for research.
26
The first phase consists of converting a concretely stated problem mto
mathematical shape, the second of carrying out the mathematical operations, and the third of validating the result.
An example: 19 workers earn 142 dollars a week each. How much
must be paid per weel.< . in total?
Phase 1 consists of translating the problem into 19 X 142, phase 2 of
the algorithmic performance of the multiplication and phase 3 of checking
the result by estimate, say 20 X 140.
According to Gagne, these three aspects should be present in every
task analysis of mathematics instruction. He arrives at the following
recommendations for instruction with respect to these essential parts.
Firstly, special attention should be paid to 'translating' word problems,
which means a variety of different problems are offered which cover one
particular 'formula'.
Secondly, emphasis must be laid on the ability to carry out automatically certain arithmetic activities, that is, techniques and procedures
which may not require insight. In the case of 19 X 142, Gagne rejects
the use of concrete material, such as sticks and blocks, which neither
simplifies the calculation nor helps automatising, and for the same reason
he rejects exercises in other number systems.
Thirdly, there should be emphasis on checking of the answer through
estimation.
At present, Gagne asserts, too much emphasis is put 'on problem
solving as a more ambitious enterprise', on basing arithmetical procedures
and formulas on insight, and too little on automatising and validating the
result. Altogether, these recommendations clearly reveal the most impor-274

tant instructional principles on which this moderately mechanistic mathematics education is based. But, at the same time, the example chosen by
Gagne himself shows the vulnerability of his argument, since this elementary word problem can be solved excellently by informal methods. There
is no need for 'straight translation' into the formula' 19 X 142. On the
contrary: the informal procedure of adding up (19) notes of one hundred,
(76) notes of ten, and (38) notes of one dollar, taking it together or, if
need be, changing it, can be an excellent start for an msightful course on
the multiplication algorithm, which at the same time links up with informal
estimating procedures. In brief, translating, automatic calculating and
estimating are interrelated to a much higher degree than Gagne suggests
with this example.
Both Gagnt\'s early and more recent views give a fair picture of a
possiBe theoretic infrastructure of mechanistic mathematics education.
Task analysis accounts for the subject matter aspect of this view on
education: the structure of the teaching matter is determined by the
increasing complexity of the task according to subject matter systematics,
that is, of the teaching matter products in the subject matter domam.
According to this course of thought, the teaching/learning process moves
on one level, that of the systematics of the subject matter, and all that
counts are quantitative rather than qualitative distinctions. This, then,
distinguishes this theory from that of progressive mathematising in a way
that is marvellously illustrated by Gagnt\'s multiplication exampJe. Besides,
this example can also be used to compare the results of other instructional
approaches, which at this moment may be left aside.
(2) Dienes and structuralism
Dienes' teaching/learning theory shows a great many similarities to Van
Hiele's, at least viewed formally, since there is a considerable distinction
between them as regards to content.
Dienes' theory rests on four pillars: the dynamical principle, the construction principle, the principle of mathematical variability and that of
perceptual variability. . .
The dynamical principle is certainly the most conspicuous feature, smce
it structures the teaching/learning process according to phases, which m a
sense are similar to Van Hi el e's micro-levels. The first phase is that of free
play in an artificially constructed environment. The second is play controlled by rules using the same material. In the third phase, an isomorphism game is played: the identical structure of seemingly different games is
explored, and the children abstract the common rules which fit the vanous
embodiments of the game. In the fourth phase, the abstract10n is visually
and audibly expressed, in order to be verbalised in the fifth phase. The

sixth phase finally is the formal system with its derivation rules (rules of
the game):
Finally, there will be the theorems of the system, which are the parts reached from the
initial description by using the 'rules of play'.
27
The construction principle is included in this phasing of instruction: the
children themselves construct the rules of the game, carry out abstractions,
and design the various representations of the structures.
Mathematical variability is, as it were, built into the material by the
designer. He can change the number system without affecting the positional idea: by this change of basis the system's essence is put in bold
relief.
Perceptual variability is accounted for by the multiple embodiments of

the abstract mathematical structures. This prevents abstraction from being
tied too firmly to one of its embodiments, and thereby becoming immobilised. Thus far we have presented Dienes' instruction theory from a
bird's-eye view.28 As mentioned above these teaching/learning principles
apply to Van Hiele's level theory as well. Formally viewed, Yan Hiele also
knows this kind of phasing where acting on one level is subjected to
reflecting and exploration in the next phase. Level raising is in Van Hiele's
view also the result of the pupil's own activity. Mathematical variability, if
interpreted (as we did \ere) in the phenomenological sense, is accounted
for by the diversity of phenomenological manifestations of a certain
concept or structure in reality. Perceptual variability can be guaranteed
by multifarious realisations in the context of dramatising, games, word
problems, themes or mixtures of them all as described earlier. However,
where the contents are concerned, there are essential distinctions to be
made between the two theories.
Whereas in the first phases of Dienes' learning cycles the children come
in touch with concretised mathematical structures, with embodiments of
games in artificially created environments, the Van Hiele basic levels entail
an exploration of those aspects of reality for which the mathematical
concepts and structures (can) serve as means of organisation: 'embeddedness' versus 'embodiment'; the naturally organisable versus the artificially
organised matter; eliciting a structuring activity in an everyday life or
physical or imagined reality versus debasing mathematical structures and
forcing them into an artificially created environment.
Because of this essential distinction at the basis of the learning process,
constructive activity, and mathematical and perceptual variability mean
completely different things. As a matter of fact, in Dienes' view, the real
world of and for children is an obstacle to mathematics instruction. A
quotation:
Let us consider for a moment the example of -glc; we need to recognize that the natural 276
CHAPTER VII
environment in which the child lives does not embrace all the attributes which we consider
as logical. It is necessary, then, to invent an artificial environment.
29
Not only for logic is this supposed to hold, but for mathematics as a
whole: the everyday reality is not pure enough, there is too much noise in
it for clean mathematics education according to Dienes. On the contrary,
in the framework of Van Hiele's level theory, reality is or can be the
source of mathematical activity and the starting point for both constructive
activity and what Dienes calls the principles of mathematical and perceptual variability.
Dienes' influence in some domains is certainly not negligible, although
he has apparently been interpreted in the wrong way. It is true that
the most important impulses in structuralism come from subject matter
systematics. But, whereas Dienes cares about the meaningfulness of
symbols, technical language, logical patterns and strategies, this is no
longer true of structuralists in general. On the contrary, they beheve that
after a short concrete introduction to the mathematical entities in question, the formal approach enables the pupils to build the mathematical
structures. The learning cycle as used by them is nominally 'exploration -
concept introduction - concept application'.
30
In the usually short introductory phase they use the materials, schemas, diagrams that have been
publicised by Dienes' work; but this way of working has in fact little in
common with that of Dienes, as little for that matter, as the sequence of
'actions first, then pictures, finally symbols' has to do with Bruner's view,
although it is ascribed to him. Let us, however, disregard this for a
moment.
(3) Piaget, Bruner, empiricism and mathematics education in general
To a considerable extent Dienes has borrowed his ideas on concept
formation from Piaget. But the system of stages perceived by Piaget in the
development of thought in general (thus admitting all possible contents)
during certain general age ranges, was applied by Dienes to concept
formation and, for that matter, both in the descriptive sense (i.e. learning)
and in the prescriptive one (i.e. teaching) - a transplantation of patterns,
which one also encounters in Bruner, Van Hiele and others.
Piaget's reserve with regard to influencing cognitive development by
instruction is well-known - we won't go into details, no more than we do
with the general characteristics of his own theory of development. Nor is
there any need for arguments stating that for Piaget himself it is sci-n
tifically absolutely illegitimate to transpose macro-levels of cogmnve
development into micro-stages of concept development - mdeed it flatly
contradicts any age-bound phasing. We would prefer to point out some
FRAMEWORK FOR INSTRUCTION THEORY
277
consequences of Piaget's ideas for mathematics education, as stated by
Piaget himself.
According to Piaget, the first and central problem of mathematics
education is how to bridge the gap between natural, unreflective thinking
in a certain domain on the one hand, and the conscions reflective thinking
on structures in the same domain and its mathematical symbolisation on
the other. In general he remarks that the acquisition of knowledge, in the
mathematical domain as well, is operational. This means that children
don't learn primarily by transfer, but by construction of knowledge via
concrete action and operations. For this reason, instruction should be an
opportunity for children to form ideas themselves. Here one should,
however, account for the fact that children pass through certain phases in
their cognitive development, starting with that of concrete actions and
finishing with that of formal operations. Therefore, according to Piaget,
there is no point in bringing children into contact with the formal system
and the underlying course of thought until they have sufficiently experienced the underlying concrete operations and ideas. In brief, one should
take care in instruction when introducing technical symbols and laying
down the logical carpet of reasoning conditioned by the systematic subject
matter. Not until the solid experimental basis of concrete operational
thought has been laid, can formal operations thrive, as-is required in the
mathematical-logical appr,oach, by defining, reasoning and proving. For
the ability of reflecting: in particular, the learner needs a rich fertile
soil of concrete-operational structures in order to pull himself up to the
higher formal-operational level of the systematic subject matter dependent
method - this is Piaget's 'conditional' recommendation for (mathematics)
education.
In his later work Piaget also indicated the importance of social interaction between fellow-pupils. Diverging opinions of members of the group
can induce the pupil in the long run to reflect on his own ways of thought
- this is Piaget's version of what now is known as the socio-cognitive
conflict.
Piaget warns against tying 'concrete', in the context of thinking, too
closely to objects, that is, perceivable or visible outward patterns, and so
on. Operations, even concrete ones, are mental actions with certain
characteristics, which are not tied to handling material objects. In
(concrete or formal) operational thinking - rather than being at the mercy
of acting on materials - is allowed to mentally keep at a distance from it,
to raise oneself above it. Identifying 'concrete' with 'palpable', concrete
operational thinking with acting on material is not allowed - an identification that seems to occur in (initial) empiricist mathematics instruction.
For an even more profound reason we may mention Piaget here in
relation to the empiricist persuasion because of this reserve with regard to
instructional influence on cognitive development, which is also found in 278
CHAPTER vn
the empiricist practice. It is true that practicians of this investigationoriented instruction offer pupils a mathematical, copiously structured and
stimulating environment, but their anxiety with regard to cautious maturing of (mathematical) structures ends up being at the expense of deliberate
vertical mathematisation, as earlier mentioned. This empiricist practice is
(most often implicitly) motivated by Piaget's ideas: there is no point in
trying to accelerate cognitive development towards (formal) operat10nal
thinking on mathematical concepts and structures, since instruction cannot
come to grips with it. Not until the age of about twelve are children ready
for a more abstract, formal, subject matter orientation on mathematics.
It should, however, be remarked that Piaget's influence extends beyond
the empiricist persuasion to the other ones as well, albeit indirectly and
not always in agreement with Piaget's own intentions.
We have already mentioned Piaget's influence on Dienes and Van
Hiele, and this is not so very different in the case of Bruner either: his
well-known gradation enactive-iconic-symbolic (e-i-s) is connected to the
phases distinguished by Piaget as pre-operational thinking, concrete and
formal operations of thought.31
The triad e-i-s regards the ways of mental
representation (coding, processing, storing) used by children consecutively
in the process of fanning the concepts they learn; the lower form of
representation lays the basis for the higher one in the process of concept
attainment.
For use in instruction, the e-i-s sequence is translated into the didactical
requirement that instruction has to be organised in a way that the concepts
to be taught can be represented first enactively, then iconically and finally
symbolically - a sequence that widely agrees with Dienes'. Bruner's
didactical triad has (had) a gigantic influence on mathematics education,
and in research, too, the so-called 'action-image-symbol sequence of
mental activity' (has) enjoyed great popularity. Actually, research has
shown that the didactical guide-line of action first, then picture and finally
symbol, allegedly drawn from Bruner's work, is too simplistic a representation of instructional matter.32 As an example consider column arithmetic:
the connections between the actions on various levels, the completeness
and extension of arithmetical procedures, their verbalisation and representation, the relations between the procedures and the positional system,
the ability to refer to elementary context situations (such as adding up
monetary quantities), partition of objects, shortening of procedures, reflecting (and learning to reflect) are only a few examples among many that play
an important part and are not accounted for by what they consider as
Bruner's requirement. Actually, the same holds true for the cognitive
representation form as such.
This ends a sketch of Piaget's and Bruner's ideas which have influenced
(and still continue to influence) the development and implementation of
instruction, in particular via textbooks where the instructional implications
of theoretical views are elaborated, albeit often in a simplistic way.
FRAMEWORK FOR INSTRUCTION THEORY 279
(4) Conclusion
We have briefly sketched a few 'classical' theoretical frameworks used as
infrastructures of mechanistic, structuralist and empiricist instruction. That
is to say, instruction as documented by textbooks and, since textbooks are
the most powerful determinant in actual mathematics education, one may
conclude: everyday instructional practice.
Only incidentally have we touched on the question of agreement and
contradiction with the teaching theory of progressive mathematising, and
when we actually have done so, it was from the viewpoint of Van Hiele's
theory, which forms a part of it. Notwithstanding disagreements with
regard to contents there were important points of agreement in the formal
sense, that is, with respect to phasing, instructional principles, the central
role of reflecting and that of building structures of knowledge.
5.2 Recent Investigations of Subject Matter in Instruction Theory
The great variety of recent theoretic views is to an extent reflected by the
large number of terms used in various theories in the teaching/learning
process - terms that ind}cate ideas or concepts, such- as schema, script,
frame, nncro-world, domain of subjective experiences, knowledge structure, conceptual model, -<:bnceptual field etc. From this variety of theoretic
frameworks we will choose a few which are significant for developing and
realising mathematics instruction on the level of textbooks and didactic
action. This issue is inspired by subject matter didactics or by mathematics
instruction theory - in the next section we will view this from the general
psychological or instruction theoretic perspective.
As. in the preceding section we will touch upon the points which agree
and disagree with our own theory only incidentally and incompletely; most
often they are self-evident. Where this is not the case we take Dienes' four
instructior principles as a basis, because they can also serve as a comprehensive means of description for realistic instruction theory.
As an example of a cognitive science approach we choose Davis' work.
Bauersfeld's will illustrate interactional theory. The conceptual modeling
view will be exemplified by Lesh's ideas.
In no case can we speak of the approach because several approaches are
feasible within anyone viewpoint. Even in specific project bound research
such as that in which Lesh participates, various theoretic frameworks can
be distinguished. (Compare in this respect Behr, Lesh, Post and Silver,
1983, with Lesh, Landau and Hamilton, 1983, that is the Rational Number
Project with the Applied Mathematical Problem-Solving Project.)'
We choose these three examples, firstly because they are considered in
general as rather important studies which have attracted wide attention
secondly because their aim is a general theory within mathematics instruc'.
tion rather than restricted to certain aspects of the teaching/learning 280 CHAPTER VII
process or to certain subjects, as are many practical theories, and thirdly
because of the diversity of frameworks for instruction theory they represent. The last argument requires some comment: they represent the
theoretic starting points of information-processing and related views as
well as the more reserved scientific attitude towards the use of the
computer as metaphor for the teaching/learning process.
Once more we stress that these theories are primarily dealt with from
the viewpoint of their implications for developing and realising instruction.
This means that we disregard the sometimes overemphasised aspects of
learning theory; these tend to impose themselves, in particular, when
models of mind are viewed microscopically, as may be the case where
information processing and concept modeling are concerned.
(1) Davis' cognitive science approach
Davis distinguishes two views on teaching and learning mathematics, the
formal-mathematical view and the cognitive science approach.
They confront each other as follows.
i. The 'Notational View':
Mathematics deals with symbols

written on paper
with the manipulation of these symbols
according to rules
that are told to the students beforehand
by using 'na-ral language' (ordinary English, ordinary German, etc.).
2. A newer 'Cognitive Science' View:
Mathematics is a matter of ideas
which a student builds up in -s/her mind
(and this is something only the student himself/herself can do).
These ideas come from experiences,
and are not primarily coded in natural language statements.
New ideas are built up from ideas the student already
has in mind,
by combining them, revising them. etc. often in a
metaphoric way.
Effective learning requires not merely 'doing something',
but also reflection on what you have done after y'ou
have done it.
Therefore an important responsibility is to help students develop appropriate metalanguage and 'meta'-notatiorn.
34
In the above description Davis uses the term 'idea' where in the theoretic
framework (our terminology) of his cognitive science approach he would
speak of 'frame'.
35
A frame is a stable concept or, as Pavis would say, an
information representation structure. In the terminology of computer
programs it is a subroutine of a higher level programme. Examples of
FRAMEWORK FOR INSTRUCTION THEORY 281
frames, in Davis' sense, are the function concept, the division algorithm,
the negative number - that is, such as understood by the pupils, accordmg to their ideas and representations.
What matters in instruction is building mental representation structures
that are stable, meaningful and useful, which is often not quite that easy.
How adequate frame-building should be realised can be made clear by
means of two layers of mathematical thinking that he distinguishes: the
calculator layer and the layer of experience. In the first layer - that of the
calculation world - symbols, operations and routines need not necessarily
be meaningful. In the second layer, on the other hand, they are taken from
concrete experience and therefore must be meaningful. The so-called
paradigm teaching strategy, which has a central place in Davis' theory,
runs at founding the activity of operating mathematically within the
abstract-symbolic layer upon that of the experience-bound knowledge.
As an example of a teaching strategy Davis uses the introduction of
negative numbers via the pebbles-in-the-bag paradigm. There is a bag with
pebbles and a pile of single ones. A problem like 4 - 10 = . . . is assimilated to 'first 4 into and then 10 out of the bag, thus 6 less than before',
which yields the answer 4 - 10 = -6. The assimilation paradigm of the
pebbles-in-the-bag is:
- a forceful representation
- which procures 'an accurate isomorphic image of additions and
subtractions of positive integers
- tells how pupils should solve the given problems
- and is simple.
In general, Davis remarks on assimilation paradigms:
Given the studies of recent years, however, it has become clearer that learning is primarily
17etaphoric - we build representations for new ideas by taking representations of familiar
tdeas and modifying them as necessary, (. . .)
36
Examples of forceful representations according to Davis, are among
others: fair sharing, splitting, larger, further, straight, rectangular. Therefore, activities and situations formed around these concepts can function
excellently in the paradigm teaching strategy, according to Davis.
If we consider the implications of Davis' view on mathematics education_ -om the perspective of Dienes' four instructional principles, we can
put 1t m the following way.
The mathematical variability is structuralist rather than realistic: the
pebbles-in-the-bag paradigm is envisaged mainly because of its value for
calculating bare sums. Davis does not notice that such a paradigm could
possibly block the applicability of the envisaged structure. In other words,
not much attention is paid to the various manifestations of mathematical
structures in reality and their relation to the use of assimilation paradigms. 282 CHAPTER VII
With regard to perceptual variability Davis refers to Bruner's modes of
representation. However, when emphasising the use of experience he
refers to situations such as fair sharing, which can, indeed, be represented
mentally quite clearly, although it is not quite clear to which mode of
representation these real scripts might belong.
The meaning of 'meaningful' is sometimes structuralist (being able to
insightfully manipulate Dienes blocks in relations to arithmetic) and sometimes realistic (situations in which column arithmetic is applied), but more
often it is the former.
The dynamical and the construction principle are also cornerstones of
Davis' instructional framework, as appears from our first quotation. With
regard to contents these principles are determined by the moderate structuralist basic view on mathematical instruction with realistic influences
- at least according to our interpretation of Davis' cognitive science
approach to mathematics education.
Non-cognitive and interactive aspects are hardly mentioned by Davis.
They will be dealt with in (2).
Another information processing view on a theory of mathematics
education inspired by subject matter didactics, but with the 'expert system'
as central concept, is Nason and Cooper's, and with 'microworld' in the
centre Lawler's, about which we will say more in a moment.
37
In general the computer metaphor is not widely used in theorising
about mathematics education. And as far as it is done, one most often
subscribes to Kilpatrick's statement:
To conclude that the computer is the last metaphor for the mind requires the assumption,
first, that the computer will not change in its nature and, second, that cognitive theory m.ust
be computational. To conclude that the computer offers a complete metaphor for the rmnd
requires the assumption that all knowledge can be reduced to information and all wisdom
to knowledge.
38
(2) Bauersfeld's interactional theoretical framework
Bauersfeld, Krummheuer, Voigt et al. are busy developing a theory of
learning and teaching mathematics where emphasis is laid on the social
interactive component of the teaching/learning process - an interactional
theory.29 Within \his framework Bauersfeld's construct of 'domains of
subjective experiences' is central.
40
The meaning of this concept can be described very well by means
of Lawler's psychological interpretation of microworld (which differs from
Papert's didactical one).
41
A microworld is a cognitive structure in the
shape of a microcosm, but then a domain-specific structure, which is- quite
different from Piaget-style general cognitive schemas where the thinking
operations are considered to be independent of the contents. A microFRAMEWORK FOR INSTRUCTION THEORY 283
world organises the knowledge of a certain domain. For instance, young
children may possess various numerical worlds - a counting world, a
money world, a paper-and-pencil calculations world - which initially may
be clearly separated from each other. As a consequence, they might be
able to solve problems set in the money context (such as 25 + 35) and
unable to solve bare calculation sums (2 + 7), and conversely.
It is a general characteristic of these microworlds that they are not
governed from above by a central authority, a homunculus, in order to
find problems to work on but that they work autonomously and competitively in a kind of self-governing system. Or, as Hatfield formulated: 'a
child's microworld may be less like a parliament where some executive
officer attempts to keep order, and more like the floor of a stock
exchange, where the loudest voice gets heard.'
42
It depends on the context
in which the problem is set and on the relevant knowledge structure of the
microworld in question.
Different microworlds can be connected with each other in order to
cooperate rather than to compete. This requires shaping a new microworld, while however, allowing the old ones to subsist: the components
are, as it were, coexistent with the composed world. In creating microworlds the learning process is cumulative. -,
Within the connections made between the microworlds a kind of
hierarchy develops: mi'c-oworlds are constituted, connected and integrated
(to become new microworlds), while the relations of one layer become, as
it were, the thinking object of the next thanks to the active and reflective
engagement of the learner - the same genesis as that of the Van Hiele
levels, as Bauersfeld rightly remarks.
How are Lawler's microworlds and Bauerfeld's domains related to each
other?
One could state that the Bauersfeld's domains may be considered as an
extension of Lawler's. A domain of subjective experiences includes the
totality of subjectively relevant experiences in a specific class of situations,
that is not only the cognitive dimension of knowledge but also emotional
and motor experiences.
On the other hand, in a number of respects they can be described as
the systems of microworlds as understood above: they are also determined
by the domain specificity of the subject matter, cumulatively ordered and
in principle competitive. They do not allow themselves to be subdivided
into separate domains of lower and higher sorts of learning (knowledge
and metacognitive abilities), or into different experiential fields of knowing, feeling, willing - in other words, they are holistic. They can intertwine
with each other in a new domain. The active and reflective engagement of
the learner determines his learning, in this case the creating of new
domains. It is highly stimulated by social interactions. To quote Bauersfeld:
The subject does not form concepts as internal images or through copying other people's 184 CHAPTER VII
activities. The subject actively constructs meaning and relations through social situations of
interaction and negotiation.
43
Altogether, it appears that this model of domains of subjective experiences, which aims at understanding the coming into being, the nature and
the course of learning processes, sheds specific light on learning concepts
such as transfer, abstracting, generalising, visualising etc. In what follows
we will in particular consider a few consequences for instruction.
Firstly, the importance of social interaction has already been discussed.
It highlights the crux of the role of the teacher as mediator where new
domains are constituted and as a stimulator where meanings are conveyed,
engagement is activated and connections are made in interactive instruction.
Secondly, and partly as a consequence of the first point, the formal,
subject area oriented structure of the teaching/learning process is put
sharply into perspective and reduced. There is one more reason for this
within the domains model: only by the intertwining and integration of
domains (into new domains) are abstractions and generalisations made
possible. In terms of instruction theory this means first: constitute rich
context-bound domains, then organise them first locally and then globally
by means of the earlier mentioned active and interactive processes of
reflection (let me use this level theory formulation). Here is a concrete
example taken from initial instruction to illustrate this recommendation:
develop money arithmetic, elementary applied problems, mental arithmetic, column arithmetic etc. in an optimal way within given contexts and
do not restrict your activities by the girdle of the stepwise subject area
oriented structure of the world of numbers. Then, at an appropriate
moment, tie the strings between these arithmetic domains.
Thirdly, a conclusion drawn by Bauersfeld from the domain model,
which is of course connected to the previous ones, generally runs as
follows: allow informal subjective approaches also within the subject
matter system, and beware of aiming for standard methods, otherwise you
may ruin the fertile soil of learning. Or, formulated in the language of
domains: by repressing the informal element and imposing the formal one,
domains are isolated and cut off from fundamental experiential domains,
and too little opportunity is granted to holistic 'coincidental' learning of
knowledge, abilities, strategies and attitudes.
Fourthly and again closely connected to the preceding points, not only
does Bauersfeld on the grounds of his theory, show a certain reserve
towards the formal structuralist view but also structuralism of the Dienes
persuasion. This kind of instruction can, no doubt, fairly quickly claim
success, but this is, in fact, an illusion. It is, according to Bauersfeld, stenle
instruction, with no opportunity for interaction and communication, isolated from reality, and therefore from the fundamental domains of subjective experiences.
FRAMEWORK FOR INSTRUCTION THEORY 285
Fifthly and last among the instructional implications of Bauersfeld's
domains model, which aim specifically at learning difficulties and remedial
instruction. Rather than founding diagnosis and remediation on subject
area logic and mathematics, Bauersfeld concludes:
Investigating relevant subjective experiential domains by means of long term case studies at
preschool age (and after) would lead to more trustworthy appreciations of, for instance,
what --nceptual distinctions are also subjectively important, what connections of meanings
are difficult or rather obvious or even self-evident, what kind of experiential domains are
appropriate as up to date foundations and which contextual contradictions could possibly
obstruct their tying up to the mathematical concept.
44
The kind of instruction Bauersfeld is aiming at, strongly emphasises:
subjective experiences and the development of comparing and connecting
domains by means of reflection, incited by interactive processes. In brief,
we may rightly conclude that the model of domains of subjective experiences generally leads to realistic mathematics instruction as described in
the preceding chapters.
So far, we have sketched Bauersfeld's attempt at forming an interactionalist theory. We should, however, mention that in particular with respect
to interactionism in the teaching/learning process, other theoretically

oriented research is being carried on in the mathematical area. First,
Brousseau's work ,on the crux of the so-called didactic contract for the
analysis and construction of teaching/learning situations.
45
Then, Balacheff
and Laborde's studies, which pay attention to the importance of the pupils'
own productions in a communicative context and to the resulting sociocognitive conflict.
46
Finally, Bishop's placing of interaction within the
broader context of the social dimension of mathematics education with its
cultural, societal, institutional, pedagogical and individual levels' and his
call for further development of this area of research in mathematics
instruction.
47
Bishop and Goffree also stress the importance of interactivity, and of communication and negotiation in the classroom.
The last paragraph was meant as additional information with regard to
an important aspect of Bauersfeld's and related work.
(3) Lesh 's conceptual model
In studies of Lesh et al. the theoretic construct of 'conceptual model' is
central. In this construct the following components are distinguished:
- a concept is decomposed into subconcepts; for instance, where the
number concept is concerned, this could be the numerosity aspect,
the measuring aspect; the ordinal aspect, the calculating aspect, the
label aspect; or where the concept of fraction is concerned, it could 286 CHAPTER VII
be the operative aspect, the part-whole aspect, the ratio aspect etc. -
or, in general the various structural manifestations of the concept in
the reality: the within concept networks;
- the relation between these within-concepts and those with related
concepts - such as fractions - are related to ratio, division,
geometry, decimals, magnitudes: the between-concept networks;
- the embedding in various systems of representation: concrete materials, pictures, symbols, real world situations; the system of modeling
processes for problem solving, that is, the way to translate problems
into mathematics, solving within mathematics and feeding back into
the original situations.
48
In this way a conceptual model filters the information couched in the
problem and organises and transforms its data. Lesh et al. are not only
concerned with the identification of the subjective conceptual models but
also with the search for the mechanisms that influence their origination
into being. This is, indeed, a typical learning theory concern: not only is
the status quo described but also how to model the students' modeling.
In the affirmative part of the research on conceptual models and on
the corresponding applied mathematical problem-solving processes, the
most striking results on rational numbers can be generally formulated as
follows:
- there is an 'instability of the subjective conceptual models': a minor
change in the problem can have a major impact on performance
with, as a consequence, a major regression in conceptualising in a
(short) period where instruction is not oriented towards the concept
in question;
- the external mode of representation reveals nothing about the degree
of difficulty of a problem: problems which are posed in terms of
concrete material are not necessarily easier than structurally equivalent ones which are formulated in the writing of symbols (possibly
surprising for Brunerians);
- representing a problem can be a quite active process in which pupils
alternate between modes of representation (manipulative models,
pictures, symbols, real scripts) and use several ones simultaneously;
- the internal representation influences the external representational
expression and, conversely, the externalisation allows the pupils to
refine the internal representation: a cyclic process of internal and
external structuring;
- pupils are inclined to work straightforwardly towards the precise
answer; there are few instances of estimates or approximations;
- pupils do not care whether different procedures applied to the same
problem lead to different answers (this recalls the 'microworlds' and
'domains of subjective experiences').
FRAMEWORK FOR INSTRUCTION THEORY 287
All in all Lesh states that pupils can better be characterised as modelers
than as processors. And as far as processing is concerned, it is a processing of the conceptual models themselves rather than that of rough data.
According to Lesh, this is one of the reasons why problem solving and
concept formation should not be considered separately - 'thinking is
domain specific, says Lesh.
Passing from these theoretic facts to the constructive part of his
research, Lesh emphasises the role of the focus on real math real
situations and real pupils. In brief his choice is a realistic starting -oint.
Let us quote:
It is not necessarily the case that students first learn an idea, then add some general
p.roblem-solving processes, and finally (if ever) use the idea and processes of real
situations, that is, those in which some knowledge about the situation is needed to supplement the underlying mathematical ideas and processes.
We believe that applications and problem solving should not be reserved for consideration only after learning has occurred; they can and should be used as a context within
which the learning of mathematical ideas takes place.
49
Extensive research undertaken by Lesh, Behr, Post, Silver, Landau,
Hamilton, Wachsmuth and others has not yet made plausible that this
starting point yields better instructional results than other systems. One
may even state that a long term developmental process of realistic
mathematics instruction was not (yet) possible in this broad area within
the various projects." Nonetheless, the results of the affirmative research
as presented above and of the micro-constructive research are highly
valuable.
Lesh also mentions an experiment in computer-based instruction with a
realistic starting point as explained above:
. . . we have compared groups of students receiving a traditional 'teach first, apply later',
instructional approach to groups receiving a computer-utilities-based 'application first,
conceptualization refinement' approach. The results have shown that, for comparable
amounts of instructional time-on-task, the utilities groups consistently have outperformed
the control groups; and they have done so not only, on 'applications' or 'problem solving'
post-test items, and on items focussing on the meanings of the underlying concepts, but
also on 'computation' items associated with the topics - even though the utilities groups
had no practice at all on the pencil-and-paper computations.
50
If, summarising, we compare Lesli's conceptual model view with the theoretic framework of progressive mathematisation, we may ascertain a
close agreement with regard to the starting point of the global phenomenological basis, although more strongly than Lesh we emphases the pupils'
own productions, interactive learning (in which we agree with Bauersfeld,
Brousseau etc.) and the importance of teaching paradigms (as does Davis).
Nevertheless, agreement preponderates. Here we should also mention the
important part that Lesh plays in the discussion on subject-area-oriented
versus more general psychology-oriented research and with regard to the 288
CHAPTER VII
issue of various methods of analysis, such as task analysis, analysis of
children's cognitive characteristics, information processing analysis versus
conceptual analysis of mathematical ideas introduced by himself. However it would lead us too far away to discuss agreements and disagreemen;s between conceptual and didactic phenomenological analysis. It may
suffice to remark that they complement each other excellently as far as the
first is more research-oriented, whereas the second is based on broad and
profound contemplations from various perspectives and fundamental
thought experiments, and thereby stands at a distance from mstruct1Onal
practice.
The problem solving approach in concept formation, adhered to by Lesh
and others, is also shared by Vergnaud, who in this context speaks about
conceptual fields fitting related concepts and relations.
51
Vergnaud's
standpoint is that concepts develop gradually through problem solvmg
processes; he adheres to the re-invention principle which was mentlOned
earlier in connection with Freudenthal's didactical phenomenology. Vergnaud, however, at variance with Lesh, uses formal mathematical structures
as tools to analyse learning processes, which leads him to statements on
rational numbers such as:
It is true that most general properties of rational number cannot be expressed and
explained unless rational numbers are viewed as pure numbers. This is the case of crossmultiplying, for instance: a + b = c + d, ad= be, a + c = b + d.
What would it mean to multiply a and d if a were an M,-measure and d an
M--measure? But it is true and important that understanding multiplicative structures does
n-t rely upon rational numbers only, but upon linear and n-linear functions and vector
spaces too.
52
In spite of this statement, Vergnaud does not choose a formal point of
view. On the contrary, he turns sharply against structuralism. But by
means of such formally oriented statements he tries to briefly and sharply
analyse and typify the system of concepts and the structural variations in
theirapplicability in reality. . , .
Finally, again referring to rational numbers, we ment10n. Regme
Douady's work where the relation between conceptual acqu151t10n and
technical competence was studied.
53
She uses the instructional method of
'tool-object didactics' and, related to it, the 'interplay between settings'. In
the tool-object didactics she distinguishes six phases which are pas-ed
through after a set of meaningful problems have seen offered, which
initially cannot coll).pletely be solved by the pupils. It runs as follows:
1. available knowledge is applied explicitly
2. this newly acquired knowledge implicitly unfolds and
3. is made explicit and locally organised in order to be
4. globally inserted into the knowledge inventory, from which
5. its applicability is exercised, after which,
FRAMEWORK FOR INSTRUCTION THEORY
289
6. the concept is brought in contact with other concepts in complex
situations.
The 'interplay of settings' means, according to Douady, that a certain
problem can externally be represented multifariously (by numbers, letters,
graphs, geometrically etc.) and that dealing with the problem in various
settings can yield unexpected results, new techniques and, finally, a richer
knowledge in the original setting. This is illustrated by multiplication of
fractions in a long term research project which precisely exemplified what
Lesh calls 'how to model the children's models'.
(4) Final remarks
Our presentation of the work of subject-area-oriented researchers has
shed new light on, and contributed more profound understanding of the
theoretic framework of progressive mathematisation. In a random order
we recall:
- the metaphoric character of learning;
- the importance of paradigms;
- the crux of interaction;
- the domain specific aspect of knowledge structures, frames, microworlds, conceptual models, domains of subjective experience or
however one wishes to indicate this 'idea';
- the embedding of problem solving into processes of conceptual
acquistion;
- the virtual independence of mutually related knowledge structures;
- the possibility of connecting and integrating them in reflective
processes;
- the interaction between internal and external representations in
problem solving;
- the instability and progressive structuring of conceptual models.
All these ideas and quite a few others can in principle serve to describe in
greater detail and to understand more profoundly the phenomenological
start, the level theory framework and the five tenets of progressive
mathematising.
It is worthwhile observing that subject-area inspired research globally
bears a non-mechanistic and non-structuralist signature, in contradiction
to the general psychological research to be dealt with in the next section.
5.3 The Almost Complete Absence of Instruction Theory Ideas in General
Cognitive Psychological Research
The implications of general psychological research for instruction theory
can be dealt with rather briefly, because most of it is affirmative learning 290 CHAPTER Vil
theory rather than constructive instruction theory, Resnick and Ford
express their cognitive psychological view as follows:
Instructional processes cannot be greatly clarified and improved unless we can both look
into the mind and chart changes in capability.
54
The primacy of the learning psychology component is above all conspicuous in the attitude towards developmental research via teaching
experiments,55 Macro-teaching experiments with groups of pupils where
the researcher determines the teaching matter sequence are in general not
considered as part of cognitive psychological research - this in contrast
with the activity-psychological work in the Davydov schooL
56
Microteaching experiments, however, that are thought-oriented rather than
curriculum-oriented, fit fairly well into cognitive psychological research,
They are usually undertaken with individual subjects,
Such a dichotomy of thought- and curriculum-oriented research, however, is hardly acceptable for subject area-oriented didactic research, as
we noticed earlier, With Davydov and his followers we are inclined to
believe that, in the domain of mathematics instruction, cognitive development is for a non-negligible part determined by instruction, which includes
the choice of the teaching matter sequence, For them, and also for us, this
means that instruction too should be an object of research, Therefore the

best and most appreciated instructional courses should be implicated in
developmental research. As long as, for instance, for learning the long
division procedures no new instructional environment is created in which
the pupils can themselves develop the standard algorithm, then according
to the realistic conception, no conclusions can be drawn of a teaching/
learning theory character about the part played by elementary contexts in
partition and distribution situations for the performance of mental actions,
the enchainment of informal and formal procedures, the meaning of
schematising and shortening in this chain, and so on - this would be our
subject area-oriented didactic reasoning.
(1) Learning-oriented versus teaching-oriented,'
background of a disagreement
Gal'perin distinguishes two kinds of analysis of the teaching/learning
process: the logical and the psychological analysis, The distinction is quite
useful if one tries to understand what is behind attributing various weights
to the learning and the teaching component in research and theory
building,
57
So, the cognitive psychological theories in general start from weak
mathematical-logical and powerful psychological structures or thinking
processes, whereas according to the subject area didactic persuasion it is
just the other way round - relatively speaking,
50
In other words: -eneral
FRAMEWORK FOR INSTRUCTION THEORY
291
cognitive psychology views the mathematical structures primarily within
the subject area systematics, They are abstract in the sense of being
removed from the real manifestations and they are situated on the formal
symbolic level. Although general and comprehensive, as such they are
structurally poor. In particular, most information processing analysis
systems are satisfied with rather simple networks of knowledge structures,
where the structural element of mathematics is more conspicuous than the
phenomenological aspect There is hardly any analysis and research where
the real manifestations of structures and operations serve as source of
concept attainment. In brief, as far as teaching experiments are undertaken, they are mostly structuralistically organised, and thus grafted onto
rather weak contents structures and rather powerful thinking processes,
which in turn are intended to connect different knowledge structures,
As repeatedly emphasised, according to the didactic view, the mathematical content is not exclusively structured according to the subject area
systematics, The mathematical structures are primarily found in the context of real manifestations, There they are no less general and comprehensive than in the structuralist form but, in addition, their phenomenological
structure is richer, As we noticed above, structuralism is hardly espoused
by those who hold that view, More room is left for design in educational
development than is enjoyed in the cognitive psychological camp, since
one is not locked into in the organisational framework of the teaching
matter according t- subject area systematics, Learning long division,
mentioned above, is an example which illustrates the consequences.
(2) Learning-oriented versus teaching-oriented' causes of a disagreement
But why does cognitive psychology lean towards structuralism in contradistinction to subject area didactic approaches?
Well, the reasons have partly been pointed out in the discussion on
microworlds and domains of subjective experiences, Roughly stated, there
are two categories of 'model of mind', According to the first, mind is
unitary and mental operations are essentially domain-independent According to the second there is, as it were, a 'society of mind', Kilpatrick says:
The mind is a collection of partially autonomous smaller minds, each specialized to its own
purpose, that operate in parallel rather than sequential fashion.
59
In this kind of model, thinking is domain specific,
Cognitive psychological research prefers the first kind of model while
the second is the choice of subject area-oriented researchers and theoricians, The model of the all-purpose mind with its context-independent
mental operations fits smoothly, in particular, into the computer metaphoric picture of cognition: the information processing occurs step-by-step
and the information storing takes place at certain places and addresses, 292 CHAPTER VII
just as is the case with digital computers, where the programs are
expressed in high-level language. However, more recently 'It has been
pointed out from various sides that conventional computers are not such a
good model of cognitive processes (take arithmetic on the one hand and
geometry on the other), probably for the reason the brain operates not so
much sequentially as simultaneously, thus as a network of parallel computers which are more specialised in certain domains than a generalpurpose computer, perhaps something - _let's say - . like fifth generat10n
computers. This picture, then, would possibly be a bit more m agreement
with the model of mind prefered by subject area didactics.
60
(3) General cognitive psychological theories and
realistic mathematics instruction
It might seem too far-fetched to reduce the discussed disagreement in
orientation on either learning or teaching exclusively to disagreement on
models of mind. The researcher's or theoricians's unsophisticated view on
mathematics might be highly influential too. If this is correct we should not
be surprised that psychologists (as well as most mathematicians) choose a
structuralist approach. But starting from a general cognitive theory, which
might be either an activity theory or a cognitive psychological theory, _one
should in principle be able to arrive at structuralist as well as at realtstic
developments and actualisations of mathematics instruction. In other
words, in principle no impediments, not to mention obstacles, arise from
these theories - for instance in the case of column arithmetic - in the
way of choosing and investigating applicability more dosely_. .
Take for instance Gal'perin's theory of the stepwise buildmg of mental
actions.- 1 According' to this instructional procedure each mental activity
should be prepared by an activity on material or materialised level. that
already bears all features basic to the performance of the mental actlVity.
Thanks to this mirroring of the nuclear elements on the vanous levels of
performance (material-perceptive-mental) the pupils can orient themsel-es
from the very beginning completely and concretely towards the anthmetical activity. Then both in the course of column arithmetic according
to progressive complication and the course according to progressive
schematisation the performance can take place on different levels. The
difference is that, in the first case the phasing affects every partial instance
separately whereas, in the second, it concerns the totality of the course.
Exactly the same holds for Gal'perin's second parameter: m the first
case shortening takes place in each special instance, in the second
'vertically' across the whole course. .
The two other activity parameters, the degrees of generality and of
mastery, tend to be broadened by the realistic approach: not only column
arithmetic but also its applicablity is affected.
FRAMEWORK FOR INSTRUCTION THEORY 293
In Gal'perin's theoretic framework this should not be a disadvantage at
all. Therefore starting from a general instruction theory of the activity
psychology kind, one can arrive at two essentially different teaching
courses. Gal'perin himself would hold logical analysis responsible for this
difference: obviously one can view mathematics in two radically different
ways.62
He would therefore recognise that a general framework for
instruction theory alone does not offer enough points of support for
developing acceptable mathematics instruction.
Indeed, in our example the essence of algorithmising can be found in
the straightforward conveying of insight into the standard procedures, as
well as in the process of schematising and shortening. Gal'perin - unlike
Davydov - leaves this choice to the subject area expert, thereby withdrawing a fundamental part of organisation of teaching matter from
psychological research. But in his own research he often implicitly takes
the structuralist stand although this is not inherent, as we have shown, to
his theory of instruction.
Mutatis mutandis this also holds for the instructional component of the
information-processing approach. Again, the structuralist design of the
micro-teaching experiments and the clinical investigation is not, or cannot
be, justified within the general theoretic framework, although there would
be every reason for not restricting oneself to the psychological component
of the learning. 'Thought-oriented versus teaching-oriented' is no valid
excuse; indeed, such a separation can hardly be maintained against the
earlier mentioned arguments on subject matter didactics.
From an instruction theory perspective one might regret the lack
of new thrusts supplied by general psychology. As mentioned above,
Davydov is an exception, although even his developmental research,
aiming at the developing of scientific concepts, is rather structuralistically
designed. However, we would be digressing too far here were we to
outline in which direction his orientation to both Bourbaki and Lakatos(!)
is leading.
63
(4) Nuances
Here our only intention is to show that general cogmve and activity
psychological theories cannot serve as instruction theories for mathematics. Hardly any rules for developing and actualising instruction can be
borrowed from them - none, at any rate, for realistically oriented mathematics instruction, unless one is satisfied with rules about what should not
be done. As a matter of fact, in this respect and with respect to early
instruction, affirmative cognitive psychological research can teach us
lessons. Striking examples can be found in the studies of Carpenter &
Moser, Riley, Greeno & Heller, and De Corte & Verschaffel.
64
From their
research one general positive conclusion for instruction can be drawn, 294 CHAPTER VII
namely that real situations can function excellently at the start of instruction (developing the number concept). This, then, is exactly the realistic
starting point, which in general is shunned in the micro-teaching experiments of general cognitive psychological research.
5 .4 Overview
Let us pass the foregoing as viewed through the framework for instruction
theory of progressive mathematising in review - short references to the
discussed theoriticians and researchers will suffice. By this sketchy review
we will demonstrate that the present chapter was not meant so much to be
a description of numerous frameworks for instruction theory but rather as
a means to deepen various nuclei of the realistic framework as described
here.
Starting points for mathematical instruction were expressis verbis discussed in the case of Davis' cognitive science approach. They appeared to
be broader than that of structuralistic mathematics instruction.
The framework for Van Hiele's level theory was put into relief against
the background of Dienes' learning cycles, as well as of Piaget's and
Bruner's theories.
In the micro-sphere of mathematising the levels in the learning process
appeared in our sketches of Lawler and Gal'perin.
The phenomenological approach can be deepened through Lesh's
conceptual models and Bauersfeld's domains of subjective experiences,
and by way of contrast, through the work of Gagne and Dienes.
The important part played by situation models (context models) was
recognised in Davis' paradigm teaching strategy, as was that of modes of
representations in Bruner's, Davis', Lesh's and Douady's theories, and the
relation between internal and external representations mainly in Lesh's
theory.
The constructive aspect is present in almost all the theories we discussed, although the pupils' own productions, such as defined by us as one
of the most powerful means of organisation and reflection, was not (or
almost not) explicitly mentioned by others.
Attention to the interactive aspect was paid in Piaget's (later) work, by
Bauersfeld, Brousseau, Balacheff, Laborde, Bishop and Goffree.
Intertwining of courses is found in the theories of Lesh, Bauersfeld,
Vergnaud and Douady and in a general sense, in cognitive theories.
The more recent didactically oriented theories show a trend towards a
kind of interactive realistic mathematics instruction. The more general
cognitive psychological theories, on the contrary, choose in their microteaching experiments a structuralist mathematics instruction. Although this
is not implied by their general psychological standpoint, their models of
mind, with the computer metaphor, emphasis more strongly psychological
FRAMEWORK FOR INSTRUCTION THEORY
295
processes than rich content structures. This, then, is one of the reasons
why subject area didacticians react with reserve to the metaphorical use of
the computer for the learning process.
Finally, we point out that the theory of progressive mathematisation as
presented here should properly be viewed in close connectioh with its
operationalisation in the concrete Wiskobas programme covering a large
part of mathematics instruction from ages 4-12. The theoretic framework
is in a sense a composite of partial theories as developed and described
for a number of courses. Or.I more to the point: it is an attempt on the
third Van Hiele level to arrive at a global theoretical organisation via local
organisations on the second level which, in turn, came into being by reflection on developing and actualising mathematics instruction for the primary
school. Certainly more than is the case with many of the cited theoreticians, we have placed ourselves primarily on the level of educational
development, with the emphasis on textbooks. For this reason, our
analysis of the different persuasions was mainly concerned with the
textbooks and manuals available on the educational market, rather than
with material of certain projects or ideas of individual researchers of
theoreticians. In the present chapter, however, this textbook picture was
supplemented by that obtained from more theoretically oriented studies
related to instructional practice, from Gagne to Gal'p-erin.
5.5 Closure
We started the present study with a sketch of the cube of goals. With
Steiner we believe:
that value and goal orientation should be also important factors of every systems view of
mathematics education commencing with the fact that mathematics itself - like other
sciences - is not a value-free human activity.65
In this goal-space we made a theoretical Lissajous flight in which we
touched all teaching subject faces of the Wiskobas programme. The three
parameters by which this flight of thought was described are Van Hiele's
level theory, Freudenthal's clidactical phenomenology and Wiskobas' progressive mathematisation, operationalised in a concrete programme of

mathematics instruction at the primary school. And we considered this
flight from outside too.
The reason why the goal descriptions were followed by a description of
the framework for instruction theory is found in the great diversity of the
various concrete instructional situations which we described. Their paradigmatic force was not strong enough to evoke an adequate impression of
the curriculum in its totality. For this reason, we passed in review in this
last chapter the general instructional patterns of the themes and the
curriculum, that is, of Wiskobas' framework for instruction theory. (We
. I
.!, .
'I
I296 CHAPTER VII
say 'general', because we let the 'specific' instruction theories, placed
within the general framework, about for example, the basic facts, column
arithmetic fractions, area etc. out of view. A detailed study of the
theoretical framework as a whole would take a new volume.) Against this
background the goals themselves might be better understood. In the
chapters on goals as well as in those on theory we applied the so-called
one- two- and three-dimensional description, thus 'three dimensions as a
mod-' of goal and theory description in mathematics education'.
.
NOTES
CHAPTER I

Curriculum-Reform in den USA mit Ausblicken auf Schweden und England, Berlin
1968.
For an overview of the situation around 1977 see:
Kapur, J. N.: 'New Mathematics movement, is it over?', International Journal of
Mathematics Education in Science and Technology8 (1977), 259-267.
1
This distinguishing of three directions in mathematics education alongside the existing
pluriform arithmetic instruction connects fairly well with the division made by Dienes and
Williams:
a. the basic-set approach;
b. the arithmetically-oriented approach;
c. the geometrically-oriented approach;
d. the science-oriented approach;
e. the symbol-game-oriented approach;
f. the object-game-oriented approach.
We consider a. and b. to belong tO the New Math and the innovative arithmetic instruction;
c. and d. agree in our view with the empirical trend;
e. and f. are in our division related to the structural direction.
These divisions are idealised, pure types: in reality blends will be encountered in which the
various approaches are found in varying proportions.

Mr B 20 July 2016

Interviewer: Thank you very much sir, for coming and for being willing to take part in the research. I'm going to ask a few questions, you can answer freely, speak about the experience that you have from school, from any source that you have, as you feel comfortable to do. You said earlier that you are teaching grade eights currently?
Participant: yes
interviewer: Is it the only grade that you are teaching?
participant: Mathematics, it is only grade 8.
interviewer: what sections of the curriculum are most problematic for you?
Participant: At grade 8, it's .... for me, or for the learners?
Interviewer: both, let's hear what is a problem for you and what is a problem for the learners
participants: Uhm, it's algebra
interviewer: algebra, is that for you or for the learners?
Participants: for the learners, I don't have a problem. Learners do have a problem with algebra and integers in fact. If they do have a problem with integers, it is going to give them a problem when dealing with algebra
interviewer: right
participant: then the other one is geometry.
interviewer: okay, geometry
participant: yes. geometry gives them a hell of a problem.
Interviewer: why do you think that is the case?
participant: I think it's because they lack a proper foundation, the problem starts at the foundation phase.
interviewer: okay
Participant: so if they don't have a good foundation, they are going to have a problem at the higher grades
interviewer: so, it's a problem with foundations of geometry basically
Participant: yes. And then with integers, I'm not sure what's the problem.
Interviewer: Hmm. Perhaps it's because it's new to them, when do they learn about integers? do you start teaching them about integers in grade 8?
Participant: Ja, we start at grade 7, but it is just basic.
Interviewer: Hmm
Participant: actually they start at grade 8.
Interviewer: okay
Participant: Grade seven they are just introducing it, then they leave it
interviewer: all right. And for you personally, which sections of the curriculum are problematic for you to teach, or are you comfortable with the whole curriculum?
Participant: at grade 8 I'm comfortable.
interviewer: if you were to teach higher up, other than grade 8, what would be challenging for you then, should you teach higher grades?
participant: which grades?
Interviewer: anything higher than grade 8
Participants: great eight and nine I think I will be comfortable
interviewer: okay
Participant: because I have experience with those two grades, but I have never taught grade 10, 11, 12. So I think ..... I'm not sure which areas would give me a problem in grade 10, 11 and 12. I've never taught it before.
interviewer: okay. Perhaps I can mention a few then you can tell me from your years of studying and so on if there was a problem there or not. Something like probability? Do you know anything about probability?
participant: yes, they do it in grade 9, probability.
Interviewer: okay. Statistics also then?
participant: yes.
Interviewer: you are familiar with that?
participant: yes
Interviewer: okay, what about calculus?
participant: Ja, maybe calculus, I'm not sure about that.
Interviewer: okay, what about financial maths?
Participant: Ja, financial maths, it is also problematic to learners, financial maths
Interviewer: at grade 8 level?
participant: Grade 8 and nine, hmm.
Interviewer: Okay. The next question I want to ask is: how often are you able to relate the content that you are teaching to real life situations?
participant: how often?
Interviewer: Hmm.
participant: (laughs)
interviewer: you can be honest, you can say that you never do it, or you try but you're not sure how
participant: Hmm, there are topics that we can relate to real-life situations, the others they are a little bit more confusing or difficult to relate.
interviewer: True
Participant: So to tell the honest truth, it depends on the topic.
Interviewer: Right, So in line with what you are saying, which sections of work do you think will be easiest to relate to real-life?
Participant: financial maths is easy to relate, exponents will be a bit difficult, and then even integers is easier to relate.
interviewer: okay, any more topics?
Participant: Then, probability you can relate, what are the other topics? Data handling is easy to relate, even measurement is easy. I think exponents is problematic and algebra, functions.
interviewer: okay, so there are a few sections that you think can be related to real-life, like those that you have mentioned already.
Participant: yes
Interviewer: In which sections of the curriculum do you need help to link the content to real-life situations?
participant: Sections of the curriculum?
Interviewer: Yes.
participant: I think the ones that I have mentioned, even integers I think I need help, because learners are not doing well when it comes to integers. Then if they are not doing well, I used to think that maybe I need some sort of development.
interviewer: Good
Participant: And algebra.
Interviewer: Algebra, okay. Then you also mentioned functions?
Participant: Ja also functions.
Interviewer: Okay, good. So even though you do try to relate integers to real life, you still feel you need a little bit of support in that area?
Participant: Yes, because when you are teaching integers, it may look as if learners understand, but if you give them a test, they fail it.
interviewer: Right
Participant: But when you are teaching integers, you may think they understand.
interviewer: I see, do you think it's important to relate your teaching to real-life situations or is it not important?
participant: It is important
interviewer: Why do you say that?
Participant: Because if you relate it to real-life situations, it becomes easier for them to understand and they can also relate other things to the topic that you are teaching.
Interviewer: Good
participant: It is important.
Interviewer: It is important. So in that module of mine that you do at honours, it comes up there relating anything new to something familiar, is quite important. So in that respect, it helps the learners to understand better.
participant: And to remember.
Interviewer: And to remember. How do you feel about using technology in your teaching?
participant: Technology, such as?
Interviewer: Anything, think of what is available to you and even things that are not available to you. Perhaps the overhead projector is available to you, I'm not sure, think beyond that as well. Think in terms of electronic whiteboard, computers, handheld devices like tablets, cell phones, think of any kind of technology
Participant: At present we don't have technology devices at our school, but I think those devices if we can have those devices they are going to help us ... because it will ease the burden ... uhh ... especially of, how can I put it ... uhh ... let me just think about it for a while.
Interviewer: Okay, while you thinking about that, let me ask you this. Of the technology that I have mentioned now, which ones do you think would be the best to use? I realise at schools the technology is not available at the moment, but imagine it was a perfect world and you could get any technology to use in your classroom. Which ones do you think would work the best?
Participant: I think computers will work the best.
Interviewer: Okay, for each learner? Or for the teacher to use?
Participant: Both the teacher and the learner, computers will be the best, if they are used properly. Because they will have a negative effect at times
Interviewer: Of course, anything else? Any other form of technology?
Participant: Except for the? .... okay the tablet. About the cell phones, I don't think it's good
Interviewer: Okay, why do you say cell phones are not good?
Participant: (laugh) I think with cell phones, ... uhh ... you can say cell phones are not designed for teaching and learning, it's just for communication purposes, so if you use them for teaching and learning, I don't think it's a good idea, unless if you want to communicate with them, send them homework, maybe the results, something like that.
Interviewer: Okay, so again a form of communication?
Participant: Yes
Interviewer: This question links to what we have just spoken about: how do you feel about using mobile technology such as Whatsapp, SMS, for you to discuss with me and with other colleagues, possible ways of making the maths more realistic for your learners. So not for your learners, but more a communication between you and me and other maths teaching colleagues?
Participant: Ja, in that way it is good. Like I said, for communication, it is going to work.
Interviewer: Okay.
Participant: Even between the teacher and the learner. If the learner is phoning the teacher to discuss something related to school work, at least in that way it is good.
Interviewer: Okay. Do you have any experience with Whatsapp? Do you use Whatsapp?
Participant: Yes I do use Whatsapp.
Interviewer: How would you feel about using Whatsapp also to be part of a group, to communicate with me and other colleagues about issues about Mathematics. Would you be willing to join a group like that?
Participant: Yes.
Interviewer: Or would you prefer to use it just for your personal use?
Participant: No, I'd be willing to use it with other colleagues to discuss tasks related to Maths.
Interviewer: What experience do you have with Facebook?
Participant: No, I don't like Facebook
Interviewer: Why not?
Participant: (laugh)
Interviewer: Have you used it before?
Participant: No, not at all
Interviewer: Do you prefer not use it?
Participant: I prefer not use it, because even those people who do not know me will invite me even if I do not know them, to join them the Facebook and then everyone will get the information. So I prefer those ways which are a little bit personal.
Interviewer: Perhaps you are concerned about the security issues of Facebook?
Participant: Yes.
Interviewer: Okay, also this is a follow-up question: How do you feel about using Facebook to discuss Maths, issues related to Maths, for your learners, again it will most likely be with me and with other colleagues. Similar to the Facebook group that I've started for the BEd honours group, Would you be willing to do that? Or would you prefer not to be involved with Facebook?
Participant: I would prefer not to join.
Interviewer: Okay, rather something like Whatsapp would suit you better?
Participant: Yes

Interviewer: Okay that's fine. What experience do you have regarding interactive whiteboards?
Participant: Interactive whiteboards? Like the ones which are used at the University? I don't have any experience.
Interviewer: Other than attending contact sessions?
Participant: No
Interviewer: Haven't you attended contact sessions with the presentation has been done on the whiteboard?
Participant: Okay, okay (laugh) it's because the lecturer is there. So I think that one is good. For me it's good.
Interviewer: Okay, you are fortunate enough to attend the contact session at Potch, where the lecturer is. If you were to be a student elsewhere in South Africa and it wasn't possible for you to come to Potchefstroom, tell me how you would feel then about the interactive whiteboard. What you think they would experience it like?
Participant: Hey .... (laugh). I think for them it's good. It's good because they are getting what we are getting, but to tell the honest truth, I won't be happy. It's just like listening to the radio, but it's good. Sometimes we listen to the radio, and we get the information. And even the television, we watch the television and we get that information that we need from the television.
Interviewer: Without being there with the person that is presenting?
Participant: Yes it's good, it's good. We watch a match there, a rugby match, and then you just feel as if you are at the stadium.
Interviewer: Okay, how would you feel about using the interactive whiteboard also to discuss issues of making Maths more realistic for your learners? Again, imagine a group between you and me and other colleagues. If we were to for example meet over the whiteboard so that there might be somebody in KwaZulu Natal, they might be somebody in Polokwane and you at one place and me at another place, how would you feel about communicating through the interactive whiteboard?
Participant: I would feel good.
Interviewer: You would be happy to do that?
Participant: Yes
Interviewer: Any particular reason why?
Participant: It's just like the reasons I mentioned earlier.
Interviewer: Okay
Participant: That you are going to get that information looking at that person, even if it is in the screen, at least you can communicate with that person. And especially sharing those ideas of Mathematics, it will help a lot.
Interviewer: How do you think is the interactive whiteboard different to for example just a telephone conversation? Because that is also a way of communicating? Do you think there is a difference? Or do you think it is just a matter of talking?
Participant: There is a difference, because with a whiteboard, they will be those writings, and with a cell phone it will just be communication.
Interviewer: Good, so you can share documents and many other things?
Participant: Yes.
Interviewer: What type of technology will you personally be most comfortable with in this project?
Participant: In the project ....
Interviewer: To communicate with me and other colleagues, and should you be able to use it for your learners, which type of technology would you feel comfortable with?
Participant: To communicate with you and other colleagues, cell phone is okay, tablet because those are the ones which are available. The others I don't have, they are not available. But if the whiteboard was there I would also prefer the whiteboard.
Interviewer: Okay
Participant: Uh, ja, I think those are the ones.
Interviewer: And in your classroom for your learners? Imagine that there is no, you know, say for example, if it could be provided to you, what would you be willing to use in your classroom for your learners?
Participant: I like that with the whiteboard
Interviewer: The whiteboard? Okay.
Participant: Because if you are prepared, it could save time. You don't have to write again. As long as you prepare in time, then you just put your preparation there and you go on, so a lot of time will be saved
Interviewer: Good, so that'll work for you?
Participant: Yes. Even there the computer also, more or less that is almost the same as the whiteboard
Interviewer: So, you would like to have a computer in your classroom?
Participant: Yes
Interviewer: Any particular reason, other than for the presentation, would you use it for anything else other than presenting to your learners?
Participant: With a computer, I think there are other programmes which might help. When I was doing ACE in Potch, there are those programmes where you will be tested on a certain topic. Then the computer will immediately correct you and show you how to do this problem if you are doing it wrongly.
Interviewer: Good, so there is software that can be used on a computer?
Participant: Yes. It will help the learners, even with speed. Uh, marking, even that immediate feedback, because if you are given feedback immediately, you can try it again.
Interviewer: True. Mr B, is there anything else that you want to add or say? Anything you can think of relating to real-life teaching Maths, and relating to using technology in the classroom? Anything else you feel strongly about?
Participant: Uhm, I think we have said a lot. What about these calculators? Because with the grade eight, let me say grade six, seven and eight, I think that using calculators is not good. Because they tend to ....., how can I put it - to lose those skills, calculating skills or basic skills of Mathematics. Even a simple problem, they want to use a calculator instead of doing it themselves.
Interviewer: True. What about ... I know that you teach grade 8 to 9, but what about the higher standards? Do you feel the same about them and calculators? Or do you feel differently?
Participant: No, no, calculators at least with them, it saves time. Because there, they are doing more complicated things. For example with financial Maths, they have to use a calculator.
Interviewer: They don't really have a choice for certain sections?
Participant: There are so many formulas that they have to use.
Interviewer: Ja, trigonometry also?
Participant: Trigonometry also. You cannot do trig .... okay you can do some basic things, but trig needs a calculator.
Interviewer: Thank you, I think that wraps it up. Thank you very much for your time.
Participant: You are welcome.

Mrs S 15 July 2016

Interviewer: Welcome, ma'am and thank you for taking part in the research. Thank you for coming to Potchefstroom to talk to me. I am going to be asking you a few questions, and like I said you can answer freely, talk about your experience at school and even if it comes to something that perhaps you haven't used in your classroom before, feel free to think about possibilities. Perhaps if you were to use certain things in your class, what would you like to do? How would you like to change things? So we are looking at what you are doing currently, but also possibilities for future development. Let me ask you, what grade level do you teach at the moment?
Participant: I'm teaching Grade 12 Maths Grade 12 Maths literacy and Grade 11 Maths literacy and Grade 9 technology
Interviewer: So you have a full load
Participant: Yes, a full load
Interviewer: What sections of the curriculum are most problematic for you to teach?
Participant: Hmm ... Permutations, those factorials. Not data handling, but part of it ...
Interviewer: Counting techniques?
Participant: Yes, counting principles, yes.
Interviewer: That's also new to the syllabus?
Participant: Ja, it's new. I once did it at university, but I couldn't even remember it, but .... We even went to the workshop, but you know those workshops are only for three days. And we were doing so many things - we were doing geometry because they also introduced geometry. But we did it in our times - those theorems.
Interviewer: So they did everything in one workshop?
Participant: Yes, for three days.
Interviewer: Do you feel that it was not enough training?
Participant: Yes, all of us feel that it was not enough training, really it was not enough.
Interviewer: Any other sections that you find problematic? Perhaps you are comfortable to teach it, but you find it problematic, perhaps it's a section that the learners don't cope well with.
Participant: Okay, financial maths. In financial maths - future value and present value, where there is maybe a loan and then there is a gap for three years .... The learners sometimes don't understand that - what should be done there. It means that it is going to affect the value of n. So they struggle with financial Maths, and before and immediately. There is just confusion with them.
Interviewer: How long has that been in the curriculum, financial maths? That has been in the curriculum for quite some time but yet the children battle with it?
Participant: Ja, they battle. And also the children ... Uhm .. mostly the graphs. And we teach them graphs using the calculator, because they have got the tablet, but they can't use it.
Interviewer: Do they have tablets?
Participant: Yes, they have the tablet. We have the interactive whiteboard, but we the teachers are still struggling to use the interactive whiteboard. Most especially for Maths. They say that somebody from the department will come and help us, because if I want to write x squared, then I can't write x squared - I must use that rubber (eraser). There is a rubber that I have to write with. I can't use the text pen to write with.
Interviewer: Really? Are your interactive whiteboards the same as ours or is it a different kind?
Participant: I don't understand whether they are the same, but there are more or less the same. We are writing or maybe I can select a topic, and the children can listen. Then I can stop and explain.
Interviewer: So, are there pre-recorded lessons on the interactive whiteboard?
Participant: Ja, ja. For each and every topic
Interviewer: That's interesting. Tell me, is it part of the department's project?
Participant: Yes, it's part of the department's project.
Interviewer: Tell me more about the tablets that the learners have.
Participant: Every learner has a tablet in grade 12. So, this year it was supposed to be the grade 11's, next year grade 10's, the other year grade 9's. And also in the primary, there are. I don't know which grade they have started, but they have the tablet.
Interviewer: So, each learner has a tablet?
Participant: Ja.
Interviewer: And on the tablet, is there material loaded as well?
Participant: It is loaded. Some of the questions, previous question papers are there with memos, and they can research, they can do whatever they want there.
Interviewer: Do they have Internet access, or is it off-line?
Participant: It's off-line at night, but during the day it's online.
Interviewer: Okay, that's very interesting because for the project that I'm busy with, to know that you've got the whiteboard and the learners have tablets. Perhaps I can assist you with that. Assist you to assist them, so it's very good that you have those facilities.
Participant: Thank you, thank you, thank you. I'm still struggling using the interactive whiteboard.
Interviewer: Yes. Maybe I can help you with some of that. Back to the problem areas, just to summarise: you say that it is financial maths, counting techniques and graphs.
Participant: Ja, and functions.
Interviewer: How often are you able to relate the content that you are teaching to real-life situations?
Participant: Oh .... and also, in calculus. Not drawing .... The last part of calculus .....
Interviewer: Applications?
Participant: Ja, application of calculus. You know these children tend to forget, you know the area, the formulas, the surface area ...
Interviewer: So, the application of calculus is another problem area.
Participant: Ja, maximise ....
Interviewer: Good, how often are you able to relate their work to real life situations, or not at all?
Participant: I sometimes use real-life situations.
Interviewer: Sometimes? Where you can?
Participant: Ja.
Interviewer: Which sections of the work do you think will be the easiest to link to real-life situations? Forget about time for a moment, time can be an issue. What sections do you think will work best if you think of real-life examples?
Participant: Data handling, and also probability, and financial maths.
Interviewer: Calculus?
Participant: Yes, calculus, ja, and also calculus. Equations, no?
Interviewer: It will be difficult. In what sections of the curriculum do you need help to link the content to real-life situations? So, maybe those that you've mentioned now, which of those do you think you need help with to link it to real life?
Participant: Counting principles.
Interviewer: And also those others that you mentioned? Calculus, financial maths, data handling?
Participant: Yes.
Interviewer: What was the other one that you mentioned? I think it was just those.
Participant: Yes, financial maths
Interviewer: Data handling
Participant: Calculus
Interviewer: Probability also?
Participant: Ja, ja.
Interviewer: So, those areas you feel you need help to link it to real-life
Participant: Yes
Interviewer: Do you think it's important to relate your teaching to real life situations?
Participant: Yes, because learners can grasp quickly. They will remember that oh ... I can link maybe this glass, maybe with ... you know .... they can grasp easily.
Interviewer: Good. You know, in the module that I teach we always talk about linking prior knowledge to existing knowledge.
Participant: Ja, ja.
Interviewer: Do you think it has something to do with that?
Participant: Yes.
Interviewer: Because then we are linking the new work to something that they are familiar with.
Participant: Ja.
Interviewer: Good. How do you feel about using technology in your teaching?
Participant: Because I didn't even study or do technology from high school, even from teaching, I'm still struggling with it, I'm really ..... Technology as a subject or you said ...?
Interviewer: More technology in any teaching. So, think of technology in the Maths classroom. How do you feel about it? Are you positive, negative, excited? How do you feel?
Participant: I'm excited, but mostly in Maths there must be a lot of explanation, I can use maybe ..... They can listen, but I feel that if I write then the learner can, maybe I can write some examples the learners can .... ja
Interviewer: Your whiteboard at the moment, you can't actually write?
Participant: I can write, I can't use the text pen, because in our interactive whiteboard we can select the pens that you write with. So, the text pen writes like this and the other pen is my writing.
Interviewer: Okay?
Participant: It's the same like I write on the board.
Interviewer: So that's the problem now because you can't do it properly, the way you want to?
Participant: Yes, I can't use the text pen.
Interviewer: So, obviously because you want to write the sums for your learners ...
Participant: I wanted to write x cubed minus two x squared, I can't write it.
Interviewer: So, you can't write because it's typing it.
Participant: Yes, I must write it. And also ... Um ... like in Calculus maybe I want to draw a cylinder, a nice cylinder, not mine. I want a cylinder that is already drawn, you know ... I'm still struggling with that.
Interviewer: Back to how do you feel ....um .. What emotion do you think comes up when I say use technology in the Maths class? What do you feel?
Participant: I feel that maybe if I can maybe have more knowledge or used to do that, then maybe I can accept it.
Interviewer: But are you willing to use it?
Participant: I am really willing to.
Interviewer: Good, but you think that if you have a bit more training and a bit more help ...
Participant: There was training, and then the department sent someone from them to come. But, it was not only for Maths, you understand?
Interviewer: Oh, yes.
Participant: We were doing so many things, linking those things .... And it was just a short space of time.
Interviewer: Okay.
Participant: But they say in August again they are going to send someone again.
Interviewer: Okay, good. How do you feel about using mobile technology like things like Whatsapp, SMS to talk to me and to talk to other colleagues about how we can make the Maths more realistic for your learners?
Participant: Yes, like with my group of learners, I've got 33 learners for pure Maths
Interviewer: Grade 12?
Participant: Yes. We've got a group Whatsapp. If there is maybe something that they don't understand, we chat.
Interviewer: Excellent
Participant: Ja, or maybe I want to see them maybe next week I prepare them. Or if maybe it is something that I forgot to tell them in class, I Whatsapp them see page this on .... Because in their tablet there are also textbooks, and also on the interactive whiteboard, there are textbooks.
Interviewer: Right.
Participant: Yes, the textbooks that we are using.
Interviewer: Wonderful. That Whatsapp group works well for you to communicate with your learners?
Participant: Ja, but you know ... Our Maths teachers don't use only one textbook. We also use the old, old textbooks, it's very good, I also use it
Interviewer: There was almost more structure in those old textbooks.
Participant: Ja, ja. Those higher grade old textbooks, it was excellent. So, I usually take the answers, then I sometimes take a camera, and then I send it to them.
Interviewer: Do you take a picture?
Participant: Ja, I take a picture, and send it to them.
Interviewer: Okay excellent, that's also a nice idea. So, you actually use technology more than you realise.
Participant: Yes, I use it but ... you know what .... at school there are laptops for Maths. We were four maths teachers, the other one has passed on, so now we are three. So, we have to borrow it and then take it back.
Interviewer: Okay
Participant: Since the department said that every grade 12 teacher must have a laptop, but we are still waiting for them to give that to us, the laptop
Interviewer: For each one?
Participant: Ja, for each one. For each and every one.
Interviewer: So you have to share at the moment?
Participant: Yes
Interviewer: Okay, excellent
Participant: But I'm using, it's not a laptop, I'm using a computer at my home.
Interviewer: Okay, good. And the tablets, do you get to use the tablet? You don't have access like the learners have got?
Participant: No, no. The tablet is only for learners.
Interviewer: Okay
Participant: It's only for learners. But I can borrow one from the office. If I'm using it, then I use it now, then return it again.
Interviewer: Right. And for communication, say in this project, if we start working on things together ... would you be willing to join a Whatsapp group with me and say one or two other colleagues? Would that suit you?
Participant: Yes.
Interviewer: Good. That's the next question, how do you feel about being part ....
Participant: Yes, because it will be proper because there are some other challenging questions, maybe I can Whatsapp the Whatsapp group and they ....
Interviewer: Good, ja and then share ideas also and say I'm having a problem ...
Participant: Yes, or how do I tackle this topic? ..... you know, you understand?
Interviewer: Hmm, nice. What experience do you have with Facebook?
Participant: I'm not, I'm not, truly speaking, I haven't used Facebook. How is it?
Interviewer: I think it can be used in different ways. Obviously the main purpose is for social things, you know, to have your friends and communicate with friends, tell them what you're doing, tell them where you are et cetera. But there is an educational use to Facebook as well.
Participant: Is it? I'm not aware of that.
Interviewer: Yes

Participant: Then I'm going to download it (laugh)
Interviewer: What some people do ... For example I've started a Facebook page for the BEd Honours group, where students can join the page and ask each other questions and sometimes ... I always keep an eye on the page, so I can see if somebody asked a question but nobody was able to help, then I will step in and help. Try and answer the question, or give advice. I might say to the student send me and email and I will forward you some material or whatever the case may be.
Participant: Okay
Interviewer: So that is one way that I have started to use Facebook with my lecturing. One tends to think that it is just social, but there are people that use Facebook for educational purposes. So would you be willing in other words?
Participant: Yes
Interviewer: What experience do you have regarding interactive whiteboards? You've actually answer this question already, because you've got one in your classroom
Participant: Yes, yes, I can write x squared. Sometimes if I'm using the pen, the text pen sometimes it's quick.
Interviewer: Do you think it's better than a normal, old-fashioned whiteboard?
Participant: Yes, it's better because sometimes they advise us if we can have the sticks and put our things on the sticks, then put it there, then maybe everything that I'm going to do, step by step like you are using here.
Interviewer: Okay, good. So, you can prepare in advance and then bring your stick and present the work on the whiteboard?
Participant: Yes
Interviewer: So, there are advantages over a normal old-fashioned whiteboard?
Participant: Yes, very very much. Because the chalk is just a waste of time.
Interviewer: Hmm, because you have to erase, and then it's gone, if you want it again ....
Participant: Ja, that's because with that one if it is gone and you can just take it back and see it again.
Interviewer: Good, so in other words it can save time.
Participant: Yes and I can also save my lessons. I can even use it next year for the other groups.
Participant: Good, so there are advantages.
Interviewer: Yes. You know, I liked the overhead projectors also. I liked it, but unfortunately in our schools we don't have it
Participant: Really?
Interviewer: Ja, we don't have it.
Participant: Why did you like them, how did you use them?
Interviewer: Maybe explaining, writing, then they can do you know, yes ...
Participant: And that could also be more permanent because you could write on transparencies and keep them.
Interviewer: Yes.
Participant: That was also an advantage.
Interviewer: Back to the interactive whiteboards, how would you feel about discussing issues with me and with colleagues on the interactive whiteboards. Say for example, like our classes where we connect three or four different centres, different whiteboards together and you stand at your whiteboard and I stand at my whiteboard and some other colleagues stand at their whiteboards and we could communicate about how to make maths teaching easier for you. How do you feel about that?
Participant: You know, our whiteboard is not like yours, because I've seen you have something there in the ears. I don't know what is that.
Interviewer: It's a microphone, so that other people can hear my voice from other whiteboards all over the country.
Participant: Okay.
Interviewer: You see, ours works like this, and this is what I'm talking about over here. I stand in Potchefstroom, with a microphone and I present a lesson. You sit in the classroom here, but then they are 30 other centres around South Africa that also have whiteboards. They don't see me physically, but they see everything that's on the screen, they hear my voice and they can even stop and ask questions. So that is the interactive part of the whiteboards.
Participant: Okay.
Interviewer: So that is why we have a microphone, because then they can hear my voice clearly.
Participant: Yes okay. It's not like those may be Calculus is there and someone is talking.
Interviewer: No, it's not pre-recorded. It is live.
Participant: Ja, I understand, because in our interactive whiteboards there are pre-recorded lesson.
Interviewer: Oh, so you are used to using pre-recorded stuff.
Participant: Yes.
Interviewer: How would you feel about live, connecting live with other people?
Participant: Yes, yes. I think it is easy, it is not time-consuming.
Interviewer: Okay, what type of technology would you personally be most comfortable with should you get involved in this project with me? What technology would you say, yes, I'm willing to use this technology, to communicate, to receive information, to send information? What are you most comfortable with?
Participant: Like maybe Whatsapp or Facebook. Because ja, I've got Whatsapp, I am comfortable with Whatsapp. Facebook I'm not into that, but as you've just explained, I can do it. Twitter, I don't know how to tweet, I don't know. But Whatsapp, yes.
Interviewer: Okay, so more mobile technology would suit you?
Participant: Yes
Interviewer: Okay, good. Thank you Mrs S, that is all I want to ask you. You have helped me a lot already. You have given me lots of good information. I'm glad that you're involved with the project with the whiteboards and the tablets, because it's going to be really interesting working with you.
Participant: Ja because, the learners, they are not supposed to carry books but we've got many types of books like in Maths. We don't use only the textbook which is on the tablet, we normally have extra textbooks that we are using.
Interviewer: Okay.
Participant: But for the tablets, it was supposed to, they must just come with the tablet not with anything else
Interviewer: Okay
Participant: According to them, even the tests they are going to write on the tablet, then it marks everything. But we are still going to learn. They have just delivered those things, I don't know what is that ....
Interviewer: Clickers?
Participant: Yes, yes (laugh). We are still going to learn more. So it's going to be easy, we are no more going to mark.
Interviewer: Okay.
Participant: So they mark, I give them questions, they mark even the tests, everything. I'm going to just put the learners and then the marks will automatically .....
Interviewer: Who designs those tests? Do you design them or are they also sent by the Department?
Participant: Uhm, even the class work, they are also going to do it there. And the homework, they are also going to do it, then they do it at home.
Interviewer: Right.
Participant: So they say, no more paper for the children.
Interviewer: Okay.
Participant: Yes, as they said, but we are still waiting. Maybe after we reopen, because they came with the clickers.
Interviewer: Let me tell you about the clickers ...
Participant: Ja, the clickers. They say clickers. You click, then "ah ... yes, I've got it correct"
Interviewer: Yes, each learner is somehow connected to the whiteboard. Say for example you put a question on the board, then they can click the correct answer. Then you can ...
Participant: If you are wrong and if you're right, it shows.
Interviewer: That also helps you because say for example you have just taught a section and you put up a question relating to that section
Participant: Then I can see that most learners didn't understand that question, then I can go back ...
Interviewer: Exactly. That is excellent, it is exciting for you.
Participant: Yes, I am eager I am eager you know, to let them come and use that.
Interviewer: Nice. Thank you very much. I appreciate it very much that I can talk to you and I will definitely continue to talk to you. I am going to be designing things to help you, talking, finding out where can I help, what I can help with. I'm looking forward to working with you because I see that you are enthusiastic about your teaching and about the technology and about Maths.
Participant: Yo, I like Maths. My child is doing Maths, but, she is not so .... She's doing Maths, Physics, Life Science and Accounting. She is in Grade 12 now.
Interviewer: Hmm.
Participant: But she is so lazy. She is so lazy. Sometimes, there is this learning channel on the DSTV. I asked her to watch it, maybe she can learn more. I even watch the subject that I don't do, like accounting. Like the day before yesterday night I was watching Accounting. They were explaining and asking questions, and I got it correct. I was so excited.
Interviewer: Nice. That's another form of technology.
Participant: Yes, I always ask my learners to watch it. But, maybe only, let me say 10% of our children have got a good background, they have got a satellite dish. So mostly they are from shacks, where they do not have electricity, you know ...
Interviewer: So, that makes it difficult to encourage them to do that?
Participant: Yes, because I once asked them to watch that learning channel. Then I realised that most of our learners, 90% of them don't have that. Some they have the TV, but they don't have the dish, they can't afford to pay the dish every month.
Interviewer: Those channels, are they just on satellite?
Participant: Yes.
Interviewer: Are there any of those channels on a SABC?
Participant: There are on SABC, ... because the day before yesterday .... On SABC 1 or 2 or 3, I don't remember, they were also doing that topic, explaining the topic of probability.
Interviewer: But, obviously the learning channel is a better one.
Participant: Yes.
Interviewer: Good, you've given me some nice ideas today. Thank you very much. Is anything else you want to add? Anything else you want to talk about?
Participant: Uhm, what is the best way of teaching Maths? Are you teaching Maths?
Interviewer: I used to teach Maths at school, now I'm at the University I am lecturing, which is a bit different to teaching, but there are many things in common. At school level, the best way that I found is you must be well prepared.
Participant: Yes, because they are clever learners. They are clever learners, because I just tell them tomorrow we are going to do this topic. You can even notice that some learners are far from you.
Interviewer: They are not with you?
Participant: They are not behind, they are for ahead of you in the syllabus
Interviewer: Okay. Is that because of the tablets?
Participant: No.
Interviewer: Would they have done that on the own anyway?
Participant: Sometimes I have got some clever learners in the class. I just tell them tomorrow you are going to do uh ... let me say uh ... this topic. Then I ask this one to do this thing, uh or maybe ... I want to recall maybe a topic? Any topic?
Interviewer: Calculus?
Participant: Yes, in Calculus. Because in Calculus you can't do many things in one day. You can't do the limits, the graphs and also the rules and applications in one day.
Interviewer: Hmm.
Participant: So I asked maybe to ... ja like the rules of differentiation. I can ask one learner to do the first rule, the other one to do the next rule. Then I am just watching and I will assess.
Interviewer: So the learners present?
Participant: Yes, the learners present and they present it so well, they present it so well. In the meantime they are also learning, you understand? They are also learning. So, I also tell some other learners they must also do it, because you gain more knowledge by just standing there and going home to prepare the topic to do it. They come prepared and then they do it so nicely. Sometimes, you know, if you are a teacher, if you are a Maths teacher, maybe someone comes in. Because our department, last year, they said, we must also exchange, the teachers must also exchange. I can go and teach at your school a certain topic then you can come to my school and teach. So the learners they are not used to you. They are going to listen to you. Because to me, they are used to me. So, to the other teacher they are not .... They are going to listen clearly and understand maybe.
Interviewer: That in a way a nice idea, peer teaching.
Participant: Yes, peer teaching.
Interviewer: But, I like your idea of using the learners to sometimes show or explain a section.
Participant: Yes, I usually do it, and I am just facilitating and guiding. Maybe if there is confusion between the learners and the one who is teaching, then I can intervene and explain. And maybe I can explain it better, but if I can see that he has left some of the things ...
Interviewer: I like that idea very much. I think we are done. Is anything else you would like to talk about?
Participant: No.
Interviewer: Thank you so much for your time.
Participant: I thought it was difficult, you are going to ask me such difficult questions (laugh)
Interviewer: No. I just wanted to chat and hear what you think, how do you do things, how do you feel. Thank you so much for your time, I appreciate it.
Participant: Thank you Dorothy.

Mr K

Interviewer: Thank you for agreeing to meet with me. The purpose of the meeting is to get your ideas about things like the curriculum and especially the use of technology in the Maths curriculum. So, I would like to get your ideas and feelings about some of these issues. So, if you don't mind we can have a look at the questions.
Participant: Okay, I read through all of them.
Interviewer: Good, so then you can speak from experience, what you have worked with, what you have not worked with, and your opinions about these things is actually what I am interested in. What sections of the curriculum are most problematic for you to teach?
Participant: Uhm, ja. In this case I will dwell on grade 11 Mathematics. The curriculum is broad, but here I'm going to talk about content in grade 11 for example. We have a problem in functions, but the problem emanates from the fact that they don't understand for example exponential function - if learners don't understand how to solve exponential equations then when you go to functions it becomes very difficult. Yeah, that's one area, secondly trigonometry. I don't know what is supposed to be done, but learners in general struggle with trigonometry. So mainly its function and trigonometry, but in particular trigonometry is the major problem. Then, recently we have Euclidean geometry which has been introduced. Uhm, it's also a major problem, but I think the problem is not the learners but maybe the majority of teachers who are teaching that, they did not even do it during their times at school. It's something that was brought in as a crash programme for teachers to be taught as well. So, those are the main three areas: Euclidean geometry, trigonometry and functions.
Interviewer: Good, How often are you able to relate the content that you are teaching to real-life situations?
Participant: Uhm, for example, when you are talking about analytical geometry as a topic. There are areas like if you are driving, there are areas like what people call black spots
Interviewer: Right?
Participant: In most cases that had to do with gradient. The gradient of that particular road is not evenly balanced. In mathematical terms that has to do with gradient.
Interviewer: Right.
Participant: Uhm, in Financial Mathematics as well. Through and through it every day life situation where you talk of borrowing, investments and other areas of activities.
Interviewer: Good. Which section the work do you think would be easier to relate to real-life situation?
Participant: It's also.... Everything depends on the cognitive level of the learners you are teaching. For example if you're talking about calculus, maybe up to grade 12, not so many will have pre-requisites of the cognitive level to understand that calculus also works in real-life situations. Only when someone goes beyond grade 12, then they will be able to relate to what they have been taught in grade 12. But calculus on its own, like I've talked about gradient, it also comes in as part of calculus. How it is introduced in grade 11 and 12. It appears as if there is no link but calculus it also talks about gradient and so forth. That is real-life situations.
Interviewer: Absolutely. Do you think important to relate are teaching to real-life situation?
Participant: Uhm, so many writers have written different meanings of what Mathematics is. Some call it a natural science, some have called it a philosophical science, because in a natural science you don't have x and you don't have y, that's a bit philosophical. So, I believe in the prior, who talks about Mathematics is a natural science. So, you cannot do Mathematics without modelling. And, once you talk about modelling, you are now talking about real-life situations.
Interviewer: Excellent. How do you feel about using technology in your teaching?
Participant: Maybe I must am speaking from the background of being a traditional teacher. But how I think is also influenced by the way I was taught myself although I have changed a bit but what I have discovered is that the moment technology takes over everything, the learners lose the naturality of Mathematics. Now, it is only supposed to be used in conjunction with .... For example with Euclidean geometry, the curriculum statement does not give the teacher the opportunity for learners to discover where these theorems are coming from. Even, I happened to use the HeyMaths programme which was in the Northern Cape province. Now, the HeyMaths programme, if you want to show a learner that the angle at the centre is double the angle at the circumference attended by the same chord for example, you can do it by technology. But, it's just like watching a TV. How many learners will ...., maybe some learners can learn by seeing but some learners need hands-on for them to understand. So, now so the word technology the way we are using it is deeper because yes, for example if a learner uses a protractor to draw a circle, draw a radius and so forth, that is using technology, which means they can still have the correct feel of what they are doing. Maybe, the focus now, we have shifted away from that type of technology which we thought was very traditional, to this one that is so electronic. Everything now is very electronic. So, I feel learners have lost a lot because they now don't have hands-on experience, for example what I went through. It is easier to tell a learner by using a computer. When he knows things practically, it is much easier. But what is happening now, technology, we are just telling learners things which they don't have a feel for. That's my take on it.
Interviewer: You think we are neglecting the more practical side of Maths by focusing on the electronic technology?
Participant: Yes, we have moved from this technology which we think is traditional, we have moved out right to electronic technology.
Interviewer: Do you see any benefits of technology in Mathematics?
Participant: Okay, maybe we need to go back to..... We in Third World countries we have borrowed much of technology, especially electronic technology. Looking back to where these things have started, looking at China, Japan. They have benefited a lot, but maybe there are so many things that have to do with their culture. Because, yes, it is them who started it. It fuses well within their cultural confines. Now, what happens now is ... Are we having the same culture of the people who started these things? Our understanding is different. For example you will discover that ..... I am teaching at a school that is almost in a peri-urban area. We have the smart boards, we have the overheads but the teachers moves from one class to another. Therefore, we teachers do not have one class where we can say "This is my Maths class." Though it's not easy for me to move on with my screen, overhead projector, laptop et cetera
Interviewer: That makes it very difficult.
Participant: Yes, and my experience as well is that learners might be fascinated with the use of the computer and the overhead for one or two days, then they will lose interest. That is my experience.
Interviewer: How do you feel about mobile technology, things like Whatsapp, SMS to communicate with colleagues and even with me about any research project in the line of what we are talking about? Are you open to using mobile technology?
Participant: There are so many things which have changed now. We no longer live the way we used to live in communities that used to come together. It is completely different. Yeah, communicating in different forms.... You can go back to learners, you will discover that even at school, they no longer sit down together and talk. Everybody is busy on Whatsapp. It's no longer interesting to be a storyteller. No one will listen to you. Because there are things now that are taking their time. So, I don't think I will be having any problem. I have tried it even with my learners, but I also discovered that yes, you might capture very few who will be interested in ..... Because Mathematics on its own is a subject like for learners - it stresses them physically ....
Interviewer: It's challenging?
Participant: Ja, it's challenging. But you will get one or two that are interested, yes.
Interviewer: What did you do with your learners? Did you have a Whatsapp group, did you make use of SMS? How did you use technology with your learners?
Participant: I had a Whatsapp group.
Interviewer: Okay, good and on the group, you could give them information, or answer their questions? Was that the purpose?
Participant: Yes, like I give them homework, somebody's stuck along the way they don't have any, you know they don't have many resources even to refer to. I will give them one or two tips on how to continue with the problems.
Interviewer: That excellent, I like that idea. Did you find that it worked? Or was the focus not on the right thing?
Participant: It goes back to what I said, there are so many factors within the community which are inherent on how this will work. I did not think that I had enough support from their parents. Because learners in their own, they have a lot of things they need to do. There are so many things that are fascinating, more than doing Mathematics on Whatsapp.
Interviewer: True
Participant: Other social issues to discuss with. But, maybe if I could have involved the parents, it could have worked. So even now, I cannot say that it worked or did not work.
Interviewer: Good, but I like the idea that you have tried. How would you feel about being part of a Whatsapp group to discuss issues about making maths more realistic perhaps with other colleagues, myself, with other researchers. Would you be willing to do it?
Participant: I don't have a problem doing it, it's welcome.
Interviewer: Good, thank you
Participant: It's welcome
Interviewer: Facebook, you have any experience of Facebook in an educational context?
Participant: In an educational context, no, but I have followed LinkedIn. I have not done anything, but I follow the articles which I return, especially .... It seems there is not much writing on the South African context. I rarely find anyone, I think I have one guy who returns comments, but the majority is on the UK curriculum.
Interviewer: Right.
Participant: Even those who are in South Africa normally comment about the UK curriculum, not the South African curriculum.
Interviewer: That's interesting.
Participant: That's what I have discovered.
Interviewer: Would you, how would you feel about using Facebook to discuss issues about making maths more realistic for your learners, as a medium of communication? Or would you feel more comfortable with other means?
Participant: What I have observed is, yes ....., there are some Mathematics problems that are normally flouted there. But what I have discovered those are more of puzzles. But I think that the basic point is to make sure that it will catch the eye of everybody who is at school at the moment. Maybe to adapt the minds, but not suddenly to say you can talk of algebra. But I think much of puzzles, I've tried to follow on Facebook.
Interviewer: Good, you said you have an interactive whiteboard in your classroom. What experience you have in relation to interactive whiteboards?
Participant: Unfortunately at the moment, because we have only one interactive whiteboard in one of the computer labs. So, any specific teacher who wants to use it will have to discuss it with other teachers when and so on. So, I have not agreed to having a class with them because of the congestion of the programme of the curriculum. Because for example in grade 10 we have nine classes, grade 11 around seven, grade 12 we have close to two hundred learners. It has not been easy. But we have used overhead projectors, the interactive whiteboard .... It was only me going there to see how I can use it . Effectively, with learners it's not easy, depending on our environment, requires a more civilised programme to make sure that everyone benefits. But at the moment, it's not so easy. One whiteboard for the whole school.
Interviewer: If the situation were different and you had a whiteboard in your own class and you did not need to move in this situation would be different.
Participant: It's the teachers who move from one class to another. The learners remain in one class.
Interviewer: That makes it almost impossible to use it effectively.
Participant: Yes.
Interviewer: how would you feel about using an interactive whiteboard to discuss issues of making maths more realistic for your learners? Again as communication means?
Participant: I'm not understanding the question.
Interviewer: If it were possible for you to connect via Internet, almost like a Skype discussion, would you be willing to interact with other colleagues and with myself via interactive whiteboard, to discuss issues relevant to Mathematics?
Participant: It would be a pleasure. Because at my school, we already have telematics, but it's been done through Stellenbosch University.
Interviewer: Okay.
Participant: For all grade 10's to12's.
Interviewer: Okay. The final question - what type of technology will you be most comfortable with in a project such as this one? The project which you have read a little bit about, it is about integrating technology in maths education. So, I know a little bit how you feel about technology. Should you use technology, what type of technology would you be most comfortable with? You can even refer to the more traditional technology.

Participant: Like I've said, it would be much beneficial for example if I use the interactive whiteboard, almost all learners like it at our school. The whole generation of today, they can all use computers. Now, there are so many things that come into interplay, like the community for example. You have a situation here where there is no electricity in the community, electricity is gone. But, for me I think through my experience, I have tried both electronic and the traditional. I think they should all be used concurrently in such a way that for example after using the traditional one, you can move onto technology so that the learners can understand it better.
Interviewer: Right.
Participant: It will be like watching a film, they will understand it better. It will promote the situation of real-life examples. Even those who developed the technology, I'm talking about HeyMaths. You cannot develop it if you don't understand it using the traditional way.
Interviewer: You are absolutely correct.
Participant: Yes.
Interviewer: You need to understand the basics, and you need to understand the content before using all kind of technology to present it.
Participant: That's what I'm thinking.
Interviewer: that's one of the core problems, wanting to think that technology is the answer, but you need the basics before you can actually get to the technology. That's all I need to discuss with you Mr K. Thank you so much for your time and for your opinions, I really value them. Is there anything else that you would like to talk about in relation to what we have discussed today?
Participant: Not at the moment, I don't think so, but all in all it's too beneficial to use technology. It also saves time, instead of you writing notes on the board for one hour, it's easier using the technology.
Interviewer: Thank you so much for your time, I will keep contact and we will keep in touch.
Participant: Okay have a good day.
Interviewer: Have a good evening, bye bye.
Participant: Bye bye.

Focus Group Interview 1

P1: Ah, it's so easy!
P2: In this way you can attend to individual learners.
P1: So, you can even ask for the formula. Because sometimes they struggle to know which formula they should use.
P2: They can play with this and still arrive at the right answer.
P2: They can teach themselves with this, while they are revising and doing this, they can check on themselves. It means that the teacher is there. This one will rectify them - it will lead them to the right answers and so on.
I: Why is mobile technology suitable to present Mathematics content in a realistic way?
P2: Because the learners will be directly involved. They won't sit back and just listen to you saying everything. They will just type it in, rectify themselves. They are actively involved, and they can interact with others.
I: Is it different giving the app on a cell phone compared to using a computer?
P1: Cell phones, there are many. Let's say more than 90% of them they have cell phones.
P2: They can afford to buy cell phones rather than computers. Even though that can't afford to buy computers they can buy cell phones.
P1: Because computers are very expensive
P2: It's more accessible to them and it's easy to carry, where they are and while they are relaxing they can learn while you are sitting outside.
P1: It's good!
I: How can this app address the principles and characteristics of RME?
P2: The topics are intertwined. They can bring topics together. They can see how this one is intertwined with the next topic. They can see for themselves. And they are actively involved.
I: What about modelling?
P2: They can use formulas for themselves. They can try to put figures and see what they get, whether this formula is the right one to use you or not.
I: How can this app assist teachers to teach Maths in a meaningful way? Do you think it can?
P2: It can. It can. One, as a teacher - because each and every teacher wants their learners to be involved. You can get them involved if they have got this. You can communicate with them through this. Maybe it's at home, while they are doing homework they can ask you- I've been trying this and this, what is the problem? We can answer them and say "try this one". Before they come to class they know what to do.
P1: The weaker learners can be able to do it. If they can't then they click on the icon for help. It helps the weaker learners.
P2: There are learners who are so shy when they are in class they can work comfortably when they are alone. I think this will be so helpful especially for the weaker learners.
I: What knowledge of technology would a teacher need to effectively use the app? How easy was it for you to navigate the app?
P2: It wasn't a problem to navigate. The fact is we own cell phones and we have been fiddling with the app. To work on this technology, is easy. But for a person who has got this for the first time it will be a challenge. Based on what we know about learners, most of them do have cell phones. I think they can use it.
I: What about the teachers? Do teachers have a good knowledge of technology?
P1: It's a challenge for some teachers.
P2: It's a challenge for teachers. Based on the needs for the content, we must acquaint ourselves first with the content before we can use it here. Then there's that challenge. The teachers must know how to download it. Without downloading it, I will be stuck. There are some features that I know that I can apply. But, a teacher is a leader - they must always be in front of the learners. Teachers must learn more.
P1: They must be able to know it first before they can take it to the learners. Because sometime we don't understand what this yes means and what the no means.
P2: Most of the icons are familiar, they used this almost daily. Once they are stuck you can ask them what about this icon? The teachers and learners will be motivated to use this app. They will love it!
P1: The demotivated learners will also be motivated.
I: Why do you say that?
P1: Because they like technology. They like to use cell phones. It's like playing games - they like playing games, whenever they are they play games. This is like playing a game.
I: Which role-players will influence the use of an app such as this in the school situation?
P2: The Mathematics teacher is directly involved with this app. They must convince the parents, they must convince the Department that they need this app.
P1: The Mathematics teacher will influence its use.
P2: But you cannot just convince the Department, saying that let's buy this so that I can come out clean
P1: You just show the learners first. Then we call a parents meeting. The learners would already have told their parents about the app. We will just show them how easy it will be.
P2: The Mathematics teacher must encourage all the stakeholders to be involved in using the app. By showing them how possible, how easy and how economical it is to use it. But if you have no facts to support your statement then you will fail, the Department will fail to deliver this. But if there is a need and it can be shown to the stakeholders that if we apply this app - we save time, all learners are involved, all learners are interested. Maybe we should have one class where we use the traditional method and one classroom use this technology and show the difference between them.
I: School principals, will all school principals be happy for teachers to be using something like this?
P1: Not at all. They like teachers to work. They think we are lazy.
P2: Not at all. It involves money. This involves money. If for example you go to the principal and say that you want to use this app, you we will work out the feasibility - how much will it cost - It will work out to be thousands. If the principal had never seen it being applied, it will not be easy to convince them. It was for the Maths teacher to convince. That's why I said if I bring the principal to class and show him how wonderful this app works, then maybe he can buy the story. Then we'll be fine.
P1: It should mostly be used by the Maths learners, because the other learners will download pornography and other things. Cell phones are not allowed in the class.
I: Learners get busy with other things in the class if they have cell phone. That's why I ask the question.
P1: For me as a teacher I must move around the class and make sure that they are doing the right thing.
I: The teacher would have to convince the principal why it is important.
P1: Because I am also going to be actively involved to check whether they are doing the subject that they are supposed to do, not outside things.
P2: To guard against the wrong information that can be used here, some schools - not all, they are getting there, the schools are having tablets - that is for the school. They can only access that thing while they are in class and do what is expected of them and then it gets taken back.
I: It can be feasible?
P2: When I get to class, everyone gets his tablets and we start working. When I am finished with the period then I collect the tablets again. In class it must be this. But once they are there and they are used to it- even at home then they will know that with a cell phone that they must use it fruitfully and effectively. I must do the school work on the cell phone at home. Then we won't have problems if they come to school with cell phones but for now they are problems that we will first have to sort out.
I: How did you experience using this app?
P1: Knowing the stuff that you're supposed to learn, the content - I think it was easy. Like now it seemed should I give you the formula, we said no, then we could punch it in. We know the information already. We learn fast in that way.
I: What is easy to navigate?
P1: It was for the first time, but it was not so difficult. But once used, I'm telling you it will come easy to them.
I: How would you use this app to improve your teaching practice?
P2: At any time when they feel like using it, while revising they can just use it. Because with the classroom situation, we they are to revise, they want to come to the classroom for help. They can't do it on their own. But once they have this, they will do it there. When they encounter a problem they will contact the teacher and get help
P1: It will help them
I: Which sections of the curriculum would benefit most from an app such as this one?
P1: Calculus, mostly the real-life, financial Maths
P2: Financial Maths. The only one that will suffer will be Algebra. But the rest, even number patterns will be fine.
P1: Number patterns, because learners use different formulas, the wrong formulas. So this will help them.
P2: Even probability, I think it can work. It only Algebra that will be left out, not all of it but part of it - the rest will work perfectly with this.
I: Last question - What can be done to improve this app?
P2: I think putting all the questions that could be available - so that you can attempt each and every question that is possible. Otherwise if the question is not there and they are applying this - there will be a challenge, even if I don't know how to do it now. They will be a challenge; I can contact whoever to help me. So to improve it, let's have as many questions as possible , especially those in real life. Having all the questions will give an opportunity for interaction with other learners and with the teacher. Once they are loaded it will put a challenge to the user each and every time they open the phone. I think it can be improved in that way. Secondly, I would say how can I show this to someone else - how can this be shown to a colleague, while I am working, so that other colleagues can help me.
I: Do you mean connectivity between users?
P2: They should be away to contact fellow users, like with Whatsapp. I can say how do you do this? I couldn't get to the right answer, how do I tackle it? They can look into your steps and say no, you are using the wrong formula. Let's try this formula. By a friend, the learners feel so proud when they can help a fellow learner.
P1: It is good, but it is also bad. Those lazy learners will not learn, but they will know which formula to use - it helps them a lot.
I: Perhaps if the user keeps asking for help they should be something built in that can block it so that the user can try it themselves.
P2: Block it and then they can't access it anymore. Then they know they must try themselves.
P1: They must be able to think
I: What about having a tutor that they can talk to?
P2: It works nicely. A tutor can work on different learners with the same problem. While he helped this one, this one can help another one.
P1: Even for the teachers. In our district we have got a peer- learning group. We get together and discuss how we tackle different topics - how we tackle this and that topic.
P2: We have a WhatsApp group where we can communicate with fellow teachers. I can get information from her. Or I am doing this and my learner struggle to understand, how do I tackle it?
P1: We get advice from other teachers on what is easier. It's good to get a new idea from someone else. They find it very helpful.
P2: My school has tablets and in my grade 12 Maths classes there are only 21 learners, I am going to download the app to help them. What I like most is that the users can work on the Maths at home.
P2: This app can help with very large classes.
P1: It will be easier for the new teachers because they know technology. The older teachers they might struggle a bit. The app helps to make the lesson more interesting.
P2: Those who are lazy to write in those whose handwriting is horrible - the app can help - it cuts all of that out. If the users get used to working with technology, it will be a challenge for them to write.
P1: To manage time can be a problem. If the users are used to doing maths on the technology and they now have to write it out they will not know how much time they should spend on each question.
P2: They will be those that are so motivated by the app that they will just improve.

Focus Group Interview 2

P4: The terminology helps them to differentiate between the two concepts.
P4: I think it is good. I also think that it is going to challenge the users. Especially the part where they can choose if they want help will not. Most of them will choose the no - they do not ask for help, but if they get it wrong, they will get feedback immediately from the app. Those slower ones will go for the yes. As time goes on, they will improve and will opt for the no. And then they will keep on improving.
P3: They must try to answer it first, maybe three times - and then after not answering correctly the first three times it can then give them the right answer. So definitely they will go to yes (I need help) instead of no (I don't need help). At least if you can give them three chances of doing it, it gives them the opportunity of doing it rather than going to yes, they can do it themselves. It helps by giving them three chances to do some. It will help us with lazy learners.
P4: Those brighter ones will go for the no, they will want to do it for themselves. The slower learners will go for the yes, for the help. As time goes on they will also want to go for the no. So you are catering for both.
P3: In fact there will be a competition.
P4: They will be a competition.
P3: The first ones who have done a solution and find the solution to be correct, they will boast to the others who did not find a solution.
P4: It is also going to motivate the ones who didn't get the correct solution
P3: And even improve the pace at which they work
I: Why is mobile technology suitable to present Mathematics content in a realistic way?
P3: It is suitable.
P4: Because it gives the user a chance to do Mathematics anywhere, anytime. They will get immediate feedback.
P3: Anywhere, in a taxi, in a bus - where ever they are, they can do Maths. Rather than going home, having to take out books and then learning - it can be done anywhere at any time.
P4: They will refrain from doing other things on their phones - instead they will opt for doing Mathematics, especially those who like Mathematics. Those who think they have problems with maths, there will always carry this around, always try to do some mathematical problem, at any time.
P3: Every learner has a cell phone, and they like phones
P4: They all have cell phones
P3: It is simple - when their friends are together they will be able to do some Maths together. They do not need a suitable place to do it, anywhere they can do Maths - whether they are sitting or standing, they can do Maths.
P4: Even their parents will be motivated to buy them cell phones and then even improve to buy more smart phones and install mathematical programs on the cell phones.
I: How can this app address the principles and characteristics of RME?
P3: It was very interesting. There will be collaboration, when they are together. They will ask each other: Who has done the sum first?
P4: I think all the characteristics of RME are there. There is collaboration; users will be actively involved for sure - they are doing it themselves. Intertwining of strains is there: like with simple and compound interest - showing that you can use simple interest to get to the compound interest formula.
P3: At the end the answer is the same - using the other method.
I: How can this app assist teachers to teach Maths in a meaningful way? How would it help you?
P4: First it will save time for the teacher. Secondly, it will capture the minds of the learners and maintain that for the whole period, because learners enjoy doing things for themselves. If they are using cell phones, also like this - they will be actively involved, which will help the educator. And also the feedback - they will get immediate feedback. In the end it will help them to correct their sums. If they are getting it wrong, it will tell them - this is wrong.
P3: This is going to help the teacher in the class - getting feedback immediately. Even time is not going to be wasted.
P4: You can do many problems with the learners, and they can do even more - they can try to do more. A more advanced learner can do even more work. A slow learner you can give them more time.
P3: Maybe you consider specific topics for the slower learners, for those who are willing to learn you can give them more advanced content.
I: What knowledge of technology would a teacher need to effectively use the app?
P4: I don't think that will be a problem.
I: Think of all the teachers at your school - are all the teachers at your school okay with dealing with technology?
P4: I don't think the technology will hinder them. Let's take for example, all the maths educators can use a calculator - so I don't think it will give them a problem. They will get used to smart phones. As long as they get used to using a calculator, they will get used to using the smart phone. Those educators that are not Maths educators, they struggle to work with a calculator.
P3: If they can be showed how that is working, it won't be a problem. Even the calculators - how to use the calculator - we were never taught how to use a calculator, but in the end we know how to use the calculator. There are topics that we have to use a calculator, so we were never taught how to use a calculator.
P4: With the cell phone, nowadays we all have cell phones, we use cell phones and we are also encouraged to align ourselves with the current technology. So it shouldn't be a problem.
I: Which role-players will influence the use of an app such as this in the school situation?
P3: I think this is a question of whether the school has money to buy the technology. If the Department can provide the technology, then we can always use this technology. Just like textbooks - they provide textbooks, so they can provide mobile technology, then it will be simple.
I: What about the other role players?
P4: I think all of them play a role. Because let's say for example parents - in terms of the cell phones - if we can tell the parents to buy cell phones for the learners, then parents can buy it. As long as they realise that it is effectively used and can benefit the learners, they are going to buy it. On the part of the educator - the educator, the Mathematic educators should take the initiative to show that this really works. In terms of the HODs and principals, they are the ones that should come up with the implementation and encourage the educators to implement this. So, if the Head of Department can encourage educators to implement and if the educator is prepared to implement - then from the Department to the parents - everything will run smoothly. Because the Department I think they should come up with programs where they design programs for the schools then the HOD's and the principals should check that those programs are implemented.
P3: I feel that the other stakeholders should see to it that the technology is kept safe. So there it can be used by another group of learners the next year.
P4: If they use it, will it be for the school or for an individual learner?
I: I think you can do it either way. The learners can download the app on their personal phones as well.
I: How did you experience using this app?
P4: It will work. It is interesting.
P3: This is excellent, excellent!
I: Why do you think it will work?
P4: This is a new method of doing those things which are giving learners a problem. Nowadays people like this sort of things - they like using technology.
P3: They won't find it difficult to use this technology - they are hands on.
P4: This generation like using these devices. They are interested in using cell phone, tablets. It will capture their minds. So they are focused, they will be focused.
I: Which sections of the curriculum would benefit most from an app such as this one?
P4: I think Calculus, probability, Geometry in Grade 8
P3: Geometry, data handling, the Cartesian plane which falls under graphs.
P4: Even the theorem of Pythagoras is very abstract - here they can master it. I think they can master it with this app.
P3: If I think thoroughly, all of them will be suitable for the app. Any section would be suitable.
I: What can be done to improve this app?
P3: Like we already said, just to change where the learners have to choose between yes or no. They should be given more opportunity to do it on their own first. They should be forced to try the sums on their own first, and then the help can come. Twice or thrice is enough otherwise they might become demotivated.
P4: I think if you can make it to be audio-visual - that would be great.
P3: There was also no sound. The sound can tell them what to do.
P4: Maybe make it an option for learners - those who want sound maybe have that option, those who don't want sound can switch it all.
P3: They also like sound.
P4: It will also help those who battle to read. It will also improve their reading skills if they can hear and see at the same time.
I: How would you make it more visual?
P3: I have seen that you have put some colourful pictures in there - even in the formula - maybe add some pictures but not too much.
P4: It should also depend on the grades - maybe in the senior and FET phases you can limit the images. In the lower grade you can include more pictures.
P4: What about animation? It will be good especially for the grade fours, fives and sixes - because they like cartoons - you can add it there. If you can include animations, that will be good for the lower grades.
P3: It would be good if you could develop these apps for the whole curriculum - from foundation phase right through. Then they can get used to using it.
P4: You can do Maths with something that they know - make it real life.
P3: I think this will help in other subject too - if teachers that teach other subjects can see this, they would also want to use such apps. This will help them too.
P4: Disadvantages might be: I think it would limit their basic skills - those learners will not have the basic Mathematics skill like calculating. When it comes to exam time, they will not be able to use this. They will use paper and pencil. If they are used to the technology- it can be a problem for them to write exams with paper-and-pencil.
P3: I don't think they should only use this - in the end they should also write something. So, one should create opportunities for them to answer questions on paper-and-pencil as well - after learning the content, maybe use worksheets where they get to do the sums on paper.
P3: I am very impressed. In fact we are tired of chalkboards - it will be nice to use something new.
